# MEMORANDUM 

DATE: $\quad$ August 3, 2017
TO:
Science and Statistical Committee
FROM: Skate Plan Development Team (PDT)
SUBJECT: NE Skate Complex ABCs for FY 2018-2019

This memorandum forwards the Skate PDT recommendation for ABC for the NE Skate Complex for FY 2018 and FY 2019 (Table 1). The Skate PDT also recommends incorporating newly available skate discard mortality rate estimates for winter (14\%) skate in sink gillnet gear into the specifications. This would replace the assumed $50 \%$ discard mortality rate in this gear type. The stock was last assessed at the Data Poor Stocks Working Group in 2009, but trawl survey biomass updates are provided annually.

The ABC is based on the current default ABC control rule established in Amendment 3. The control rule uses the median catch/biomass ratio as an estimate of exploitation rate applied to the three-year moving average of fall (spring for little skate) survey stratified mean weight per tow.

## Survey Data

Specifications for FY 2018 and 2019 incorporate the most recent three years of the fall survey data (spring for little skate); older survey years drop out of the calculation. Based on the updated survey data, thorny skate remains overfished ( $0.04 \mathrm{~B}_{\mathrm{MSY}}$ ) but overfishing is no longer occurring (overfishing was occurring during 2013 and 2014 according to previous stock updates). Winter skate ( $1.17 \mathrm{~B}_{\mathrm{MSY}}$ ) is also no longer experiencing overfishing (overfishing was occurring during 2013 and 2014 according to previous stock updates). The $\mathrm{B}_{\text {MSY }}$ proxy for each skate species is the $75^{\text {th }}$ percentile of the appropriate survey biomass index time series for that species. A species is overfished if its three-year moving average survey mean weight per tow is less than $1 / 2 \mathrm{~B}_{\text {MSY }}$ proxy. Survey indices for three of the seven species have decreased (Table 3). Figure 2 shows the long-term survey trends and biomass reference proxies for all seven species. Little skate and winter skate continue to dominate the survey biomass. The 2014-2016 3year average for winter skate has increased and is no longer affected by the low survey index in 2013. The 2015-2017 3-year average for little skate decreased because of a low spring survey index in 2016.

## Landings

The overall TAL was not exceeded for the skate fisheries. 2015 skate wing landings were $8,911 \mathrm{mt}$ ( $81.8 \%$ of the wing TAL), and skate bait landings were $5,541 \mathrm{mt}$ ( $100.9 \%$ of the bait TAL). Historic catch and landings are provided in Error! Reference source not found.. State landings were 941 mt . State landings have been variable over recent fishing years (Table 2), and the PDT used a preliminary three-
year average (FY 2013-2015) for specifying the assumed amount of state landings to deduct from the TAL for 2018-2019 (3.5\%). ACL accounting has not been finalized for FY2016 but preliminary estimates indicate that the wing fishery achieved $98 \%$ of its TAL; the bait fishery reached $101 \%$ of its TAL. State landings for FY2016 were not available in time for the SSC meeting.

## Discards

Discards were estimated through calendar year 2016 by gear (Table 5). Discards are estimated for a calendar year, rather than the fishing year, because they rely on the NMFS area allocation landings tables to expand observed discard/kept-all ratios to total based on landings by gear, area and quarter. The observed D/K-all ratios were derived from the NEFOP and the At Sea Monitoring programs and included both sector and non-sector vessels, but were not stratified on that basis. The hindcasted discard estimates are calculated using a three-year average of the discards of skates/landings of all species. An assumed discard mortality rate of $50 \%$ is applied for all gears and species, except for otter trawl gear, scallop dredge and sink gillnet.

Total estimated discards for 2016 were 33,271 mt (Table 5). Total discards decreased by only 13\% over the 2015 estimates. The weighted aggregate mean discard mortality rate (across all species and gear types) was estimated to be 31 \%. The assumed dead discard rate (dead discards/total catch) for 20182019 is $42 \%$, including the new sink gillnet discard mortality rate estimate for winter skates. Applying this rate to the updated specifications results in projected dead discards for FY2018 and 2019 of 9,769 mt.

## Northeast Skate Complex Annual Catch Limit Accounting

Only $79.2 \%$ of the 35,479 mt skate complex ACL was caught in 2015; accordingly, no Accountability Measures (AMs) were triggered (Table 4). The total catch for 2015 was $28,111 \mathrm{mt}$ composed of 11,189 mt of dead discards and 15,564 mt of landings (including state landings). Total catch was higher than the ACT (75\% of ACL), but less than the ACL.

## Discard mortality rates

The baseline discard mortality rate estimates are set at $50 \%$ for all species and all gear types, where new research has not allowed for the revision of that number. This was established in Amendment 3 to the NE Skate Complex FMP. Currently, revised discard mortality rates have only been implemented for little, smooth, thorny, and winter skates in otter trawl gear, and little and winter skate in scallop dredge gear. Specifications for FY 2014-2015 incorporated final trawl gear discard mortality rate estimates for little (22\%), smooth (60\%), thorny (23\%) and winter (9\%) skate as determined by Mandelman et al. (2013). For these 4 species, the $50 \%$ discard mortality rate estimate is assumed for remaining gear (scallop dredge, longline, and gillnet). Specifications for FY2016 - 2017 incorporated final discard mortality rate estimates for little (51\%) and winter (35\%) skate in scallop dredge gear.

Recent research has provided revised discard mortality rate estimates for winter skate (14\%) in sink gillnet gear (see Sulikowski et al., in review). The models estimated a discard mortality rate of $11 \%$ and $17 \%$ for females and males, respectively. It is not currently possible to determine the sex ratio of winter skate catch. The PDT recommended using an average between the two rates to apply an overall discard mortality rate estimate of $14 \%$, an approach that was supported by the principal investigators. The revised sink gillnet discard mortality rate estimate combined with the updated survey and catch data decreased the assumed dead discard rate for 2018 to $41 \%$ (from 42\%). Changes to the discard mortality rate estimates affect the catch history and therefore the catch/biomass medians. The revised sink gillnet discard mortality rate estimates were applied to the entire catch time series despite changes in gear configuration during this time period.

## Specifications

The proposed specifications for FY 2018 and 2019 use the updated discard mortality rate estimate for winter skate in sink gillnet gear, as well as the revised catch history and the catch/biomass medians. The revised catch/biomass medians have standardized years from 1969-2016. Table 1 shows a comparison of the proposed specifications for FY 2018 and 2019 including the revised scallop dredge discard mortality estimates (PDT recommendation) with both the previous specifications package (FY2016-2017) and a revised specifications based on existing discard mortality rate estimates. The changes in survey indices and revised medians contribute to slightly increasing the ABC. Discards have decreased in the last two years, however, the higher 2014 discard data point is still influencing the three year moving average. The proportion of dead discards therefore remains high, further impacting the available TAL.

MSY is defined as the catch resulting from the application of the catch/biomass medians to the target skate biomass levels. MSY, based on the revised catch/biomass medians, is estimated to be $36,794 \mathrm{mt}$ (MSY was estimated in the FY2016 - 2017 specifications to be $36,806 \mathrm{mt}$ ).

Figure 1 - Historic catch (in mt) from 1968 to 2016 compared to landings and dead discards

## Skate Complex Biomass Indices

Figure 2 - NEFSC survey biomass indices (kg/tow). Thin lines with symbols are annual indices, thick lines are 3-year moving averages, and the thin horizontal lines are the biomass thresholds using consistent FSV Albatross/Bigelow strata.

Table 1 - Comparison of PDT recommended revised specifications for FY2018 and FY2019, with revised specifications for FY2018 \& FY 2019 based on status quo discard mortality estimates, and specifications for FY2016 and YF2017.
