## GEORGES BANK YELLOWTAIL FLOUNDER

[5Zhjmn; 522,525,551,552,561,562] DRAFT

## Summary

- Combined Canada and USA catches in 2021 were 51 mt.
- The declining trend in survey biomass to low levels, despite reductions in catch to historical low amounts, indicates a poor state of the resource.
- Stock biomass is low and productivity is poor.
- The Transboundary Resource Assessment Committee (TRAC) recommends continued low exploitation to allow for the possibility of rebuilding.
- The new USA commercial fishery data processing system (Catch Accounting and Monitoring System [CAMS]) was used to produce USA landings estimates for 2020 and 2021.
- Fall and spring National Marine Fisheries Service (NMFS) survey estimates were updated to account for tow-specific area swept. Updated estimates were not meaningfully different than previous estimates.
- 2022 Fisheries and Oceans Canada (DFO) survey estimates were not available due to the use of a new survey vessel and an absence of a calibration factor. For the sake of completeness and comparability with previous TRAC Status Reports (TSRs), a number of tables and figures that could not be updated due to this missing data are included in the Appendix.
- The average survey biomass for 2022, using the adjustment from Miller et al. (2021), was $1,500 \mathrm{mt}$. The average survey biomass for 2022 adjusted for the missing DFO survey was $1,211 \mathrm{mt}$. Both estimates are between the survey bounds of the Limiter Approach (lower limit: $1,000 \mathrm{mt}$; upper limit $7,300-8,500 \mathrm{mt}$ ). Thus, TRAC recommends the constant catch advice of 200 mt .

## Fishery

Total catches of Georges Bank Yellowtail Flounder peaked at about 21,000 mt in both 1969 and 1970 (Figure 1). The combined Canada/USA catch increased from 1995 through 2001, averaged $6,300 \mathrm{mt}$ during 2002-2004, but declined to 51 mt in 2021 (Table 1) due in part to restrictive management measures.

The 2021 Canadian catch of 4 mt was $9 \%$ of the 45 mt quota, with landings of less than 1 mt and estimated discards of 4 mt from the sea scallop dredge fishery.

USA catches in calendar year 2021 were 47 mt , with landings of 1 mt and discards of 46 mt . The USA landings in calendar year 2021 were predominantly from the trawl fishery, while discards were predominantly from the scallop dredge fishery. Preliminary estimates of the USA catches (landings plus discards) for fishing year 2021 were $38 \%$ of the 80 mt quota.

Table 1. Catches (mt)

|  |  | 2016 | 2017 | 2018 | 2019 | 2020 | 2021 | 2022 | Avg ${ }^{1}$ | Min ${ }^{1}$ | Max ${ }^{1}$ |

${ }^{1} 1973$ - 2021
${ }^{2}$ unless otherwise noted, all values reported are for calendar year
${ }^{3}$ for fishing year May 1 - April 30
${ }^{4}$ preliminary estimate
${ }^{5}$ for Canadian calendar year and USA fishing year May 1 - April 30
${ }^{6}$ sum of Canadian landed, Canadian discard, and USA catch (includes discards)

## Harvest Strategy and Reference Points

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=0.25$ (established in 2002 by the TMGC). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding. However, due to the lack of an assessment model, an estimate of fishing mortality rate cannot be calculated. Status determination relative to reference points is not possible because reference points have not been defined for the Empirical or Limiter approaches.

## State of Resource

The declining trend in survey biomass to low levels, despite reductions in catch to historical low amounts, indicates a poor state of the resource. Recent catch is low relative to the biomass estimated from the surveys (relative F; Figure 2), but catch curve analyses (Sinclair Z) indicate conflicting information between USA and Canadian surveys (Figure 3). However, the low
catches in the survey in recent years make interpretation of the current relative F and survey Z difficult. Fishing does not appear to be a major driver of stock status currently.

## Productivity

Recruitment, spatial distribution, and fish growth typically reflect changes in the productive potential. Recent recruitment has generally been below average (Figure 4) and age structure is truncated (i.e., both fewer young fish and fewer old fish). Recent spatial distribution patterns from the bottom trawl surveys generally follow the ten-year average, although low survey catches make these comparisons difficult. Growth, as measured by length-at-age in the surveys, has been variable without trend, and condition (weight at length) has been average or poor recently, although low survey catches makes interpreting these trends difficult. Stock biomass is low and productivity is poor.

## Outlook and TRAC Advice

This outlook is provided in terms of agreements reached through a series of meetings of the TRAC and TMGC regarding the Empirical Approach and a Limiter Approach ${ }^{1}$. Both the Empirical and Limiter approaches rely on average estimates of biomass from the Fisheries and Oceans Canada (DFO) survey, National Marine Fisheries Service (NMFS) spring, and NMFS fall surveys (Figure 5). The Empirical Approach applies an exploitation rate to this average to generate catch advice. The Limiter Approach sets constant catch advice as long as the average survey biomass remains within predetermined limits.

In 2021, Miller et al. (2021) presented a new method to estimate NMFS spring and fall expanded survey biomass accounting for catchability-at-length and day/night effects. This method was further revised in 2022 to account for the tow-specific area swept. In 2022, the DFO survey was conducted with a new vessel. Conversion factors between the old and new vessel are not currently available so catch advice for 2023 from both approaches was computed using only the 2021 NMFS fall and 2022 NMFS spring surveys.

During the 2014 Benchmark, considerations were provided as reasons to decrease or to maintain or increase the quota. Like in 2014, findings this year show both positive and negative signals. The following is a positive signal: the relative $F$ continues to be low. The negative signals are: both available surveys decreased; the two available surveys (NMFS fall and NMFS spring) were the second lowest surveys in their respective time series; recent recruitment continues to be below average; and the abundance of age 6+ fish in both available surveys decreased. Three independent surveys, funded by USA Atlantic Sea Scallop Research SetAside program, were updated with additional data and showed similar trends to the relative abundance estimates produced by the DFO and NMFS surveys.
USA landings estimates for 2020 and 2021 are from the newly implemented Catch Accounting and Monitoring System (CAMS). In addition, USA discard estimates for 2020 have been revised since the 2021 TRAC meeting. Observed trips in 2020 were processed and an updated discard estimate was calculated. As a result, scallop dredge fleet discard estimates for 2020 were higher than prior estimates reported in the 2021 TRAC meeting. However, observer coverage was low in the scallop fleet in semester two, resulting in high coefficients of variation (Figure 6).

[^0]NMFS survey estimates were adapted to account for tow-specific area swept; these revised estimates were similar to previous estimates. Revised tow-specific area swept estimates were incorporated into Miller et al. (2021) estimates used to expand biomass estimates.
During 2011 to 2021, the catch has averaged 32\% of the quota, ranging from $6 \%$ to $63 \%$. The TRAC recognizes that catch has been well below the quota in recent years and expects this to continue in the future if current management measures continue and there is not a significant change in stock abundance or distribution. The TRAC recommends continued low exploitation to allow for the possibility of rebuilding.
At the 2020 TRAC meeting, the missing 2020 NMFS spring survey was shown to have little impact on the average survey biomass by examining previous years with and without the NMFS spring survey. At the 2021 TRAC meeting, the missing 2020 NMFS fall survey was shown to have a larger impact. Adjusting for the mean relative difference between the ten years with and without the NMFS fall survey leads to a $24 \%$ increase in average survey biomass and catch advice. At the same meeting and using the same methods, it was estimated that if the DFO survey was missing, average survey biomass and catch advice would decrease by $24 \%$. The TRAC presents both the adjusted and non-adjusted values for comparison purposes to account for the missing 2022 DFO survey.

Prior to the application of the Limiter Approach, the Empirical Approach was used to provide catch advice. Application of the Empirical Approach, with the Miller et al. (2021) adjustment that incorporates tow-specific area swept and an exploitation rate of 7\%, results in catch of 105 mt for 2023. Adjusting for the missing DFO survey results in a reduced catch of 85 mt for 2023. This adjustment is based on a comparison between the average survey biomass estimated with all three surveys compared to estimates using only the DFO and NMFS spring survey, which showed an average relative difference of $24 \%$. The adjustment factor is 0.807 , which is derived from $1 /(1+0.24)$.

Low catches and poor condition of the stock, along with a desire to stop chasing survey noise, led to the development of the Limiter Approach, a tool to help make the decisions regarding the constant catch advice and average survey biomass limits. This tool is an R Shiny app available at https://github.com/cmlegault/limiter.
The catch advice for 2023 was based on the Limiter Approach. The average survey biomass for 2022 was $1,500 \mathrm{mt}$, which is between the limits (lower limit: 1,000 mt; upper limit 7,300$8,500 \mathrm{mt}$ ). The average survey biomass for 2022 adjusted for the missing DFO survey was $1,211 \mathrm{mt}$, which is between the limits. Thus, TRAC recommends the constant catch advice of 200 mt .

Table 2. Survey biomass with the Miller at al. (2021) adjustment from the three bottom trawl surveys, an arithmetic average of these biomasses, and example quota associated with an exploitation rate of $7 \%$. Quota is implemented in the following year (e.g., the row of 2022 quota would be implemented in 2023).

| Year | Biomass (mt) |  |  |  | Example Quota (mt) at 7\% Exploitation Rate |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | DFO | Spring | Fall (year-1) | Average |  |
| 2010 | 29,452 | 60,877 | 66,989 | 52,439 | 3,671 |
| 2011 | 12,344 | 27,500 | 23,517 | 21,120 | 1,478 |
| 2012 | 18,113 | 44,532 | 24,846 | 29,164 | 2,041 |
| 2013 | 2,249 | 11,879 | 24,340 | 12,823 | 898 |
| 2014 | 1,654 | 8,040 | 8,946 | 6,213 | 435 |
| 2015 | 2,650 | 5,312 | 10,964 | 6,309 | 442 |
| 2016 | 5,569 | 3,063 | 4,578 | 4,403 | 308 |
| 2017 | 1,104 | 2,558 | 4,610 | 2,757 | 193 |
| 2018 | 812 | 139 | 1,891 | 947 | 66 |
| 2019 | 182 | 2,776 | 4,728 | 2,562 | 179 |
| 2020 | 404 | NA | 3,608 | 2,006 | 140 |
| 2021 | 446 | 4,804 | NA | 2,625 | 184 |
| 2022 | NA | 929 | 2,070 | 1,500 | 105 |

Table 3. Recent quotas and catches by year and associated exploitation rates (computed by dividing by the average survey biomass in Table 2). (VPA = Virtual Population Analysis.)

| Year | Quota (mt) | Catch (mt) | Quota/Avg | Catch/Avg | Model Type |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2010 | 1,956 | 1,170 | 4\% | 2\% | VPA |
| 2011 | 2,650 | 1,171 | 13\% | 6\% | VPA |
| 2012 | 1,150 | 725 | 4\% | 2\% | VPA |
| 2013 | 500 | 218 | 4\% | 2\% | VPA |
| 2014 | 400 | 159 | 6\% | 3\% | VPA |
| 2015 | 354 | 118 | 6\% | 2\% | Empirical |
| 2016 | 354 | 44 | 8\% | 1\% | Empirical |
| 2017 | 300 | 95 | 11\% | 3\% | Empirical |
| 2018 | 300 | 45 | 32\% | 5\% | Empirical |
| 2019 | 140 | 8 | 5\% | 0\% | Empirical |
| 2020 | 162 | 68 | 8\% | 3\% | Empirical |
| 2021 | 125 | 49 | 5\% | 2\% | Empirical |
| 2022 | 200 |  | 13\% |  | Empirical |
| Mean | 699 | 342 | 9\% ${ }^{1}$ | 5\% |  |

[^1]
## Special Considerations

- Results from the most recent surveys are considered valid for use in the Empirical Approach despite the lack of a DFO 2022 survey (due to an absence of a catchability conversion factor to account for changes in survey vessel).
- Updated USA catch-at-age data were not available this year due to the transition to CAMS. These estimates are expected to be available for next year.
- Discard estimates in 2020 are uncertain due to lower observer coverage in semester two for the USA scallop dredge fleet.
- In 2022, the average survey biomass is near the lower bound of the Limiter Approach.
- While the NMFS surveys were adjusted for catchability based on Miller et al. (2021), the DFO survey was not adjusted since it uses a different gear configuration. It is possible that the DFO survey catchability estimate could be adjusted with further analysis.

| 2021 | 0.009 | 0.036 | 0.368 | 0.161 | 0.01 | 0.041 | 0.009 | 0.036 |

Table A6. Catch for 2023 associated with the full range of exploitation rates from the 2014 Benchmark adjusting for the missing DFO survey and using the Miller et al. (2021) adjusted survey values.

| Terminal Year |  |
| :---: | :---: |
| Exploitation Rate | Catch (mt) |
| $2 \%$ | 24 |
| $3 \%$ | 36 |
| $4 \%$ | 48 |
| $5 \%$ | 61 |
| $6 \%$ | 73 |
| $7 \%$ | 85 |
| $8 \%$ | 97 |
| $9 \%$ | 109 |
| $10 \%$ | 121 |
| $11 \%$ | 133 |
| $12 \%$ | 145 |
| $13 \%$ | 157 |
| $14 \%$ | 169 |
| $15 \%$ | 182 |
| $16 \%$ | 194 |
| $16.5 \%$ | 200 |

Table A7. Survey biomass from the three bottom trawl surveys, an arithmetic average of these biomasses, and quota associated with an exploitation rate of $6 \%$. Quota is implemented in the following year (e.g., the row of 2021 catch would be implemented in 2022). Note these values use the previously accepted survey catchability of 0.31 for all three surveys and are shown for comparative purposes only.

|  | Biomass (mt) |  |  |  | Catch (mt) |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Year | DFO | Spring | Fall (year-1) | Average | 3,634 |
| 2010 | 29,452 | 68,752 | 83,490 | 60,565 | 1,396 |
| 2011 | 12,344 | 29,621 | 27,821 | 23,262 | 1,894 |
| 2012 | 18,113 | 46,209 | 30,354 | 31,559 | 924 |
| 2013 | 2,249 | 12,766 | 31,199 | 15,404 | 421 |
| 2014 | 1,654 | 8,564 | 10,828 | 7,015 | 424 |
| 2015 | 2,650 | 5,861 | 12,682 | 7,064 | 300 |
| 2016 | 5,569 | 3,610 | 5,811 | 4,997 | 187 |
| 2017 | 1,104 | 2,819 | 5,432 | 3,118 | 68 |
| 2018 | 812 | 143 | 2,424 | 1,126 | 199 |
| 2019 | 182 | 3,735 | 6,047 | 3,322 | 125 |
| 2020 | 404 | NA | 3,749 | 2,077 | 161 |
| 2021 | 446 | 4.912 | $N A$ | 2,679 | 1,826 |

Table A8. Recent quotas and catches by year and associated exploitation rates (computed by dividing by the average survey biomass in Table 2). (VPA = Virtual Population Analysis.) Note these values use the previously accepted survey catchability of 0.31 for all three surveys and are shown for comparative purposes only.

| Year | Quota (mt) | Catch (mt) | Quota/Avg | Catch/Avg | Model Type |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2010 | 1,956 | 1,170 | $3 \%$ | $2 \%$ | VPA |
| 2011 | 2,650 | 1,171 | $11 \%$ | $5 \%$ | VPA |
| 2012 | 1,150 | 725 | $4 \%$ | $2 \%$ | VPA |
| 2013 | 500 | 218 | $3 \%$ | $1 \%$ | VPA |
| 2014 | 400 | 159 | $6 \%$ | $2 \%$ | VPA |
| 2015 | 354 | 418 | $5 \%$ | $2 \%$ | Empirical |
| 2016 | 354 | 95 | $7 \%$ | $1 \%$ | Empirical |
| 2017 | 300 | 45 | $27 \%$ | $3 \%$ | Empirical |
| 2018 | 300 | 68 | $4 \%$ | $4 \%$ | Empirical |
| 2019 | 140 | 51 | $8 \%$ | $0 \%$ | Empirical |
| 2020 | 162 |  | 542 | $11 \%$ | Empirical |
| 2021 | 125 |  | $8 \%{ }^{1}$ | $2 \%$ | Empirical |
| 2022 | 200 |  |  | $2 \%$ | Empirical |
| Mean | 699 |  |  |  |  |

[^2]Table A9. Comparison of average survey biomass (mt) between use of the Miller et al. (2021) adjusted values for the NMFS spring and fall surveys and the previous assumption that survey catchability(q) was 0.31 for all three surveys.

| Year | Miller | $\mathbf{q}=\mathbf{0 . 3 1}$ | rel diff |
| ---: | ---: | ---: | ---: |
| 2010 | 52,439 | 60,565 | $-13 \%$ |
| 2011 | 21,120 | 23,262 | $-9 \%$ |
| 2012 | 29,164 | 31,559 | $-8 \%$ |
| 2013 | 12,823 | 15,404 | $-17 \%$ |
| 2014 | 6,213 | 7,015 | $-11 \%$ |
| 2015 | 6,309 | 7,064 | $-11 \%$ |
| 2016 | 4,403 | 4,997 | $-12 \%$ |
| 2017 | 2,757 | 3,118 | $-12 \%$ |
| 2018 | 947 | 1,126 | $-16 \%$ |
| 2019 | 2,562 | 3,322 | $-23 \%$ |
| 2020 | 2,006 | 2,077 | $-3 \%$ |
| 2021 | 2,625 | 2,679 | $-2 \%$ |
| 2022 | 1,500 | 1,826 | $-18 \%$ |
|  |  | mean | $\mathbf{- 1 2 \%}$ |

Table A10. The Management Table below was kindly initiated by Tom Nies (Northeast Fisheries Management Council). It summarizes the performance of the management system by reporting on the annual TRAC advice, the TMGC quota decision, actual catch, and realized stock conditions for Georges Bank Yellowtail Flounder. VPA=Virtual Population Analysis; SPM=Surplus Production Model.

| TRAC | Catch | TRAC Analysis/Recommendation |  | TMGC Decision |  | Actual | Actual Result ${ }^{(3)}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Amount | Rationale | Amount | Rationale |  |  |
| $1999{ }^{4}$ | 1999 | (1) $4,383 \mathrm{mt}$ <br> (2) $6,836 \mathrm{mt}$ | Neutral risk of exceeding Fref <br> (1)VPA <br> (2)SPM | NA | NA | 4,963 mt/ 50\% risk of exceeding Fref (VPA) |  |
| 2000 | 2000 | 7,800 mt | Neutral risk of exceeding Fref | NA | NA | 7,341 mt/About 30\% risk of exceeding Fref |  |
| 2001 | 2001 | 9,200 mt | Neutral risk of exceeding Fref | NA | NA | 7,419 mt/Less than 10\% risk of exceeding Fref |  |
| 2002 | 2002 | 10,300 mt | Neutral risk of exceeding Fref | NA | NA | $5,663 \mathrm{mt}$ /Less than $1 \%$ risk of exceeding Fref |  |
| Transition to TMGC process in following year; note catch year differs from TRAC year in following lines |  |  |  |  |  |  |  |
| 2003 | 2004 |  | No confidence in projections; status quo catch may be appropriate | 7,900 mt | Neutral risk of exceeding Fref, biomass stable; recent catches between 6,100$7,800 \mathrm{mt}$ | 6,815 mt | F above 1.0 <br> Now NA |
| 2004 | 2005 | 4,000 mt | Deterministic; other models give higher catch but less than 2004 quota | 6,000 mt | Moving towards Fref | 3,852 mt | $F=1.37$ <br> Age 3+ biomass decreased 5\% 05-06 <br> Now NA |

[^0]:    ${ }^{1}$ The Empirical Approach derives from the 2014 Georges Bank Yellowtail Flounder Diagnostic and Empirical Approach Benchmark, a subsequent TRAC meeting in 2014, and an intersessional TRAC conference call in June 2017. The Limiter Approach was developed during the 2020 TRAC meeting and subsequently enhanced during TMGC intersessional meetings. At the November 2021 intersessional meeting of the TMGC the group recommended use of the Limiter Approach for catch advice in 2023.

[^1]:    ${ }^{1}$ The average Quota/Avg for years 2010-2017 is 7\%.

[^2]:    ${ }^{1}$ The average Quota/Avg for years 2010-2017 is 6\%.

[^3]:    ${ }^{2}$ All catches are calendar-year catches
    ${ }^{3}$ Values in italics are assessment results in year immediately following the catch year; values in normal font are results from this assessment
    ${ }^{4}$ Prior to implementation of US/CAN Understanding
