Much of the ability to shift into other fisheries is limited to trawl gear. Gillnet and longline fishermen who in the past fished for monkfish and dogfish have few opportunities to do so because of restrictions in those fisheries (see discussion above). Whiting, squid, and herring are not harvested with gillnet or longline gear in the U.S. Some small gillnet and longline vessels may be able to target tuna at certain times of the year, or shift into the party/charter fishery in an attempt to compensate for loss of gross revenue.

	No Activity	No Groundfish		< 25% Groundfish		25% Groundfish to < 50%		50% Groundfish to < 75%		>= 75% Groundfish

Table 332 - Summary of Permits Held by Limited Access Permit Holders and Participation in Other Fisheries by Multispecies Revenue Dependence

5.5 Enforcement Analysis

The following general enforcement comments and concerns are based on the specific alternatives in draft Amendment 13 to the Northeast Multispecies FMP. These comments have not been updated based on the proposed action to achieve rebuilding objectives. The proposed action, however, adopts many of the same measures that were considered in Alternative 1. Specific comments from enforcement on the alternatives are now annotated with the proposed action.

Closed area enforcement issues remain the same. These areas must be clearly defined with limited access to the areas in order to allow for efficient and effective offshore enforcement. Ample notice and well defined rules and restrictions must be in place for successful closed area enforcement.

Possession limits do not present any new enforcement concerns although can be manpower intensive in general. Vessels fishing in specific areas with restrictions on possession limits can be monitored more effectively though the use of VMS.

Gear restrictions are enforceable at-sea when they are clearly defined and limit the use of gear with net stowage requirements and other measures remaining in place. Gear restrictions should be written to encompass dockside enforcement.

Minimum fish size can be manpower intensive. No new enforcement concerns.

Special access programs which allow certain vessels in closed areas needs to be closely monitored. VMS would be an extremely important enforcement monitoring tool for any special access programs. The NOAA Fisheries Office for Law Enforcement (OLE) recommends the issuance of a special authorization letter that defines the requirements and restrictions for special access programs. In order to maximize enforcement, NMFS Law Enforcement suggests vessels should not be allowed to fish in any other areas while operating under a special access trip.

Area management measures also pose enforcement concerns when vessels are allowed to fish in multiple areas. NMFS Law Enforcement recommends vessels who elect to fish in a particular area, should fish in that area for the entire trip. A vessel must declare its intention to fish in a particular area prior to sailing on that trip. From the enforcement perspective, VMS would be an extremely valuable enforcement tool in any area management scheme.

Sector management poses certain enforcement and legal concerns. In general, NMFS Law Enforcement does not support sector management, however, more details are required to make an informed decision.

TAC monitoring under sector and area management alternatives requires and assumes that daily electronic dealer reporting will take place. If TACs are area specific, this proposal would require monitoring of every vessel's activity to ensure they are fishing in the specified area. To successfully accomplish the monitoring, enforcement recommends mandatory VMS on all vessels involved in this fishery.

Recreational measures need to be consistent across the board in the recreational fishery. Same bag limits/possession limits for recreational and head/charter boats.

Experimental fisheries should be limited with clearly defined restrictions and limitations that are enforceable.

DAS leasing may pose significant enforcement concerns due to the burden of administrative tracking. Program requirements must be clearly identified with an adequate administrative process in place prior to implementation.

Running clocks can only be enforced with dockside presence. NMFS Law Enforcement does not support the use of running clocks.

5.5.1 Fishery Administration

This section addresses topics material to the management of the multispecies fishery.

5.5.1.1 Fishing Year

Altering the fishing year as described in this section does not present any enforcement concerns. For purposes of enforcement, fishing years should be consistent among all fishery management plans.

The fishing year is not being changed.

5.5.1.2 DAS Pro-Ration

This alternative provides two options concerning the proration of DAS. The options focus on how DAS will be adjusted if the fishing year is changed and/or if the management measures for Amendment 13 are implemented during the ongoing fishing year. DAS proration is not an enforcement issue as currently described in this alternative and poses no new enforcement concerns. NMFS Law Enforcement strongly suggests advanced notification to industry and enforcement regarding new DAS allocations.

DAS pro-ration has not been adopted.

5.5.1.3 U.S./Canada Resource Sharing Understanding

A significant problem is that the US/CA area is around CA II, where there could be a separate TAC for these two areas. Access options, some mutually exclusive, are many and yet to be determined, including: declaration, one area versus several areas, VMS or sign-in program, DAS not counted or counted 2 for 1 or 3 for1.

It is the consensus of the Enforcement committee that VMS should be required.

The proposed action adopts A VMS requirement for fishing in the US/CA area.

5.5.1.4 Special Access Programs

This section proposes a general program which would allow fishing for a specific stock or stocks which may be permitted based on gear used, techniques, DAS adjustments, specific area(s), specific stocks or any other parameters which could be developed to allow a specific fishery.

NMFS Law Enforcement reserves comment until specific measures are identified for the special access program. The NMFS Law Enforcement issues raised in 5.5.1.4.1(Georges Bank Yellowtail Flounder Access Program), 5.5.1.5(Closed Area Administration) and 5.5.3.2.4(Gear Restrictions) would also apply to this section.

5.5.1.4.1 Georges Bank Yellowtail Flounder Access Program

This measure would allow fishing vessels to make two trips per month into a specific area of Closed Area II to fish for yellowtail flounder from June through December. Under this program vessels are restricted to 30,000 pounds of yellowtail flounder, must use VMS, do not start their DAS clock until they enter CA II unless they are fishing east of 69W on Georges Bank and are restricted to no more than one-fifth of the GB cod landing limit.

This measure is similar to the Sea Scallop Exemption Program, which allows vessels to fish in closed areas under specific conditions. Enforcement's recommendation on any consideration of allowing fishing in a closed area in the multispecies fishery should be modeled after the sea scallop exemption program. For instance, vessels would not be allowed to harvest yellowtail outside of the Exemption Area, must not enter or exit the Exemption Area more than once per trip and provide daily fishing reports through VMS. Additionally, vessels electing to fish in the Exemption Area would have a specific number of DAS subtracted from its DAS allocation. If the vessel exceeds the specific DAS, then DAS would be charged as actual time.

This scheme proposes allowing vessels to fish for other species; (i.e. GB cod) after leaving Closed Area II. Permitting vessels to fish in a closed area for a specific species, then exit the area and continue to fish for other species would poses considerable enforcement concerns. Distinguishing between fish (i.e. cod) caught in the exempted area or outside of the area is highly unlikely.

All limited access multispecies vessels intending to fish in this Exemption Program would be required to have a working VMS unit. Prior to fishing in the Exemption Program, each vessel should give advanced notification for each trip. Increasing the use of VMS would escalate enforcement resources requiring additional manpower for monitoring, system evaluation and investigative matters. As the demands and functions of VMS increase, so does the cost of the VMS unit.

The proposed action adotps a VMS requirement.

5.5.1.4.2 Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program

This alternative will allow a by-catch of 200 pounds of winter flounder while fishing for summer flounder west of 72-30W. The enforcement issues are similar to those previously described under area access programs. Enforcement of this management scheme are best achieved utilizing VMS and USCG surface patrols in conjunction with at-sea boardings. Dockside enforcement would be difficult without the usage of VMS tracking.

5.5.1.5 Closed Area Administration

Consideration of allowing additional gears into closed areas will "complicate enforcement of closed areas." Increasing the number of vessels allowed to fish in closed areas without VMS will compromise enforcement, whereas vessel identification and fishing activity will be difficult to monitor. Monitoring of the additional vessels would also expand resource needs of enforcement to effectively ensure vessels do not possess multispecies.

No changes are being made to the vessels allowed into closed areas with the exception of approved special access programs, all of which include a VMS requirement.

5.5.1.6 Leasing of DAS

This alternative proposes the leasing of DAS from one vessel to another. Allocation or DAS leasing (trading) is a current management scheme in the surf clam/ocean quahog fisheries and is authorized by NOAA/NMFS. Development of a DAS leasing alternative should incorporate the leasing/trading of allocation of the surf clam/ocean quahog system into the multispecies fishery.

Program requirements must be clearly identified with an adequate administrative process in place prior to implementation. At a bare minimum, leases would have to be arranged, documented and approved and ample notification provided to enforcement and fishermen, detailing each vessel's new DAS allocation prior to the upcoming fishing year.

5.5.1.6.1 Conservation Equivalency Alternatives

These alternatives propose varying methods of leasing and subleasing DAS between multispecies vessels. As described in these alternatives, these measures do not pose any concerns to enforcement other than, those detailed in 5.5.1.6.

5.5.1.6.2 Limitations on Number of DAS Leased

Enforcement issues regarding DAS leasing are addressed in 5.5.1.6 and are applicable to this proposal.

5.5.1.6.3 Permit History Revisions

This alternative does not present any new enforcement concerns.

5.5.1.7 Recreational Fishing Permit

This alternative proposes four options;

(1) no federal permit required
(2) possessing regulated multispecies in the EEZ requires a permit
(3) fishing for regulated multispecies in the EEZ requires a permit
(4) fishing for and possessing regulated multispecies in the EEZ requires a permit

This alternative does not present any new enforcement related concerns as currently written. Enforcement of this management scheme relies primarily on at-sea boardings. Dockside enforcement of recreational permits would be extremely difficult with out the ability to determine where the vessel had fished.

Should recreational vessel operator permits and fishing vessel trip reports be required, these provisions would require an increase in enforcement resources in order to effectively monitor the recreational fleet and the new permit requirements.

The proposed action does not adopt a recreational fishing permit.

5.5.1.8 Running Clock Alternatives

Running clocks can only be enforced via a dockside presence. NMFS Law Enforcement does not support the use of running clocks.

NMFS Law Enforcement supports the use of an “Industry funded weighmaster.”

Permitting vessels to land overages and continually altering DAS poses several enforcement concerns. Vessels participating in this program should be required to do so under an extended period of time.

The “Extended Modified Running Clock” or similar versions have not been a reliable and manageable method to determine DAS. In the past, individuals who landed overages simply called-out of the DAS program upon landing, when they believed enforcement was not around. They did not call the “cod hail line” and if gone undetected, the overage was not accounted for. This proposal is manpower intensive and enforcement is unlikely.

The proposed action does not change the modified running clock.

5.5.1.9 Observer Coverage

Increasing observer coverage does not present any specific enforcement concerns and provides additional methods of discard and by-catch reporting, as well as monitoring of fishing activity. An increase in the amount of observer coverage in other fishery management plans, has added instances requiring enforcement involvement.

5.5.1.10 Vessel Monitoring System Requirements

In conjunction with this measure**,** NMFS Law Enforcement is of the opinion that any potential cost savings may be offset by deactivation/reactivation charges by the vendor.

In an effort to maintain enforcement consistency in VMS requirements, NMFS Law Enforcement does not support allowing any VMS vessel to be at-sea without a working/active unit. NMFS Law Enforcement recommends modification of the measure to allow vessels to opt out of VMS only if the vessel is to remain in port or tied to the dock.

The proposed action does not allow a vessel to be at sea without an operable VMS. Cost savings for many vessel include not just communication costs, but the costs associated with running a generator to provide power to the VMS.

5.5.1.11 Day Gill Net Block Out of the Fishery

Removing all requirements to take blocks out of the multispecies fishery does not present any specific enforcement concerns. NMFS Law Enforcement supports this measure for purposes of decreased enforcement requirements.

The proposed action does not change the day gillnet block out requirements.

5.5.1.12 DAS Counting

This alternative does not present any new enforcement concerns. *The proposed action does not change DAS counting provisions.*

5.5.1.13 Reporting Requirements

These reporting requirements are described as "broad" alternatives and can only be addressed in a very general manner.

Daily electronic dealer reporting does not present any enforcement concerns as described in the scheme. Reporting through the DAS call-in system and a separate call-in number are addressed in 5.5.3.4.2.1and are applicable.

5.5.1.14 Open Access Hand Gear-Only Permit Alternatives

These alternatives do not pose any new enforcement related concerns.

5.5.1.15 Sector Allocation

Sector allocations are described to be an "OPTION" and voluntary. This option is designed to augment the primary overall management program selected for Amendment 13.

5.5.1.15.1 Enforcement of Sector Provisions

Under this provision, the sector "is a legal entity that can be subject to NMFS enforcement action for violations of the regulations pertaining to sectors." As written, the language regarding enforcement's role is unclear. Enforcement recommends clear concise language detailing its responsibilities concerning "violations of regulations pertaining to sectors."

From the enforcement perspective, this option is vague, convoluted and complex. Given the absence of a specific detailed plan, NMFS Law Enforcement does not support this alternative.

The proposed action adopts a sector allocation system.

5.5.1.15.1.1 VMS Requirements

There is no VMS requirement specific to this alternative; however, if other alternatives must be used in conjunction with the sector allocation alternative, then any VMS requirements under those alternatives will be imposed on the sectors. Sectors may establish their own VMS requirements as long as they remain in compliance with any other VMS requirements established by other alternatives adopted in conjunction with sector allocation.

5.5.1.15.2 Georges Bank Hook/Gillnet Sector Allocation

This alternative is voluntary and creates two distinct areas for Georges Bank cod. The sectors are split between gillnetters and hook fishermen. This measure is to be utilized in conjunction with other management measures.

5.5.1.15.2.1 GB Cod Hook Sector

Gear

Refer to enforcement concerns previously detailed in 5.5.3.1.5, these comments are applicable to the above.

Trip/Possession Limits

NMFS Law Enforcement's recommendation is to define "landing" under this section as currently stated in the regulations. Land is defined as "means to begin offloading fish, to offload fish, or enter port with fish."

Monitoring

VMS has proven to be an extremely valuable enforcement monitoring tool.

5.5.1.15.2.2 GB Cod Gillnet Sector

Gear

The USCG has commented that enforcement of gillnet limits at-sea is unlikely due to their inability to haul gear.

5.5.1.15.2.3 Hook/Gillnet sector GB Closed Area I Access Program

As with vessels authorized to fish in exempted fisheries at the present time, vessels who elect to participate in this closed area access program should be required to have a letter of authorization. Vessels should also be restricted to only fishing in the closed area during these trips. Enforcement of this program can be accomplished with VMS, USCG aerial and surface patrols along with at-sea boardings by USCG units. Dockside enforcement can be conducted in combination with VMS tracking to determine area fished.

5.5.1.15.2.4 VMS Requirements

VMS is required for both the vessels in the longline sector and the vessels in the gillnet sector, as indicated above.

5.5.1.16 GOM Inshore Conservation and Management Stewardship Plan

This area management proposal is solely for the stocks in the GOM. This option was not selected.

5.5.1.16.1.1 Management Areas

Enforcement concerns of vessels electing to fish in specific zones are addressed in 5.5.3.3.3 Movement Between Areas. Enforcement issues regarding possession limits, gear restrictions, and closed areas are discussed in 5.5.3.1.3, 5.5.3.1.4, and 5.5.3.1.5 and are applicable to these proposals.

5.5.1.16.1.2 Observer Coverage

This measure would implement 100% coverage on all mid-water trawl vessels and 20% on all multispecies vessels in the GOM. Increasing observer coverage does not present any new specific enforcement concerns and provides additional methods of discard and by-catch reporting, as well as monitoring of fishing activity. Consequently, NMFS Law Enforcement recognizes that any increase in the amount of observer coverage will also result in increased referrals requiring enforcement involvement.

5.5.2 Alternatives to Control Capacity

5.5.2.1 Capacity Committee Alternatives

As currently described, this alternative poses no new enforcement concerns.

5.5.3 Management Alternatives to Address Rebuilding Requirements

These specific alternatives were not adopted. Many of the provisions, however, have been incoporated into the proposed action..

5.5.3.1 Alternative 1 – Up to 65% Reduction in Used DAS

This alternative was not selected, but many of the measures in this alternative are part of the proposed action.

5.5.3.1.1 Effort Controls

5.5.3.1.2 DAS Restrictions

This option may require vessels fishing in SNE and MA regulated mesh areas to be charged DAS at a 1.5:1 rate. The proposal would require monitoring of each vessel's activity to accurately document their time in the aforementioned areas. From NMFS Law Enforcement's perspective, the only effective manner to accurately document the DAS ratios associated with this alternative would require mandatory VMS on all vessels fishing in these areas. Consequently, increasing the number of participants into the VMS system would require additional enforcement resources for monitoring and investigative inquiries due to the increased vessel monitoring load.

Utilization of the DAS call-in system to document time spent in specific areas would be considerably less enforceable, whereas there is no discernable method to document how long a vessel was in the area.

The proposed action adopts differential DAS counting in the SNE/MA RMA in future years.

5.5.3.1.3 Closed Areas

Year-Round Closed Areas and Seasonal Closed Areas

NMFS Law Enforcement's general guidance concerning implementation of closed area management is consistent for all management plans and is based in the "Precepts for Efficient Fisheries Enforcement". This alternative proposes two types of areas (closed and rolling). As identified in our Precepts, enforcement of closed areas is enhanced when the areas are "plain-shaped and clearly defined", straight lines on a straight north/south or east/west axis and their status (open, closed, open to some vessels) is maintained for reasonably long periods of time.

It is suggested that closed areas should be designed with a surrounding buffer to prevent brief incursions into the protected area. Use of VMS to enforce closed areas is less effective whereas VMS is voluntary for limited access multispecies vessels. Mandatory VMS on all multispecies vessels would greatly enhance enforcement's ability to track vessels and determine any closed area incursions. Enforcement of closed areas can be conducted with aerial and surface patrols and at-sea boarding by USCG units.

5.5.3.1.4 Possession Limits

Vessels restricted to possession limits while fishing in specific areas can be enforced by VMS and USCG enforcement through aerial and surface patrols in combination with at-sea boardings.

5.5.3.1.5 Gear restrictions

As with the current gear restrictions, enforcement relies on at-sea boardings to measure compliance. Enforcement of at-sea gill net limits is difficult to enforce, whereas the USCG has indicated they do not have the ability to haul gear.

Under this measure, large mesh vessels are restricted to certain mesh sizes based solely on the area fished. VMS is an extremely valuable enforcement monitoring tool and would increase the ability to determine areas fished by vessels with both mesh and landing limit restrictions.

Also under this alternative, long line vessels would be allowed to fish with no more than 4,500 12/0 hooks. From an enforcement perspective, this limitation on the number of hooks in use is virtually unenforceable. Additionally, the 12/0 size hook needs to be defined whereas the 12/0 hook is sold by several different companies and differ in size. NMFS Law Enforcement recommends identification and comparison by each manufacturer as to their 12/0 hook standard.

5.5.3.1.6 Minimum Fish sizes

Minimum fish sizes as described in the settlement agreement will continue to be in effect. The minimum fish sizes do not present any new enforcement concerns.

5.5.3.1.7 VMS Requirements

There is no VMS requirement automatically implemented by this alternative. The current call-in system and voluntary VMS will be maintained.

The only effective manner to accurately document the DAS ratios associated with this alternative would require mandatory VMS on all vessels fishing in these areas. Likewise, VMS is an extremely valuable enforcement monitoring tool and would increase the ability to determine areas fished by vessels with both mesh and landing limit restrictions.

5.5.3.2 Alternative 2 - Reduction in Allocated DAS/Gear Modifications

This alternative was not selected.

5.5.3.2.1 Effort Controls

Option 1

This option reduces allocated DAS by 30% for all vessels fishing in the GOM MA. All vessels intending to fish in the GOM must declare into the fishery for a minimum of 30 days. If the TAC is not met at the end of third quarter of the fishing year, the vessels revert back to the allocated DAS initially implemented on August 1, 2002 (20%).

From an enforcement perspective, the most effective method to track each vessel's location is to require the installation of VMS on each vessel fishing in the GOM. Since vessels allocated DAS are limited to 30% less while fishing in the GOM, the most feasible method to keep track is through the use of VMS. Without VMS, vessels electing to fish in the GOM could do so without the knowledge of the NMFS, thereby circumventing the reduction in DAS.

Another enforcement issue concerns the notification process. There must be timely notice to fishermen regarding the GOM cod landings exceeding or not surpassing 75 % of the TAC at the end of the third quarter.

Option 2
Option 2 differs from Option 1 in that a vessel is limited to using no more than 70% of its allocated DAS while fishing in the GOM MA. If vessels intend to fish in the GOM they must enroll for a minimum of 30 days and all DAS used will be charged against the GOM limit.

NMFS Law Enforcement's comments described in Option 1, above, would also apply to this option.

5.5.3.2.2 Closed Areas

NMFS Law Enforcement's recommendation concerning closed area management measures is documented in our "Precepts for Efficient Fisheries Enforcement". In addition to the issues raised in 5.5.3.1.3, NMFS Law Enforcement suggests fisherman and enforcement are given appropriate notification regarding the closure of specific areas.

5.5.3.2.3 Possession Limits

This measure proposes to reduce the daily/trip limit if 75% of the GB cod or haddock TAC is harvested. The only enforcement concern is proper advanced notification to all fisherman and enforcement of the change to the possession limit.

This measure also proposes trip limits for Cape Cod yellowtail while fishing in statistical areas 514 and 521 or in certain thirty minute squares in the inshore GOM. Vessels should be required to declare into this fishery and would be limited to the aforementioned trip limit while enrolled. Therefore vessels choosing to fish outside of this area while enrolled would still be subject to the 50/lb trip limit. Possession limits while fishing in specific areas are more readily enforced by VMS and USCG aerial and surface platforms, as well as at-sea boardings by USCG units. Dockside enforcement can only be conducted if the vessels are enrolled to fish in the above referenced statistical areas and are limited to 50 lbs of yellowtail per trip, regardless of the area fished

5.5.3.2.4 Gear Restrictions

Georges Bank and Gulf of Maine
This measure requires the mandatory use of separator trawl net and/ or a flounder net. A flounder net is not defined in current regulations, but this Amendment proposes the following definition: "a flounder net is defined as a two-seam low-rise groundfish net." It is still unclear what a low-rise net is fro this definition. For example, would low-rise be less than some height, the distance between top and bottom, etc.

Further, a separator trawl is defined as:

> A separator trawl is defined as a groundfish trawl modified to a vertically-oriented trouser trawl configuration, with two codends arranged one above the other. The bottom cod end is left open. A horizontally oriented large mesh (6 ½ inch square mesh minimum) separating panel is installed between the selvedges joining the upper and lower panels, extending from the front of the trouser junction forwards to the aft section of the first belly behind the fishing circle.

Trip and Day gillnet vessels are restricted to the number of nets they can possess, fish, haul or deploy. Establishing restrictions on "no tie-down gillnets" can only be enforced with at-sea boardings.

Also proposed in this measure is the requirement of all multispecies permitted vessels to use 12/0 hooks while fishing with long line gear. 12/0 hooks must be clearly defined as this size hook differs from company to company. NMFS Law Enforcement recommends a comparison by each manufacturer as to acceptable standard. Without a concise definition, this limitation on the number of hooks in use is virtually unenforceable.

The USCG has indicated at-sea enforcement of gillnet and hook limits at-sea are unlikely because of there inability to haul gear.

Gulf of Maine

Specifically in the GOM, trawl gear used inshore of 70 W must be a separator trawl net and/or flounder net, trawl gear would be restricted to the Raised footrope trawl in blocks 114,115,123,124 and 125, no-tie down gillnets in blocks 114, 115, 123, 124 and 125 and 10 inch twine top for scallop dredges while fishing in blocks 114, 115, 123, 124, and 125. Gear requirements should be uniform regardless of the area fished. Gear restrictions in specific areas are more readily enforced if vessels are restricted to possessing only the gear type described in this management measure. Vessels fishing in gear restricted and non restricted areas during the same trip and possessing different gear types would be very difficult to catch and require more enforcement manpower. Enforcement of these measures would only be conducted through at-sea boardings. Effective enforcement is improbable under this measure.

5.5.3.2.5 VMS Requirements

VMS is required for all vessels that fish in both the Gulf of Maine and Georges Bank. It is unclear whether this means only those fishing in both areas, and vessels fishing in either GOM or GB are not required to use VMS, or not.

From an enforcement perspective, the most effective method to track each vessel's location is to require the installation of VMS, on each vessel, fishing in the GOM. Possession limits while fishing in specific areas are more readily enforced by VMS and USCG aerial and surface platforms, as well as at-sea boardings by USCG units.

5.5.3.3 Alternative 3 - Area Management

This alternative was not selected.

5.5.3.3.1 Calculation of TACs

These two options determine the how the TACs will be identified for six different management areas. Enforcement does not have any specific concerns regarding which option is used to establish the TACs.

5.5.3.3.2 Consequences for Exceeding TACs

No new specific enforcement concerns.

5.5.3.3.3 Movement Between Areas

This measure describes five options allowing vessels to fish and move into one or more management areas at any time, during a trip, a different area on each trip, or one area during the entire fishing year.

Using the DAS call-in system to elect an area fishers intend to fish while at-sea or before leaving the dock would dramatically increase the need for at-sea enforcement presence to determine the specific area(s) fished. Although Options one, two and three requires vessels to be held to the more restrictive trip limit if they fish in more than one area, using the call-in system can not ensure enforcement's ability to determine any of the areas fished, except as reported by the vessel. Monitoring of hundreds of multispecies permitted vessels would be conducted through USCG aerial and surface patrols in conjunction with at-sea boardings by USCG units. Dockside enforcement would not be possible without the use of VMS.

(The use of the DAS call-in system for these proposals would increase resource needs by enforcement in order to determine if this system could be utilized effectively to track movement between areas. Modifying the current DAS call-in system would require reprogramming and script changes at additional costs.) Option one and two also require using Vessel Trip Reports in conjunction with the DAS call-in system to evaluate the management measures for each area. Enforcement's concern is raised with the use of VTRs as a management measure. Enforcement has encountered numerous instances where individuals have submitted inaccurate and incomplete VTRs, as well as not submitting them at all. Often times VTRs are submitted in an untimely fashion.

Under Option four vessels may fish in one area per trip, however if they choose to fish in more than one area during the fishing year, they are required to install a Vessel Monitoring System. VMS is a valuable enforcement tool in identifying each vessels location. Vessels that are not required to have a VMS will be able to enter different management areas without the knowledge of enforcement.

Option five limits vessels to fishing only one management area per fishing year. Enforcement's concern is with vessels limited to fishing in a specific area, and is addressed in the other four options above.

Enforcement recommends any vessel electing to fish in any area should be required to enroll with a letter of authorization indicating the area(s) to be fished. Each vessel must fish in the selected area for a minimum period of time.

Use of VMS for all involved vessels would enhance enforceability of unauthorized fishing in management areas and aid in the enforcement of species quotas trip limits.

An increase in observer coverage would assist in monitoring both discards and fishing activity, whereas the TAC management scheme mandates accurate and dependable reporting.

5.5.3.3.4 VMS Requirements

VMS is required for all vessels moving between areas within a single trip. This applies to movement between areas options 1-4 but not option 5.

Determining the location of hundreds of vessels could only be enforced through the use of VMS. Use of VMS for all involved vessels would enhance enforceability of unauthorized fishing in management areas and aid in the enforcement of species quotas trip limits.

5.5.3.4 Alternative 4 - "Hard" Total Allowable Catch (TAC)

This alternative will develop TACs for "all stocks in the multispecies FMP on a single or multi-stock basis". A TAC may be designed for the recreational fishery and if one is developed, it will be observed independently from the commercial TAC. *This alternative was not selected.*

5.5.3.4.1 Hard TAC with Input Controls

This management measure incorporates a hard TAC with input controls. The term "input controls" should be clearly defined to identify which management measures they incorporate. The input controls as described in this alternative are derived from one of three options:

<u>Option 1</u>
The input controls in option 1 are the management measures outlined in Alternative 2 (5.5.3.2- Reduction in Allocated DAS/Gear Modifications). The enforcement issues are outlined in Alternative 2 and are the same for this option.

<u>Options 2 and 3</u>
Option 2 is based on the measures implemented by the Framework 33 court order effective April 30, 2004. In other words option 2 is the management measures currently in place. Option 3 is the management schemes implemented during the 2001 fishing year. Option 3 is also described as the No Action Alternative.

Option 2 and option 3 are very comprehensive management schemes. Enforcement reiterates it's recommendations outlined in the "Precepts for Efficient Fisheries Enforcement".

NMFS Law Enforcement does not foresee any new enforcement related concerns associated with this measure. NMFS Law Enforcement recommends review of previous enforcement comments relating to VMS, closed areas, Days-at-Sea, trip limits, possession limits, special access programs, and gear restrictions.

5.5.3.4.2 Monitoring the TAC

This measure requires up to date information to NMFS in order to accurately manage the TACs. Increased reporting (real time) of catches will be necessary as the TAC becomes closer to being fulfilled. Successful implementation of this management plan will require comprehensive monitoring, and as part of the monitoring system, enforcement recommends increasing observer coverage to monitor fishing activity.

5.5.3.4.2.1 Reporting System Options

The concept of "daily electronic dealer reporting" is supported by enforcement. At this time, this alternative does not identify the details regarding electronic dealer reporting and a vessel's trip identifier number. NMFS Law Enforcement's general concern regarding reporting is accountability and veracity of the reports and ensuring that these issues are sufficiently addressed.

Under option one, two and three dealer reporting will be accomplished by way of electronic reporting. Also under option one all limited access multispecies vessels will be required to have a VMS system and use this system to report the area they intend to fish. Vessels who have been issued a small vessel permit and open access vessels will be able to report utilizing a call-in number. Option two and three do not insist on VMS for limited access multispecies vessels and rely on call-in systems for all vessels.

Mandatory VMS for all limited access DAS multispecies vessels is supported by enforcement. Determining vessel incursions into areas which may be closed or have stock restrictions can be accomplished through the use of VMS and to a lesser extent at-sea enforcement. Determining where a vessel has fished is unlikely through dockside enforcement.

The expansion of VMS to hundreds of vessels would likely increase resource needs of enforcement to effectively oversee the administrative tasks and monitoring of escalated VMS usage.

Establishing a call-in number for "small vessel permit category and open access vessels" to report specific information would expand resource needs by enforcement and require implementation of infrastructure and administrative processes set up to collect, extract, and break down the information. The cod hail line was a variation of this call-in number and was set up for fishermen to report information regarding their cod landings. Very few fishermen called the cod hail line, and from the enforcement perspective, was an unsatisfactory mechanism to document the required information.

Enforcement concerns requiring fishermen to identify area fished through the DAS call-in system have been raised in 5.5.3.3.3 and are applicable under this option.

5.5.3.4.2.2 VMS Requirements

VMS is required for all vessels in Option 1 only. There are no VMS requirements for Options 2 and 3.

Mandatory VMS for all limited access DAS multispecies vessels is supported by enforcement. Determining vessel incursions into areas which may be closed or have stock restrictions can be accomplished through the use of VMS and to a lesser extent at-sea enforcement. Determining where a vessel has fished is unlikely through dockside enforcement.

5.5.3.4.2.3 Reaching the Total TAC

This management measure has two options:

Option 1- Closure of Stock Area

Under this proposal, the NMFS would close a particular area or entire statistical area(s) to gear capable of catching a particular species, if all of the TAC for that stock is projected to be caught. However, fishing gear believed to be incapable of catching the species for which the TAC would be reached, will still be able to fish in the closed area(s).

With area specific TACs, there will be an increased emphasis on enforcement of closed areas, possession limits, vessel inspections at sea (to determine gear used and retention of prohibited species), and accurate and timely reporting.

NMFS Law Enforcement strongly suggests that closed areas should be clearly defined in large, plain shapes and maintained for sensibly long periods of time. Multiple possession limits for various stocks in different areas will be difficult to enforce, particularly without ubiquitous VMS coverage. Use of VMS for all limited access multispecies vessels would greatly enhance enforceability of closed areas regardless of the reason for the closure. *See comments in 5.5.3.1.3 with regards to VMS and closed area enforcement and 5.5.1.5 concerning closed area administration.*

Possession limits can be monitored via dockside enforcement, however, enforcement would be limited without the ability to determine the specific area where the fish were caught. See comments in 5.5.3.1.4 with regards to possession limit enforcement.

To effectively monitor and report the catch in these TAC management areas this alternative may require an increase in observer coverage. The enforcement concerns related to increased observer coverage are addressed in 5.5.1.16.1.2. and 5.5.3.4.2.

Option 2 - Prohibition on Retention

Under this alternative, possession of a species is prohibited in an area for which all of the TAC for a specific stock is projected to be harvested, except for transiting purposes. If the vessel possesses the same species harvested from other stock areas, this alternative allows the vessel to transit the closed area as long as the gear is stowed appropriately and prohibits the vessel from fishing in the closed area.

NMFS Law Enforcement is concerned that this scheme would allow vessels to fish in the closed stock area with gear capable of catching the prohibited species and then move to other stock areas and catch the same species. Enforcement of the closed stock areas would be most effective through VMS, however, VMS can not identify where the closed species were caught. Vessels allowed to fish in closed stock areas with gear capable of catching closed stocks would require at-sea or aerial patrol units to enforce the closed areas.

As previously identified, multiple possession limits for various stocks in different areas along with transiting in closed stock areas while possessing prohibited stocks pose significant enforceability concerns.

With regards to both Option 1 and Option 2, NMFS Law Enforcement suggests appropriate advanced notification to industry and enforcement regarding any upcoming closed stock areas.

5.5.3.5 Recreational Fishing Measures

The minimum size and bag limits listed under the recreational fishing measures do not present any new enforcement issues.

Option 3 states "any trip in excess of 15 hours and covering two consecutive calendar days will be considered more than one day." Enforcement of this option with out being able to verify period of time fished would be difficult and extremely resource intensive.

Option 3 is part of the proposed action. Vessels subject to this restriction are required to file VTRs recording time of sailing and the end of the trip.

5.5.4 Alternatives to Minimize the Adverse Effects of Fishing on Habitat

Alternative 2 – Complementary Benefits of Other Amendment 13 Alternatives *(Preferred Alternative)*
See the other alternatives.

Alternative 3 – Habitat Closed Areas
Enforcement recommends following the guidance provided in the "Precepts for Efficient Fisheries Enforcement". Closed Areas that are clearly defined in large, plain shapes for reasonably long time spans with minimal exceptions, exemptions or transiting provisions (except for compelling safety reasons). Again, use of VMS for all involved vessels would enhance enforceability of the closed area regardless of the reason for the closure. Increased use of VMS would, in all cases, require additional enforcement resources for monitoring as well as verification that the system is prepared to handle the increased vessel monitoring load.

Alternative 4 – Modified Groundfish closed areas with habitat subsets identified
This alternative would create "blocks", "each approximately 75 square nautical miles in size, by the existing grid of latitude and longitude lines at 10 minute intervals." The blocks would be further grouped into five areas (Gulf of Maine, Georges Bank, South Channel, Hudson Canyon, Southern). Closures would be applied to these areas in various ways by this alternative. From the enforcement perspective, the discussion of possible scenarios of closed and open areas created by this alternative seems fairly complicated. We again recommend a simple, long term closure practice whenever possible.

This alternative was not selected.

Alternative 5 - Closed areas designed to protect important EFH and balance fishery productivity*)*
Enforcement recommends following the guidance provided in the "Precepts for Efficient Fisheries Enforcement". Alternatives 5A, 5B, and 5C show narrow, fishable corridors between two closed areas. Alternative 5D is preferred because it has the shortest corridor, but enforcement would prefer no narrow corridors at all. Again, use of VMS for all involved vessels would enhance enforceability of the closed area regardless of the reason for the closure.

This alternative was not selected.

Alternative 6 - Closed areas consistent with the Framework Adjustment 13 Scallop Closed Areas Access Program *(Preferred Alternative)*
The shapes/sizes of some of the areas designed off of the New England coast (such as CAI and NLCA) do not meet the general enforcement recommendation of large, plain shaped. Larger areas with straight line boundaries and the ability to provide a buffer between the area boundary and the stocks would enhance enforceability of this alternative.

This alternative was not selected.

Alternative 7 – Expand the list of gears prohibited in closed areas
Echoing the general enforcement comments on page 5, with respect to closed area enforcement, areas must be clearly defined with limited access to the areas in order to allow for efficient and effective offshore enforcement. Expanding the list of gears prohibited in year-round closed areas will further limit access, thus making offshore enforcement more efficient and effective. Transit rules are necessary, particularly for pots

and traps.

This alternative was selected, but only hydraulic clam dredges were added to the list of prohibited gear.

Alternative 8 – Restrictions on the use or rockhopper gear and/or roller gear *(Preferred Alternative)*
Like the proposed scallop restriction on rock chains, region wide (i.e., throughout the entire range of the multispecies fishery) restrictions on rockhopper and roller gear do not pose any significant enforcement related concerns. Any gear restrictions *by area* do pose enforcement concerns similar to the general enforcement comments on area management measures (page 6). As with other gear restrictions, this alternative would rely on at-sea boardings.

Additionally, clear and concise definitions of 'rockhopper' and 'roller' gear, and stowage rules, are necessary.

This alternative was not selected.

Alternative 9 – VMS on all groundfish vessels
One of the Enforcement Precepts is 'Assisted by VMS'. Vessel Monitoring Systems are a tremendous asset to enforcement for monitoring days at sea as well as closed areas. Additionally, the knowledge of the whereabouts of fishing vessels eases the logistical burdens of extensive surveillance, which can be extremely manpower intensive. When developing new management plans consideration should be given to requiring implementation of VMS on vessels. This alternative does just that.

This alternative was not selected.

Alternative 10 – Habitat Closed Areas the are modifications of existing mortality closures and other proposed habitat closures *(Preferred Alternative)*
Alternative 10A modifies the borders of existing closed areas, or areas proposed for closure under the other alternatives. Alternative 10B is actually the same as scallop habitat alternative 8b; thus, a larger area is preferable to a small area, and an area with fewer edges is preferable to one with lots of edges. All other general enforcement comments relative to all gears being prohibited, VMS requirements, stowage and transit, apply.

This alternative was selected.

5.5.5 Other Issues

5.5.5.1 Northern Shrimp Fishery Exemption
This alternative does not pose any new enforcement related concerns.

5.5.5.2 Tuna Purse Seine Vessel Access to Groundfish Closed Areas
This alternative does not pose any new enforcement related concerns, other than those described in 3.4.7.

5.5.5.3 SNE General Category Scallop Vessel Exemption Program.
This alternative does not pose any new enforcement related concerns.

INTENTIONALLY BLANK

5.6 Social Impact Analysis

5.6.1 Social and Community Impacts

5.6.1.1 Introduction and Background

This social impact assessment characterizes the magnitude and extent of the social impacts likely to result from the alternatives considered in Amendment 13 to the Northeast Multispecies FMP as compared to the no action alternative. To the extent possible, the following assessment provides a comparison of alternatives under consideration to support the Council's decision-making process.

This assessment was prepared in accordance with NEPA and the Magnuson-Stevens Fishery Conservation and Management Act, as well as other applicable laws. NEPA requires that economic and social impacts of regulatory actions be considered and evaluated through a decision-making process that involves the public. National Standard 8 of the Magnuson-Stevens Act states that:

> Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

It is important to note that the current interpretation of National Standard 8 requires the Council to consider the importance of fishery resources to affected communities and provide those communities with continuing access to fishery resources, but it does not allow the Council to compromise the conservation objectives of the management measures. *Sustained participation* is interpreted as continued access to the fishery within the constraints of the condition of the resource. The long-term conservation and rebuilding of stocks often require that limits be placed on particular gears and/or the harvest of specific stocks. Thus, the law interprets National Standard 8 only as a consideration of continued overall access to fishery resources and not as a guarantee that fishermen will be able to use a particular gear type, harvest a particular species of fish, fish in a particular area, or fish during a certain time of the year.

A fundamental difficulty exists in attributing social change to specific factors such as management regulations when communities or other societal groups are constantly evolving in response to numerous additional external factors, such as market conditions and technology. Increasingly important influences in coastal communities include demands for recreational uses of the waterfront and tourism (these influences are referred to as *gentrification* in the MARFIN Report). Certainly, management regulations influence the direction and magnitude of social change, but attribution is difficult with the tools and data available. Attribution is particularly difficult considering the dynamic and fluid nature of fishing communities. As a result, while this assessment focuses generally on the social impacts of the proposed fishing regulations, it is recognized that external factors are also influencing change, both positive and negative, in the affected communities. In many cases, these factors contribute to a community's *vulnerability* and ability to adapt to new or different fishing regulations.

5.6.1.1.1 Scale of Assessment – Fishing Communities

Section 316 of Magnuson-Stevens Act defines a fishing community as:

> a community which is substantially dependent on or substantially engaged in the harvesting or processing of fishery resources to meet social and economic needs, and includes fishing vessel owners, operators, and crew and United States fish processors that are based in such community.

As discussed in the Affected Human Environment (section 9.4), there are a number of issues involved in whether a port meets National Standard 8's legal definition of a fishing community. But fishery impact statements, such as the social impact analysis, must examine the impacts to all the participants, including all communities and other groups that participate in the fishery. Thus for the purposes of this social and community impact assessment, the primary and secondary port groups identified and described in the Affected Human Environment (section 9.4.5) will serve as the primary scale of measurement. ***Primary groups*** are those communities that are currently most substantially engaged in the groundfish fishery (see the Affected Human Environment for a discussion of the distinction between substantially engaged and substantially dependent in National Standard 8). For the most part, primary groups are fishing communities that are likely to be the most significantly and directly impacted by Amendment 13 management measures, and the analysis of impacts on them speaks to the analytical requirements of National Standard 8. However, the impacts of Amendment 13 are predicted to be large in scale, affecting most ports engaged in the groundfish fishery. This assessment, therefore, has sought to gain a wide perspective on the magnitude and extent of the impacts of the alternatives under consideration. Thus the analysis also considers ***Secondary groups***, which are those ports that currently may not be substantially involved in or dependent on the groundfish fishery but have demonstrated some participation in the groundfish fishery since the 1994 fishing year (FY94). They also may consist of places that were historically more involved in the groundfish fishery, but are not recently for many reasons (loss of nearshore fishery, concentration of fishery in larger ports, external factors, etc.).

Current guidance on National Standard 8 defines a community as a town or city, a geographic unit which might fit the Census Bureau's definition of a "place." But it is important to note that fishing communities are not bounded or separated from the commerce and institutional apparatus of the larger cities and towns in which they are located. In fact, most fishing communities rely on a rather complicated network of business and social ties that extend well beyond their geographic boundaries and often into other communities in the region. The grouping of communities in this assessment and the socioeconomic context provided by the IMPLAN model allows for some consideration of the interconnected nature of ports and communities when predicting the impacts of Amendment 13. Moreover, because the size and diversity of the groundfish fishery makes it impractical to consider impacts on each secondary port individually, their grouping with other secondary ports in the same county or geographically adjacent counties has been done consistently with the regions analyzed using the IMPLAN model (see section 5.4.6), so that it can be used to better characterize the impacts on these community groups.

When predicting social impacts of management measures, it is important to consider impacts on the following, which will be discussed to the extent possible in the following sections:

- the fishing fleet (vessels grouped by fishery, primary gear type, and/or size);
- boat owners and captains;
- crew;
- fish buyers (dealers);
- seafood markets;
- community cooperatives;
- fishing industry associations;
- cultural components of the community;
- fishing families.

5.6.1.2 SIA Information Sources

An updated and comprehensive description of the affected human environment (multispecies fishermen and fishing communities) is presented in section 9.4. Additional fishery and community information as well as an assessment of the social impacts of the multispecies rebuilding program are presented in Amendments 5, 7, and 9 to the Northeast Multispecies FMP. Frameworks 25, 26, 27, 30, 31, and 33 also contain useful information on affected fishing vessels and communities as well as predictions about the social impacts of recent groundfish management measures. The information in these documents supplements this social impact assessment and provides background information to help assess the impacts of the Amendment 13 management alternatives.

New information is available for use in assessing the social and community impacts of the Amendment 13 alternatives. Recent studies, inventories, and other important publications containing social, economic, and community information are summarized in section 9.4.5. New information includes the recently-published MARFIN Report, other community profiles, the ME DMR Groundfish Regulation Impact Survey, and Council staff initiatives including the Social Impact Informational Meeting Report. While it is not practical to include all of the information in this document, readers and reviewers should reference these additional sources of information to gain a more complete perspective on the issues. Where appropriate, key findings and important information from these documents are summarized to support the conclusions drawn in this impact assessment. These additional materials can be obtained by contacting the Council office. The Social Impact Informational Meeting Report serves as Appendix I to the document.

5.6.1.2.1 Background

Amendment 7

This EIS is the first since Amendment 7 to the Northeast Multispecies FMP in 1996 (Framework 36 was never submitted). Amendment 7 was the most comprehensive program in a ten-year long sequence of management actions designed to rebuild and manage the Northeast multispecies fishery. It built on the management system implemented in Amendment 5 with controls on the number and size of vessels that may fish for regulated multispecies, the number of days-at-sea a vessel may fish for those species, and the size of the fish that can be caught. Specifically, Amendment 7 contained the following measures:

- modifications to the limited access and open access permit categories in the permit moratorium;
- target Total Allowable Catch (TAC) levels to provide a basis for evaluating the effectiveness of the rebuilding program;
- continuation of Regulated Large Mesh Areas (minimum mesh size for **all** fishing activities);
- a certification process for fisheries using mesh smaller than the minimum mesh with less than 5% regulated species bycatch;
- adjustments to the Days-At-Sea (DAS) Effort Reduction Program (an accelerated timeline for reducing available DAS);
- gear restrictions (minimum mesh size, restrictions on the number of nets);
- year-round and seasonal area closures;
- possession limits for some stocks (for example, the haddock possession limit was 1,000 pounds);
- additions to the measures that can be implemented through the framework adjustment process; and
- mandatory data reporting requirements for vessel operators and dealers.

When the Council implemented the multispecies stock rebuilding program in Amendment 7, it recognized that the measures required to achieve the plan objectives would have significant social and community impacts. It stated that the breadth and scope of those measures would likely cause social change proportional to the individual or community dependence on the affected stocks. The Council also noted that the social impacts of the management measures are largely related to their economic impacts, and as such would be severely negative in the short-term and positive in the long-term, although some fundamental changes would occur for which a value cannot be assessed.

The "Social Impacts" section of Amendment 7 was framed by six guiding precepts:

- Will standards, style, or pace of living change?
- Will cooperation and interaction patterns change?
- Will change be sudden or gradual?
- How does the proposed action fit with historical trends and participation in the fishery?
- Does the change fit with cultural or normative expectations of behavior in the fishery or community?
- How do fishermen and the community members view the alternatives?

Significant social impacts predicted in Amendment 7 are summarized below, categorized by the management measure they were associated with in the analysis.

Modifications to limited access and open access categories: Amendment 7 proposed modifications to the previously instituted permit moratorium, including the elimination of two open access categories (possession-limit-only and hook-gear-only); transfer of vessels permitted in these categories to similar, limited access categories; creation of one additional small-scale or subsistence open access category (handline/rod-and-reel); and creation of a charter/party permit class. The social impacts of these permit modifications as predicted by Amendment 7 were mixed. For example, some open access permit holders would likely not qualify for limited access permits in the short-term, resulting in a potential loss of revenues; however, creation of the handline/rod-and-reel category (with its accompanying 300-pound trip limit) was seen as a way to mitigate the resulting impacts of this by not completely shutting out the previously open-access fleet. An additional positive impact associated with the modifications was the potential incentive they would provide for smaller vessels to remain flexible in gears used and species fished, which could help compensate for a projected loss of revenues from groundfish harvesting.

Implementation of target Total Allowable Catch (TAC) levels to provide an evaluative basis for rebuilding efforts: The potential social impacts of this management decision as outlined in Amendment 7 were all positive in nature. Amendment 7 characterized target TAC levels as tools for assuring long-term compliance with rebuilding goals and considered important for rebuilding the resource and the fishery in its entirety.

Certification of bycatch fisheries: This provision of Amendment 7 outlined a certification process for the exemption of certain fisheries using mesh smaller than the minimum standard, but with less than 5% regulated species (groundfish) bycatch. Predicted impacts of this measure were again largely characterized as positive, by providing fishermen options for diversification into other fisheries (dogfish, silver hake, herring, fisheries west of 72°30').

Accelerated effort reduction program (Days-at-Sea): This proposed action reduced Days-At-Sea (DAS) for affected vessels at an accelerated rate of 50% over two years, while simultaneously adding hook and gillnet vessels to the DAS requirements. Amendment 7 clearly anticipated significant social impacts resulting from these enhanced reductions in allowable groundfish DAS, primarily that some vessels, particularly those already in a financially uncertain position, would not be able to survive the reductions. The amendment supported this assessment with a presentation of the findings of an analysis that evaluated the "break-even" (operating costs equal to revenues) levels of DAS for a variety of vessel types and ports of landing. The analysis predicted a significant failure of both large and small vessels across ports, particularly in Year 2 of the program which would see allowable DAS reduced to 88 for Fleet DAS vessels and by 50% for Individual DAS vessels. Another predicted impact arising from DAS reductions was an increase in conflict in inshore fisheries between vessels fishing with different gear types, driven to those fisheries by the desire to avoid losing DAS to steaming time.

Gear Restrictions: Both minimum mesh sizes and square mesh requirements were unchanged by Amendment 7; minimal impacts were predicted for gillnetters, as the majority of gillnet vessels were already operating with mesh larger than that required by existing regulatory minimums at the time Amendment 7 was implemented.

Area Closures: Closed Areas I and II and the Nantucket Lightship Area would remain closed on a year-round basis as earlier mandated by Framework Adjustment 9, generating a prediction of no additional impacts.

A process for establishing seasonal spawning closures was provided for in Amendment 7, but impacts were considered beyond the scope of the Amendment's analysis prior to specification of the specific closure area(s). The amendment did note that large area closures lead to crowding of the remaining fishing grounds and conflicts between those fishing with different gear types. It also briefly discussed the possible impacts on family and social cohesion from disruption of the traditional routine of fishermen, and from the possibility that small-vessel fishermen could be converted to laboring on larger vessels, with accompanying longer hours at sea.

Possession Limits: The decision to raise the possession limit for haddock from 500 to 1,000 pounds was seen as having a substantial positive impact on large otter trawls operating from Gloucester, New Bedford, and Portland. This impact was largely characterized in the amendment as an opportunity for large vessels landing haddock at these ports to increase revenues generated by haddock, particularly as a proportion of all revenues received from groundfish harvesting.

Mandatory Data Reporting: Amendment 7 categorizes the Northeast groundfish fishery as heterogeneous and highly competitive, which therefore heightens the importance of monitoring and data reporting by vessel operators and dealers to successful management of the resource. This provision was added as a means of assessing actual activity and ensuring that enforcement actions are taken when the requirements of the FMP are violated. One positive social impact implied here is a reduction in perceptions among fishermen that voluntary compliance with regulations puts them at a disadvantage to other resource users who do not similarly comply.

Framework Adjustments: The amendment states that "leaving open the possibility of adjusting any measures, as needed, to meet rebuilding goals greatly increases the long-term effectiveness of this amendment." The perceived flexibility associated with adjustments – particularly in the case of the DAS limitations – is projected as something which ultimately will benefit the entire fishing industry by allowing the Council to respond to updated information about the evolving condition of the stocks.

A complete discussion of the social and community impacts predicted from the Amendment 7 management measures can be found in the Amendment 7 EIS.

Cumulative Impacts

Much has happened in New England fisheries management since the implementation of Amendment 7. The Magnuson-Stevens Act was reauthorized in 1996, and the SFA amendments to the MSFCMA added three new National Standards, including one relating to fishing communities, safety at sea, and bycatch. The reauthorized MSFCMA also emphasized the need to conserve and manage fisheries resources and rebuild each stock to levels that can sustain MSY on a long-term basis. The New England Council has responded to the requirements of the new law with modifications to groundfish regulations almost on an annual basis since Amendment 7 was implemented.

The Council's response to the mandates of the MSFCMA has resulted in the implementation of management measures through the framework adjustment process, the impacts of some of which were not fully considered or predicted in Amendment 7. Framework 25 was considered a multispecies annual adjustment but was actually the first in a series of framework adjustments implemented to address concerns about Gulf of Maine cod (Frameworks 20 and 24 also included measures to reduce fishing mortality on Gulf of Maine cod, but they were not as comprehensive as the effort that was initiated with Framework 25).

Framework 25 became effective at the beginning of the 1998 fishing year (May 1, 1998). The purpose of Framework 25 was to significantly reduce fishing effort on Gulf of Maine cod through a combination of direct and indirect measures. Direct measures included area closures and Gulf of Maine cod trip limits, and indirect measures included an incentive for vessels to shift fishing effort from the Gulf of Maine to Georges Bank with an increase in the Georges Bank haddock trip limit. Since Framework 25 and over the past 3-1/2 years, ten additional framework adjustments have been implemented, and all but three included measures to protect and rebuild Gulf of Maine cod (two were for whiting management, and one addressed marine mammal issues).

One example of social impacts that were not predicted in Amendment 7 is what resulted from increased regulatory discarding of Gulf of Maine cod due to low trip limits. When Amendment 7 was implemented, there was no Gulf of Maine cod trip limit, nor were there any proposals in Amendment 7 to establish a trip limit for Gulf of Maine cod. The first Gulf of Maine cod trip limit was implemented as part of Framework 20 on May 1, 1997 (1,000 pounds per DAS up to four days, 1,500 pounds per day greater than four days). It was reduced again in Framework 24 to 700 pounds, and then reduced to 400 pounds in an interim action on June 12, 1998. Framework 27 reduced the trip limit to 200 pounds and gave authority to the Regional Administrator of NMFS to again reduce the trip limit to 5-100 pounds when 51 percent of the target TAC was projected to be reached. Less than one month after the start of the 1999 fishing year, the Regional Administrator, based on NMFS' calculations, lowered the Gulf of Maine cod trip limit to just 30 pounds. Large-scale public outcry ensued. Fishermen claimed that they were being forced to throw overboard hundreds, sometimes thousands of pounds of cod. They were disgusted about wasting valuable fisheries resources, and they reported experiencing stress, loss of morale, and loss of job satisfaction as a result of regulatory discarding (see Social Impact Meeting Report in Appendix I). The Council attempted to address this discard situation and eventually increased the trip limit back to 400 pounds in Framework 33.

In addition to increased groundfish restrictions since the reauthorization of the MSFCMA, regulations in other fisheries have increased considerably, thereby reducing opportunities for groundfish vessels to pursue many of the alternative fisheries that were identified in Amendment 7. For example, the federal dogfish fishery has all but disappeared. The annual quota for dogfish is around 4 million pounds, and the trip limits have been reduced to 600 and 300 pounds, eliminating this fishery as a viable alternative to groundfishing and generating a significant amount of regulatory discards. More recently, skate resources have been identified as management concerns, and the Council is currently developing a Fishery Management Plan for the northeast region's skate complex, a resource that was once promoted as an underutilized species. Management of the shrimp, monkfish, squid, scup, and other fisheries has become increasingly restrictive, making it more difficult for groundfish vessels to effectively shift their effort from groundfish to other species.

2002 in particular has been a difficult year full of uncertainty, confusion, and change. The outcome of the recent lawsuit on Framework 33 and the resulting court order implementing additional reductions in the 2002 fishing year and establishing a timeline for Amendment 13 have disrupted fishing activity throughout the region, the social and community impacts of which have not yet been fully realized. Two major adjustments to groundfish measures occurred through the court-ordered NMFS Interim Action (settlement agreement) on May 1, 2002 and August 1, 2002. These actions followed a reversal of a court decision to implement a much more restrictive baseline for allocating DAS for the 2002 fishing year. Changes occurred quickly and numerously in the groundfish fishery during the 2002 fishing year, leaving most affected entities with little opportunity to plan their businesses and/or adapt to the new restrictions. The most significant component of these restrictions included a new baseline for DAS allocations followed by a 20% reduction in allocated DAS. Many vessels remained uncertain about their new DAS allocations right through the beginning of the 2002 fishing year and were disadvantaged in terms of their ability to try to plan their business strategy and maximize what remaining DAS they had. The social impacts of the recent DAS reductions as well as many of the other measures recently implemented in the court order are discussed throughout this assessment.

Another development that is important to consider in the context of this assessment is the recent discovery that an error was made in the measurement of the trawl warps on the NEFSC's Research Vessel Albatross. This error has apparently affected surveys for 2000-2002, which are used in part to assess the status of groundfish stocks. While the impacts of this error are not yet fully understood, the Council is under a court order to move forward with the development of Amendment 13. The trawl survey error has shaken the confidence of fishermen in the scientific and management process and has further compromised the credibility of NMFS and the NEFSC in the eyes of the industry and other sectors of the public. Fishermen feel that scientists must finally acknowledge their longstanding claims that many fishery resources are in better condition than recent scientific information indicates and that major problems exist with the trawl survey. At the time of this writing, scientists remain equivocal about the impacts of the trawl survey error on the current status of the groundfish resources and Amendment 13. Both NEFSC(2002b) and Payne et al. (2003) concluded that the information was suitable for use in making management decisions, but these conclusions did not allay the concerns of fishermen. Resolution of this issue could result in additional social impacts, depending on perceptions about the transparency of the scientific process and the formation of attitudes towards the resolution.

The Council recognizes that a byproduct of continuous incremental plan modifications combined with other factors that have caused disruption and uncertainty in recent time is that cumulative impacts may not be adequately assessed. Even as the individual adjustments themselves are determined to have no significant social impacts beyond those predicted in Amendment 7, they may have generated additive or synergistic effects contributing to a change in the overall magnitude and intensity of social impacts affecting participants in the fishery. Cumulative impact assessment is a process that attempts to provide a broader perspective on these types of changes by characterizing the impacts on a system across time and space occurring in an additive or synergistic manner. To the extent possible, this assessment considers the cumulative impacts of recent fishery management actions as well as the potential impacts of foreseeable future actions not only in the groundfish fishery, but also in other associated fisheries. Many cumulative social impacts since Amendments 5 and 7 are discussed in detail in the Social Impact Informational Meeting Report contained in Appendix I to this amendment.

5.6.1.3 SIA Communities of Interest

The communities that are likely to experience significant impacts from the alternatives under consideration include those with at least one of the following characteristics:

- an active and large multispecies fishing fleet,
- vessels and shoreside facilities that currently depend on groundfish for a substantial portion of their business,
- geographically close to areas proposed for additional seasonal or year-round closure, and
- vessels that hold a substantial amount of latent effort (inactive DAS).

The above criteria qualify almost every one of the 40 primary community and secondary port groups described in the Affected Human Environment, except for the "other" categories and some of the most southern states. Because it is not practical to identify all of these groups as *communities of interest* for this assessment, the following groups have been chosen to represent the diversity, scale, and extent of those involved in the groundfish fishery. Inferences can be drawn about social impacts on other port groups based on the information presented in the Affected Human Environment and the likely distribution of other predicted impacts. All primary community groups have been identified as *communities of interest* for this assessment.

Primary Community Groups

1. Portland, Maine
2. Portsmouth, New Hampshire
3. Gloucester, Massachusetts

4. Boston, Massachusetts
5. Chatham/Harwichport, Massachusetts
6. New Bedford/Fairhaven, Massachusetts
7. Point Judith, Rhode Island
8. Eastern Long Island, New York

Secondary Community Groups

9. Upper Mid-Coast 1, Maine
10. Lower Mid-Coast 1, Maine
11. NH Seacoast
12. South Shore, Massachusetts
13. Provincetown, Massachusetts
14. Eastern Rhode Island
15. Northern Coastal New Jersey

It is important, however, to consider the impacts of the proposed alternatives across all communities. Social impacts can be defined as the changes that a fisheries management action may create in people's way of life (how they live, work, play, and interact), people's cultural traditions (shared beliefs, customs, and values), and people's community (population structure, cohesion, stability, and character). As such, social impacts may result from changes in flexibility, opportunity, stability, certainty, safety, and other factors that are not specific to any community, but oftentimes to any individual or entity experiencing changes resulting from a fishing regulation.

It is possible that the social impacts of some measures under consideration will not be experienced solely by one community group or another; rather, it is likely that some impacts will be experienced across communities, gear sectors, and vessel size classes. An example of this would be a reduction in allocated DAS if it is applied to all multispecies permit holders. Another example would be a mesh restriction for otter trawl vessels. While extra consideration is given to the *communities of interest* for this framework, the potential social impacts of the measures under consideration are discussed generally in this assessment so that their impacts across communities can be understood more clearly.

The following paragraphs summarize recent fishing activity in the *communities of interest*. More information about these and other communities is presented in the Affected Human Environment.

Portland, Maine: In FY99 and FY00, Portland averaged 13,770,600 pounds of groundfish landings and $15,620,900 in groundfish revenues, establishing it as an important port of landing for groundfish vessels and a primary port for the multispecies fishery. The community of Portland is also substantially dependent on groundfish for a significant portion of its total fisheries revenues. In FY99 and FY00, 46 active multispecies vessels homeported in Portland earned more than $10,800,000 in revenues from groundfish. More than 64% of Portland's total fisheries revenues from federally-permitted vessels came from groundfish from FY99 – FY00. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Portland are even more than 64% dependent on the multispecies fishery. Vessel-level impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Portland, residents of Portland reported having experienced the most significant social impacts from the Amendment 5/7 DAS reductions (Appendix I). Many of Portland's active groundfish vessels possess Individual DAS permits and have experienced a 50% reduction in their Individual DAS. Moreover, most Individual DAS vessels use the majority of their allocated DAS. The measures proposed in Amendment 13 that are likely to impact this community the most are those that modify or further reduce DAS allocations. However, because Portland is such a large and important groundfish port, and because of its location, it is likely that most measures proposed in Amendment 13 will affect this community. The EA for the settlement agreement estimated that 84.9% of groundfish activity in Portland could be affected by the recently-implemented Interim Action.

Portsmouth, New Hampshire: In FY99 and FY00, Portsmouth averaged 2,265,300 pounds of groundfish landings and $2,199,500 in groundfish revenues. The increasing number of multispecies vessels landing in Portsmouth as well as activity at the Portsmouth Co-op indicate that Portsmouth is an important port of landing for groundfish vessels. The community of Portsmouth is also dependent on the groundfish fishery for a significant portion of its total fisheries revenues. In FY99 and FY00, Portsmouth's dependence on groundfish for its total fisheries revenues from federally-permitted vessels averaged about 55%. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Portsmouth are even more than 55% dependent on the multispecies fishery. Vessel-level impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Portsmouth, residents of Portsmouth and the NH Seacoast reported that they have experienced the most significant social impacts from the Gulf of Maine inshore area closures and the low Gulf of Maine cod trip limits (Appendix I). The measures proposed in Amendment 13 that are likely to impact this community the most, either positively or negatively, are those that modify inshore Gulf of Maine area closures and the Gulf of Maine cod trip limit. However, depending on the alternative selected, other measures have the potential to significantly affect this community (for example, large-scale DAS reductions).

The EA for the settlement agreement estimated that 77.2% of groundfish activity in Portsmouth could be affected by the recently-implemented Interim Action. In addition, business at the Portsmouth Co-op has been affected by the recent reductions. The Co-op even closed temporarily as a result of the measures that were implemented on May 1, 2002.

Gloucester, Massachusetts: In FY99 and FY00, Gloucester averaged 13,670,200 pounds of groundfish landings and $15,553,450 in groundfish revenues. The significant amount of landings and revenues as well as the importance of the Gloucester Seafood Display Auction and other shoreside facilities indicate that Gloucester is an important port of landing for multispecies vessels and a primary port for the multispecies fishery. In FY99 and FY00, an average of 133 vessels homeported in Gloucester generated about $12,207,750 in revenues from groundfish. Since FY94 and probably prior to then, more than 60% of Gloucester's total fisheries revenues from federally-permitted vessels have been generated from groundfish, illustrating Gloucester's substantial dependence on the groundfish fishery. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Gloucester are even more than 60% dependent on the multispecies fishery. Vessel-level impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Gloucester, residents of Gloucester reported that they have experienced the most significant social impacts from the Gulf of Maine area closures, both year-round and seasonal (Appendix I). Therefore, the measures proposed in Amendment 13 that are likely to impact this community the most, either positively or negatively, are those that modify the Gulf of Maine rolling closures. However, because Gloucester is such an important groundfish port and because of its location, it is likely that most measures in Amendment 13 will impact this community. Large-scale DAS reductions will undoubtedly have significant impacts on this port. The EA for the settlement agreement estimated that 84.5% of groundfish activity in Gloucester could be affected by the recently-implemented Interim Action.

Boston, Massachusetts: In FY99 and FY00, Boston averaged 3,983,150 pounds of groundfish landings and $5,118,750 in groundfish revenues. These landings as well as the historical importance of Boston as a provider of fishing-related support services for smaller communities indicate that Boston is an important primary community. In FY99 and FY00, almost all active vessels homeported in Boston fished for groundfish during some or all of the year. These vessels averaged $4,440,750 in groundfish revenues for Boston. The community of Boston was dependent on the multispecies fishery for almost 56% of its total fisheries revenues from federally-permitted vessels from FY99 – FY00. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Boston are even more than 56% dependent on the multispecies fishery. Vessel-level impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Boston, participants reported that they have experienced the most significant social impacts from the Amendment 5/7 DAS reductions (Appendix I). Many of Boston's active groundfish vessels possess Individual DAS permits and have experienced a 50% reduction in their Individual DAS. Moreover, most Individual DAS vessels use the majority of their allocated DAS. The measures proposed in Amendment 13 that are likely to impact this community the most are those that modify or reduce DAS allocations and those that change the ways that DAS are counted. The EA for the settlement agreement estimated that 83.2% of groundfish activity in Boston could be affected by the recently-implemented Interim Action.

Chatham/Harwichport, Massachusetts: In FY99 and FY00, Chatham and Harwichport averaged 5,980,850 pounds of groundfish landings and $7,254,100 in groundfish revenues, establishing it as an important port of landing for groundfish vessels and a primary port for the multispecies fishery. Chatham and Harwichport also serve as homeports for a significant number of multispecies vessels. In FY99 and FY00, an average of 95 multispecies vessels homeported in Chatham/Harwichport generated $6,844,500 in revenues from multispecies. Chatham's overall community dependence on multispecies as a percentage of total fisheries revenues from federally-permitted vessels averaged about 71% from FY99 – FY00. It is likely that at least some of the active groundfish vessels in Chatham and Harwichport are even more than 71% dependent on the multispecies fishery.

At the social impact informational meeting in Chatham, a few residents of Chatham and Harwichport submitted comments reporting that they have experienced the most significant social impacts from the May closure on Georges Bank to protect cod (Appendix I). The majority of multispecies vessels from Chatham/Harwichport fish for Georges Bank cod and not Gulf of Maine cod. The measures proposed in Amendment 13 that are likely to impact this community group the most are those that modify or add nearshore area closures on Georges Bank and those that modify the Georges Bank cod trip limit. The EA for the settlement agreement estimated that an average of 46.5% of groundfish activity in Chatham and Harwichport could be affected by the recently-implemented Interim Action.

New Bedford/Fairhaven, Massachusetts: In FY99 and FY00, New Bedford and Fairhaven averaged 26,995,750 pounds of groundfish landings and $30,005,500 in groundfish revenues, establishing it as an important port of landing for groundfish vessels and a primary port for the multispecies fishery. New Bedford/Fairhaven is also an important port of landing for scallop vessels, and its dependence on the scallop fishery for revenues reduces its overall dependence on the multispecies fishery, although many individual vessels may be more dependent on groundfish. In FY99 and FY00, an average of 165 multispecies vessels homeported in New Bedford/Fairhaven generated $24,821,550 in multispecies revenues. Despite these high numbers, New Bedford/Fairhaven's community dependence on groundfish is relatively low compared to other communities of interest, averaging 22% for FY99 and FY00. It is likely, however, that at least some of the active groundfish vessels in New Bedford and Fairhaven are more than 22% dependent on the multispecies fishery. The data suggest that from a community-impact perspective, impacts from the measures in Amendment 13 may be less significant in New Bedford/Fairhaven because the community is less dependent on groundfish for its overall fisheries revenues and because some impacted vessels may have the ability to offset losses in groundfish revenues with revenues from other fisheries. In addition, the multispecies vessels in New Bedford/Fairhaven are significantly larger than multispecies vessels in many other communities, so they may be more suited to adapt to some measures (for example, area closures) by shifting to different fishing areas or changing their fishing practices. However, because they tend to fish offshore on multi-day trips, they could be more impacted by trip limits and DAS reductions. The vessel-level impacts of the Amendment 13 measures will vary.

At the social impact informational meeting in New Bedford, residents of New Bedford and Fairhaven indicated that they have experienced the most significant social impacts from the Amendment 5/7 DAS reductions (Appendix I). Many of New Bedford's active groundfish vessels possess Individual DAS permits and have experienced a 50% reduction in their Individual DAS. Moreover, most Individual DAS vessels use the majority of their allocated DAS. The measures proposed in Amendment 13 that are likely to impact this community the most are those that modify or further reduce DAS allocations and those that change the ways that DAS are counted. The EA for the settlement agreement estimated that 73.3% of groundfish activity in New Bedford could be affected by the recently-implemented Interim Action.

Point Judith, Rhode Island: In FY99 and FY00, Point Judith averaged 2,830,900 pounds of groundfish landings and $2,847,150 in groundfish revenues. Groundfish landings and revenues in this community have increased considerably since the 1994 fishing year, suggesting that Point Judith is becoming a more important port of landing for multispecies vessels. Point Judith's dependence on groundfish for its total fisheries revenues from federally-permitted vessels has also increased significantly in recent years. In FY99 and FY00, an average of 66 multispecies vessels homeported in Point Judith generated $4,868,050 in multispecies revenues for the community. This represented about 18% of Point Judith's total fisheries revenues from federally-permitted vessels (versus 5.5% in FY94). Similar to New Bedford, the data suggest that from a community-impact perspective, the impacts of the measures in Amendment 13 may be less significant in Point Judith because the community is less dependent on groundfish for its overall fisheries revenues and because impacted vessels may have the ability to offset losses in groundfish revenues with revenues from other fisheries. Many of Point Judith's vessels are actively involved in fisheries in the Mid-Atlantic region (squid, fluke, etc.). However, increasing reliance on groundfish in recent years suggests that vessels may have more difficulty shifting effort as restrictions in these other fisheries increase and opportunities decrease. In addition, on an individual-vessel basis, impacts may be more severe. It is likely that at least some of the active groundfish vessels in Point Judith are more than 18% dependent on the multispecies fishery.

At the social impact informational meeting in Point Judith, residents reported that they have experienced the most significant social impacts from gear restrictions and DAS reductions (Appendix I). Gear restrictions were cited compromising the ability to plan a business and ultimately costing everyone affected by the regulation more money. The measures proposed in Amendment 13 that are likely to impact this community the most are gear restrictions and modifications to and/or further reductions in DAS. DAS reductions may affect Point Judith vessels the most by compromising their ability to fish for groundfish as an alternative for other fisheries. The EA for the settlement agreement estimated that 82.7% of groundfish activity in Point Judith could be affected by the recently-implemented Interim Action.

Eastern Long Island, New York: In FY99 and FY00, Eastern Long Island averaged 1,486,600 pounds of groundfish landings and $1,577,500 in groundfish revenues. Groundfish landings and revenues in this community group have increased considerably since the 1994 fishing year, suggesting that Eastern Long Island communities are becoming more important ports of landing for multispecies vessels. Eastern Long Island's dependence on multispecies revenues for its total fisheries revenues from federally-permitted vessels has also increased considerably since the 1994 fishing year. On average, from FY99 to FY00, this community group depended on groundfish for almost 17% of its total fisheries revenues from federally-permitted vessels (versus 2.4% in FY94). It is likely that at least some of the active groundfish vessels in Eastern Long Island are more than 17% dependent on the multispecies fishery. Similar to New Bedford and Point Judith, however, from a community-impact perspective, impacts from the measures in Amendment 13 may be less significant in Eastern Long Island than in other communities because this area is less dependent on groundfish for its total fisheries revenues and because impacted vessels may have the ability to offset losses in groundfish revenues with revenues from other fisheries. Also, most of the multispecies vessels homeported in Eastern Long Island are not using all of their DAS. However, increasing reliance on groundfish in recent years suggests that vessels in Eastern Long Island may have more difficulty shifting effort as restrictions in other fisheries increase and opportunities decrease.

At the social impact informational meeting in Riverhead, residents of Eastern Long Island communities reported that they have experienced the most significant social impacts from increased restrictions in fisheries other than groundfish. DAS were cited as providing flexibility and opportunities for groundfishing when quotas for other fisheries closed or became too restrictive. This is apparent in the increased landings for this community group as well as its increased reliance on groundfish for its total fisheries revenues. Therefore, the measures proposed in Amendment 13 that are likely to impact this community group the most are those that modify or further reduce DAS allocations and those that change the ways that DAS are counted. In addition, the alternatives to address capacity have the potential to significantly impact this community group. The impacts of Amendment 13 will be significant to the extent that DAS changes constrain vessels in Eastern Long Island from shifting effort onto groundfish and increasing their DAS usage in response to regulations in other fisheries. The EA for the settlement agreement estimated that an average of 84.5% of groundfish activity in Eastern Long Island ports could be affected by the recently-implemented Interim Action.

Upper Mid-Coast 1, Maine: This community group includes Rockland, Port Clyde, and surrounding communities. In FY99 and FY00, this group averaged 1,100,250 pounds of groundfish landings and $1,106,300 in groundfish revenues. These values have significantly increased since the 1994 fishing year, suggesting that ports in this community group are becoming more important ports of landing for multispecies vessels. Rockland was historically a very important multispecies port, so increased multispecies activity in this area in recent years may somewhat reflect a return towards historical patterns and/or a re-emergence of groundfish activity lost due to stock declines. In contrast, this community group has become less dependent on multispecies in recent years. The 16 vessels homeported in this area earned an average of $1,192,400 in groundfish revenues from FY99 – FY00. The community group's dependence on groundfish for its total fisheries revenues from federally-permitted vessels averaged 23.1% for this time period (versus 46.1% in FY94). While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Upper Mid-Coast 1 are more than 23% dependent on the multispecies fishery. Individual vessel impacts, therefore, will vary.

During the social impact informational meetings, some comments were received from Upper Mid-Coast 1 community residents suggesting that DAS reductions since Amendment 5 have had the most significant social impacts on them and their communities (Appendix I). It is difficult to predict which Amendment 13 measures will most significantly impact this community group. Because of its location and multispecies activity, it is likely to experience impacts from most of the Amendment 13 measures that address Gulf of Maine cod, including gear restrictions and modifications to area closures. The alternatives to address capacity are also likely to significantly impact this community group. The EA for the settlement agreement estimated that an average of 86% of groundfish activity in Upper Mid-Coast 1 ports could be affected by the recently-implemented Interim Action.

Lower Mid-Coast 1, Maine: This community group includes Bristol, Boothbay, and surrounding communities. In FY99 and FY00, groundfish landings in Lower Mid-Coast 1 averaged 680,650 pounds and $665,700. These values have significantly declined since the 1994 fishing year, along with landings and revenues from other fisheries, suggesting an overall decline in (federal) fishing activity in the area. Vessels that are homeported in Lower Mid-Coast 1 have become somewhat less dependent on multispecies in recent years. The decline in this community group's dependence on the multispecies fishery is not as significant as the overall decline in fishing activity in this area. The 18 active multispecies vessels homeported in this area earned an average of $1,228,000 in groundfish revenues from FY99 – FY00. This group's dependence on groundfish for its total fisheries revenues from federally-permitted vessels averaged 34% from FY99-00 (versus 46.3% in FY94). While these data reflect the community's declining relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in

Lower Mid-Coast 1 are more than 34% dependent on the multispecies fishery. Individual vessel impacts, therefore, will vary.

It is difficult to predict which Amendment 13 measures will most significantly impact this community group. Because of its location and multispecies activity, it is likely to experience impacts from most of the Amendment 13 measures that address Gulf of Maine cod, including gear restrictions and modifications to area closures. The alternatives to address capacity are also likely to significantly impact this community group. The EA for the settlement agreement estimated that an average of 88% of groundfish activity in Lower Mid-Coast 1 ports could be affected by the recently-implemented Interim Action.

NH Seacoast: This community group includes Hampton, Rye, and Seabrook NH. In FY99 and FY00, the NH Seacoast averaged 970,600 pounds of groundfish landings and $1,066,850 in groundfish revenues. For these two fishing years, an average of 40 multispecies vessels homeported in the NH Seacoast earned $1,542,750 in groundfish revenues for the community group. This community group has become somewhat more dependent on groundfish revenues for its total fisheries revenues from federally-permitted vessels. In FY99 and FY00, community dependence averaged 44%, compared to 37.8% in the 1994 fishing year. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in the NH Seacoast group are more than 44% dependent on the multispecies fishery. Individual vessel impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Portsmouth, residents of Portsmouth and the NH Seacoast reported that they have experienced the most significant social impacts from the Gulf of Maine inshore area closures and the low Gulf of Maine cod trip limits (Appendix I). The measures proposed in Amendment 13 that are likely to impact this community the most, either positively or negatively, are those that modify inshore Gulf of Maine area closures and the Gulf of Maine cod trip limit. However, depending on the alternative selected, other measures will significantly affect this community group (for example, large-scale DAS reductions). The EA for the settlement agreement estimated that an average of 58.7% of groundfish activity in NH Seacoast ports could be affected by the recently-implemented Interim Action.

South Shore, Massachusetts: This community group includes Scituate, Plymouth, and Marshfield, Massachusetts. In FY99 and FY00, the South Shore of Massachusetts averaged 1,499,450 pounds of groundfish landings and $1,619,900 in groundfish revenues. This community group is substantially dependent on groundfish revenues for its total fisheries revenues from federally-permitted vessels. In FY99 and FY00, an average of 50 multispecies vessels homeported in the South Shore group generated $1,582,800 in revenues from multispecies. The South Shore group depended on groundfish for about 48% of its total fisheries revenues in the 1999 and 2000 fishing years, similar to the level of dependence in FY94 (50.2%). Groundfish landings in FY00 were significantly higher than in FY94. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in the South Shore group are more than 48% dependent on the multispecies fishery. Individual vessel impacts of the Amendment 13 measures, therefore, will vary.

At the social impact informational meeting in Scituate, residents of South Shore communities reported that they have experienced the most significant social impacts from the Gulf of Maine inshore rolling closures (Appendix I). Currently, waters adjacent to the South Shore are closed for groundfishing four months of the year, which significantly precludes fishing opportunities and reduces flexibility for the relatively small-sized multispecies vessels in this area. Prior to the Interim Action, these areas were closed for six months. The measures proposed in Amendment 13 that are likely to impact this community group the most, either positively or negatively, are those that modify inshore Gulf of Maine area closures and the Gulf of Maine cod trip limit. However, depending on the alternative selected, other measures will significantly affect this community group (for example, large-scale DAS reductions). The EA for the settlement agreement estimated that an average of 42% of groundfish activity in South Shore ports could be affected by the recently-implemented Interim Action.

Provincetown, Massachusetts: In FY99 and FY00, Provincetown averaged 988,000 pounds of groundfish landings and $989,250 in groundfish revenues. Groundfish activity in Provincetown increased significantly in FY00 and was higher in FY00 than when Amendment 5 was implemented in the 1994 fishing year. In FY99 and FY00, 22 multispecies vessels homeported in Provincetown earned an average of $1,169,700 in multispecies revenues for the community. For these two fishing years, Provincetown's dependence on multispecies for its total fisheries revenues from federally-permitted vessels averaged 45.4% (versus 52.7% in FY94). Provincetown's activity in the whiting fishery has increased since FY94, contributing in part to decreased dependence on large-mesh groundfish. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in Provincetown are more than 45% dependent on the multispecies fishery. Individual vessel impacts of the Amendment 13 measures, therefore, will vary.

Although no social impact informational meeting was held in Provincetown, it can be assumed that impacts in P-town have been somewhat similar to those experienced by residents of South Shore communities. The measures proposed in Amendment 13 that are likely to impact this community the most, either positively or negatively, are those that modify inshore Gulf of Maine area closures and the Gulf of Maine cod trip limit. However, depending on the alternative selected, other measures will significantly affect this community (for example, large-scale DAS reductions). The EA for the settlement agreement estimated that 77% of groundfish activity in Provincetown could be affected by the recently-implemented Interim Action.

Eastern Rhode Island: This community group includes Newport, Tiverton, Portsmouth, and surrounding communities. In FY99 and FY00, Eastern RI averaged 1,320,750 pounds of groundfish landings and $1,321,000 in groundfish revenues. Relative to other communities of interest, this community group is not as dependent on the groundfish fishery. In FY99 and FY00, an average of 25 multispecies vessels homeported in Eastern RI communities generated $1,049,300 in revenues from multispecies. The Eastern RI group depended on groundfish for about 11.5% of its total fisheries revenues in the 1999 and 2000 fishing years, similar to the level of dependence in FY94 (10.5%). While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in the Eastern RI group are more than 11% dependent on the multispecies fishery. Individual vessel impacts of the Amendment 13 measures, therefore, will vary.

It is difficult to predict which Amendment 13 measures will most significantly impact this community group. Because of its location and multispecies activity, it is likely to experience impacts from most of the Amendment 13 measures that address Southern New England stocks, including gear restrictions, trip limits, and further DAS reductions. The alternatives to address capacity are also likely to significantly impact this community group. The EA for the settlement agreement estimated that an average of 52% of groundfish activity in Eastern RI ports could be affected by the recently-implemented Interim Action.

Northern Coastal New Jersey: This community group includes Point Pleasant, Belford, Barnegat Light, and surrounding communities. In FY99 and FY00, Northern Coastal NJ averaged 783,750 pounds of groundfish landings and $735,150 in groundfish revenues. Relative to other communities of interest, this community group is not dependent on the groundfish fishery despite the large number of active multispecies vessels in the area. In FY99 and FY00, an average of 62 multispecies vessels homeported in Northern Coastal NJ communities generated $766,700 in revenues from multispecies. Yet the Northern Coastal NJ group depended on groundfish for only 3% of its total fisheries revenues in the 1999 and 2000 fishing years, similar to the level of dependence in FY94 (3.1%). These vessels are generating much higher revenues from other fisheries. While these data reflect the community's relative dependence on the groundfish fishery, it is important to remember that at least some of the individual groundfish vessels in the Northern Coastal New Jersey group are more than 3% dependent on the multispecies fishery. Individual vessel impacts of the Amendment 13 measures, therefore, will vary.

It is difficult to predict which Amendment 13 measures will most significantly impact this community group. Because of its location and multispecies activity, it is likely to experience impacts from most of the Amendment 13 measures that address Southern New England stocks, including gear restrictions, trip limits, and further DAS reductions. Its low dependence on groundfish suggests that there is a substantial amount of latent effort in the area, so the alternatives to address capacity are likely to significantly impact this community group. The EA for the settlement agreement estimated that an average of 81% of groundfish activity in Northern Coastal NJ ports could be affected by the recently-implemented Interim Action.

5.6.2 Dependence Rankings for Communities of Interest

Both dependence on fisheries in general and dependence on the multispecies fishery are important to consider for the communities that are involved in groundfish harvesting that are most likely to be impacted by the proposed management measures. The MARFIN Report focuses on overall community dependence on fisheries; the additional information presented in this amendment focuses on dependence on the multispecies fishery in particular. Both measures of dependence are summarized below.

In the MARFIN Report, *fishing dependence* was assessed based on three indices: 1) the percentage of labor force involved in fishing, 2) the percentage of related occupations within the Bureau of Labor Statistics category of fisheries/forestry/farming, and 3) a summary measure of a series of dependence ratios that compare the number of fishermen per hundred community residents to various alternative occupational roles that fishermen could enter with their particular skill profiles. The last of the indices described above, the occupational alternative index, is the most useful tool for comparison across different communities in the region (MARFIN 2001).

The MARFIN Report divides the New England region into eleven sub-regions, which are also consistent with the sub-regions analyzed for this amendment using the IMPLAN model, and then ranks these sub-regions from highest to lowest, based on fishing dependence. Table 333 below is from the MARFIN report and provides the fishing dependence indices for each sub-region. The MARFIN report explains that the three sub-regions with the highest dependence (Downeast Maine, Upper Midcoast Maine, Cape and Islands) share some characteristics that make these communities significantly more dependent on fishing resources than other regions of New England. These three regions are all relatively isolated from other parts of New England and have small islands and harbors, which give fishermen easy access to nearby fish and shellfish grounds. MARFIN suggests that the occupational alternative index is significantly lower for the Cape and Islands as compared to the two sub-regions in Maine because the Cape has experienced intense pressures from tourism and gentrification. However, there is variation among ports within these sub-regions. For example, Chatham is one town on Cape Cod that has remained an active fishing port over the years and has supported a successful fishing industry despite low biomass levels, increased regulations, and pressures from the recreational fishing and tourism industries.

MARFIN SUB-REGION	% Related Occupations	% of Total Employed	Alternative Occupation Ratio Summary
Downeast Maine	45	3.6	255.54
Upper Midcoast Maine	36	2.0	171.05
Cape and Islands	27	0.79	104.43
Lower Midcoast Maine	23	0.46	51.32
New Bedford/South Shore	27	0.40	38.95

Table 333 Comparative Fishing Dependence Indices for the Eleven Sub-regions of New England (MARFIN 2001)

**The MARFIN Report did not examine communities south of Connecticut.*

For the purposes of this assessment, groundfish revenues expressed as the percentage of total fisheries revenues from federally-permitted vessels homeported in a particular community group represents the community group's current dependence on the groundfish fishery. Information about dependence for all community groups can be found in the Affected Human Environment. Table 334 ranks average dependence on multispecies from FY99 and FY00 for the *communities of interest*. (Note that there may be other community groups that rank higher than some of the following groups. See the Affected Human Environment for more information.)

RANK	COMMUNITY GROUP	AVERAGE GROUNDFISH DEPENDENCE FY99-FY00
1	**Chatham/Harwichport, MA**	71.1%
2	**Portland, ME**	64.3%
3	**Gloucester, MA**	61.7%
4	**Boston, MA**	55.7%
5	**Portsmouth, NH**	54.7%
6	**South Shore, MA**	47.7%
7	**Provincetown, MA**	45.4%
8	**NH Seacoast**	44%
9	**Lower Mid-Coast 1, ME**	34%
10	**Upper Mid-Coast 1, ME**	23.1%
11	**New Bedford/Fairhaven, MA**	22.3%
12	**Point Judith, RI**	18.3%
13	**Eastern Long Island, NY**	16.9%
14	**Eastern RI**	11.5%
15	**Northern Coastal NJ**	3%

5.6.2.1 SIA Factors

To the extent possible, the social impact factors described in the following subsections will be considered relative to the management alternatives under consideration and will be used as a basis for comparison between alternatives. Use of these kinds of factors in social impact assessment is discussed in Burdge's *Conceptual Approach to Social Impact Assessment* (Burdge 1998).

A significant amount of information relating to the factors described below was collected during the Council's Social Impact Informational Meetings and can be found in the Report from those meetings (Appendix I). The information collected at these meetings formed the basis for selecting the following SIA factors. While this assessment does not quantify the impacts of the management measures relative to the individual factors, qualitative discussion of the potential changes to the factors characterizes the likely direction and magnitude of the impacts. Assessment of the potential changes to the social impact assessment factors also should be considered in the following context:

1. *Size and demographic characteristics of the fishery workforce in the community* –changes in these factors reflect demographic, income, and employment impacts in relation to the community's available fishery workforce
2. *Cultural issues* – attitudes, beliefs, values of fishermen, their families, and their communities
3. *Social structure and organization* – the ability of communities to provide necessary social support and services to families
4. *Non-economic social aspects* – lifestyle, health, and safety issues
5. *Historical dependence on fishery* – reflected in the structure of fishing practices and income distribution

The following five social impact factors are described below: regulatory discarding; safety; disruption in daily living; changes in occupational opportunities and community infrastructure; and formation of attitudes. Discussion of these factors below also includes important information related to cumulative impacts and the social impacts of the alternatives under consideration in this amendment.

5.6.2.1.1 Regulatory Discarding

Description: forced discarding of marketable and oftentimes dead fish as a direct result of management measures; usually a byproduct of trip limits, quotas, and minimum fish sizes

Regulatory discarding is an important social problem, just as it is an ecological problem. Low trip limits resulting in excessive discarding leave fishermen feeling demoralized and disgusted with fishing, which is more than just a job to most fishermen. Fishermen recognize that discarding marketable and oftentimes dead fish does nothing to benefit them or their families, the health of the resource, their disappearing hold on local fresh fish markets, or seafood consumers. Fishing is a family business, so the impacts of this are felt throughout the entire family and the entire community involved in groundfish harvesting.

Discussion: Although regulatory discarding has been identified as a social problem in most communities involved in groundfishing throughout the region, the inshore Gulf of Maine groundfish fleet in particular has struggled with the low Gulf of Maine cod daily trip limit and the negative social impacts of regulatory discarding since the 1999 fishing year. At the groundfish Social Impact Informational Meetings, many residents of Portsmouth NH, the NH Seacoast, Gloucester, and South Shore MA communities cited low Gulf of Maine cod trip limits as having resulted in the most significant social impacts for their respective communities since the implementation of Amendment 5. Fishing fleets in these communities consist primarily of smaller and mid-size vessels that fish short trips (<2 days) in inshore areas. Many of these vessels do not have the capability to travel safely to other areas to fish. They are therefore limited to areas that unfortunately contain concentrations of codfish, so they sometimes encounter significant amounts of cod even when fishing for other species.

The multispecies nature of the groundfish fishery and the physical limitations of the inshore fleet have exacerbated the problems associated with regulatory discarding in these areas. Some of the affected boats have reported that this problem is further worsened by the timing of the inshore rolling closures and the pulses of concentrated effort in the inshore areas during the limited opportunities in the spring and early summer for smaller vessels to fish. In addition, the cumulative effect of regulatory discarding resulting from management measures in other fisheries has increased related social impacts. For years, both commercial and recreational fishermen have testified that they are being forced to throw overboard thousands of pounds of spiny dogfish due to the very low trip limits and annual quota.

Alternatives that propose to increase the Gulf of Maine cod trip limit may reduce regulatory discarding and consequently, the negative social impacts resulting from regulatory discarding in the most affected Gulf of Maine communities involved in groundfish harvesting. Industry testimony from the inshore Gulf of Maine fleet suggests that a higher trip limit could convert at least some discards to landings and may result in even more positive impacts than can be predicted. By increasing the trip limit to a level that allows inshore boats to "make a day's pay," the industry maintains that the Council could indirectly encourage some vessels to end their trips without fishing through cod (and continuing to discard it) for other species. This could reduce regulatory discarding not only on Gulf of Maine cod, but also on other species that may be caught while fishing on a multispecies trip. While these impacts are difficult to predict, it is without question that the social impacts of an increased Gulf of Maine cod trip limit would be positive for the inshore groundfish fleet and their respective communities.

One caveat is that while short-term negative impacts may be reduced and short-term positive impacts may result from an increase in the Gulf of Maine cod trip limit, long-term negative impacts could be more severe if a higher trip limit increases fishing mortality on Gulf of Maine cod and consequently compromises the objectives of this amendment. Fishermen's behavior cannot be predicted definitively, and there is some concern that increasing the trip limit could increase directed fishing on Gulf of Maine cod. There is a fine line that cannot be identified between allowing vessels to make a day's pay and encouraging them to increase their directed trips on Gulf of Maine cod, especially in the inshore areas where the resource may be more easily accessible for short, directed trips. It must be acknowledged and understood that if an increased trip limit results in increased fishing mortality on Gulf of Maine cod, additional and perhaps more severe restrictions may be required in the future. Some sectors of the fleet that claim that they are not experiencing problems with regulatory discarding at this time are particularly concerned about this potential outcome. Most alternatives under consideration in this amendment address these concerns by proposing very modest increases in the trip limit, only seasonal increases in the trip limit, and/or additional measures to reduce Gulf of Maine cod fishing mortality.

Alternatives that propose new trip limits on species like Southern New England yellowtail flounder, Cape Cod yellowtail flounder, and Georges Bank cod affect regulatory discarding negatively for other communities south of the Gulf of Maine. To minimize this, trip limits should be set at the most reasonable level to affect behavior on the target stock without compromising the intent by simply converting landings to discards. The Council should consider past history with Gulf of Maine cod when selecting new trip limits for other groundfish species.

Hard TACs may also affect regulatory discarding if they are so low that discarding results in non-directed fisheries once the TAC is reached and the directed fishery is closed. This is very likely in the groundfish fishery, which is multispecies in nature. Most vessels catch 3-4 species of groundfish on any given trip, so they may continue to fish for some groundfish despite the TACs being reached for other species that they catch. This is even more likely if DAS are reduced to the point that vessels must maximize their remaining days in order to maintain their viability.

Measurement: The best tools for measuring this factor include surveys, focus groups, and key informant interviews to gain more perspective on individual perceptions about regulatory discarding and its effects on stress, morale, job satisfaction, and quality of life. For this assessment, information about this factor was obtained primarily from the Social Impact Informational Meeting Report, summarizing a series of ten focus group meetings throughout the region. Additional information relative to this factor was gained from the Council's Advisory Panels, scoping meetings, public hearings, and discussions with other community groups and panels.

Assessment of this factor should address the following questions:

- Is the proposed action likely to force fishermen to throw marketable fish overboard?
- Is the level of regulatory discarding under the proposed action likely to be higher than that under the no action alternative?
- Is the difference between regulatory discarding under the proposed action and the no action alternative likely to be high enough to generate significant negative social impacts?

5.6.2.1.2 Safety

Description: the ability of fishermen to maintain safe operations at sea; this factor can be compromised by various adaptations to additional regulations and decreased fishing opportunities; usually a result of closed areas and DAS modifications

The safety of fishermen and fishing operations at sea is an extremely important social impact factor, as decreased safety often increases stress at the individual and family level, which can exacerbate many other family and societal problems. In addition, the impacts of fishing-related casualties can be felt throughout communities involved in fishing, many of which are close-knit groups with longstanding family and social networks.

Discussion: Updated safety information for the multispecies fishery is presented in the Affected Human Environment. In addition, safety was an important social issue discussed during the groundfish Social Impact Informational Meetings in many contexts:

- Many vessels are carrying reduced numbers of crew in order to adapt to decreased income from fishing. In Gloucester, meeting participants reported that larger vessels used to fish with numerous crew members; now, in order to offer their crew members an adequate share, these boats are fishing with far fewer crew. Many owner-operators on smaller vessels fish alone for some or all of the year. This problem is coupled with the fact that the regulations have made it difficult to offer crew members a reliable/consistent source of income from fishing, so even when carrying reduced numbers of crew, vessels are having trouble finding crew members at all.
- Vessels are traveling much farther from shore to fish for groundfish. This shift has resulted primarily from the Gulf of Maine area closures. There are many boats in the Gulf of Maine less than 50 feet in length that were not designed to fish far offshore, especially in adverse weather conditions.
- For boats that are traveling farther from shore to fish, the length of the workday has increased considerably. Today, it is common to see day trips lasting 18-24 hours, primarily because of added steam time to reach open fishing grounds. These fishermen are probably more exhausted than ever, and this can lead to more injuries and accidents, especially since many of these fishermen are now working alone.
- Overall, fishermen feel as though they must take more risks to fish when they have the opportunity to do so. Instead of staying home when the weather is bad, some fishermen are choosing to fish through the bad weather because of an impending area closure and/or because they fear that they may not be able to fish for some period of time in the future.

Measures implemented in this amendment may affect the safety of fishermen and fishing operations, and to the extent possible, the Council should strive to implement measures that maximize the safety of human life at sea. To the extent that the Council can maximize safety at sea, negative social impacts resulting from the Amendment 13 management measures and related to concerns about safety can be minimized. For Amendment 13, changes to area closures have the potential to affect safety at sea to the extent that they force, directly or indirectly, small vessels to fish farther from shore.

Proposed DAS modifications also could affect safety. For example, counting DAS at a 2:1 rate during some portion of the year may indirectly encourage vessels to fish during the other times when their DAS are not counted at a higher rate. If these other times are during the winter, fishing effort could increase when weather is more extreme and less predictable, possibly reducing the ability of some vessels to remain safe at sea. In addition, since fishing for groundfish is currently quite limited for the dependent vessels (those that use most or all of their DAS), further reducing DAS could compromise safety if fishermen take more risks to maximize their diminishing opportunities. During the Social Impact Informational Meetings, these kinds of adaptations to DAS reductions were noted to have occurred throughout the region after Amendments 5 and 7. It is therefore likely that additional negative social impacts related to safety occurred as a result of the Interim Action and will occur in Amendment 13 if DAS are further reduced.

Hard TACs are also likely to negatively affect the safety of fishing operations at sea to the extent that they force a derby fishery or a race to fish. Sometimes, low quotas can encourage pulses of fishing effort, especially if the species is commercially valuable. This can be exacerbated by DAS reductions that create a need to maximize profits on remaining DAS. If the quota creates a derby during the winter, it could compromise safety at sea.

Measurement: The best tools for measuring this factor include surveys, focus groups, and key informant interviews to gain more perspective on individual perceptions about safety and its effects on stress, families, and overall quality of life. For measurement in this assessment, information was obtained primarily from the Social Impact Informational Meeting Report, the MARFIN Report, and McCay and Cieri 2000. Additional information relative to this factor was gained from the Council's Advisory Panels, scoping meetings, public hearings, and discussions with other community groups and panels. GIS-based technologies are also useful to assess the potential impacts on this factor by examining the for vessels to fish farther from shore as a result of the proposed management measures.

Assessment of this factor should address the following questions:

- Is the proposed action likely to compromise the safety of fishermen and/or fishing operations more than the no action alternative?
- Will fishermen need to travel to new fishing grounds or fishing grounds further away from their homes as a result of the proposed action?
- Is it likely that fishermen will make adaptations to the proposed management action that could compromise their safety (taking less crew, fishing in bad weather)?

5.6.2.1.3 Disruption in Daily Living

Description: changes in the routine living and work activities of affected fishery participants, including the potential for alteration in their regular social and work patterns to adapt to new management measures

Consideration of this factor includes vessel flexibility and the ability of fishermen to switch between fisheries, areas, and gears seasonally and/or in response to market conditions. Year-round and seasonal fishing opportunities are important to consider. These opportunities also relate to fishermen's chances to successfully adapt to new regulations. Impacts on this factor are associated with the ability of affected industry members to develop both short-term and long-term business plans. Another related impact can be experienced through the loss of crew and/or the inability to retain reliable crew members on a year-round basis.

Discussion: Changes in established daily patterns – patterns that, in the case of communities involved in fishing, are often internally-generated and regulated and highly-regimented – can provide a key component to social impact assessment. Although the existence, nature, and evolution of these patterns in communities involved in fishing is well-documented by marine anthropologists, the effects of changes to them have often been overlooked in conducting social impact assessments for fisheries management. Ideally, measurement of disruption in daily living should include an assessment of the outcomes of any periods of inactivity, including changes in social stress and stress-related health problems, job satisfaction, crime rates, and family cohesion.

The most obvious impacts related to this factor occur when fishermen lose the ability to fish for some period of time; negative impacts increase as the time during which the fishermen cannot fish increases. Periods of inactivity disrupt daily living patterns and increase stress that can affect the entire family. In addition, if these periods of inactivity are experienced by many residents within a community, negative social impacts can be experienced throughout the community. Shoreside businesses may find it difficult to maintain year-round income without a functional local fleet, so over the long-term, significant impacts can result from disruptions in daily living that ultimately change occupational opportunities and community infrastructure. Impacts related to these factors are discussed in more detail in following sections of this assessment.

The following summarizes some of the discussion relative to disruption in daily living patterns from the groundfish Social Impact Informational Meetings:

- Because of increased regulations in many fisheries, small vessels have lost much of their flexibility to move from one fishery to another. In Chatham, meeting participants felt that regulations have "boxed them in" to particular fisheries, making it difficult or impossible for them to maximize their opportunities and/or adjust to changing conditions. When combined with the inherent limitations of small vessels, the regulations have reduced fishing opportunities to the point that many fishermen cannot guarantee a year-round income from fishing for themselves or for their crew.
- Uncertainty about the regulations and the future of the groundfish fishery in New Bedford has made both business and family planning difficult, if not impossible. Uncertainty has contributed to the lack of new entrants in the fishery as well as family stresses associated with long-term finances and planning for the future.
- Some meeting participants in Portland discussed the loss of flexibility resulting from the groundfish regulations. They reported that historically, groundfishing used to be a fishery that the Portland fleet would use to "fill in" seasonally and/or with fluctuations in other fisheries. Ironically, groundfish regulations have limited some of these other fishing opportunities and made much of the fleet almost entirely dependent on groundfish.
- Increased regulations in many fisheries have limited the flexibility of the Long Island fishing fleet and made it more difficult to make a year-round income from fishing. Long Island vessels have depended on the diversity and flexibility of switching target species (squid, whiting, scup, and others including groundfish) as stocks fluctuate, the mix of species in an area changes, and/or market conditions change. Seasonal quotas and other management measures have decreased fishing opportunities and limited the flexibility of this fleet, particularly smaller vessels.
- The core of Boston's fishing fleet has diminished significantly; in addition, fewer transient vessels are landing in Boston and taking advantage of the convenient services the pier has to offer (proximity to transportation, processing facilities, ice, etc.). Landings are down, and overall activity in the port has decreased. Meeting participants estimated that the number of vessels landing at the Boston Fish Pier fell from more than 30 in 1995 to less than 12 in the past year. Most of the remaining vessels maximize their DAS usage in the winter to capitalize on better prices and then tie-up for several months at a time. This adaptation has exacerbated financial and employment problems for shoreside support services.

The implementation of new or additional seasonal and year-round closed areas is likely to negatively affect this factor. Nearshore closed areas can induce significant periods of inactivity, especially for small vessels that cannot travel to other areas to fish. In the more extreme cases (closures for six months or more, for example), some fishermen may be forced to seek alternative employment opportunities to support their families. These fishermen often lose their crew members and face additional problems during the time when they can fish. They also encounter more difficulty maintaining their fishing operations due to the loss of a reliable income. For vessels that can travel to other areas to fish, the closed areas still result in disruption in daily living patterns and negative social impacts, as most of these vessels end up traveling farther from shore to fish, potentially compromising their safety and increasing stress at the family level because fishermen are forced to spend more time away from home and fish longer days.

DAS modifications, particularly reductions, and Hard TACs can also cause significant disruption in daily living and fishing patterns. In communities with vessels that rely on the groundfish fishery and use the majority of their DAS, additional DAS reductions can cause major alterations in fishing practices. Some larger boats will be forced to maximize their remaining groundfish opportunities by fishing only during times when market conditions are best, which can be during winter when weather is less predictable and more extreme. In order to reduce their fishing-related expenses, some vessels may fish their remaining DAS during one time of the year and tie up their vessels during another time. This causes disruptions for related shoreside businesses and can ultimately result in further social and economic dislocation. Hard TACs can produce similar impacts related to disruptions in daily living to the extent that they create a derby or a race to fish.

Measurement: The best tools for measuring this factor include surveys, focus groups, and key informant interviews to gain more information about daily living patterns and the impacts of changes to these patterns on stress, families, and overall quality of life. For measurement in this assessment, information was obtained primarily from the Social Impact Informational Meeting Report, the MARFIN Report, McCay and Cieri 2000, and the ME DMR Groundfish Regulation Impact Survey in 2002. Additional information relative to this factor was gained from the Council's Advisory Panels, scoping meetings, public hearings, and discussions with other community groups and panels.

Assessment of this factor should address the following questions:

- How could the proposed action alter the daily living and work patterns of fishing families in the affected communities?
- Will fishermen need to travel to new fishing grounds or fishing grounds farther away from their homes as a result of the proposed action? Will fishermen be spending more time away from home as a result of the proposed action?
- Will fishermen experience longer periods of inactivity as a result of the proposed action?
- Compared to the no action alternative, could the proposed action increase stress at the family level as a result of disruptions in daily living patterns?

5.6.2.1.4 Changes in Occupational Opportunities and Community Infrastructure

Description

Changes in Occupational Opportunities: the degree to which the implementation of the management measures in this amendment could alter the occupational profile of the affected communities.

Changes in occupational opportunities can lead to changes in household/family income, classes, and lifestyles. In assessing this variable, both the short-and long-term shifts in job opportunities should be considered. This includes changes to year-round and seasonal fishing opportunities, short-term and long-term dislocation from the fishery, employment opportunities, and the ability to find and keep crew.

Flexibility for the fishing fleet and the ability to plan business ventures over the short-term and long-term also are related factors. Changes in occupational opportunities are not only important to consider for the commercial fishing fleet, but also the recreational and party/charter fleet.

External forces (status of economy, community shifts away from fishing and towards tourism, etc.) can influence the magnitude and direction of changes in occupational opportunities. Emphasis should be placed on identifying potential changes in the unique social and family arrangements that characterize the communities under consideration, particularly on changes in household employment patterns, trends in family-run fishing businesses, and participation in job retraining programs. Special consideration should also be given to social and cultural values and norms that may be affected by changes in opportunity, such as long-term family involvement in the fishery, job satisfaction, and respect for fishing as an occupation and a way of life.

Changes in Community Infrastructure – the increase or decrease in the demand and supply of basic infrastructure services and facilities essential to fishing in the affected communities, including processors, seafood markets, boat and equipment repair shops, bait and ice providers, display auctions, cooperatives, creditors, legal services, etc.

The cost, quality, availability, and location of fishing-related services can affect community members' business practices, satisfaction with their community, and overall well-being. Additionally, these service industries provide alternative fishing-related employment opportunities in communities and can contribute significant revenues to the city and county in which the community involved in fishing is located. Impacts on this social impact factor are directly connected to disruptions in daily living patterns and other factors. They are also more long-term in nature.

Discussion

Changes in Occupational Opportunities: Over time, many groundfish regulations have affected occupational opportunities for communities involved in fishing throughout the region. The following summarizes some of the discussion relative to changes in occupational opportunities from the groundfish Social Impact Informational Meetings:

- In Gloucester, community residents feel that the rolling closures have severely reduced the flexibility of the fleet and have precluded fishermen from making a year-round income from fishing. Fishermen have difficulty taking advantage of seasonal fluctuations in stocks, markets, and/or fisheries and fishing accordingly. In addition, they report that the western Gulf of Maine closure has precluded many vessels from seeking viable alternative fisheries (pollock, some flatfish) and thus further limits their flexibility and ability to adapt to regulations.
- In Portsmouth, some people reported that they have had a very difficult time keeping up with the changing regulations, and it has become impossible to plan ahead and develop financial and other mechanisms to adapt to new or different regulations. In addition, meeting participants cited problems keeping year-round crew, loss of employment stability, and resultant increased stress at the individual and family level as direct consequences of the inshore Gulf of Maine rolling closures.
- In Portland, residents reported that with increasing regulations and uncertainty about the future, fishermen are more reluctant to invest in alternative fisheries. As a result, the fleet has adapted by relying less on the flexibility to switch between fisheries as they did historically, and more on maximizing their limited opportunities in the groundfish fishery. Vessel owners also are finding it increasingly difficult to employ reliable and experienced crew members on a year-round basis. Eighty eight groundfish days-at-sea alone does not offer enough opportunity to maintain an adequate crew on a large dragger, and some of these boats have few alternatives (some fish for shrimp and/or herring seasonally).

- DAS reductions were cited as having precluded year-round fishing opportunities in Boston; now, most vessels from Boston fish most or all of their DAS during the winter and tie-up their vessels for 3-5 months.
- Several meeting participants from the South Shore agreed that the six-month rolling closures (Blocks 124 and 125 in particular) represent a 100% groundfish closure for them. Currently, October, November, and January – April are closed to gear capable of catching multispecies; in December, 400 pounds of cod cannot cover trip expenses. The other five months (May – September) are historically when most of the South Shore fleet would shift their effort from groundfish to dogfish. Dogfish is no longer a viable fishery for federal permit holders, so many of these vessels are experiencing great difficulty maintaining occupational opportunities on a year-round basis.

Some measures under consideration may reduce opportunities for recreational and party/charter vessels that currently may be able to access offshore areas. Long-term occupational opportunities in some communities could be impacted by this action to the extent that these measures would reduce employment in the recreational sector and overall community revenues generated from recreational fishing.

Some measures implemented in this amendment could intensify negative social problems associated with changes in occupational opportunities over the long-term. Examples include changes to the inshore area closures that reduce flexibility and opportunities and modifications that reduce DAS and/or make DAS less efficient or productive. Depending on the economic costs, gear restrictions and new mesh regulations could also contribute to reductions in occupational opportunities to the extent that marginal vessels are not able to absorb the costs of the new gear. DAS reductions, however, are likely to be most responsible for the changes in occupational opportunities that may occur in communities involved in fishing over time as a direct result of fisheries management actions. Changes in occupational opportunities are important to consider in relation to the alternatives under consideration to address capacity.

Changes in Community Infrastructure: Increasing restrictions in groundfish and almost all fisheries are reducing opportunities throughout the industry and resulting in a significant downsizing of commercial fleets in most communities. For example, industry members in Boston estimated that the number of vessels landing at the Boston Fish Pier fell from more than 30 in 1995 to less than 12 in the past year. Some of these vessels relocated to other ports because of the regulations, while some exited the fishery altogether. Downeast Maine and other community groups in Maine also have experienced significant fleet downsizing as Maine's groundfish fleet has concentrated around Portland. A resident of Bar Harbor recalled that there were 20 groundfish vessels in his community during the 1980s. There were also groundfish fleets in Southwest Harbor and Stonington. This year (2000), three vessels in these communities landed fresh fish.

While groundfish regulations have contributed to difficulty finding and keeping experienced crew, the industry reports that it also is quickly losing its shoreside labor pool due to more attractive alternative employment opportunities. The fleet and industry have downsized, and so have remaining shoreside support services. The industry reported the loss of cutting houses, processing plants, and ice houses throughout coastal communities. This has eliminated job opportunities and caused qualified laborers who rely on year-round employment to seek jobs elsewhere. Many people worry that this trend is irreversible given uncertainty in the fishing industry and the benefits and stability that many other shoreside labor industries are able to offer their employees.

Competition for commercial and residential waterfront property has increased and resulted in higher real estate prices and taxes, as residents of most communities involved in fishing are witnessing a long-term shift towards recreational and tourist-oriented uses of the waterfront. Downeast Maine residents described transitions in their own communities, still very dependent on fisheries, as local tackle and supply businesses are replaced with art galleries and bookstores. The industry is finding it more difficult to afford to live in their communities and maintain the shoreside infrastructure necessary to support their fisheries. Many people worry about whether their community will be able to support increased activity as stocks continue to recover and yields continue to increase.

Related to these problems is the loss of new and young entrants to the fishery. Uncertainty, instability, and loss of opportunity are discouraging the younger generation from pursuing fishing as a way of life. According to meeting participants, parents are no longer encouraging their children to carry on the family tradition of fishing; instead, they are encouraging them to seek higher education and enter a more promising and stable career. Unfortunately, this sometimes requires the children to leave the community because employment opportunities outside of fishing and similar industries are scarce.

The groundfish measures most likely to impact this factor over the long-term may be those that generate the most significant economic impacts, as economic impacts can affect business opportunities and the ability for the industry to diversify over the short-term. Some examples of the measures to consider in this framework adjustment include DAS reductions, mesh changes (if they are costly and affect a large number of groundfish-dependent vessels), and area closures.

Measurement

Measurement of this factor is the most complex and involves many sources of information. This factor relates most directly to economic aspects of the fishery; therefore, the analysis of economic impacts provided in this amendment helps most to predict changes to occupational opportunities and community infrastructure as well as resulting social impacts. Predictions about the impacts of the alternatives on gross revenues (section 5.4.4) and the results of the IMPLAN I-O model (section 5.4.8.3) are primary sources of information to measure this factor and provide a basis to quantify the social impacts related to this factor.

Social and demographic data including Census data and information from regional retraining centers is helpful to assess this factor. In addition, measurement tools like surveys, focus groups, and key informant interviews often provide information related to occupational opportunities for the fishing industry and specific aspects of community infrastructure. For this information, the Social Impact Informational Meeting Report, MARFIN Report, McCay and Cieri 2000, and the ME DMR Groundfish Regulation Impact Survey were referenced. Additional information relative to this factor was gained from the Council's Advisory Panels, scoping meetings, public hearings, and discussions with other community groups and panels.

Assessment of this factor should address the following questions:

- Could the proposed action change the structure and/or composition of New England's fishing fleets?
- Is the proposed action likely to result in a significant loss of employment opportunities within the affected communities?
- Will affected fishermen have alternative fishing opportunities under the proposed action?
- Compared to the no action alternative, will the proposed action significantly affect the ability of shoreside infrastructure to maintain year-round business opportunities?

5.6.2.1.5 Formation of Attitudes

Description: positive or negative feelings, beliefs, or positions expressed by impacted members of communities involved in fishing regarding the proposed action

This factor provides information about the community climate that prevails and can help to assess the potential for success with Amendment 13 and the need for mitigation in some circumstances. Consideration of this factor can provide for a better understanding of how changes induced by the proposed action could influence the affected communities. In addition, management measures that are more preferred or supported by the fishing industry generally encounter more success over the long-term than measures that are opposed or that the industry feels are forced upon them. Some support the notion that compliance with regulations is directly related to the degree of support for the regulations or faith that they will be effective in achieving their objectives.

Discussion: It is difficult to predict which measures in Amendment 13 will affect this variable the most. On one hand, the formation of attitudes towards regulatory discarding in the recent past has been so negative that any measure reducing regulatory discarding should generate positive impacts. On the other hand, proposals to further reduce DAS or change the way that DAS are counted have already been met with strong opposition by fishermen throughout the region. While some measures may improve attitudes towards groundfish management measures (those that decrease regulatory discarding and improve safety at sea), others may worsen negative feelings (those that decrease occupational opportunities and flexibility).

In general, current industry perceptions about the effectiveness and direction of groundfish management are negative. Constantly changing groundfish regulations and layers of confusing management measures and their disproportional impacts have resulted in a loss of credibility for the Council and NMFS and a loss of faith in the federal fisheries management process. Some industry members are bitter because they feel that regulations are never given time to work before additional ones are implemented. In addition, analyses for numerous actions that the Council has taken since Amendment 5 projected that objectives would be met and that the industry would begin to reap the benefits of its sacrifices. Much of the industry feels that they are still waiting for the opportunity to reap these benefits, yet additional management measures continue to be proposed.

Another development that has affected the industry's faith in the management process is the new reference points proposed for all stocks. NEFSC 2002a adopted new modeling assumptions for assessing the resource and as a result, proposed increasing some biological reference points three-fold. This has created a general perception among the industry that scientists and managers are "moving the goal posts" just as the stocks were rebuilding to target levels and leaves the industry concerned that they will never have the opportunity to experience the benefits of a rebuilt resource. These negative perceptions are coupled with increases in fish abundance and catch rates that the industry reports to be experiencing in many areas and recent discoveries about errors associated with the NEFSC trawl survey.

Measurement: The best tools for measuring this factor include surveys, focus groups, and key informant interviews to gain more information about perceptions about the current management process, management regulations, and the entities involved in the management process. For measurement in this assessment, information was obtained primarily from the Social Impact Informational Meeting Report, the MARFIN Report, McCay and Cieri 2000, and the ME DMR Groundfish Regulation Impact Survey in 2002. Additional information relative to this factor was gained from the Council's Advisory Panels, scoping meetings, public hearings, Committee and Council meetings, and discussions with other community groups and panels.

Assessment of this factor should address the following questions:

- In comparison to the no action alternative, is the proposed action likely to result in the formation of negative attitudes by affected parties?
- If negative attitudes are predicted to result, are they likely to compromise the effectiveness of the proposed action?

5.6.2.2 Social and Community Impacts of Amendment 13 Alternatives

5.6.2.2.1 General Impacts of Measures Under Consideration

This section provides a discussion of the social impacts that are most likely to result from DAS modifications, area closures, trip limits, gear restrictions, hard total allowable catches (TACs), and special access programs, six of the management tools that form the basis for most of the alternatives under consideration in this amendment. The unique aspects of each of the alternatives are discussed in subsequent sections of this assessment.

5.6.2.2.1.1 DAS Modifications

In comparison to the status quo alternative (Amendment 7 DAS, 88 Fleet DAS, Individual DAS), Alternatives 1A, 1B, 2A, 2B, 3 and 4 specifically propose modifications to DAS. Alternatives 4A uses quota management to attain mortality reductions. Alternatives 2A, 2B, 3 and 4 incorporate the DAS baseline that was implemented in the Interim Action (settlement agreement), and freeze the baseline at settlement agreement levels. Alternatives 1A and 1B use the pre-settlement agreement average days at sea, and reduce total days at sea used to 28,400 and 41,050 days respectively. These translate into reductions of 55% and 35% respectively for each vessel. Coincidentally, 41,050 days is approximately what was used in fishing year 2002. The DAS modifications considered in this amendment also included changes in the way that DAS are counted in the Southern New England mid-Atlantic regulated mesh area under Alternative 1. There are also measures included which could be part of any of the alternatives chosen to address capacity and remove latent days at sea.

The EA for the Interim Action includes analysis of the settlement agreement DAS allocations (maximum DAS usage in one year from FY96-00; minimum 10 DAS allocation) and a 20% reduction from the allocation baseline. All of the EA measures were effective during the 2002 fishing year and are included in some of the alternatives under consideration in Amendment 13.

Reductions in DAS are proposed in the rebuilding alternatives and by the capacity alternatives. The proposed action will change the way DAS are allocated by using a baseline different than that used in the court settlement. In addition, the use of allocated DAS wil be restricted, with only 60 percent available to fish on all stocks. The remaining 40 percent are limited ot special access programs; half of those may be available in the future to target healthy stocks. Of the original alternatives, only Alternatives 1A and 1B require a days at sea reduction beyond what was implemented by the interim agreement. Further reductions in DAS beyond what was implemented in the settlement agreement would affect vessels and communities which are more active in the groundfish fishery as demonstrated by their percentage of allocated days at sea actually used. In other words, vessels which use close to 100% of their allocated days would be impacted more by a cut in allocated days at sea than vessels which only used 50% of their days at sea. Examples of communities where these highly dependent groundfish vessels reside include primary communities like Portland ME and New Bedford/Fairhaven MA. Communities where vessels reside that are not as dependent on groundfish include Upper Mid Coast 1 ME, Lower Mid Coast ME, Eastern RI, Northern Coastal NJ, and other similar groups.

Changes in the way that DAS are counted can sometimes equate to DAS reductions. This Is not part of the proposed action. If DAS are counted at a 1.5:1 rate year-round in the inshore Southern New England/Mid-Atlantic regulated mesh area, for example, vessels that are able to fish only in that area effectively receive a further reduction in the DAS available for them to use. For vessels that may be able to access other areas to fish at a 1:1 DAS counting rate, it is likely that they will move to those areas where the regulation may not impact them. This could be farther from shore, possibly compromising their safety.

The proposed action implements restrictions on how DAS can be used. Sixty-percent of allocated DAS can be used to target any stock, while the remainder can only be used to target healthy stocks. In effect, the number of DAS that can be used to target any stock has been reduced from over 71,000 to about 41,000. This is expected to reduce the number of DAS used by forty to fifty percent compared to FY 2001. At the same time, however, the proposed action has created an opportunity to target healthy stocks under specific programs. The use of these Category B DAS can be expected to mitigate some of the impacts of the overall DAS reduction.

Social impacts of DAS reductions tend to be more far-reaching and long-term in nature than social impacts from other management measures like trip limits, gear restrictions, and seasonal area closures. They tend to have the most significant impacts on *disruption in daily living* and *changes in occupational opportunities and community infrastructure*, although they also can affect *safety*. They result from direct reductions in groundfishing opportunities and revenues for vessels that are most active in the fishery. Reductions in groundfishing opportunities through the loss of DAS also compromise vessels' flexibility and can have direct impacts on fishing activity within a port, consequently impacting the shoreside facilities that are dependent on the affected vessels. Other impacts of DAS reductions include increased uncertainty and instability in the fishery and/or community; problems finding and keeping crew members on a year-round basis; social impacts related to family and business financial problems; overall increased stress at the individual, family, and community level; and reductions in perceptions about job satisfaction.

At the social impact informational meeting in New Bedford, one large vessel crew member indicated that individual DAS reductions have complicated fishing schedules, eliminated predictability, and significantly limited income potential. As a crew member, he has sought employment on other vessels because his primary vessel is tied up at the dock for 50% of the year. A vessel owner commented that the DAS reductions converted year-round businesses that relied on groundfish in New Bedford to seasonal operations and that this has had significant impacts on the fishing families as well as other support businesses in the community. Another vessel owner's wife characterized the social impacts of the DAS reductions as "twice as much husband, half as much pay."

At the social impact informational meeting in Portland, one vessel owner remarked that DAS restrictions affected every sector of the Portland fleet: the big boats lost 50% or more of their groundfish opportunities, and gillnetters and smaller vessels were left with few alternatives except for the hope of a decent shrimp season for smaller draggers. Larger boats are trying to maximize returns from their DAS by fishing most or all of their DAS in the winter when prices are better. This again increases concerns about safety.

Indirect negative social impacts resulting from DAS reductions relate to adaptations that vessels make to compensate for reduced opportunity and reduce income, which can oftentimes increase their risk-taking and compromise their safety at sea. As income is reduced, some fishermen will try to minimize their operating costs in order to stay viable, sometimes reducing or eliminating crew, especially on smaller vessels. More owners of smaller vessels could be forced to fish alone for some or all of the year. Vessels may also try to maximize their remaining DAS by fishing during the winter when prices are usually better. Winter weather is more extreme and less predictable, increasing dangers that fishermen may encounter.

DAS reductions were cited as having been difficult for the Boston fleet and the dependent support services in the community to adapt to because the fleet is not highly diversified and historically depended primarily on groundfish. DAS reductions have precluded year-round fishing opportunities; now, most vessels from Boston fish most or all of their DAS during the winter and tie-up their vessels for 3-5 months. This has negative impacts on the economy of the shoreside support services that depend on year-round income to cover the costs of maintaining their businesses.

In addition, the disproportionate impacts of DAS reductions can create perceptions of inequity, which often exacerbate social impacts occurring in communities involved in groundfishing harvesting. Some people think that DAS allocations from Amendments 5 and 7 were unfair and created inequities and tensions between sectors involved in the fishery. Those who switched from groundfish to other fisheries with the decline of the groundfish stocks feel that they were punished by not receiving their true historical allocation of DAS. Some fishermen view DAS allocations as unfair because those who depend most on the fishery were impacted the greatest, while others who never depended on the fishery were allowed to potentially increase their effort eighty-eight fold (88 Fleet DAS were allocated to any vessel that could prove one pound of groundfish landings). Many fishermen feel that they have sacrificed more than their share to rebuild the resource and are concerned about their future ability to realize the benefits of their sacrifices. Six years later, this amendment includes alternatives that propose to reduce used DAS by another 50% and 65%. Similar to Amendments 5 and 7, this measure will again significantly affect those who are most active in and dependent on the multispecies fishery. It is likely that if implemented, reductions as large as 50% and 65% will cause significant economic dislocation in most of the communities involved in groundfishing identified in the Affected Human Environment.

Reductions in allocated DAS proposed in the capacity alternatives have the potential to exacerbate problems associated with the disproportionate impacts of DAS reductions. Vessels that stand to lose the most allocated DAS in this amendment are those that currently have the highest levels of latent DAS. Some proportion of latent DAS in the fishery can be attributable to vessels that are still active, but have shifted their effort from groundfish to other fisheries for many reasons, including groundfish stock declines, market conditions, and opportunities and encouragement to pursue alternative fisheries. As a result, some vessels may feel unfairly treated and disproportionately impacted by the capacity alternatives.

One concern about the long-term impacts of DAS reductions is that once allocated or used DAS are reduced, the DAS that are eliminated from the fishery will never be returned to the vessels. Whether or not this is the case cannot be predicted at this time, but it should be noted as a serious concern relative to long-term social and community impacts of DAS reductions. As noted in the report from the social impact informational meetings, losses of shoreside support infrastructure like cutting houses, ice facilities, processing facilities, and other important services have been experienced in communities throughout the region. While these losses may be due in part to external factors, additional losses will be experienced in some communities that depend on the groundfish fishery if DAS are further reduced by large amounts in this amendment. The long-term concerns relate to the ability of the community to remain actively involved in the groundfish fishery and the ability of the community to support increased participation in the fishery as the stocks continue to recover and support larger yields. This is a significant concern for communities that are marginally involved in the fishery at this time (northern Maine and southern New England communities).

Another important concern is the potential for increased conflicts between user groups resulting from DAS reductions. If DAS are reduced significantly in this amendment or if this amendment changes the way that DAS are counted, it is possible that vessels that historically fished offshore will fish closer to shore to minimize steam time and maximize their DAS usage. This could mean that larger vessels from Gulf of Maine ports that may traditionally fish on Georges Bank will instead fish in the Gulf of Maine to save the DAS that they lose from their steam time to Georges Bank. Conflicts between user groups were identified during the social impact informational meetings (big boats/little boats, Individual DAS/Fleet DAS) and could intensify as a result of adaptations that vessels make to DAS modifications. The vessels likely to make these kinds of adaptations are the larger vessels and those with Individual DAS permits since Individual DAS vessels are currently using most or all of their DAS. Conflicts between user groups can exacerbate intra- and inter-community conflicts, create additional perceptions of inequity, and weaken overall cohesion within communities involved in groundfish harvesting.

The economic impacts of DAS reductions that are being considered in this amendment are discussed in section 5.4.4. Certainly the most significantly impacted vessels from an economic perspective will be those that currently use most or all of their DAS. Many of these vessels possess Individual DAS permits. Similarly, the most significantly impacted communities will be those that currently depend on vessels that use most or all of their DAS and communities that include a relatively large percentage of Individual DAS vessels.

The following table provides percentages of the total multispecies permit holders homeported in the communities of interest that possessed Individual and Fleet DAS permits in the 2000 fishing year. When combined with the information presented in section 5.4.4, it becomes possible to deduce which community groups are likely to be most significantly impacted by reductions in used DAS proposed under alternatives 1a and 1b.

HOMEPORT COMMUNITY GROUP	%Individual Multispecies Permits Within Group (number of permits)	%Fleet Multispecies Permits Within Group (number of permits)	Total Number of Multispecies Permits Homeported in Group
Portland	29.6% (24)	46.9% (38)	81
Portsmouth	10.7% (6)	51.8% (29)	56
Gloucester	6.9% (17)	46.8% (116)	248
Boston	23.3% (7)	37.5% (12)	32
Chatham/Harwichport	0% (0)	43.6% (79)	181
New Bedford/Fairhaven	22.2% (53)	21.3% (51)	239
Point Judith	1.6% (2)	56.5% (70)	124
Eastern Long Island	0% (0)	41.7% (90)	216
Upper Mid-Coast 1, ME	5.6% (3)	50% (27)	54
NH Seacoast	1% (1)	43.5% (40)	92
South Shore, MA	1.2% (2)	39.8% (68)	171
Provincetown	2.8% (1)	47.2% (17)	36

Table 335 – Distribution of Multispecies Permit Holders in FY00 that were Homeported in the Communities of Interest

Note that Lower Mid-Coast 1 ME, Eastern RI, and Northern Coastal NJ are not included in the above table. All three of these community groups are assumed to exhibit patterns in multispecies permits similar to Upper Mid-Coast 1 ME and Eastern Long Island.

Portland, Boston, and New Bedford are homeports to the largest percentages of vessels that have Individual DAS permits, use more of their allocated DAS, and will be most impacted by the large-scale reductions in DAS proposed in Alternatives 1a and 1b. These ports are followed by Chatham/Harwichport, Provincetown, Gloucester, the NH Seacoast, and Portsmouth, which exhibit a relatively high dependence on the multispecies fishery and are homeports to a significant number of active Fleet DAS vessels. Communities like Eastern Long Island, Point Judith, Eastern RI, and Northern Coastal NJ are currently less dependent on the groundfish fishery and are likely to be impacted by the DAS allocations through the loss of flexibility and the opportunity to pursue the groundfish fishery as an alternative to other fisheries.

B DAS

The identification of programs to use Category B DAS is intended to help mitigate the social and economic impacts of the measures needed to rebuild overfished stocks. The use of Category B DAS distinguishes between B reserve DAS - only used in special access programs (SAP) (e.g., closed areas) - and regular B DAS used to target healthy. Two of the proposed SAPs are located offshore and target resources in CA II. Smaller vessels are less likely to have the capacity to steam such a distance and may not find the use of DAS coupled with operating costs and safety risks worth the effort. Conversely, the CA I SAP for hook gear is closer to shore and may provide an opportunity for smaller, selective hook gear to use Category B (reserve) DAS. Massachusetts vessels have easier access to this SAP.

Future programs to use Category B (regular) DAS will be limited to targeting healthy stocks. Present stock conditions suggest that there may be more opportunities for these programs on Georges Bank, given the status of GB haddock, yellowtail flounder, and winter flounder. There are almost no opportunities for these programs in the southern New England area given the status of SNE/MA yellowtail flounder and SNE/MA winter flounder. Within the Gulf of Maine, there may be limited opportunities for programs to target GOM haddock and pollock. For example, there may be an opportunity for a hook gear SAP in the WGOM closed area analogous to that in CA I.

5.6.2.2.1.2 Area Closures

Area closures are proposed throughout the alternatives under consideration in the form of additional and/or modified year-round and seasonal closures. Area closures are used as a management tool in the alternatives to address rebuilding requirements as well as the measures to minimize adverse impacts on habitat. In the alternatives to address rebuilding requirements, most proposed area closures have been developed to address fishing mortality of Gulf of Maine or Georges Bank cod, although some are proposed to address fishing mortality reductions across many groundfish stocks.

The recently implemented Interim Action (settlement agreement) implemented modifications to area closures, the impacts of which also must be considered in this social impact assessment. The EA for the Interim Action includes analysis of the settlement agreement year-round area closures (addition of Cashes year-round) and modifications to seasonal closures (124-125 open Jan-Mar; 80, 81, 118-120 closed May). All of the EA measures were effective during the 2002 fishing year and are included in some of the alternatives under consideration in Amendment 13. Only Alternative 4A reverts back to the pre-settlememt agreement area closures. The proposed action will maintain the year round and seasonal closed areas adopted under the settlement agreement.

The continuation of the Cashes closure on a year-round basis is being considered in all of the Amendment 13 alternatives, with the exception of 4A. Cashes Ledge is an offshore area (compared to other areas in the Gulf of Maine that are proposed for closure), and the vessels and communities that will be most impacted by a year-round closure on Cashes are those that depend on it for fishing during some or all of the year. There is an active gillnet fleet that fishes on Cashes during some part of the year. If possible, these vessels will be forced to relocate their operations. On the other hand, this area will have been closed year-round in the 2002 fishing year, so some adaptations may have already been made by vessels that fish in this area.

In general, two categories of fishing vessels will be most affected by changes to the area closures: (1) vessels from communities involved in groundfish harvesting directly bordering the proposed additional area closures, and (2) vessels from other communities that have traditionally accessed the proposed additional closed areas to fish. Affected vessels from both categories include not only those vessels that fish for Gulf of Maine or Georges Bank cod, but also those vessels that fish for other species like flatfish or scallops. Of the SIA factors under consideration, area closures tend to produce the most significant impacts on *safety* and *disruption in daily living*, although impacts on *occupational opportunities* and *formation of attitudes* can also be expected.

The vessels in Category (1) will be the most directly affected by additional inshore and rolling area closures because the area closures border on the coastlines of their communities and, in some cases, extend up to 80 or 100 miles offshore for a period of time. For the communities of interest in the Gulf of Maine, these vessels are primarily based in Gloucester, Portland, Portsmouth, the NH Seacoast, Provincetown, and the South Shore of Massachusetts. For the communities of interest in Georges Bank, these vessels are primarily based in Chatham/Harwichport.

Within this category of affected vessels, smaller vessels (less than 50 feet) will be at a greater disadvantage to adjust to the regulations because of their inability to travel beyond the area closures to fish. Medium and larger-sized vessels will undoubtedly be constrained and inconvenienced, but the physical characteristics of these vessels may allow them to sustain some level of offshore fishing activity during the time period of closure. A majority of the vessels in question, especially those from Gloucester, Chatham/Harwichport, Portsmouth, the NH Seacoast, Provincetown, and the South Shore are relatively smaller-sized vessels and may be forced to seek alternatives to fishing for multispecies due to the closures. This held true for the inshore area closures implemented through Frameworks 25, 26, 27, 31, and 33. The communities in which these vessels conduct their fishing activities and are homeported are likely to experience the greatest short-term social impacts resulting from additional area closures proposed in this amendment.

The second category of affected vessels is comprised of vessels that have accessed the proposed additional closed areas to fish for a variety of species and may now be facing closure of these fishing grounds. Although some of the affected vessels in this category include those coming from communities involved in groundfishing bordering the area closures (Category (1)), others come from other communities throughout the region. These vessels, while inconvenienced and limited in terms of their flexibility, may still have the opportunity to fish in other parts of the Gulf of Maine and Georges Bank as well as in other regions, although usually at increased expense. Affected vessels in Category (2) but not in Category (1) are more likely to shift their effort into other areas and perhaps onto other species. The communities in which these vessels conduct their fishing activities and are homeported (New Bedford, Point Judith, and Eastern LI, for example) are less likely to experience short-term social impacts resulting from the additional area closures proposed in this amendment.

There are other sectors of the groundfish fishery that will be affected by additional area closures. Shoreside facilities that supply bait, ice, fishing gear, and other supplies may suffer from a decrease in fishing activity in their communities, especially if vessels in their communities are unable to access fishery resources for a period of time. Greater dependence on fishing for groundfish in communities like Gloucester could ultimately lead to a greater potential for community economic dislocation resulting from the area closures implemented in this amendment. As an example, according to information from the 1990 U.S. Census, Essex County, Massachusetts employs close to 6,000 persons in fishing related businesses (processing, seafood markets, vessel repair, etc.). Support infrastructure in communities such as Gloucester (located in Essex County) is estimated to be at a premium, and very little additional infrastructure could be lost without having a major impact in the ability of the fleets in these communities to operate (Aguirre International 1996).

Loss of income and displacement from the fishery are likely to result in the short-term from additional area closures, and these losses are likely to be most significant in communities like Portsmouth, the NH Seacoast, Gloucester, the South Shore of MA, Provincetown, and Chatham/Harwichport MA. In extreme cases, the need for financial assistance as a result of loss of occupational opportunities, when combined with the perception of lowered social status resulting from decreased income, can often result in lowered self-esteem and negative impacts on job satisfaction. These social impacts are often consequences of any management plan directed at reducing exploitation. They also tend to result from alternatives that include either large-scale, long-term area closures or nearshore area closures that preclude opportunities for smaller vessels.

Some area closures proposed in the Amendment 13 alternatives may require that vessels find new fishing grounds and/or travel farther to fish. The potential need to spend more time at sea as a result of Amendment 13 area closures may produce negative social impacts. In fact, length of time at sea has been cited as an important characteristic affecting job satisfaction because of the amount of time fishermen are required to spend away from their families and communities and because of the potential for smaller vessels to compromise their own safety to maintain income during the closure time (Pollnac and Littlefield 1983).

To summarize, the area closures proposed in Amendment 13 will require fishermen and their respective communities to adjust to the regulations aimed at rebuilding commercial groundfish stocks and minimizing adverse impacts on habitat. How these adjustments will affect individuals, their families, and their communities varies with a number of factors, such as their dependence on Gulf of Maine or Georges Bank cod and other groundfish species as well as their ability to increase the value of a reduced catch or to shift effort to other fisheries in order to maintain a year-round stream of revenues.

The proposed action continues the year round and seasonal closed areas adopted by the FW 33 settlement action.

5.6.2.2.1.3 Trip Limits

In comparison to the no action alternative (400/4,000 for GOM cod; 2,000/20,000 for GB cod; no trip limits for SNE or CC/GOM yellowtail):

- Increases to the GOM cod trip limit were proposed for all alternatives, with the exception of 4a, to reduce regulatory discards without compromising fishing mortality.
- Reductions to the GB cod trip limit were considered in Alternatives 2a and 2b to reduce fishing mortality.
- New trip limits are being proposed for Southern New England/mid-Atlantic yellowtail flounder in all alternatives with the exception of 4a.
- A 50-pound trip limit is being proposed for Cape Cod/Gulf of Maine yellowtail flounder in Alternative 2a and 2b. The yellowtail trip limit for Cape Cod/Gulf of Maine yellowtail flounder is the same as Southern New England/mid-Atlantic yellowtail in alternatives 1a and 1b. There are no trip limits for Cape Cod/gulf of Maine yellowtail in alternatives 3 and 4.
- The Haddock trip limits are the same as currently exist.

The proposed action:

- Increases the GOM cod trip limit to 800 lbs/4,000 lbs
- Reduces the GB cod trip limit to 1,000 lbs/10,000 lbds for most vessels, with a seasonal limit for hook gear.
- Adopts a trip limit for CC/GOM yellowtail flounder and SNE/MA yellowtail flounder. While the amounts are the same as implemented in the settlement agreement, the months are different.

The recently implemented Interim Action (settlement agreement) implemented modifications to trip limits, the impacts of which also must be considered in this social impact assessment. The EA for the Interim Action includes analysis of the following changes to trip limits: 200 pounds for open access handgear vessels; 250 pounds Mar-May and 750/3,000 pounds June-Feb for Southern New England yellowtail founder; and 500/4,000 pounds for GOM cod. All of the EA measures were effective during the 2002 fishing year and are included in some of the alternatives under consideration in Amendment 13.

Trip Limits are most likely to affect *regulatory discarding* and *formation of attitudes*. In general, trip limits can affect the structure of a fishery. If the trip limit is set very low, the inshore sector of the fleet can sometimes manage to fish economically, while the offshore sector of the fleet cannot cover trip expenses to direct fishing effort on the species managed by the trip limit. This can change the structure of revenues generated in the fishery and can ultimately change the long-term structure of the fishery itself. These types of outcomes, however, have not been evident to a large extent in the GOM cod fishery because trip limits have been set too low for most vessels to target GOM cod.

Instead, social impacts have resulted because the trip limits themselves hold a socially-undesirable characteristic – *regulatory discarding*. The impacts of regulatory discarding are discussed in Section 5.6.2.1.1.

Based *only* on the likelihood of reducing regulatory discarding, the Gulf of Maine cod trip limits under consideration rank as follows:

No Action	**400 pounds per day/4,000 pounds per trip**	(LEAST LIKELY)
Alternatives 2a, 2b and 3	500 pounds per day/4,000 pounds per trip	

Alternative 1/Proposed Action 800 pounds per day/4,000 per trip (MOST LIKELY)

Different trip limits for cod on Georges Bank and in the Gulf of Maine also have created perceptions of inequity between some sectors of the fishery. Currently, vessels can land 2,000 pounds per day/20,000 pounds per trip when fishing on Georges Bank and 400 pounds per day/4,000 pounds per trip when fishing in the Gulf of Maine. Although they are separate stocks of cod and there are many reasons for different trip limits, codfish are marketed similarly no matter where they are caught (sometimes prices may vary depending on how they are caught). Fishermen in the Gulf of Maine may be disadvantaged in terms of the fresh fish market for cod. Moreover, larger vessels from Gulf of Maine ports may be able to fish on Georges Bank and land more cod, increasing perceptions of inequity in some communities. This often exacerbates conflicts between sectors of the industry, which create social impacts in the form of intra-community conflicts and loss of community cohesion. The proposed action will reduce the difference between these two trip limits.

While the true magnitude of Gulf of Maine cod discards is unknown, any alternative in Amendment 13 that increases the Gulf of Maine cod trip limit to a level that minimizes regulatory discarding without compromising long-term stock recovery will mitigate the social impacts of the trip limit itself. While it may improve perceptions of inequity, creating a significant regulatory discarding problem on GB can be expected to have similar social impacts as the recent low GOM cod trip limits. This would be a likely result for both day boats and trip boats. In addition, if the GB cod trip limits are set too low, disproportionate impacts are likely to be experienced by the hook sector in Chatham/Harwichport, as discussed in the economic impact analysis. The most significant negative social impacts in Chatham/Harwichport and other Cape Cod communities are expected to result from Alternatives 2a and 2b because of a 500 pound per day GB cod trip limit.

5.6.2.2.1.4 Gear Restrictions

In comparison to the no action alternative, several gear restrictions are being proposed in the alternatives under consideration. These include changes in otter trawl codend mesh size; various limits on the number of stand-up and tie-down gillnets that can be used in different areas; requirements to use separator nets, raised footrope trawls, or other gears; limits on the number and size of hooks; and various restrictions on bottom-tending gear to minimize adverse effects on habitat.

The recently implemented Interim Action (settlement agreement) implemented modifications to gear restrictions, the impacts of which also must be considered in this social impact assessment. The EA for the Interim Action includes analysis of the following changes to gear restrictions: 6.5-inch diamond or square mesh codends in the GOM; limits on the numbers of gillnets in the GOM and on GB; limits on the number of hooks to 2,000 in the GOM and SNE and to 3,600 hooks on GB; and 7-inch diamond or 6.5-inch square mesh codends in the newly-defined SNE area. All of the EA measures were effective during the 2002 fishing year and are included in some of the alternatives under consideration in Amendment 13. The impacts of the Interim Action measures are especially important to consider in the context of gear restrictions; in some cases, the no action alternative may have more significant impacts because it would lessen the gear restrictions from the status quo (settlement agreement), leaving fishermen with recently-purchased gear that would no longer be required. The proposed action makes minor changes to gear requirements, but on the whole retains most of the measures adopted by the settlement agreement.

In terms of the SIA factors, gear restrictions affect *changes in occupational opportunities and community infrastructure* and *formation of attitudes* the most, although they can also affect *regulatory discarding* and *disruption in daily living* to a lesser extent. Gear restrictions can compromise business planning for shoreside support services and impose an economic burden on a large number of vessels. The social impacts likely to result from changes to gear restrictions are related to the cost for vessels to comply with and the ability of gear suppliers to adapt to the new gear restrictions. An assessment of the impacts associated with the Interim Action gear restrictions is provided in the Interim Action EA (NMFS 2002).

If a new mesh size is required by the proposed action and not readily available, gear suppliers must order the twine well in advance of the effective date of the new regulation. Gear suppliers have indicated that ordering enough new mesh for the groundfish fleet could take between 3-6 months. In addition, new mesh requirements can sometimes leave gear suppliers with a significant amount of the "old mesh" that may no longer be marketable if it cannot be used in the fishery anymore (or in other fisheries). This results in a more significant loss of income for the gear suppliers.

Gear changes can affect short-term and long-term business planning for gear suppliers and related support services. The uncertainty associated with the implementation of new groundfish regulations necessitates gear suppliers to wait until it is definite that a new gear will be required. It is too risky and too expensive to order new twine or other gear prior to an official announcement of a new regulation. Quite often, this leaves gear suppliers uncertain about the short-term future needs for their business and makes it impossible for them to plan accordingly when developing longer-term business strategies. It is rare that a supplier can plan his/her business needs annually if gear restrictions change on as frequent a basis.

Gear restrictions place an additional economic burden on all affected fishing vessels. The ability to adapt to the new gear regulations will depend on vessels' current economic situation and ability to cover the short-term costs of the gear. If the new gear requirement is significantly different from current gear requirements, it is likely that the most marginal vessels will not be able to cover the costs of the new gear and will be forced to seek alternative fisheries or stop fishing altogether. For the vessels that can cover the short-term costs of the gear, long-term impacts are related more to the loss of revenues from fishing that may occur because of the new gear. For example, vessels are likely to lose some of their catch of species other than groundfish if they are required to fish for groundfish with a larger mesh. Over the long-term, this may result in more significant economic impacts and, ultimately, more severe dislocation of vessels in the fishery.

The magnitude and nature of the impacts of the gear restrictions under consideration in Amendment 13 will depend on the cost of the new gear, the current availability of the new gear, and vessels' choices as to whether or not to fish in the areas where the new gear is required. Some additional discussion of specific gear restrictions proposed in this amendment is provided within the discussion of the various alternatives.

5.6.2.2.1.5 Hard TACs

Hard TACs, or quotas, are being considered as management tools in many of the alternatives proposed in this amendment. Alternatives 2a, 2b and 3 include Hard TACs as backstop measures; Alternatives 4 and 4a represents a Hard TAC approach to managing the groundfish fishery. While the proposed action focuses on effort controls, it does adopt a hard TAC to implement the US/CA Resource Sharing Understanding for cod, haddock, and yellowtail flounder on eastern Georges Bank.

The EA for the recently-implemented Interim Action (settlement agreement) contemplated Hard TACs in the groundfish fishery. Attachment A to the EA described two options for Hard TACs and generally discusses the socio-economic impacts of Hard TACs (NMFS 2002). The EA concluded that the Hard TAC alternative would have the most significant negative impacts of the measures under consideration. The EA document should be referenced for more information and analysis.

Hard TACs have the potential to significantly impact all five SIA factors that have been identified in this assessment: *regulatory discarding*, *safety*, *disruption in daily living*, *changes in occupational opportunities and community infrastructure,* and *formation of attitudes*.

Especially in a multispecies fishery, social impacts of Hard TACs can be a byproduct of several changes in fishing behavior, including derby-style fishing, highgrading, and regulatory discarding. If a TAC is set low enough on a commercially valuable species, it can create a derby or a race for the fish. Derby-style fishing can negatively affect the price for the species and the revenues from the fishery if too much product is put on the market at one time. These negative economic impacts can affect occupational opportunities in the fishery and may impact community infrastructure over the long-term. In addition, derby-style fishing can create unsafe conditions for a vessel or a fleet depending on how competitive the race is and what time of year the fleet is catching the fish.

Once a quota is reached, further landings of the species are usually prohibited. This can create a regulatory discard problem, worsened by the race to fish and a consequently shorter period of time during which the species can be landed. In a multispecies fishery like the groundfish fishery, it is likely that some TACs will be reached, while others will not, allowing some groundfish species to continue to be landed. Depending on the time of year and stock area in question, this could exacerbate problems with regulatory discarding, as the race to fish for the other quota-managed species may force most vessels to continue to fish while discarding the species for which the quota has already been reached.

This outcome is very likely if Hard TACs are set for each stock in the multispecies fishery and if they are combined with other measures in Amendment 13. For example, DAS reductions could increase the race to fish under Hard TACs, as fishermen may try to maximize their remaining DAS by targeting the highest-valued species. This also can lead to highgrading, discarding that occurs when fishermen select only the highest-valued fish to land. For example, if large cod are worth the most, fishermen may discard other marketable sizes to keep only the largest cod, especially if the total quota is low and their opportunities to fish for groundfish are further restricted.

The alternatives that minimize negative social impacts resulting from Hard TACs are likely to be those that include set-asides for bycatch fisheries once the quota in the directed fishery has been reached. This reduces regulatory discarding. Other alternatives with fewer impacts are those that establish Hard TACs for only some of the groundfish species. Negative impacts can be expected to increase proportionately with the number of groundfish stocks managed under Hard TACs.

A Hard TAC management approach does have some potential social benefits. It can provide some stability to the fishing regulations, at least on an annual basis. This can allow for better business planning over the short-term. Assuming that regulatory discards do not increase fishing mortality beyond target levels, Hard TACs have the potential to generate long-term positive social impacts resulting from the ability to meet the conservation objectives of the management program. If Hard TACs are set appropriately and enforced adequately, biological objectives should be met, eliminating the need to increase restrictions on the fishery in the future. This is why some alternatives under consideration set Hard TACs as backstops. Meeting biological objectives ensures an improved revenues stream over the long-term as well.

Since the intent of a Hard TAC is to guarantee that fishing mortality targets will be achieved and management objectives will be met, it is likely that a Hard TAC management program will include fewer other kinds of measures to reduce fishing mortality like area closures, gear restrictions, and DAS modifications (except for programs that use Hard TACs as backstops). To the extent that this is true, the negative social impacts of these other measures can be reduced. It seems reasonable to assume that a Hard TAC management program would eliminate nearshore seasonal area closures in order to provide all vessels with equal access to the resource. This would reduce the impacts associated with derby-style fishing and improve safety, especially for smaller fishing operations that are pursuing the quota.

5.6.2.2.1.6 Special Access Programs

Special access programs are being considered in combination with the alternatives proposed in this amendment. In concept, Amendment 13 endorses the concept of a Special Access Program (SAP) to allow for the establishment of groundfish fisheries that target stocks that can support increased fishing mortality, while avoiding stocks that require reductions in mortality. The positive impacts of these access programs would be from increased groundfish fishing opportunities for vessels that are able to participate in them. Participation could generate additional revenues and help to provide year-round fishing income. Over the long-term SAPs could mitigate some of the negative social impacts resulting from the broader management measures that affect mortality on all stocks like DAS modifications. SAPs are most likely to positively affect *changes in occupational opportunities and community infrastructure*, *disruption in daily living*, and *formation of attitudes*.

There are four SAPS proposed for Amendment 13. Three of those SAPs are on Georges Bank. Two in particular – targeting stocks near CAII – are not likely to be used by small vessels, since they do not have the range to participate safely in these SAPs. One SAP for hook gear vessels in CAI may rovide limited opportunities for small vessels, primarily from Cape Cod and other Massachusetts ports. The fourth SAP will reduce regulatory discards of winter flounder taken while fishing for fluke.

5.6.2.2.2 Impacts of Fishery Program Administration

There are several measures proposed within the administration of the fishery management program (section 3.4) that may generate some social impacts. These measures and their likely impacts are discussed generally below.

FMP Review and Adjustments

The proposed modifications to the periodic adjustment process include revisions to the structure of the Groundfish PDT and establishment of a biennial management adjustment (instead of an annual adjustment). These changes could result in positive social impacts by streamlining and simplifying the management process and improving *formation of attitudes*. In recent times, the Council's annual review/adjustment process and the resulting series of framework adjustments (Framework 25, 27, 31, 33, etc.) have created perceptions of an ever-changing management system that does not allow adequate time for stock recovery to occur before additional, usually more severe, measures are implemented. Adjusting measures less frequently will reduce uncertainty and improve stability for fishery participants. This should allow for better business planning over the short-term. Extending the duration of time between each periodic review and adjustment also would allow measures to affect stocks, ultimately enabling the PDT to more accurately evaluate the impacts of the management measures before recommending additional measures. In the long-term, this approach could lead to more effective management of the multispecies resources.

DAS Leasing

A conservation-neutral DAS leasing program may be a very important mitigating factor for vessels that experience DAS reductions through Amendment 13 and are able to participate in the leasing program. It is possible that the DAS reductions in Amendment 13 will be severe enough for many vessels that they can no longer remain viable in the groundfish fishery. A leasing program offers an option for some vessels to temporarily increase the number of DAS they may fish by leasing the DAS from another vessel that chooses not to fish them. For vessels that are able to participate, this program is likely to mitigate the impacts associated with *disruption in daily living, changes in occupational opportunities and community infrastructure,* and *formation of attitudes.* If a particular community is home to a large number of vessels that can participate, this program may provide for the sustained participation of the community in the groundfish fishery.

The selection of a mechanism to ensure conservation-equivalency is important and may determine the extent to which some vessels are able to participate in the DAS leasing program. Option 1, leasing within categories, limits vessels to leasing DAS that are within similar bounds of size and gear. First, a lessor may not lease DAS to any vessel with a main engine horsepower rating that is more than 20% that of the lessee and may not lease DAS to any vessel that is more than 10% of the lessee vessel's LOA, GRT, and NT. Second, lease agreements would be restricted by gear such that vessels with hook-only permits may lease

DAS only from other hook-only permit holders, trip gillnet vessels may lease DAS only from other trip gillnet vessels with a FY2001 trip gillnet designation, etc. This reduces flexibility within the program and significantly limits the pool of DAS available to a lessor. The largest and most unique fishing vessels are likely to be disadvantaged by this approach; these are the same vessels that may benefit most, economically and socially, from a DAS leasing program. Option 2, calibrating DAS, provides much broader opportunities to match buyers and sellers of leased DAS. Both approaches proposed within Option 2 appear to improve flexibility within the leasing program and maximize the economic and social benefits associated with such a program.

DAS Leasing - Flow

The proposed action will implement a DAS leasing program. The following gives some indication of the possible social impacts from leasing DAS. This analysis is based on part on the predicted outcomes from economic modeling (section 5.4.9.2.7) further aggregated by port, state, and vessel size to give an indication of the differential effects of DAS leasing within the groundfish industry. This analysis should be interpreted as an indication of the *direction* of pressures or trends, rather than a precise estimate of impacts. The economic model itself is highly stylized and makes a number of theoretical assumptions about perfect markets (such as the overall ability and willingness to trade and the full information to do so, and simultaneous execution of all trades) that are not reasonably expected to occur. There are also a number of reasons to expect, based on anthropological perspectives, that such trading will not take place as economic modeling may predict. Anthropological studies have demonstrated repeatedly that for many fishermen and fishing families, a commitment to fishing is based not solely on income or profit maximization but rather on fishing as a way of life (Gatewood and McCay 1988, Gatewood and McCay 1990). Other studies have shown that many fishing businesses are family-run enterprises where income pooling and other forms of resource sharing mitigate against the more traditionally-capitalist assumptions about firms in economic analyses (Doeringer et al. 1986).

The economic modeling assumes that a vessel owner would only lease DAS if the income from leasing is more than the expected income from fishing those DAS; in other words, the impacts from such a leasing arrangement are expected to be positive, or at least no worse than status quo. Given the coupling of this alternative with other alternatives in order to meet conservation neutrality, leasing would at best mitigate the negative impacts from the overall reduction in fishing activity. However, since the income accrues to the owner of the vessel, crew members on vessels that lease DAS away may see a negative impact to income, depending on to what extent the vessel engages in alternative fishing activities (about which the model makes no predictions). Alternatively, crew on vessels that lease DAS in may see positive impacts from increased fishing activity. Changes in landing patterns that could occur with net outflows of DAS from particular ports (as indicated below) could have negative impacts on buyers and processors, depending again on to what extent vessels engage in other fishing activities. Moreover, the social impacts from policy changes extend beyond changes in income. Studies on the social ramifications of ITQ's (though fundamentally different from the policy proposed here since DAS are only leased and not permanently sold) have, for example, pointed to the significant impacts on social relations that stem from the commodification of fishing activity (Pálsson 1998, Pálsson and Helgason 1995). Moreover, such ITQ studies have pointed to the ramifications of changing market shares that enable the domination of particular segments of the industry over others without further protective legislation (McCay 1995, McCay et al. 1995).

In terms of the distributional effects within the groundfish industry, the economic modeling indicates a movement of DAS from large/medium to small vessels (see Table 336). For all size categories, there is a movement to vessels more dependent on groundfish income, though this is more pronounced for the larger vessels. At the state level (Table 337), the influx of DAS is primarily to Massachusetts, which is also the state with the highest groundfish income from the vessels modeled. Maine, though with the second highest income and with income that comes from vessels dependent or highly dependent on groundfish, sees significant loss of DAS. Rhode Island also shows significant loss of DAS. It is therefore expected that the negative impacts (as detailed above) from DAS leasing would be felt most there. At the port level, ports such as New Bedford and Gloucester see a net gain of DAS while ports such as Portland, Point Judith, Newport, and Hampton might see a net loss (Table 338).

Size Class	Groundfish income*	Percent of which comes from dependent vessels	Percent of which comes from highly dependent vessels	Net gain in days-at-sea	Percent of days leased out by dependent vessels	Percent of days leased out by highly dependent vessels	Percent of days leased in by dependent vessels	Percent of days leased in by highly dependent vessels

5.6.2.2.3 Impacts of Measures to Control Capacity

For the most part, the social impacts of the measures proposed to control capacity are discussed in Section 5.6.2.2.1.1. The capacity measures propose to eliminate some proportion of unused (latent) DAS from the pool of DAS that can be used in the multispecies fishery. This can be achieved through several strategies: (Alternative 1) Permit Absorption; (Alternative 2) Permit Transfer; (Alternative 3) DAS Transfer; (Alternative 4) Freeze on Unused DAS; (Alternative 5) DAS Reserve.

Alternative 1, permit absorption, allows a permit holder to transfer all permits held to another vessel. This allows permit holders to combine scallop and multispecies limited access permits, with some restrictions in the form of a conservation tax. Under this alternative, the transferring vessel is required to retire from fishing, and all of its limited access permits must be transferred to other limited access permit holders, or they will expire. Retirement from fishing means that a vessel may not participate in any other state or federal open access or limited access fisheries after its permits are transferred. DAS that are acquired by a vessel through a permit transfer and absorption would be made available through a schedule that allows for 20% of the DAS acquired to be reactivated each year. To an extent, this alternative increases flexibility and enhances opportunities in the multispecies fishery for vessels that are able to participate. It may mitigate some of the negative social impacts resulting from DAS reductions and other restrictions in Amendment 13. The social impacts of this alternative for participating vessels may be similar to those associated with a DAS leasing program (Section 5.6.2.2.2). However, the benefits of this alternative are limited to those vessels that may have the financial ability to participate in the program. In addition, the long-term benefits of reducing capacity in the fishery may not be very significant under this alternative.

Alternative 2, permit transfer, allows limited access groundfish permit holders to transfer their multispecies permits to another vessel or vessels, with some restrictions in the form of a conservation tax. Under this alternative, the selling vessel is required to retire from fishing, and all of its limited access permits must be sold to other limited access permit holders, or they will expire. Retirement from fishing means that a vessel may not participate in any other state or federal open access or limited access fisheries after its permits are sold. DAS that are acquired by a vessel through a permit transfer would be made available through a schedule that allows for 20% of the DAS acquired to be reactivated each year. This alternative is very similar to Alternative 1 (permit absorption), so similar impacts can be expected. Benefits may accrue to those vessels that are financially capable of participating in the program. Again, however, the long-term benefits of reducing capacity in the fishery may not be very significant under this alternative.

Alternative 3 allows limited access multispecies permit holders to permanently transfer DAS to other limited access multispecies permit holders, with some restrictions on vessel size and the percentage of active and inactive DAS that can be transferred. Alternative 3 may be adopted as a stand-alone capacity reduction measure, or it may be incorporated into Alternatives 1 or 2. Similar to Alternatives 1 and 2, this approach may have positive impacts for vessels that are financially capable of participating in the program. It could increase DAS available to participating vessels, thereby mitigating the negative impacts of the DAS reductions and other restrictions in Amendment 13. The social impacts of Alternative 3 are expected to be similar to those associated with Alternatives 1 and 2, as well as the proposed DAS leasing program. More significant long-term benefits associated with reducing capacity in the fishery can be expected under Alternative 3 when compared to Alternatives 1 and 2.

Several options are proposed in Alternative 5 so that reductions in fleet capacity are achieved through changing the way that the baseline of DAS is calculated for individual vessels. These measures essentially allocate all limited access multispecies permit holders Individual DAS based on the permit holder's recent level of participation in the groundfish fishery. For the purposes of this assessment, a freeze on unused DAS (Alternative 4) and the DAS Reserve (Alternative 5) equate to reductions in allocated DAS and are discussed in Section 5.6.2.2.1.1.

<u>Effective Effort Baseline</u>

The proposed action adopts a different baseline for determining effective DAS than the baseline used under the court settlement agreement. Under the FW 33 settlement agreement, all vessels received at least 10 DAS, even if they had not fished for groundfish during the qualification period. The proposed action would prevent these vessels from participating either directly by fishing or indirectly by leasing or transferring their DAS.

The distribution of vessels with no DAS under the proposed action can be divided into two overlapping groups of ports (homeports): those having vessels with more than 10 DAS under the court settlement agreement and those having no vessels with more than 10 DAS under the settlement agreement. The ports having a significant number of vessels with more than 10 DAS under the settlement agreement but also having a significant number of vessels that would lose all their DAS under the proposed action are Boston, MA, Gloucester, MA, Barnegat Light, NJ, and Montauk, NY. The other ports in this category have from 0 to 3 vessels that would lose all their DAS (Table 339).

The other category of ports, those with a significant number of vessels allocated only l0 DAS under the court settlement, includes the above ports as well as many ports without any vessels with more than 10 DAS under the settlement agreement. This category includes Boston, Ma, New Bedford, Ma, Portland, ME, Swans Island, ME, Barnegat Light, NJ, Cape May, NJ, Montauk, NY, Point Judith, RI and Newport, RI. In many of the smaller homeports in this group no vessels will have an allocation of DAS. The comparison of overall impacts for the two separate port groupings show that the allocation of no DAS will significantly affect many ports that had vessels allocated fewer than ten DAS (Table 340). Vessels that qualified for less than 10 DAS are likely to be smaller vessels or those that did not have sufficient landings history in the multispecies fishery to qualify for more days. This action removes future potential participation of vessels with less than ten DAS from either directly participating in the fishery or indirectly participating in a lease or transfer program (at least unless Category C DAS are allowed to be used in the fishery). A substantial number of vessels with greater than 10 DAS received an increase in DAS.

Table 340 - Comparison of Settlement Agreement and Proposed Action Baseline DAS by Homeport (Permits < 10 DAS)

5.6.2.2.4 Impacts of Management Alternatives to Address Rebuilding Requirements

A significant amount of discussion about social impacts already has been presented in this assessment (Sections 5.6.1.3, 5.6.2.1 and 5.6.2.2.1). Discussion of the alternatives in the subsections below is brief and refers to previous sections of this assessment where appropriate.

5.6.2.2.4.1 Proposed Action

The major components of the poroposed action include:

- Categorization of allocated DAS into Category A, Category B (regular) Category B (reserve) and Category C DAS based on effective effort. Category A DAS can be used to target any stock, Category B DAS can only be used to targey healthy stocks. Details for the use of Category B (regular) DAS, outside of special access programs, remain to be developed. Effective effort option 9 is used, with the split of effective effort into A and B DAS set at 60/20/20.
- Year round and seasonal closed areas as adopted by the settlement agreement
- GOM cod trip limit increased to 800 lbs/4,000 lbs
- GB cod trip limit reduced to 1,000 lbs./10,000 lbs, with a seasonal limit for hook gear
- CC/GOM yellowtail flounder trip limit of 250 lbs (May/June and October/November), 750 lbs/3,000 lbs remainder of year
- SNE/MA yellowtail flounder trip limit of 250 lbs (March through June) and 750 lbs/3,000 lbs remainder of the year
- Minor revisions to gear requirements

The proposed action anticipates a large reduction in the number of DAS used to target any groundfish stock. This will reduce opportunities and participation in the fisher by many vessels. The categorization of DAS and identification of opportunities to use B DAS may reduce some of the negative impacts of the DAS reduction. This depends on how successful the Council is in identifying ways to use B DAS outside of special access programs. If the Council is unsuccessful in doing so, then the possibity of using B DAS may be viewed as a sham by some fishermen and their families, and there will eb a negative reaction ot the regulations.

Increasing the GOM cod trip may help reduce regulatory discards. It will also help make each of a limited number of DAS more profitable, helping to mitigate the negative impacts of the DAS reductions.Lowering the GB cod trip limit to a level closer to that of GOM cod may help defuse many of the complaints about the discrepancy between the trip limits for the two stocks. The lower GB cod trip limit could result in increased discards. Analysis of observer nad study fleet data indicate that the limit may be at the right level to reduce mortality without significantly increasing discards. The trip limits on yellowtail flounder will probably increase discards on stocks that have not been subject to a trip limit prior to the settlement action. This will create more negative attitudes concerning the discard levels.

The changes to gear requirements focus on gillnet vessels. Many gillnet fishermen flet the settlement agreement gillnet measures were unfair. The proposed action addresses some (but not all) of those complaints. It increases the number of trip gillnets that can be used on Georges Bank to the same number used in the Gulf of Maine, addressing one perceived inequity. It also removes restrictions on the use of stand-up nets in the GOM, providing a limited opportunity to target healthy roundfish stocks in the winter months.

One of the most contentious elements of the proposed action is adopting Option 9 for the definition of effective effort. This option uses a qualification period of fishing year 1996 through 2001, and adds a requirement that a vessel document landings of regulated groundfish during this period. It is a significant re-shuffling of the DAS allocations authorized under the settlement agreement. By extending the qualification period to 2001, the Council did not use a control date announced in 1999 for evaluating DAS. Some argue that this rewards those who ignored the control date and began fishing after its adoption. Establishing a landings requirment is viewed as prejudicial to those who either did not have access to groundfish during the period because of low stock sizes, or who targeted other species for any reason (better economic opportunities, to allow groundfish to rebuild, etc.). In effect, the use of Option 9 favors current active participants in the fishery while limiting future opportunities for those who were not active during the qualification period. While many active fishermen believe this is more equitable, those who see stocks rebuilding and who cannot fish on them are concerned that they will not be allowed back into the fishery in the future.

5.6.2.2.4.2 No Action Alternative (Not selected)

For the purposes of Amendment 13, the no action alternative is considered to be the regulatory environment which would exist if Amendment 13 is not implemented and the interim action (settlement agreement) expires. In general, this includes the following:

- Amendment 7 DAS allocations and reductions (Individual DAS and 88 Fleet DAS)
- Seasonal/rolling area closures implemented through Frameworks 27, 31, and 33 – effective until modified by future Council action
- Extension of the existing WGOM closed area until modified by future Council action
- Continuation of the triggered closures if 50% of the Target TAC is landed by July 31 (Cashes in November and Blocks 124 and 125 in January)
- Gulf of Maine cod trip limit of 400 pounds per day/4,000 pound trip maximum
- 2001 gear restrictions (6-inch diamond, 6.5-inch square mesh, 80/160 gillnets)
- 2001 recreational fishery restrictions (10 fish recreational bag limit, minimum size of 21-inches for cod, access to Gulf of Maine closed areas with 3-month exemption letter)
- Georges Bank cod trip limit of 2,000 pounds per day/20,000 pound trip maximum
- No trip limits for yellowtail flounder.

Analysis indicates that the no action alternative will not meet the objectives of Amendment 13. The long-term impacts of the no action alternative are therefore likely to be more negative than the long-term impacts of any alternative that can meet the mortality objectives and rebuild the stock to sustainable levels. Under the no action alternative, landings can be expected to decline within a few years, consequently reducing revenues from groundfishing and causing long-term related problems in communities. However, it should be noted that from a social impact perspective, because the Amendment 13 rebuilding alternatives are major in scope and nature, the short-term impacts of any of the Amendment 13 alternatives are likely to be negative and significant when compared to the no action alternative.

The long-term social impacts of taking no action also relate to the probability that future additional action would be necessary to further reduce mortality to rebuild some of the groundfish stocks. If fishing mortality on these stocks remains too high, it is likely that stock biomass would decline, possibly below the threshold levels. The Council would then be required by law to take additional management action, the social consequences of which could be more severe and much larger in scale. Moreover, further declines in stock levels would lengthen recovery periods and, therefore, the period over which the greatest negative social impacts are experienced by affected communities.

A related and important consideration is that in this case, the no action alternative actually represents a step backwards from the current regulatory environment in terms of fishing mortality reductions. The Interim Action implemented through the court order is effective for the 2002 fishing year even though it technically does not represent the no action alternative in this amendment (it represents the status quo). Measures currently effective include significant reductions in DAS allocations through a new baseline; a 20% reduction in DAS; gear restrictions including increased mesh and limits on the numbers of gillnets and hooks; and trip limits on Southern New England yellowtail flounder. While this essentially guarantees that the short-term social impacts of the no action alternative would be positive, any conservation gains from the Interim Action measures would be lost, increasing the likelihood that additional management measures may be necessary in the future.

5.6.2.2.4.3 Alternative 1A (55% Reduction in Used DAS) and 1B (Phase-in of 65% reduction in Used DAS) (Not selected)

The major components of this alternative include:

- Increase in the trip limit for Gulf of Maine cod to 800/4,000.
- An option to maintain the Southern New England yellowtail flounder trip limit implemented in the settlement agreement: 250 pounds Mar-May and 750 pounds June-Feb.
- Reduction in allocated DAS by one of the capacity alternatives
- 50% reduction in used DAS, or phase-in of 65% reduction in used days at sea.
- Seasonal rolling closures.
- Gear restrictions including increased mesh size for trawls and gillnets in some areas and limits on the number of allowable gillnets and hooks.

For measures that were implemented in the settlement agreement, the EA for the Interim Action should be referenced for more detailed information about the social and community impacts.

Relative to other trip limits under consideration, the cod trip limits proposed in this alternative (GOM and GB) are likely to have the least impact on *regulatory discarding*. The social impacts, when compared to the no action alternative, will be positive for the GOM cod trip limit. The GB cod trip limit will have the least impact on regulatory discarding . The GB cod trip limit proposed in Alternatives 2a and 2b is much more likely to have more significant negative impacts.

The previous discussion about SIA factors and DAS modifications should be referenced for more information about the social impacts of DAS reductions proposed in both Alternatives 1 and 1A. If combined with a capacity alternative to reduce DAS allocations, a 55% reduction in used DAS has high probability of causing significant impacts on vessels and most communities in the groundfish fishery. DAS reductions affect the economy of the fishery and have the most significant long-term effect on *changes in occupational opportunities and community infrastructure*. A 35% reduction in the first year of the phase-in of a 65% DAS reduction would yield a similar amount of days to what was used in Fishing year 2002.

5.6.2.2.4.4 Alternative 2A and 2B – Settlement Agreement Days at Sea baseline minus 20% (Not selected)

The major components of this alternative include:

- Settlement agreement DAS baseline minus 20 percent (30% reduction in DAS for GOM vessels).
- Increase in the trip limit for Gulf of Maine cod to 500 pounds per day/4,000 pounds per trip as implemented in the settlement agreement
- Georges Bank cod trip limit of 500 pounds per day/ 4,000 pounds per trip.
- Seasonal Southern New England yellowtail flounder trip limit implemented in the settlement agreement: 250 pounds Mar-May and 750 pounds June-Feb.

- Cape Cod yellowatil Flounder Trip Limit of 50 pounds per trip in statistical areas 514 and 521.
- Potential reduction in allocated DAS by one of the capacity alternatives
- Seasonal and year-round closures.
- Gear restrictions including increased mesh size for trawls and gillnets in some areas and limits on the number of allowable gillnets and hooks.

This alternative allocates days at sea using the settlement agreement baseline, and then reduces them by 20% (30% for GOM vessels). The difference between 2a and 2b is how vessels fishing in the Gulf of Maine are treated. Under alternative 2A, any vessel which fishes in the Gulf of Maine will have their days at sea reduced by 30% from the settlement agreement baseline. Under alternative 2B, vessels will only be able to use 70% of their days at sea in the Gulf of Maine after their 20% reduction is imposed. For measures that were implemented in the settlement agreement, the EA for the Interim Action should be referenced for more detailed information about the social and community impacts.

Relative to other trip limits under consideration, the GOM cod trip limits proposed in this alternative is likely to have a slight positive impact on *regulatory discarding*. The GB cod trip limit essentially is likely to have a large impact on hook vessels fishing out of major Cape ports, and increase regulatory discards on Georges Bank. Hook vessels catch almost exclusively cod, and those that depend heavily on the groundfish fishery will be most affected by the GB cod trip limit

The previous discussion about SIA factors, the impacts of DAS modifications, and the impacts of Alternative 1 should be referenced for more information about the social impacts of the DAS reductions proposed in Alternative 2.

5.6.2.2.4.5 Alternative 3 – Area Management (Not selected)

The area management alternative is intended to provide for development of management measures that are more consistent with fishing activity and resource conditions in a particular area; encourage a greater sense of stewardship, simplify participation by interested parties in the management process, and insure that fishing activity in one area does not adversely affect fishing activity in another area.

The major components of this alternative include:

- Trip limits for GB cod: 2000 pounds per day/20,000 pounds per trip.
- GOM Cod trip limit of 500 ponds per day/4,000 pounds per trip.
- Seasonal Southern New England yellowtail flounder trip limit implemented in the settlement agreement: 250 pounds Mar-May and 750 pounds June-Feb. No retention south of 40N
- Ssettlement agreement DAS baseline with 20% reduction.
- Seasonal and year-round closures.
- Gear restrictions including increased mesh size for trawls and gillnets in some areas and limits on the number of allowable gillnets and hooks.

For measures that were implemented in the settlement agreement, the EA for the Interim Action should be referenced for more detailed information about the social and community impacts.

Relative to the status quo alternative, regulatory discarding should decrease with a higher GOM cod trip limit (500 pounds per day instead of 400). There may still be a perception of inequity between GOM and GB fishermen as the GB cod trip limit will remain at 2000 pounds per day/20,000 pounds per trip.

The settlement agreement EA as well as the previous discussion about SIA factors, the impacts of DAS modifications, and the impacts of Alternatives 1 and 2 should be referenced for more information about the social impacts of the DAS reductions proposed in Alternative 3.

5.6.2.2.4.6 Alternatives 4 and 4A– Quota Management (Not selected)

Alternative 4 and 4A use hard TACs for all stocks in the groundfish fishery. The difference between the two options is that under alternative 4, vessels are allocated days at sea based on the settlement agreement baseline reduced by 20%, while under alternative 4a, vessels have their amendment 7 baseline. Additionally, alternative 4a reverts back to the "no action" seasonal closures, while alternative 4 adopts the seasonal closures proposed under the other 3 alternatives. The social impacts of Hard TACs are discussed in Section 5.6.2.2.1.5.

The major components of this alternative include:

- Trip limits for GB cod: 2000 pounds per day/20,000 pounds per trip.
- GOM Cod trip limit of 500 ponds per day/4,000 pounds per trip.
- Seasonal Southern New England yellowtail flounder trip limit implemented in the settlement agreement: 250 pounds Mar-May and 750 pounds June-Feb. No retention south of 40N (Alternative 4 only)
- **S**settlement agreement DAS baseline with 20% reduction (Alternative 4). Amendment 7 baseline (Alternative 4A).
- Seasonal and year-round closure ("no-action alternative" for alternative 4A).
- Gear restrictions including increased mesh size for trawls and gillnets in some areas and limits on the number of allowable gillnets and hooks.

This alternative has the potential to cause significant short-term and long-term social and community impacts. Immediate economic impacts, loss of employment, and dislocation from the groundfish fishery will disrupt fishing operations, families, and community networks. Long-term impacts will result from loss of fresh fish markets and shoreside support businesses. This has the potential to change the structure and character of the groundfish fishery. This alternative will most negatively affect *changes in occupational opportunities and community infrastructure*. A TAC-management program intended to minimize negative social impacts could set separate hard or target TACs for incidental catch fisheries to reduce regulatory discarding.

5.6.2.2.4.7 Recreational Fishery Measures

In addition to the no action alternative, the recreational fishery restrictions considered in this amendment included:

- Option 1 (not selected): settlement agreement measures – minimum size for cod/haddock 23 inches; 10 fish cod/haddock for private recreational vessels, except 5 cod in GOM December-March; party/charter 10 cod/haddock GOM April-November and 5 cod creel limit in GOM December-March; 3-month or more declaration into party/charter fishery to fish in GOM closed areas
- Option 2 (not selected): 10 cod/trip for private recreational vessels and party/charter vessels in the GOM; minimum size for cod 23 inches and haddock 19 inches; closed season in GOM December-March
- Option 3 (proposed action): 10 cod/person/day for private recreational vessels and party/charter vessels in the GOM; minimum size for cod 22 inches and haddock 19 inches.

The impacts of Option 1 are discussed in the EA for the Interim Action (settlement agreement). Because the options are similar, elements of Options 2 and 3 also are discussed in the EA for the Interim Action. Additional discussion of some of the proposed measures is provided below.

Minimum Sizes
The analysis shows that any increase in the recreational minimum size for cod will have a greater impact on private boat/shore mode anglers than on party/charter vessels. This is because more private anglers fish in state waters, and some states currently allow cod smaller than the federal minimum size to be landed. Recreational anglers from ports in New Hampshire and Rhode Island are therefore likely to be most impacted.

Increasing the recreational minimum cod size should not result in significant negative social impacts. While private anglers are impacted, it is unlikely that they will stop fishing recreationally, especially if they already own boats and/or gear. Their landings will be impacted, and for those who fish for subsistence, this may be a concern. However, most will likely continue to fish under the new minimum size and possibly shift some effort onto other fisheries.

Three-Month or More Declaration to Fish in GOM Closed Areas
For vessels that operate as party/charter vessels on a year-round basis, this measure will have no significant impact. However, it could further reduce opportunity and limit flexibility for vessels that operate as party/charter only seasonally and use DAS to fish commercially during other times of the year. This is an adaptation that some smaller vessels have made in recent years to maintain a year-round business. This measure prevents a party/charter vessel that wants to fish in any of the Gulf of Maine closures from using any DAS to fish for groundfish during its time of enrollment, which could be year-round if the vessel wants to access the western Gulf of Maine closed area. Vessels that take party/charter trips during times when waters adjacent to their communities are closed to commercial fishing could no longer have the opportunity to do so. These vessels may not be able to adapt to this measure by fishing on party/charter trips outside of the closed areas because they cannot safely access the areas outside the closed areas; if they could, they would most likely be fishing commercially.

From 1995-2000, an average of 72.7% of vessels that reported taking party/charter groundfish trips made 100% of their fishing income from party/charter operations. The remaining 27.3% earned income from other fishing activities. About ten percent earned less than 50% of their fishing income from party/charter operations. These vessels could be commercial vessels that are taking party/charter trips to compensate for reduced income from commercial fishing or to maintain a year-round income during times of area closures. The communities most likely to be impacted by this measure are those that are adjacent to Gulf of Maine closure areas and those in which the most party/charter vessels are homeported. These communities are Gloucester and the North Shore of Massachusetts, Portsmouth and the NH Seacoast, southern Maine, and the South Shore of Massachusetts.

Economic Impacts
The economic impacts of the proposed recreational measures are discussed in section 5.4.7. Social impacts from recreational measures are related to economic impacts to the extent that the economic impacts reduce the value or satisfaction derived from taking a recreational trip. For the most part, it is assumed that recreational groundfish fishermen derive more satisfaction from keeping fish than from the sport of catching them. As a result, the social impacts associated with the measures that reduce the ability to keep fish are expected to be more significant than they would in other recreational fisheries where catching fish for sport is more important. These measures include minimum fish sizes and recreational possession limits.

The economic analysis indicates that party/charter vessels will be most affected by the proposed recreational restrictions, especially Option 2, followed by Option 1 and then Option 3. Total losses are predicted to range from $306,000 in sales, $125,000 in income, and 8 jobs under a 25% reduction in trips for Option 3 to $697,000 in sales, $284,000 in income, and 18 jobs under a 25% reduction in trips for Option 2. Since party/charter operations stand to be most affected, the communities that will likely experience the most negative impacts are those with a high proportion of party/charter operations and those whose vessels fish in the GOM. These communities include the NH Seacoast, Gloucester MA, and the South Shore of Massachusetts.

5.6.2.2.5 Habitat Alternatives

In addition to the no action alternative, the Council considered the following alternatives to minimize the adverse effects of fishing on habitat in Amendment 13:

- reliance on the incidental benefits of other Amendment 13 measures;
- options for establishing additional closed areas designed to mitigate the impacts of fishing on EFH;
- options for establishing additional closed areas designed to protect important EFH and balance fishery productivity;
- closed areas consistent with the Framework 13 scallop closed area access program;
- prohibition of shrimp trawls, herring mid-water trawls, clam dredges, and pots and traps from the closed areas;
- options for restricting the use of rockhopper and/or roller gear; and
- requirement for all groundfish vessels to use VMS.

The social impacts of the alternatives under consideration to minimize adverse impacts on habitat have been discussed in previous sections of this assessment (Sections 5.6.2.2.1.2 and 5.6.2.2.1.4). In addition, the EA for the Interim Action (settlement agreement) provides information about social and economic impacts associated with various kinds of gear restrictions.

The habitat alternatives are most likely to affect *safety, disruption in daily living,* and *formation of attitudes*. Over the long-term, large-scale area closures can affect *changes in occupational opportunities and community infrastructure*. The social impacts of the habitat alternatives should be considered **additional** to any impacts resulting from the alternatives to address rebuilding requirements and the capacity alternatives.

The most significant social impacts associated with the habitat alternatives are likely to result from options that include the additional year-round closure of inshore areas. Communities with smaller vessels that fish exclusively in the inshore Gulf of Maine have already experienced significant impacts from inshore area closures and stand to be disproportionately impacted from some of the habitat alternatives proposed in this amendment. These communities include Lower Mid-Coast 1 ME, Portsmouth NH, the NH Seacoast, Gloucester MA, South Shore MA, and Provincetown MA, among others.

It is important to note that some of the habitat alternatives will affect more than just groundfish vessels; prohibitions on fishing in closed areas have the potential to affect vessels that fish for shrimp, herring, and other species. The vessels and communities affected by such prohibitions are likely to be the same as those affected by all of the Amendment 13 measures. On an individual-vessel basis, however, these kinds of prohibitions could exacerbate some of the negative impacts associated with Amendment 13 to the extent that they further reduce opportunities in other fisheries and overall vessel flexibility. Vessels may find it more difficult to adapt to the Amendment 13 measures if they are limited in terms of alternatives to groundfishing.

5.6.2.2.5.1 Alternatives to Minimize Adverse Effects of Fishing on Essential Fish Habitat

Many of the habitat measures considered have limited data with which to evaluate social and community impacts. The one exception is for the proposed habitat protection areas. The impacts of closing these areas on vessel revenue can be bound by analyzing recent landings. Community level analysis is based on port level VTR data that is also aggregated by sub-regions identified by Hall-Arbor et. al., (2001) in New

England's Fishing Communities and by McCay and Cieri (2000) in Fishing Ports of the Mid-Atlantic: A Social Profile. Community and regional impacts are expressed in relative terms to total revenue loss impacts. This analysis estimates the magnitude of revenue impacts in the affected port communities which would have corresponding social impacts.

The impacts of a habitat protected area depend in large part on the level of protection provided. The Council considered four levels of closure. Overall, the relative difference between a Level 1 and Level 3 habitat closure mitigates about 22% of total revenue losses for Alternatives 3a, 3b, and 4 (Table 296). For the Alternative 5 variants the revenue losses are reduced by as much as 46% (Alternative 5c). Much of this reduction in revenue impact is associated with savings of monkfish gillnet and lobster trap fishery revenues. A Level3 habitat closure would have the largest mitigating effect on Alternatives 6, 10A, and 10B.

Alternative	Level 1	Level 3 (Proposed)	Reduced Impact ($)	Reduction in Loss (%)
3a	23,237,630	18,098,883	5,138,747	22%

10B (Proposed)	3,768,834	1,570,002	2,198,832	58%

Table 341-Summary of Revenue Impacts by Alternative and EFH Level

Data and Methods

The subregions designated herein were based on several criteria. First and foremost, data particularly on the non-fishing industrial sectors were available only at a county-level. Thus, the subregional impact area designations represent either an individual county or groups of counties within each of the five New England states. Data obtained from Northeast vessel trip reports, Northeast dealer weigh-out slips, Northeast permit applications, and County Business Patterns information on processors were used to classify Subregions that have similar economic networks and fishing-related attributes. In general, these data provided the ability to identify the regional distribution channels of seafood as it flows from harvesters through dealers and finally on to processors in New England. The subregional designations mainly consist of a coastal county or groups of coastal counties, for these are the counties where the majority of the losses accrue and where the harvesters, dealers, and processors reside. However, if it was determined that fish are regularly being sold to dealers and processors in adjacent noncoastal counties, the subregional designations were expanded to account for these transactions. Subregions 2 through 11 show the impact areas considered in the model. Subregion 1 (Downeast Maine) was not included in this assessment as no revenue impacts due to any one of the habitat alternatives were found.

5.6.2.2.5.2 Port and Regional Impacts

The concentration of revenue loss for Level 1 EFH alternatives 3a, 3b, and 4 are localized in the New Bedford, Gloucester, and Cape Cod regions with a minimum of approximately 2/3 of the revenue loss coming from the community of New Bedford. A level 3 closure generally reduces overall revenue losses across ports except for New Bedford for which revenue loss remains constant for both closure levels. This results in an increase in the relative proportion (> 80%) of impact for New Bedford for these alternatives. Smaller impacts were found for the communities of Gloucester followed by Harwichport, and Chatham which were generally lower for level 3 closures. This contrasts with alternatives 5a, 5b, 5c, and 5d for which smaller revenue losses were more evenly distributed across five regions (New Bedford, Gloucester, New Jersey, Cape Cod, and Boston).

Table 351 - Revenue Loss Impacts by Port and Region for Habitat Alternative 10B(cont.)

Surf Clam and Ocean Quahog Fishery**:**

The potential impacts on the surf clam/ocean quahog fishery were evaluated separately using methods similar to that which was used for other fisheries. However, because landings in the clam VTR's are reported in bushels rather than pounds, an average price from dealer records (reported in terms of $ per pound meat weight) could not be assigned. For this reason impacts are reported in physical rather than dollar units and are aggregated at the state level.

Alternatives 3a, 3b and 4 would have no impact on the surf clam/ocean quahog fishery. Alternative 6 would mitigate impacts for the most states but would have the largest overall impact and would affect the state of Massachusetts exclusively. Of the Alternatives that would affect the fishery, Alternative 5a would have aggregate impacts similar to that of Alternatives 5b and 5d but would these impacts would be more broadly distributed across states in the Northeast region.

In terms of how surf clam/ocean quahog impacts may be distributed across states, the Massachusetts share of impacts is higher than any other state with the exception of New Jersey under Alternative 5a. Specifically, Massachusetts represents 100% of landings losses for Alternative 6; 87% under Alternative 5b; 51.2% under Alternative 5d and 45.4% under Alternative 5c (Table 352). Distributive impacts under Alternative 5a were estimated to be greatest for New Jersey (56.3%) followed by Massachusetts (23.4%), Maryland (19.4%) and Rhodes Island (0.9%). Distributive impacts under Alternative 5b were estimated to be greatest for Massachusetts (87.1%) followed by New Jersey (11.7%) and Rhode Island (1.3%). Distributive impacts under Alternative 5c were estimated to be greatest for Massachusetts (45.4%) followed by New Jersey (40.1%), Maryland (13.8%), and Rhode Island (0.7%). Distributive impacts under Alternative 5d were estimated to be greatest for Massachusetts (51.2%) and Rhode Island (48.8%).

State	Alternative 3a, 3b, & 4	Alternative 5a	Alternative 5b	Alternative 5c	Alternative 5d	Alternative 6	Alternative 10A & 10B
MA	0	23.4%	87.1%	45.4%	51.2%	100.0%	92.5%
MD	0	19.4%	0.0%	13.8%	0.0%	0.0%	0.0%
ME	0	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
NJ	0	56.3%	11.7%	40.1%	0.0%	0.0%	0.0%
RI	0	0.9%	1.3%	0.7%	48.8%	0.0%	7.5%

Table 352 - Share of Total Surf Clam/Ocean Quahog Landings Loss (in bushels) by State and EFH Alternative

For the surf clam/ocean quahog fishery, aggregate landings from retained VTR records were 5.6 million bushels for calendar year 2001. Based on locations provided in these data no trips were reported as having occurred inside the confines of any of the specified habitat closure for Alternatives 3a, 3b, or 4. Therefore, the habitat closures for these three alternatives would have no impact on the surf clam/ocean quahog fishery. The remaining alternatives would affect between 2 and 7% of total fishery landings (Table 299).

State	Total Bushels	Alternative 3a, 3b, & 4	Alternative 5a	Alternative 5b	Alternative 5c	Alternative 5d	Alternative 6	Alternative 10A & 10B

Table 353 - Proportional Loss of Surf Clam/Ocean Quahog Landings (bushels) by State and Alternative

5.6.2.2.5.3 General Revenue Loss Impacts

Alternative 5b level 1 will result in the most significant revenue losses nearing 38 million dollars. The revenue impact for Alternatives 6, 10A, and 10B are approximately 4 million dollars; significantly less than all other alternatives. Any one of these three alternatives would be 33 million less than the losses that may be experienced under alternative 5b, the most restrictive.

Vessel length class

Alternative 5b has the greatest over-all impact across all vessel sectors for level 1 EFH closures ranging from income impacts of 10% for large and medium vessels to 23% for small vessels. Level 3 impacts remain the same for large vessels and fall below 10% for medium and small vessels. Alternative 6, 10A, and 10B have the least impact on revenue across all vessel categories, all of which are less than 3%. Revenue impacts for small and medium vessels are most affected by alternatives 5a - 5d while large vessels are more affected by alternatives 3a and 3b. Level 3 revenue impacts are generally lessened for medium and small vessels while large vessel impacts remain constant.

Length Class	Alternatives - Level 1									
	3a	3b	4	5a	5b	5c	5d	6	10A	10B

Table 354- Revenue Impacts Within Vessel Length Class by Alternative and EFH Level

Number of affected vessels

The number of small vessels impacted is substantially less for a level 3 closure while the number of vessels impacted for large and medium vessel classes is not significantly different between level 1 and 3 closure alternatives. The number of boats affected and the average revenue loss of impacted vessels is greater for alternatives 5a, 5b, 5c, and 5d as compared to other alternatives.

Table 356- Percent Total Impact Within Gear Type by Alternative and EFH Level

5.6.2.2.5.4 Analysis by Alternative

Alternative 1 - No Action (Not selected) and Alternative 2 (Proposed Action)
Neither of these alternatives includes habitat specific measures beyond what is included for management measures already under consideration. Therefore, there will be no additional social and economic impacts beyond what has already been evaluated for Amendment 10 or will be evaluated for the SEIS for Amendment 13.

Alternative 3a - Area Closure (Not selected
The gross loss of revenue for a level 1 EFH closure is $23,237,630. The community of New Bedford, MA will experience the greatest percentage of this loss at 63% ($15,408,480) followed by Gloucester (13%), MA. Ten percent of the loss will affect the Cape Cod region and is largely distributed between the communities of Harwichport and Chatham, MA (Table 342). Revenue losses will be 22 % ($5,138,747) lower for a level 3 EFH closure (Table 296). The disproportionate loss found in the level 1 closure for New Bedford, MA will rise to 83% (Table 342).

Vessel – The revenue for the large vessel sector will be impacted by eleven percent for both level 1 and 3 EFH closures. Five percent to 7% of revenue for medium and small vessels will be impacted for level 1 closure with the range reduced to 1% to 3% for a Level 3 EFH closure (Table 354). The average revenue losses for level 1 closures will range from 30% for large vessels to 22% for medium vessels. Revenue for one-third of all large vessels will be affected. Level 3 closures will result in fewer affected small vessels (Table 355).

Gear – Revenue for hook (25%) and trawl (12%) gear sectors will be the most affected for level 1 EFH closures followed by gillnet (8%) and scallop dredge (7%). Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 3b - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $22,047,497. The community of New Bedford, MA will experience the greatest percentage of this loss at 70% ($14,676,812). Eleven percent of the loss will affect the Cape Cod region and is largely distributed between the communities of Harwichport and Chatham, MA (Table 343). Revenue losses will be 21 % ($4,544,127) lower for a level 3 EFH closure (Table 3). The disproportionate loss found in the level 1 closure for New Bedford, MA will rise to 86% for a level 3 closure (Table 343).

Vessel – The revenue for the large vessel sector will be impacted by eleven percent for both level 1 and 3 EFH closures. The impact on revenue for medium and small vessels, 4% to 5% for a level 1 closure, is reduced for medium vessels and eliminated for small vessels for a level 3 EFH closure (Table 354).
The average revenue losses for impacted vessels for level 1 closures will range from 30% for large vessels to 21% for medium vessels. Revenue for one-third of all large vessels will be affected. Level 3 closures will result in fewer affected small vessels and smaller revenue losses (Table 355).

Gear – Revenue for hook (24%) and trawl (12%) gear sectors will be the most affected for level 1 EFH closures followed by gillnet (7%) and scallop dredge (7%). Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 4 - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $15,599,271. The community of New Bedford, MA will experience the greatest percentage of this loss at 63% ($9,803,675). Fourteen percent of the loss will affect the Cape Cod region and is largely distributed between the communities of Harwichport and Chatham, MA (Table 344). Revenue losses will be 23 % ($3,629,039) lower for a level 3 EFH closure

(Table 3). The disproportionate loss found in the level 1 closure for New Bedford, MA will rise to 83% for a level 3 closure (Table 344).

Vessel –The large vessel sector will be impacted by 7% and 3% for medium vessels for both level 1 and level 3 EFH closures. Small vessel revenue impacts, 4% for level 1, are alleviated for a level 3 closure (Table 354). Average revenue losses for affected vessels for level 1 closures will range from 20% to 27%. The number of affected small vessels is substantially reduced for a level 3 closure (Table 355).

Gear – Revenue for hook (22%) and trawl (10%) gear sectors will be the most affected for level 1 EFH closures followed by gillnet (4%) and scallop dredge (4%). Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 5a - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $19,768,983. Seventy-seven percent of the loss is distributed across five regions in descending order of impact - New Bedford (23%), Gloucester (21%), New Jersey (12%), Cape Cod (11%), and Boston (10%). Communities within these regions most impacted by this alternative are New Bedford, MA (21%), Gloucester, MA (18%), Boston (7%), Chatham, MA (6%), and Belford, NJ (6%) (Table 345). Revenue losses will be 43 % ($ 8,520,746) lower for a level 3 EFH closure (Table 296). The proportionately distributed loss found in the level 1 closure remains for a level closure 3 however increases to 27% for New Bedford and 16% for Boston, MA (Table 345) .

In relation to the surf clam/ocean quahog fishery, alternative 5a would affect 2.9% of total landings but would affect 5.1% of total Maryland landings; 4.1% of Massachusetts landings; 2.4% of New Jersey Landings; and 0.9% of Rhode Island landings. None of the habitat alternatives would affect surf clam/ocean quahog landings in Maine (Table 352).

Vessel – Revenue of small vessels (13%) and medium vessels (10%) will be affected by a level 1 closure. The impact for small vessels is reduced to 3% for a level 3 closure (Table 354). Approximately one-third of the affected medium and small vessels will experience a 35% to 33% average loss in revenue. While average losses are slightly less for all vessel classes for a level 3 closure, the number of affected small vessels is less than one-fourth of the total affected for a level 1 closure (Table 355).

Gear – Revenue for gillnet (19%), trawl (11%), and hook (10%) gear sectors will be the most affected for level 1 EFH closures followed by traps (6%). Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 5b - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $37,829,644. Seventy-six percent of the loss is distributed across three regions in descending order of impact - New Bedford (37%), Gloucester (23%), and Cape Cod (16%). Communities within these regions most impacted by this alternative are New Bedford, MA (34%), Gloucester, MA (17%), and Chatham, MA (10%) (Table 346). Revenue losses will be 37 % ($ 13,923,311) lower for a level 3 EFH closure (Table 296). The distribution of loss found in the level 1 closure remains for a level closure however increases disproportionately to 51% for New Bedford, MA (Table 346).

In relation to the surf clam/ocean quahog fishery, alternative 5b would affect 2.1% of total landings. Across states, Alternative 5b would affect 11.0% of Massachusetts landings and 0.4% and 0.9% of landings in New Jersey and Rhode Island respectively. Alternative 5b would have no impact on either Maine or Maryland landings (Table 352) .

Vessel – All vessel size sectors will be impacted by a 10% or greater loss of revenue for a level 1 EFH closure with small length vessels (23%) experiencing the greatest impact as compared to other alternatives. The percentage loss of revenue remains constant at 10% for large vessels under both EFH closure levels. Impacts fall below 10% for small and medium length class vessels for level 3 closures (Table 354). Approximately one-third of the affected small and medium vessels will experience an average revenue loss of 35% and 51% respectively. While average losses are the same for all vessel classes for a level 3 closure, the number of affected small vessels is one-fourth of the total affected for a level 1 closure (Table 355).

Gear – Revenue impacts for hook (28%) and gillnet (25%) gear sectors will be most impacted followed by trawl (14%), scallop dredge (12%), and traps (11%) sectors will for level 1 EFH closures. Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 5c - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $24,762,205. Eighty-one percent of the loss is distributed across four regions in descending order of impact - Gloucester (37%), New Bedford (20%), Boston (14%)and New Jersey (10%). Communities within these regions most impacted by this alternative are Gloucester, MA (28%), New Bedford, MA (17%), Boston (6%), Scituate (5%), and Chatham (5%) (Table 347). Revenue losses will be 46% ($ 11,509,291) lower for a level 3 EFH closure (Table 347). The relative distribution of loss found in the level 1 closure remains similar for a level 3 closure (Table 296).

In relation to the surf clam/ocean quahog fishery, alternative 5c would affect 4.0% of total landings. Across states, Alternative 5b would affect 11.0% of Massachusetts landings; 5.1 % of Maryland landings; and 2.4% and 0.9% of landings in New Jersey and Rhode Island respectively. Alternative 5b would have no impact on Maine landings (Table 352).

Vessel - Revenue losses for small (18%) and medium (11%) vessel sectors will be the most impacted for a level one EFH closure. All impacts fall below 10% for level 3 closures (Table 354). Approximately one-third of the affected small and medium vessels will experience an average revenue loss of 35% and 46% respectively. While average losses are slightly less for all vessel classes for a level 3 closure, the number of affected small vessels is one-fourth of the total affected for a level 1 closure (Table 355).

Gear – Revenue impacts for gillnet (17%), traps (14%), trawl (14%), and hook (10%) gear sectors will be most impacted for level 1 EFH closures. Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 5d - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $16,630,724. Sixty-four percent of the loss is distributed across three regions in descending order of impact - Gloucester (39%), New Bedford (13%), and Cape Cod (12%). Communities within these regions most impacted by this alternative are Gloucester, MA (34%), New Bedford, MA (13%), and Chatham, MA (7%). The remaining 36% percent is distributed across ten regions (Table 348). Revenue losses will be 45% ($ 7,529,998) lower for a level 3 EFH closure (Table 296). The relative distribution of loss found in the level 1 closure is similarly distributed across four regions (Table 348).

In relation to the surf clam/ocean quahog fishery, alternative 5d would affect 2.9% of total landings. Across states only Massachusetts and Rhode Island would be affected with reductions of 8.8% and 44.6% respectively (Table 352).

Vessel – The small vessel length sector will have the greatest loss of income (12%) for a level 1 EFH closure. The impact on all vessel length sectors is less than 10% for a Level 3 EFH closure (Table 354). Approximately one-third of the affected small and medium vessels will experience an average revenue loss of 38% and 33% respectively. While average losses are slightly less for large and small vessel classes for a level 3 closure, the number of affected small vessels is one-fourth of the total affected for a level 1 closure (Table 355).

Gear – Revenue impacts for gillnet (17%) and hook (10%) gear sectors will be most impacted for level 1 EFH closures followed by trawl gear (9%) and traps (4%). Under a level 3 closure, revenue loss impacts are eliminated for gillnet, hook, and trap sectors while impacts remain the same for scallop dredge and trawl sectors (Table 356).

Alternative 6 - Area Closure (Not selected)
The gross loss of revenue for a level 1 EFH closure is $3,960,131. Ninety-one percent of the loss is distributed across five regions in descending order of impact - New Bedford (29%), New Hampshire Coast (19%), Cape Cod (17%), Gloucester (16%), and Lower Mid-Coast Maine (10). Communities within these regions most impacted by this alternative are New Bedford/Fairhaven, MA (17%), Gloucester, MA (16%), Portsmouth, NH (8%), Newington, NH (10%), and Barnstable, MA (10%) (Table 356). Revenue losses will be 64 % ($ 2,553,501) lower for a level 3 EFH closure (Table 296). The proportionately distributed loss found in the level 1 closure remains for a level 3 closure (Table 356).

In relation to the surf clam/ocean quahog fishery, alternative 6 would have the largest impact (6.8%) on surf clam/ocean quahog landings. Further, Alternative 6 would mitigate all potential impacts on states other than Massachusetts but would impact 40.7% of State landings (Table 352).

Vessel – This alternative represents the least impact to revenue across all vessel classes for both EFH levels. The greatest impact on revenue, across all size sectors, will be for small vessels (2%) for a level 1 closure which is eliminated under a level 3 closure (Table 354). Average revenue losses range from 13% for large vessels to 20% for small vessels. The number of affected vessels is substantially less than for all other alternatives. While average losses are less for large and small vessel classes for a level 3 closure, the number of affected small vessels is one-sixth of the total affected for a level 1 closure (Table 355).

Gear – Revenue impacts for this alternative are the least affected compared to the other alternatives. Hook (5%) and traps (4%) will be most impacted for level 1 EFH closures. Under a level 3 closure, revenue loss impacts for trawl gear (1%) remain the same and eliminated for all other gear sectors (Table 356).

Alternative 7 – Gear (Proposed action)
Data used to evaluate this habitat alternative has been determined inadequate for this purpose. Alternative data configurations and years will need to be evaluated to improve the reliability of this analysis.

Alternative 8 – Gear (Not selected)
This alternative offers five levels of restrictiveness ranging from the least restrictive (8a) to the most restrictive (8e). Level 8a freezes the maximum size of rockhopper and roller trawl gear at the maximum size currently in use. For New England, this size range ranges approximately from 31” to 36”. This level would not impact vessels currently working with this gear specification. However, it would prevent vessels currently operating with this configuration from increasing roller gear size to enable future fishing in areas with greater bottom relief. Level 8e gradually restricts the size of otter trawl ground gear over a multi-year year period from, for example, maximum allowable size of 24” in the first year to a maximum allowable size of 5” in the last year. This is an example scenario for which gear size and incremental gear reductions as well as the length of time at each interval may vary from this profile. This alternative allows more time for vessels to plan for and acquire required gear. Multiple changes in gear configurations increase the cost of adapting to increasingly restrictive management measures exponentially each time gear modification are made while increasingly restricting the fishing area to bottoms with incrementally less relief.

Alternative 9 – Gear (Not selected)
If this alternative is done specific to monitor habitat measures, then VMS acquisition costs can be attributed to these measures. However, if this gear requirement is adopted under Amendment 13, then costs would be allocated to that management measure. In addition to purchase and maintenance costs born by vessel owners, agency program monitoring costs are also an important consideration. Purchase and maintenance costs are estimated below.

To cover the entire fishing fleet (Table 358) of 1484 vessels, at $2900 per unit including the PC, would cost $4.3 million initially, or less than 1% of the ex-vessel value of New England fisheries ($681 million in 2000). Although fishing effort is reduced to half the 73,063 DAS allocated, it is expected that the vessels will place those days-at sea (one-for-one) in other fisheries, in order to stay in business. With 73,063 days-at-sea (with the VMS shut off while the vessel is tied to the dock) adds $73 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $70 thousand annually. Safety may be enhanced by including distress buttons on each unit, and costs $1.6 million for the 1484 boats and vessels, but this is not a requirement for groundfish management.

However, the benefits of total fleet coverage, especially to a multispecies fishery like that managed by the groundfish FMP, are much greater than tallying the official DAS and protecting the large, fixed closed areas. If all vessels require VMS, even partial closed areas become somewhat more inviolate because the enforcement agencies can identify every boat that enters them at any time. Likewise, corroboration of other reporting will be comprehensive rather than piecemeal, as it is with less than full VMS coverage. Safety at sea coverage will be comprehensive, and the extra $1100 per unit for this purpose adds only $1.6 million, to protect nearly 1500 U.S. vessels at sea. Any requirements for sampling at sea will be greatly enhanced with full VMS coverage, because the density of fishing vessel activity in the various fish stock areas will be known. Observer and Homeland Security programs will be enhanced, in similar fashion. Finally, trip limits, gear restrictions, fish sizes and other management measures may be affected.

Optionally, to cover that portion of the fishing fleet (Table 358) that has over 10 DAS allocated will eliminate VMS costs on vessels minimally involved in the multi-species fishery. These 1083 vessels, at $2900 per unit including the PC, would cost $3.1 million initially. Their 72,473 days-at-sea (with the VMS shut off while the vessel is tied to the dock) add $72 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $69 thousand annually. Additionally, safety would be enhanced by including distress buttons on each unit, and costs $1.1 million for the 1083 boats and vessels.

Finally, to cover that portion of the fishing fleet (Table 358) that has over 20 DAS allocated will eliminate VMS costs on even more vessels involved in the multi-species fishery. These 988 vessels, at $2900 per unit including the PC, would cost $2.8 million initially. Their 71,074 days-at-sea (with the VMS shut off while the vessel is tied to the dock) add $71 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $68 thousand annually. Additionally, safety could be enhanced with distress buttons on each unit, and costs $1.1 million for the 988 boats and vessels.

The benefits of such programs are reduced, somewhat, from those attainable with total VMS coverage, particularly the enforcement effectiveness on secondary measures like partial closures and trip limits. The costs are reduced fleet-wide, but are the same for each vessel in the program. The downside for vessels in the program is that, although they pay the same cost, the effectiveness and thus the benefits of management are reduced proportionate to the percent of the fleet with mandatory VMS. The incentive, however, is that mandatory-VMS vessels may participate in exempted fisheries in the closed areas.

Device	Boatracs	Thrane & Thrane 3022D	Thrane & Thrane 3026M	Comments:
Cost	$6,000	$2,650	$*1,550*	Inmarsat has *no* service connection fee
Communication (flat fee; add'l amount above some limit)	$3/day two-way	$1/day two-way (requires PC)	$1/day two-way (requires PC)	e.g. Thrane & Thrane sells a terminal for $1,350
Distress buttons	Yes	Yes	No	
Delay	5-10 minutes	5-10 minutes	5-10 minutes	No transmit, no cost with Inmarsat
Maintenance	Replacement parts available	2 year warranty	2 year warranty	

Table 357 - Comparison of VMS Vendors

Note: Trimble is dropped from consideration; they no longer provide Inmarsat based units. Likewise, Argos is dropped because it is only approved for use in Alaska.

Boats	Initial Cost ($1550 plus $1350 PC per boat)	Communication Cost ($1 per DAS)	Pinging Cost* (24/DAS)	Safety ($1,100 per boat)
1484 Vessels	$4,303,600	$73,063	$70,140	$1,632,400

Table 358 - Cost of VMS

Note: currently, NE OLE pays all costs associated with the advisory email messaging and extra positioning costs when a vessel enters a closed area; monthly charges average $1,500.

Boatracs cost 7 cents per ping, or $1.68 per DAS for 24 pings; Inmarsat, 4 cents, or $0.96. Pinging costs are shown using Inmarsat.

Alternative 10A – Area Closure (Not selected)

The gross loss of revenue for a level 1 EFH closure is $4,162,998. Eighty-three percent of the loss is distributed across four regions in descending order of impact - New Bedford (30%), New Hampshire Coast (19%), Cape Cod (17%), and Gloucester (17%). Communities within these regions most impacted by this alternative are New Bedford/Fairhaven, MA (20%), Gloucester, MA (17%), Portsmouth, NH (9%), Newington, NH (9%), Chatham, MA (7%), and Harwichport, MA (6%) (Table 356). Revenue losses will be 67 % ($ 2,817,060) lower for a level 3 EFH closure (Table 296). The proportionately distributed loss found in the level 1 closure remains for New Bedford and Gloucester regions for a level 3 closure (Table 356) with the loss nearly mitigated for the Cape Cod and New Hampshire coast. However, the proportionate loss increases for Lower Mid-Coast Maine region (Table 212).

In relation to the surf clam/ocean quahog fishery, alternative 10A would have less than 1% impact on surf clam/ocean quahog landings. Alternative A would mitigate all potential impacts on states other than Massachusetts and Rhode Island. However, in both cases the impact on state landings would be relatively small (4.8% in Massachusetts and 2.1% in Rhode Island) (Table 352).

Vessel – This alternative represents nearly equivalent revenue losses to that of Alternative 6 for both EFH levels. The impact on revenue, across all size sectors, will be the same for both small and medium vessels

(2%) and would have least impact on large vessels for a level 1 closure. The level 3 closure would eliminate impacts on small vessels and would have equal impact on medium and large vessels (1%) (Table 354). Average revenue losses range from 8% for large vessels to 22% for small vessels. The number of affected vessels is less than for all other alternatives. While average losses are less for large and small vessel classes for a level 3 closure, the number of affected small vessels is less than one-sixth of the total affected for a level 1 closure (Table 355).

Gear – Revenue impacts for this alternative are the least affected for trap and trawl gear compared to the other alternatives. Hook (9%) gear impacts are similar to that of Alternative 5a while gillnet gear impacts are similar to impacts under Alternative 4. Under a level 3 closure, revenue loss impacts for trawl gear (1%) remain the same but are eliminated for all other gear sectors (Table 356).

Alternative 10B – Area Closure (Proposed action)
The impacts of Alternative 10B are similar to that of 10A although gross revenue impacts are lower ($3,768,834). Eighty-eight percent of the loss is distributed across five regions in descending order of impact - New Bedford (33%), Gloucester (18%), Cape Cod (17%), New Hampshire Coast (11%), and Lower Mid-Coast Maine (9%). Communities within these regions most impacted by this alternative are New Bedford/Fairhaven, MA (21%), Gloucester, MA (18%), Portsmouth, NH (10%), Chatham, MA (8%), and both Harwichport, MA and Portland, ME (7%) (Table 356). Revenue losses will be 58 % ($ 2,198,832) lower for a level 3 EFH closure (Table 296). Note that these losses are distributed across regions in roughly the same order of impact but that the proportional impact in New Bedford increases to 50% of total revenue losses. (Table 356).

In relation to the surf clam/ocean quahog fishery, alternative 10B would have the same impact as that of Alternative 10A (Table 352).

Vessel – This alternative represents nearly equivalent revenue losses to that of Alternative 6 and Alternative 10A for both EFH levels. The impact on revenue, across all size sectors, will be the same for both small and medium vessels (2%) and would have least impact on large vessels for a level 1 closure. The level 3 closure would eliminate impacts on small vessels and would have equal impact on medium and large vessels (1%) (Table 354). Average revenue losses range from 9% for large vessels to 22% for small vessels. The number of affected vessels is less than for all other alternatives. Average losses are less for small vessel classes for a level 3 closure (Table 355).

Gear – Revenue impacts for this alternative are the least affected for trap and trawl gear compared to the other alternatives. Hook (9%) gear impacts are similar to that of Alternative 5a while gillnet gear impacts are similar to impacts under Alternative 4. Under a level 3 closure, revenue loss impacts are eliminated for all gear sectors (Table 356).

5.6.2.2.5.5 Summary of Social and Community Impacts of Habitat Alternatives

In general, impacts across all forms of analyses identified habitat alternative 5b as having the greatest impact and alternatives 6, 10a, and 10b as having the least. In between these extremes, more severe impacts (gross sales impacts of about $100 million; income losses of about $30 million; and employment losses of up to 1,400 jobs) will result from alternatives 3a, 3b, and 5c. Less severe impacts (losses of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs) will result from alternatives 4, 5a, and 5d.

In relation to area closure habitat measures considered here, the state of Massachusetts will experience the greatest share of impacts resulting from alternatives 3a through 6 and 10a through 10b. The region of New Bedford will be proportionately most affected followed by (depending on the alternative) Gloucester, Cape Cod, and Boston, and New Jersey. Overall impacts for New Jersey are likely to increase when the surf clam and ocean quahog analysis is folded into an aggregate analysis. The community of New Bedford will generally be most impacted by these alternatives. Medium and large vessels are more impacted by alternatives 3a and 3b while small vessels are more impacted by alternatives 5a-5d. The number of small vessels impacted by level 3 closures is significantly less than for level 1 closure. Hook, gillnet, and trap gear sectors are impacted less by level 3 closures

5.6.2.2.6 Northern Shrimp Fishery Exemption Area

The Council is proposing to eliminate the Small Mesh Fishery Exemption Area boundary for the northern shrimp fishery. All other restrictions would remain in effect. This measure is difficult to assess from the social impact perspective because impacts will vary depending on the availability of shrimp outside the boundary line and the ability of the fleet to increase revenues from shrimp fishing because of the opportunity to fish in areas east of the line.

It is important to note, however, that shrimp fishing serves as a valuable alternative to groundfishing and can be the only option for some vessels during the season. Removing the restriction on the boundary line and providing shrimp fishermen with more opportunity could serve to mitigate some of the negative social and community impacts of other groundfish restrictions. Therefore, this measure will be positive so long as it does not increase fishing mortality on groundfish species or compromise the objectives of the amendment, both of which would result in more severe restrictions for the groundfish fleet in the long-term.

The Atlantic States Marine Fisheries Commission very recently completed some additional analyses for the shrimp fishery, including information about the vessels and communities engaged in the shrimp fishery and a social impact assessment of the shrimp management measures. This information should be referenced as needed to supplement this amendment.

5.6.2.2.7 Tuna Purse Seine Vessel Access to Groundfish Closed Areas

The following information summarizes the social impact information relative to the bluefin tuna purse seine fleet (based in New Bedford and Gloucester) contained in NMFS' Highly Migratory Species FMP (1999):

- The bluefin tuna purse seine fishery lasts for only a few weeks each year. The participating boats either tie up the rest of the time or they engage in alternative fisheries.
- The purse seine fleet's success is heavily dependent on price and hence on the value of the Japanese yen. The boats are expensive to maintain and those that tie up the rest of the year accumulate costs while they do so. This is a valuable fishery and finding crew for these vessels is not a problem, indeed many of the present crew have had their berths for many years. The fish traders to whom these vessels sell depend quite heavily on them to maintain their current profit margins. However, they report that the structure of their companies is such that there would be no lost jobs even if the purse seine bluefin tuna landings were to be significantly curtailed.
- The owners and many of the crew, even some who do not reside in the community, of the four New Bedford-related purse seine vessels are integrated through kinship ties into the community involved in fishing. The fleet enjoys the respect of the extended fishing communities in both New Bedford and Gloucester. They are generally seen to have done the most to create the bluefin tuna fishery and to still contribute a great deal to both communities.

Allowing access to the closed areas without restriction should not result in significant social impacts on the purse seine fleet or the communities on which these vessels depend. Any impacts should, in fact, be positive. The tuna purse seine fishery is managed through an individual transferable vessel quota system. Each participating vessel must stop fishing when it catches its quota once the season opens on August 15 of each year. None of the measures proposed for the tuna purse seine fleet will allow vessels to catch more than their quota or increase their revenues significantly. Some positive impacts may result from increased flexibility for the tuna purse seine fleet (more options for areas in which to fish, better ability to plan business in the short-term and long-term) and decreased operating costs (see economic analysis).

5.6.2.2.8 Southern New England General Category Scallop Exemption Program

The proposed exmption program removes a groundfish plan restriction that prevented scalloping in the area south of Rhode Island unless on a scallop DAS. This program, subject to any restrictions imposed by the scallop FMP, may provide a way for vessels in the area to mitigate the impacts of rebuilding measures designed to restrict catches of winter and yellowtail flounder.

5.6.2.3 Summary and Conclusions

Many groundfish-dependent communities have been significantly impacted by groundfish regulations and the cumulative impacts of other related factors since Amendment 5 in 1993. While revenues in some communities are increasing to pre-Amendment 5 levels, vessels are experiencing more difficulties operating efficiently, maintaining year-round income, and competing in domestic and international markets. Regulations in many fisheries are splintering the fleet, "boxing them in," and in many cases, making them more dependent on groundfish than ever. The loss of fishing-related infrastructure and support services in some communities has increased concerns about their future in the fishery. Increasingly complicated regulations in all fisheries, shifts from commercial fishing towards recreation and tourism, increasing employment opportunities in other industries, and the cost of waterfront property are contributing to the loss of shoreside infrastructure in many communities. The court decision on the Framework 33 lawsuit and the resulting order for the Interim Action has increased uncertainty and instability in many communities involved in groundfish harvesting. The recent discovery about the trawl survey warp error has compromised public confidence in the scientific basis of Amendment 13. The impacts of these factors individually cannot be separated from each other.

One difficulty in assessing the social impacts of the alternatives under consideration as compared to the no action alternative is that in the short-term, negative social impacts will result from attitudes and perceptions about the new regulations, adaptations that fishermen make to the new regulations, and short-term economic losses. When compared to taking no action, none of the alternatives considered, including the porposed action, are likely to produce positive short-term social impacts. This is because most affected entities have already adapted to the 2001 groundfish regulations, and those that remain in the fishery today are adapting to the measures implemented in the Interim Action (settlement agreement). Many have altered their fishing and business practices to cover the costs associated with the additional management restrictions. Any change from the current situation will create the need for additional adaptations to be made. In addition, the alternatives proposed in Amendment 13 have been met with opposition by the vast majority of the fishing industry. Whatever alternative is selected may worsen attitudes and perceptions about groundfish management, especially given the current lack of faith in the scientific information on which Amendment 13 mortality reductions are based in part.

The management measures under consideration that have the most chance of creating positive short-term social impacts are trip limit adjustments and special access programs. To the extent that increasing the Gulf of Maine cod trip limit can reduce regulatory discarding without compromising the long-term objectives of the amendment, short-term social impacts are likely to be positive. The Closed Area II yellowtail flounder access program has potential to mitigate some of the negative impacts of DAS modifications for large vessels. The positive impacts of this program will depend on which alternative is ultimately selected to address rebuilding requirements and whether or not vessels will find it worthwhile to use their remaining DAS to travel to Closed Area II.

The management measures under consideration that have the most chance of producing negative short-term (and most likely long-term) social impacts are DAS reductions and additional year-round area closures.

This includes direct reductions in allocated and used DAS as well as the possible strategy to count DAS at a 2:1 rate for vessels fishing in the inshore Gulf of Maine on a year-round basis. DAS reductions and additional year-round area closures are likely to produce long-term impacts on affected vessels, families, and communities. Just as they have in the past, vessels and communities will likely adapt and adjust to minor modifications to the area closures, additional gear restrictions, prohibitions on night fishing, etc. However, it will be more difficult to adjust to reductions in groundfish opportunities (DAS) and the year-round closure of areas on which some vessels depend 100%. It is very likely that smaller operations that are currently operating marginally will not be able to adapt to these kinds of measures. The year-round closure of the additional GOM blocks proposed in Alternative 1 is one of the most significant measures proposed in this amendment.

The differential impacts of some of the alternatives under consideration will likely exacerbate the social impacts resulting from them. For used DAS reductions, the largest and the most active vessels will be most affected. These vessels fish primarily in offshore areas. It is possible that they will resent the sacrifices they are being forced to make to protect certain species of groundfish, some of which they may not catch in significant amounts. The DAS reductions are proposed to be applied across the board, meaning that all limited access groundfish vessels will be impacted. For area closures, the smallest vessels will be the most affected. These vessels fish primarily in inshore areas and depend on these areas heavily, as many of them cannot access offshore areas safely. It is possible that they may resent the fact that they have no opportunity to fish, while larger vessels that are less limited by their size will continue to operate, some on a year-round basis. The DAS reductions appear to have a more proportional impact when compared to the proposed area closures. However, if implemented in combination, the impacts can be expected to be devastating for affected vessels and in affected communities.

Mitigation is an important consideration given the magnitude and extent of the impacts likely to result from this action. The elements of Amendment 13 that have the most likelihood of mitigating some of the negative social impacts of the measures, at least in the short-term, include some of the capacity alternatives (permit absorption, permit transfer), the DAS leasing program, and special access programs to harvest groundfish stocks that can support more effort. However, for the most part, these programs are geared towards benefiting vessels that are larger in size and/or more financially secure. The access programs that have been proposed to date allow access to predominantly offshore areas to harvest quantities of fish appropriate for larger vessels. It is unlikely that small vessels can take advantage of such programs. The programs proposed to allow the leasing of unused DAS from vessels and/or the purchase/transfer of DAS require capital investment. Many vessels that are currently marginal will not have the financial ability to participate in such programs unless they sell their DAS, further reducing their opportunities in the groundfish fishery. There is very little, if anything, proposed in this amendment, that will mitigate negative impacts of the measures for smaller and/or currently marginal vessels. Some marginal vessels may be able to take advantage of the DAS leasing progrma – leasing out DAS to reduce their operating costs – but this option may be viewed as abandoning a way of life. There may also be some opportunities to use Category B DAS, but at present those opportunities appera to be limited.

To an extent, mitigation can also be realized from the ability for affected individuals to exit the fishery altogether and capitalize on alternative employment opportunities. For fishermen, this has always been a difficult reality to face. Fishing Family Assistance Centers can help individuals seek alternative employment and train them for new/different job skills. Centers are currently located throughout communities in Maine, as well as in Gloucester, New Bedford, and on Cape Cod. It is likely that the importance of retraining centers in these communities will increase as a result of Amendment 13, especially because these are some of the communities that will be most negatively impacted by Amendment 13. However, retraining and obtaining alternative employment cannot be assumed to fully mitigate the impacts of such a severe reduction in the groundfish fishery. Only a small percentage of affected individuals can be expected to participate in the retraining programs that the centers offer. Because of the independence and freedoms associated with fishing as an occupation and a way of life, many fishermen are not interested in retraining for shoreside employment that lacks many of the characteristics that drew them to fishing in the first place. In addition, education and language barriers will continue to limit the possibilities for retraining, despite other important skills that fishermen have acquired at sea. The declining status of today's economy exacerbates these problems.

5.7 Cumulative Effects

5.7.1 Definition of Cumulative Effects

The term "cumulative effects" is defined in the Council of Environmental Quality (CEQ) regulations in 40 CFR Part 1508.7 as:

> *"the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably forseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions."*

5.7.2 General Approach

Cumulative effects are described with respect to:

(a) Communities – human communities engaged in the Northeast multispecies fishery;
(b) Resource – all stocks of regulated multispecies and protected species; and
(c) Habitat – benthic marine habitat, particularly Essential Fish Habitat (EFH).

Cumulative effects of gear use, non-fishing entities and actions, past management actions in the multispecies fishery, and the proposed alternatives in Amendment 13 (Fishery Administration, Capacity Reduction, Rebuilding, Recreational, and Habitat). Much of the cumulative effects discussion is derivative of the detailed Environmental Impacts sections in Amendment 13:

- Biological Impacts (Section 5.2) (including impacts on protected resources section 5.2.9)
- Habitat Impacts (Section 5.3)
- Economic Impacts (Section 5.4)
- Social Impacts (Section 5.6)

Additionally, the Affected Human Environment section (9.4) characterizes the multispecies fishery since Amendment 5 (1994), providing a baseline with which to compare predicted changes to the fishery and associated communities that will result from Amendment 13. Because of the lack of quantitative data on parameters that are potentially cumulative, a quantitative assessment of cumulative effects was not possible. Thus, the analyses that follow are qualitative in nature.

5.7.3 Summary of Non-fishing Impacts

Following is an assessment of non-fishing impacts on fish habitat and fishery resources. For fish habitat, non-fishing effects have been reviewed in the Essential Fish Habitat Amendment for Groundfish prepared by the New England Fishery Management Council (Amendment 11 to the Groundfish FMP, NEFMC 1998). Table 359 below, taken from that document, represents the review of the EFH Technical Team of the potential effects of numerous chemical, biological and physical effects to riverine, inshore and offshore fish habitats. Table 359 exhibits twelve representative classes of chemicals, three categories of biological and nineteen types of physical threats, which are categorized as low, moderate or high threats to habitat, based on their geographic location—riverine, inshore and offshore. In general, the closer the proximity to the coast, i.e., close to pollution sources and habitat alternations, the greater the potential for impact. Riverine and inshore habitats were generally categorized as moderate to high threats whereas the offshore areas were low to moderate. For the offshore area, with the exception of events such as oil spills and algae blooms, which can spread over large areas, moderate effects were generally localized to a well-defined and relatively small impact area such as oil/gas mining and dredged material disposal. Thus, only small portions of fish stocks would potentially use these sparsely located areas and would be adversely affected. For example, dredged material disposal sites, usually about 1 nm^2 in size, are managed by the U.S. Army Corps of Engineers and the U.S. EPA to minimize physical effect to the defined disposal area and allow no chemical effects at the site based on stringent sediment testing.

Table 359 - Potential non-fishing threats to fish habitat in the New England region prioritized within regions (H = high; M = moderate; L = low)2

[1] From NEFMC (1998)

[2] Prioritization developed by compilation of *EFH Technical Team* survey

For fishery resources, there are several non-fishing threats that could have a direct and/or indirect impact on the groundfish stocks. Several of the items identified as non-fishing threats to fish habitat, identified in Table 359, could also pose a threat to groundfish stocks, such as the oil spills, pesticides, and radioactive wastes. Similar to the discussion above on non-fishing impacts to fish habitat, generally the closer the proximity of groundfish stocks to the coast, the greater the potential for impact (although predation, a non-fishing impact, would be one threat that would occur everywhere). Many groundfish species reside in both inshore and offshore areas at different stages of their lives and during different seasons throughout the year. However, some stocks, such as SNE winter flounder, live out a large portion of their lives closer to shore and, therefore, may likely be impacted by inshore threats to a greater degree than some of the other groundfish species. In the offshore areas, such effects would likely be low because the localized nature of the effects would minimize exposure to organisms in the immediate area.

An additional inshore threat of note would be the effect on fishery resources presented by power plants. The operations of power plants are thought to be especially of consequence to fish eggs, larvae and juveniles. Entrainment, or intake of cooling seawater for the purposes of cooling power plant reactors, is known to draw in eggs and larvae and, therefore, could have a negative impact on groundfish resources that spawn in areas in close proximity to active power plants. An additional threat associated with power is the discharge of warm. This thermal discharge is believed to have a negative impact on reproduction capability and recruitment of affected fishery resources.

Although still speculative at this time, foreseeable future non-fishing threats to fishery resources could include global warming and the effects that this may have on water temperature. The impacts to the fish stocks are not certain and therefore could not be incoporated into this assessment. The possibility of windmill construction in marine waters for the purposes of harnessing alternative means of energy could also have an impact on fishery resources, especially as it relates to disruption of habitat. This is the subject of a forthcoming EIS being prepared by the Army Corps of Engineers. The impacts of this project to the fisheries are yet to be determined.

5.7.4 Summary of Fishing Gear Effects on EFH

The effects of mobile bottom-tending gear (trawls and dredges) on fish habitat have been recently reviewed by the National Research Council (NRC 2002). This study determined that repeated use of trawls/dredges reduce the bottom habitat complexity by the loss of erect and sessile epifauna, smoothing sedimentary bedforms and bottom roughness. This activity, when repeated over a long term also results in discernable changes in benthic communities, which involve a shift from larger bodied long-lived benthic organisms for smaller shorter-lived ones. This shift also can result in loss of benthic productivity and thus biomass available for fish predators. Thus, such changes in bottom structure and loss of productivity can reduce the value of the bottom habitat for demersal fish. These effects varied with sediment type with lower level of impact to sandy communities, where there is a high natural dynamic nature to these bedforms, to a high degree of impact to hardbottom areas such as bedrock, cobble and coarse gravel, where the substrate and attached epifauna are more stable. In the Northwest Atlantic, the more valued groundfish habitat is located in areas where there is a high percentage of gravel and cobble (NREFHSC 2002).

Use of trawls and dredges are common in inshore and offshore areas and somewhat less common in riverine areas. Section 9.3.1.2 of this document discusses the numerous types of gear used in estuarine and offshore habitats. This section indicates that mobile bottom-tending gears are commonly used in most inshore and offshore habitats. In the Northeast, otter trawls are used to prosecute most MSA managed fisheries including: Northeast Multispecies; Sea scallops; Monkfish; Mackerel, squid and butterfish; Summer flounder, scup and black seabass; Bluefish; and Spiny dogfish. Scallop dredges are used in the Sea scallop fishery and hydraulic clam dredges are used in the Surf clam and Ocean quahogs fisheries. Smaller trawls are used in inshore areas and lower estuaries, which are managed by states and not subject to the MSA. In addition, some states allow smaller dredges are used for harvesting oysters, bay scallops, sea urchins, quahogs, and mussels. Hydraulic dredging for softshell clams and bottom trawling for shrimp is also accomplished in certain nearshore and riverine habitats.

It is assumed for this analysis that the effects of gear are generally moderate to high in the riverine, inshore and offshore areas, depending upon the type of bottom and the frequency of fishing.

5.7.5 Summary of Existing Threats to Protected Resources:

Table 360 summarizes the past and current threats for these species as described in Section 9.2.2 and the Biological Opinion (NMFS 2001). It should be noted that all these species have a special status because of threats to their continued sustainability. Six of the large whale species (Right, Humpback, Fin, Sei, Blue and Sperm) and three sea turtles (Leatherback, Kemps' Ridley and Green) are listed as endangered under the Endangered Species Act. The Loggerhead is listed as threatened while two other species, Harbor Porpoise, Barndoor Skate, are candidates for listing. The remaining mammal species are protected under the Marine Mammal Protection Act. The Right Whale continues to be at the highest risk for extinction because of its low numbers and low reproductive rates.

For the Right, Humpback, Fin, and Minke whales, ship strikes and fishing gear entanglements continue to be the most likely sources of injuries and mortality. Gear entanglements occur in the vertical buoy lines of sink gillnet and pot/trap gear, the groundlines of pot/trap gear, and also in the net panels of gillnet gear. Other species such as Sei, Blue, and Sperm whales are vulnerable too but less strikes/entanglements are recorded. Over the period 1996-2000 within U.S. Atlantic waters, an average of 3.2 whales (right, humpback, fin, sei, sperm, blue, and Minke combined) were killed by ship strikes and 7.8 were killed or suffered injuries likely to cause death as a result of gear entanglements (Waring et. al, 2002). Mobile bottom trawls, which are common for the groundfish fishery, are less of a concern for these large whale species. Other marine mammals such as Harbor Porpoise, dolphins and seals are also at risk to be entangled in net gear (seines, gillnets, drift nets). Turtles have been entangled in these and are particularly vulnerable to shrimp trawls, pound nets and bottom trawls. Shrimp trawls are now required to use turtle-excluder-devices to reduce the potential for entanglement.

These species are also affected by habitat alternation/destruction. Species such as turtles may be more prone to such impacts because their nests are particularly vulnerable to disturbance or predation. The impacts of pelagic habitat alteration on these species are less known. Water quality in coastal areas is particularly vulnerable to coastal pollution from nutrients, which can alter the phytoplankton and the food of species such as the Right whale, and toxic contaminants. The latter can be accumulated through prey species and cause adverse effects to a predator(s) higher in the food web, such as PCBs and DDT which are suspected of causing reproductive failures in many vertebrates including marine mammals (Reijnders and Aguilar, 2002)). The potential impact of pollution is more likely problematic in nearshore areas closer to the sources such as land runoff, sewer outfalls and urbanized areas. Nutrients can also promote toxic phytoplankton blooms, which have been known or suspected in killing humpback whales and other marine mammals (Geraci et. al, 1990; Harwood 2002). These and other factors potentially have had cumulative adverse effects on all these species to varying degrees. Because of a lack of cause-effect data, little is know how much these factors have contributed to their special listing. The third column of Table 360 lists the cumulative impacts for each of the alternatives evaluated in this Amendment. The detailed evaluation of effects of each alternative on protected resources is provided in Section 5.2.9 and is summarized in Table 363 - Table 366.

Species	Status	Threats			
		Ship Strikes	Gear Entanglement	Habitat	Other
Right Whale	Endang Highest risk	High Potential	High potential due sink gillnets, pots, traps	Unkown: Water Quality: Nutirents; Toxic contaminants; Biotoxins; Noise	Unknown: Low Genetic diversity; Low reproductive rates; Reduction/ Competition of prey; Harassment
Humpback	Endang	High Potential	High potential	Unkown: Water Quality: Nutirents; Toxic contaminants; Biotoxins; Noise	Unknown: Reduction/ Competition of prey; Harassment
Fin	Endang	High Potential Mortality Less Certain	High potential Mortality Less Certain	Unkown: Water Quality: Nutirents; Toxic contaminants; Biotoxins; Noise	Unknown: Reduction/ Competition of prey; Harassment
Sei	Endang	Potential but few recorded instances	Potential but no recorded instances	Offshore Species Less likely but still vulnerable to Offshore Development	Unknown: Reduction/ Competition of prey; Harassment
Blue	Endang	Potential but few recorded instances	Potential but few recorded instances	Offshore Species Less likely but still vulnerable to Offshore Development	Unknown (no data): Ice entrapment
Sperm	Endang	Potential but few recorded instances	Potential but few recorded instances	Offshore Species Less likely but still vulnerable to Offshore Development	
Minke	Protected under MMPA	Potential but few recorded instances	Sink Gillnets known threat; Pot/Trap Gear	Unkown: Water Quality: Nutirents; Toxic contaminants; Biotoxins; Noise	Aboriginal subsistence whaling on West Greenland stock (non-U.S. stock)

Table 360 - Summary of Threats to Protected Species Potentially Affected Amendment 13 Multispecies Plan.

Harbor Porpoise	Protected under MMPA; ESA Candidate Species	Potential but few recorded instances	Sink Gillnets known threat	Biotoxins: Noise	Unknown: Reduction/ Competition of prey; Harassment
Atlantic White-sided Dolphin, Pelagic Delphids	Protected under MMPA	Potential but few recorded instances	Sink Gillnets known threat; Frequent Takes with longline and Trawl Gear	Offshore Species Less likely but still vulnerable to Offshore Development: Biotoxins; Noise	
Harbor and Gray Seal	Protected under MMPA	Potential but few recorded instances	Sink Gillnets known threat	Unknown: Possible Biotoxin exposure	Disturbance at haul out sites/Harassment
Harp Seal	Protected under MMPA	Potential but few recorded instances	Sink Gillnets known threat	Unknown: Possible Biotoxin exposure	Fishery in Canada
Leatherback, Kemp's Ridley, Green Turtle	Endang	High Potential Boats and Ships	Bottom and midwater Trawls, seine nets, longlines gillnets drift nets, pound nets; Shrimp Trawls impact reduced with TEDs; Lobster/Crab Trap, pots;	Loss of Nesting Habitat; Consumption of ocean debris; Water Quality: Habitat Destruction/degradation; (Beach erosion/nourishment); Toxic contaminants; increased human presence; Noise	Egg Predation/Exploitation; Cold Stunning (Leatherback less than others); Hurricanes destroying beaches
Loggerhead	Threatened	Same as above	Same as above	Same as above	Same as above
Barndoor Skate	Candidate Species	NA	Overfished Species	Bottom Mobile gear effects on habitat/prey	Limited Reproductive capacity

5.7.6 Review Of Past Groundfish Management Actions That Affected Groundfish Resources, Fishing Communities, And EFH

5.7.6.1 Impacts associated with Groundfish Resources and Fishing Communities

The groundfish fishery of New England in the 19th Century was originally accomplished on sailing vessels using such low impact techniques such as handlines, jigging and later longlines. When steam-powered vessels came into prominence in the early 1890s, mobile gear such as trawls were found to be very efficient harvesters of groundfish. By 1930, otter trawls became the dominant gear. As a result of more efficient gear, faster and larger vessels and better preservation, haddock landings, for example, grew from 20,000 mt/year in 1900 to over 100,000 mt/yr in 1920 (Collette & Klein-MacPhee, 2002). Using landings as an indictor of fishing effort, one can see how trawling has increased over a relative short timeframe. Fishing effort expanded in the 1950s due to the influx of foreign vessels after World War II, and in the late 1970s/early 1980s, when the domestic fishery expanded in the wake of the Magnuson Act of 1976. There are currently several gear types employed in the multispecies fishery. As reported in the Amendment 13 Affected Environment section, the major gear types used now are bottom trawl, bottom longline, hook and line, and sink gillnet gear.

Although management measures for groundfish were first enacted in 1977 under the original Groundfish Fishery Management Plan, the dramatic increase in larger vessels, bigger gear and electronic aids such as fishfinders and navigation equipment, contributed to a greater efficiency and intensity of fishing, which, in turn, resulted in a precipitous drop in landings during the 1980s to an all-time low in the early 1990s. Table 361, below, describes the major regulatory actions taken to manage the New England groundfish fishery since the original Magnuson Act was enacted and their effect on groundfish resources, community, and EFH. The first several years of groundfish management included annual and quarterly catch quotas for cod, haddock and yellowtail flounder, quota allocations by vessel class, and trip limits. The quota and trip limits imposed during the inception of the Groundfish FMP led to frequent fishery closures of one or more segments of the fishing fleet, interrupting the normal activities of the industry. Consequently, this form of management frequently imposed both economic inefficiencies and hardships on the industry, which led to a breakdown in support of these measures. This in turn, led to widespread misreporting and non-reporting by the industry as a way to circumvent the regulations. Starting in the early 1980's a new management program was implemented through the 1982 Interim Fishery Management Plan. This plan, and the next several groundfish actions (through Amendment 4 in 1991) managed the groundfish fishery (now expanded to include 13 species) primarily through seasonal closures and minimum mesh and fish size restrictions. However, these measures proved not enough since the condition of the resources, especially cod, haddock and yellowtail flounder continued to decline to record low levels.

To end overfishing and address the severe decline in the groundfish resources and the influx of more and larger vessels, the Council began developed of Amendment 5 to the FMP. This action, which became effective in 1994, implemented a moratorium on permits as well as an effort-control program that proposed to reduce a vessel's days-at-sea (DAS) by 50% over a 5-7 year period. Amendment 5, thus, was the first action to restrict both access and effort in the multispecies fishery. The FSEIS for Amendment 5 determined that this action may have significant effects on a substantial number of small entities, specifically those vessels less than 45', which, at the time, consisted of 36% of the qualified vessels. Although the FSEIS demonstrated that Amendment 5 provided economic and social benefits to the fishery in the long-term, vessels were expected to incur significant short-term loses in revenue.

Despite implementation of Amendment 5, however, stocks continued to decline rapidly and a "Special Advisory" was issued by the Northeast Fisheries Science Center in 1994 stating that Amendment 5 was "too little, too late" to address the critical status of many of the groundfish stocks. In response, the Council requested that NMFS implement an emergency action to close, on a year-round basis, three large areas to all vessels capable of catching groundfish (Closed Area I, Closed Area II, and the Nantucket Lightship Closed Area), while it developed Amendment 7 to the FMP. NMFS implemented the emergency action to close these three areas in December of 1994. These closure areas have been thought to have a major beneficial effect on groundfish stocks, as they afforded protection over large areas and for extended amounts of time. Indirect benefits to other species accrued from these closures as well, such as protection of sea scallops. Although there were large benefits attributed to these closures, it is important to note that they may have had a negative effect on other groundfish stocks as vessels moved elsewhere to fish. Framework 9, implemented in 1995, extended the emergency action permanently and also implemented a prohibition on all small mesh fisheries in the GOM, GB and SNE Regulated Mesh Areas, unless it was determined that the fishery had less than 5% bycatch of regulated species. Through elimination of small mesh fisheries where groundfish bycatch exceeded 5%, discard of groundfish was largely reduced by vessels fishing in non-groundfish fisheries. Amendment 7, implemented in 1996, accelerated the Amendment 5 DAS effort-reduction schedule and expanded the 5% bycatch rule to include a prohibition on all non-DAS fisheries, further reducing bycatch of regulated species. Amendment 7 also implemented recreational fishing restrictions and framework adjustment criteria that would allow management measures to be implemented under a more accelerated mechanism than through an amendment. These actions, in combination, have reduced fishing effort significantly and have provided large areas of year-round protection, especially on Georges Bank, for several species of groundfish. In response, the status of several groundfish stocks have improved over the past several years and landings have increased as a result (see Affected Environment section). Similar to Amendment 5, the FSEIS for Amendment 7 specified that this action was expected to have a significant impact on a substantial number of small entities in the short-term, with higher, long-term benefits accruing to the industry and to the Nation. Overall revenues were projected to be reduced by 10-25% in the first 3 years, with differential effects on gear groups, with trawlers projected to be more disadvantaged than others are.

Following Amendment 7, there have been several framework adjustments implementing further restrictions and, in some cases, extensive restrictions in the groundfish fishery. Due to concerns primarily regarding the status of GOM cod, Frameworks 20, 25, 26, 27, 31 and 33 implemented additional management measures to further protect this stock. These measures included new GOM seasonal and year-round closures, gillnet effort-reduction measures (including limits on the number of allowable nets), and adjustments of the GOM cod trip limit. Additionally, measures in these actions also increased the haddock daily trip limit and increased the minimum square mesh size throughout the GOM/GB/SNE Regulated Mesh Areas. Because the main focus of these actions was to protect GOM cod, the socio-economic impact was primarily felt within communities located in the states of Maine, New Hampsire and Massachusetts, due to the proximity of these communities to the GOM fishing areas.

In response to a Federal Court decision in the case of Conservation Law Foundation, et al. V. Evans, et al., NMFS, in August 2002, implemented management measures consistent with a Settlement Agreement through an interim final rule. Measures contained in the interim rule included a freeze of DAS at the highest annual level used during fishing years 1996-2000 and a 20% cut from that level; increased gear restrictions for certain gear types, including gillnets, hook-gear, and trawl nets; modifications and additions to the closure areas; limits on yellowtail flounder catch; and more restrictive recreational fishing measures. Biological impacts of the "Settlement Agreement" management measures that were first implemented on August 1, 2002, vary by species. Based on a quantitative analysis only, the July 2002 EA estimated the resultant decrease in fishing mortality to range from 1% for GB winter flounder and 16% for GOM cod. It has been recently projected in the June 2003 EA, completed for an Emergency Action to extend the August 2002 interim rule measures, that, based upon the number of DAS used in 2002, continuation of the Settlement Agreement for the duration of the 2003 fishing year would result in a 25-35% reduction in fishing effort.

Measures implementing the Settlement Agreement have further protected several groundfish species, most notably GOM cod, and increased the likelihood of timely stock rebuilding. A particularly important aspect of these rules is the control of latent DAS. The DAS freeze has significantly limited the extent to which latent DAS can be activated and, therefore, has limited the extent to which the increases in fishing mortality from the use of such DAS could undermine efforts to control fishing mortality. The DAS allocations for the 2002 fishing year were 45.7% less than the DAS allocations for the 2001 fishing year (including carryover days). Preliminary estimates made in June 2003 calculated a 37% decline in DAS use during the 2002 fishing year (compared with the 2001 fishing year). While the combination of measures implemented since the adoption of Amendment 5 have improved stock status (increasing biomass and reducing fishing mortality) for many stocks, as discussed in section 9.2.1.1, the improvement has not been achieved for all stocks.

Overall, the DAS restrictions resulting from the Settlement Agreement impacted most, those vessels that rely on groundfish for a majority of their income. For vessels with high dependence on groundfish income, the adverse income effects of the Settlement Agreement were nearly twice that of vessels that rely on groundfish for less than half of their annual fishing income. Estimated revenue losses were greatest for vessels bordering the GOM (Gloucester, Portland, Portsmouth, Chatham/Harwich). DAS reductions were largest for the home port states of New Jersey, New York, Maine, and Massachusetts (in descending order). Charter/party vessels experienced a decrease in the number of trips booked, however the majority of the economic impacts were borne by approximately 20-25 charter/party operators whose primary business is in offering groundfish trips.

Bottom trawl, longline gear and hook-gear are classified as Category III fisheries under the Marine Mammal Protection Act and are, therefore, determined to have a remote likelihood of, or no known, incidental mortalities and serious injuries of marine mammals. Gillnet gear has been categorized as a Category I fishery; a fishery that has been determined to have frequent incidental mortality or serious injury of marine mammals. Many of the groundfish actions discussed above have had an overall beneficial impact on protected resources. For instance, the DAS reductions have significantly reduced effort in this fishery. Extensive area closures to protect groundfish stocks, including harbor porpoise closure areas specific to gillnet vessels, and reductions in fishing gear, such as reductions in allowable gillnet gear, have all contributed to benefiting protected resources.

Development of other recent management actions, such as for whiting and monkfish, have also benefited groundfish stocks as they have likely reduced groundfish discards (e.g., through the development and implementation of a whiting grate fishery, and coupling of multispecies and monkfish DAS). Also, it should be noted that a vessel buyout program, starting in 1996, has contributed to reducing the socio-economic impacts on small entities associated with the groundfish actions.

5.7.6.2 Impacts associated with EFH

The increased intensity of trawling also has been correlated with habitat impact (Jennings et al. 2001, 2002; Thrush et al., 1998; Collie et al. 1997, 2000). Mobile gear such as otter trawls do have a more direct impact on the bottom habitat by disturbing or scraping the bottom substrate and removing, damaging or destroying benthic organisms at the sediment surface or just below. The vulnerability of the various life stages and species to this and other mobile gear are summarized in section 9.3.1.2 of this document. Even as early as the 1920's, concerns were raised over the ecological damage to bottom dwellers from increasing levels of trawling (Collette & Klein-MacPhee, 2002). Although management measures were taken as early as 1977 to control groundfish catches, there was no dedicated effort to regulate impacts to fish habitat until 1996 when the Sustainable Fisheries Act (SFA) was implemented to, in part, minimize the adverse effects of fishing to the "essential fish habitat" (EFH) of managed species. However, management measures developed to date to control fish catch, effort and capacity have incidentally benefited habitat by reducing bottom contact time of mobile bottom-tending fishing gear.

In general, measures such as area closures (depending upon size of area, time closed and habitat type within), gear restrictions/alterations, permitting restrictions, reductions in effort allowed or days at sea (DAS), and possession/trip limits can clearly benefit habitat. Some measures such as, effort monitoring, crew limits, onboard observers, recreational measures, and Total Allowable Catches (TAC) limits may also benefit habitat. Other measures, such as an increase in fish and mesh size limits, although they are designed to meet stock rebuilding objectives, may have negative habitat effects since they may encourage increased fishing effort to meet catch limits if DAS are not limiting. As noted in Table 361, each major management actions are characterized according to its probable benefit on habitat. The actions that are believed to have the greatest benefit to habitat have included Amendment 5 in 1994, due to the moratorium on new entrants and DAS reductions; Emergency Action in 1994, due to the year round closures and prohibition of scallop vessels in closed areas reductions and elimination of small mesh fisheries which were 5% or greater of the catch of regulated species; Framework 9, due to its continuance of the 1994 management measures on a permanent basis; Amendment 7, due to its accelerated DAS reductions and closer areas and expansion of the 5% bycatch rule to all fisheries; Framework 25, due to closure areas; Framework 27, due to closure areas and gear restrictions; and the 2002 Interim Action, due to additional DAS cap on use of latent effort; and expansion of the closure areas. Other management actions are believed to have moderate to negligible benefits in their protection of EFH. However, NMFS believes that the combined effect of the noted significant and moderate measures that have been implemented during the last 10 years has been to enhance the protection and preservation of EFH.

It should be kept in mind that the benefit of closure areas might be limited by the fact that when areas are closed, effort is often displaced to other fishing areas. This may reduce the beneficial effect of this management measure over a larger area, i.e., impacts in the closure area may be reduced but impacts to other areas may be increased. On the other hand, if reductions in DAS cause a shift of effort to other fisheries such as whiting, squid/mackerel/butterfish, or herring, these fisheries would have less impact to EFH since they use either a raised footrope (in some areas) on the trawl or use mid-water trawls. However, if the shift is into the scallop fishery or other fisheries utilizing bottom-tending mobile gear, then the impacts may be the same or greater as those caused by bottom trawling. Little is actually known of the true impacts of these management measures. However, it is reasonable to assume a positive benefit from the groundfish management measures that are currently in place will continue in the foreseeable future.

DATE	ACTION	FEATURES THAT AFFECT RESOURCES, HABITAT AND COMMUNITIES	RESOURCE BENEFITS	HABITAT BENEFITS	COMMUNITY IMPACTS
1977	Original FMP	Cod, haddock and yellowtail annual and quarterly catch quotas Quota allocations by vessel class Trip or weekly catch limits	Moderate	Negligible	Moderate - High
1982	Interim Plan	George Bank Closed Areas (seasonal) Minimum mesh size requirements when fishing for cod, haddock or yellowtail flounder in GB and portions of the GOM (5.5") Minimum fish size requirements Permit requirements	Moderate-High	Low	Moderate-High
1986	Multispecies Plan	Inclusion of pollock, redfish, winter flounder, American plaice, witch flounder, windowpane flounder, and white hake Additional minimum fish size restrictions Extensions of GB spawning areas closures to protect haddock (seasonal) A SNE closure to protect yellowtail (seasonal)	Moderate	Moderate	Moderate
1987-1991	Amendments 1-4	Closure of the Southern New England/Mid-Atlantic Yellowtail Area during March-May Extension of GB RMA Minimum mesh size requirements in SNE Exclusion of scallop dredge vessels from SNE closure Minimum fish size changes Gear restrictions in the Northern Shrimp fishery Inclusion of silver hake, red hake, and ocean pout	Moderate-High	Moderate	Moderate-High
1994 (01/03/94)	Emergency Action	Implementation of a 500-lb haddock trip limit Expansion of CAII in area and time (from 4 month to 6 months) Prohibition on scallop dredge vessels from possessing haddock during January-June Prohibition on pair-trawling for multispecies	Moderate	Low	Moderate

DATE	ACTION	FEATURES THAT AFFECT RESOURCES, HABITAT AND COMMUNITIES	RESOURCE BENEFITS	HABITAT BENEFITS	COMMUNITY IMPACTS
2002 (05/01/02)	Interim Action (Settlement Agreement)	Restriction on vessels using more than 25% of their DAS allocation during May-July 2002 Modification of DAS clock – all vessel trips 3-15 hours counted as 15 hours during May-July 2002 Year-round closure of Cashes Ledge Area Closure Expansion of Rolling Closure Area III and IV Prohibition on front-loading the DAS clock Increase in GOM trawl (codend) & gillnet mesh (6.5") Limitations on Day gillnets Restrictions on party/charter and recreational vessels	High	Moderate-High	High
2002 (08/01/02)	Interim Action (Settlement Agreement cont'd)	May 2002 interim measures continued Establishment of "used DAS baseline" and reduction of 20% from this baseline Freeze on Handgear permits & trip limit reduction Elimination of GOM January & February seasonal closure areas Increase in SNE trawl (codend) mesh (7.0/6.5" sq/diamond) Increase in GB gillnet mesh (6.5") Further limitations of both Day & Trip gillnets Increase in SNE gillnet mesh (6.5") Longline gear restrictions - prohibition on de-hookers (crucifiers) w/ < 6" spacing between fairlead rollers, hook size restrictions, and limit on number of hooks Increase in commercial cod fish size (22") Possession limits and restrictions on yellowtail catch Increase in GOM daily cod trip limit (500/4000 lb max)	High	Moderate	High

Table 361 - History of Management Actions and Associated Habitat Benefits

5.7.7 Cumulative Effects of Amendment 13 Measures

Table 363 - Table 366 summarize the impacts of Amendment 13 alternatives on communities, groundfish stocks, protected species and habitat. Table 367 summarizes cumulative effects of gear use, non-fishing entities and actions, past management actions in the multispecies fishery, and the proposed alternatives in Amendment 13 (Fishery Administration, Capacity Reduction, Rebuilding, Recreational, and Habitat). This section further discusses the content of these summary tables.

5.7.7.1 Fishery Program Administration Measures

The majority of the fishery administration measures have only limited or negligible effects on communities, stocks, protected species, and habitat. The additive effects of these measures in conjunction with other Amendment 13 alternatives, including measures to address stock rebuilding and capacity issues, as well as past actions in the groundfish fishery are low or negligible. In general, it is unlikely that the Fishery Program Administration measures will have any adverse cumulative effects on protected resources because the measures are primarily administrative. Should a new fishing year be selected, two options for DAS proration are considered. Neither option will result in an increase in DAS use compared to the no action alternative. Otherwise, cumulative effects of these measures ranged from none to negligible. The special access programs and DAS leasing program may slightly reduce the net benefit of rebuilding alternatives for stocks but alleviate the burden of increased regulation on communities to a limited extent. Their cumulative effects may differ among stocks and fishing communities. Those fishery program administration measures which are likely to have cumulative effects are discussed below. If the cumulative effects of a measure on communities, resources, or habitat, are likely to be negligible or none, this is indicated briefly in the following discussion.

<u>Fishing Year (Not selected)</u>
A change to the fishing year will not have any cumulative effects on communities, resources, or habitat.

<u>DAS Proration (Not selected)</u>
Because it allows for 10 carry-over DAS, DAS proration Option 1 may have a very limited negative cumulative effect on the resource (groundfish stocks), with no appreciable cumulative effects on communities or habitat. Other DAS proration options will have negligible cumulative effects on communities, resources and habitat.

<u>Periodic Adjustment Process (Proposed action)</u>
Modifying the current framework adjustment process will not have any cumulative effects on communities, resources, or habitat.

<u>US/CAN Resource Sharing Understanding (Proposed action)</u>
While the US/CAN resource sharing understanding is likely to have impacts on allocation of shared fishery resources, the cumulative effects of this program are likely to be negligible. Because the proposed agreement does not reduce overall effort or establish additional gear restrictions, closures, or effort controls, there will be no cumulative effects on the resource and habitat.

<u>Administration of Certified Bycatch/Exempted Fisheries (Proposed action)</u>
This alternative establishes closer monitoring and review of bycatch and exempted fisheries. This action will not have any cumulative effects on fishing communities. Because of an increased administrative burden associated with this alternative, it may have small negative effects on NMFS administrative staff and analysts. With closer review and monitoring of bycatch/exempted fisheries, violations of the 5% bycatch standard and other issues will be identified in a more timely and effective manner. Improvements in data and information quality may have positive, indirect cumulative effects on the resource in the long term. There are no cumulative effects on habitat associated with this alternative.

Special Access Programs (Proposed action)

The Georges Bank yellowtail flounder SAP allows vessels to access a portion of Closed Area II to harvest a limited quantity of yellowtail flounder. This program will increase fishing mortality on GB yellowtail to a small extent, resulting in minimal negative impacts on the stock. Affects of this SAP on other stocks are negligible. The SNE/MA winter flounder incidental catch program allows fluke vessels to retain a small portion of incidental catch of winter flounder on directed fluke trips. This program is unlikely to increase mortality on winter flounder, since the winter flounder retained would have otherwise been discarded. The U.S./Canada resource sharing agreement SAP encourages U.S. vessels to fish in area 5Zjm so that the United States will take full advantage of their allocated quota. The specific measures chosen for this program may result in increased fishing effort on Georges Bank cod and potentially increased incidental catch of other species. The cumulative effects of this program on resources may be negative but low. The Closed Area I Hook Gear SAP will increase catches of haddock, but will provide additional revenues to small boat hook fishermen and their communities. Special access programs are positive for communities which rely on fishing, since they provide increased harvesting opportunities and potentially increased flexibility in determining when and where to fish. Their cumulative effects on communities, however, are likely to be only slightly positive or negligible, since these programs focus on specific harvesting sectors/fisheries and do not benefit the fishery as a whole. The cumulative effects of special access programs on habitat are negligible.

Closed Area Administration (Proposed action, in part)

The options related to defining the rationale for closed areas and reviewing year-round closed areas are administrative in nature and are unlikely to have any appreciable cumulative effects on the resource, communities, or habitat. Options determining the extent to which closed areas may be accessed may have differing effects, but no changes are adopted by this Amendment. Options 1-4 allow access of current multispecies exempted gear into year-round closed areas, with certain restrictions. These options will not have a cumulative effect on the resource or habitat, since they do not liberalize existing gear restrictions and any further restrictions on the use of certain gear types in closed areas are likely to have small positive effects. Option 5 extends the restriction on access to year-round closures to all gear types. This may have small positive cumulative effects on habitat in closed areas and for species with EFH-designations in closed areas. Options which prohibit certain gear types from accessing closed areas may have negative cumulative effects on fisheries which operate in year-round closures, including certain pot and trap fisheries.

Flexible Area Action System (FAAS) (Proposed action)

Eliminating or retaining the current FAAS will not have cumulative effects on communities, resources or habitat.

Leasing of DAS (Proposed action)

Days-at-sea leasing could have a negative affect on the resource. Total allocated DAS are higher than the desired level of used DAS; a leasing program may thus result in more DAS being used and increased effort could result in fishing mortality rates that exceed desired levels. DAS leasing remains subject to vessel upgrade restrictions, which will reduce opportunities for leases.. DAS leasing is intended to increase the functional value of days-at-sea by providing fishermen with more control over how they utilize these days. Leasing programs should have a positive effect on fishing communities. The overall cumulative effects of this program are likely to be negligible for the resource and habitat, and positive for individuals who choose to participate in the program.

Recreational Fishing Permit (Not selected)

Establishing a fishing permit for recreational fishers is not likely to have appreciable cumulative effects on the resource or habitat and may incur limited negative effects on the recreational sector, if permitting leads to additional costs. Improved data on recreational harvests may have positive, indirect cumulative effects on the resource in the long term.

Running Clock Alternatives (Not selected)

The running clock alternatives are unlikely to have cumulative effects on the resource and habitat. Option 1 (no action) will have no cumulative effects on communities. Option 2 (industry funded weighmaster) may be costly to fishermen but is unlikely to incur demonstrable cumulative effects on the industry and associated communities. Option 3 (extended modified running clock) will have positive impacts on fishermen who utilize the running clock, and may have low to moderate cumulative effects on this group.

<u>Observer Coverage (Proposed action)</u>
Options that increase the current level of observer coverage in the fishery may have indirect positive long-term cumulative effects on the resource, as improved data results in more accurate understanding of the fishery. Cumulative effects of observer coverage on communities and habitat are likely to be negligible.

<u>VMS Requirements (Proposed action)</u>
VMS is expensive for individual vessel owners due to the cost of purchasing, maintenance and energy requirements. Mandatory VMS is likely to have limited negative cumulative effects on the industry, particularly for vessels with high operating costs, or those fishing less frequently. VMS will have indirect positive cumulative effects on the resource, since it will improve enforcement of regulations and improve fishery-dependent data, providing more explicit information on spatial distribution of fishing effort. It is unlikely that VMS will have cumulative effects on habitat. Providing the ability to sign-out of the VMS program will reduce costs.

<u>Day Gillnet Block Out of Fishery (Not selected)</u>
Option 1, which retains the current restrictions on gillnet vessels, will not have cumulative effects on communities, resources or habitat. Options 2 and 3, which liberalize restrictions on gillnet vessels, may have small positive cumulative effects on the gillnet sector only, and non for other gear types. Options 2 and 3 may result in increased effort on some species harvested in gillnets but the negative cumulative effects of these measures are likely to be low.

<u>DAS Counting (Not selected)</u>
The options which eliminate partial days-at-sea (Options 2 and 3), are likely to have negative effects on data quality and may have indirect adverse effects on the fishery and resource. These options also reduce the value of days-at-sea, in effect, limiting the fishing that may take place within one DAS. Changes to the way DAS are counted may have a slightly negative cumulative effect on limited access multispecies vessels, and a very limited positive cumulative effect on the resource and habitat, due to a slight reduction in effort that results.

<u>Reporting Requirements (Proposed action)</u>
If VMS is required, cumulative effects on the communities, resources, or habitat will be similar to those discussed under VMS Requirements, above. The proposed action does not adopt a VMS requirement. The proposed action adopts electronic dealer reporting, links dealer and vessel reports through a trip identifier, and may eventually result in electonic vessel reporting. The impacts on the resource are likely to be positive as a result of improved information gathering, but not to any significant degree.

<u>Hand-Gear Only Permit Alternatives (Proposed action)</u>
These alternatives establish a hand-gear only permit, and are unlikely to have cumulative effects on the resource, communities or habitat. The proposed action limits hand-gear permits.

<u>Sector Allocation (General) (Proposed action)</u>
In general, sector allocation may be positive for fishermen, since it provides them with more control over specific management measures that will affect their fishing practices. It may lend flexibility to fishers and a greater sense of involvement in the regulatory process. Cumulative effects on fishing communities are, however, unknown at this time. Cumulative effects on the resource and habitat are negligible.

<u>Georges Bank Hook/Gillnet Sector Allocation (Proposed action, in part)</u>

Designed by stakeholders in the hook and gillnet gear sectors, this proposal is likely to have some positive cumulative effects for Georges Bank hook and gillnet vessels and their associated communities, although the extent of these benefits are unknown. The cumulative effects of this alternative on the resource are positive for Georges Bank cod for which a quota is established, and positive but low for other Georges Bank stocks due to the additional effort restrictions proposed. There are no cumulative effects on habitat. The Closed Area I access program associated with this alternative may have negative effects on Georges Bank haddock if participation in the sector is high. Although this alternative allows for access into Closed Area I, cumulative effects on habitat are negligible, since the hook and gillnet gear have limited contact with the bottom. The proposed action only adopts a hook gear sector.

Gulf of Maine Inshore Conservation and Management Stewardship Plan (Not selected)
The cumulative effects of this area management alternative are unknown for communities. They are likely to be positive for stocks and negligible to none for habitat.

5.7.7.2 Capacity Reduction Alternatives

Each of the capacity alternatives is designed to provide greater economic opportunity and flexibility for multispecies fisheries and, to some extent, open access scallop fisheries while maintaining the character of the existing fleet. In addition, they are intended to achieve some long-term reduction in the number of vessels permitted to fish in Northeast fisheries. The overall cumulative effects of capacity alternatives will be generally positive for participants in the capacity reduction program, and neutral for others. The way in which effective effort is defined in Alternative 5 may create some loss in allocated DAS for some individuals. Generally, permit holders who opt to transfer, acquire, or freeze permits are those who are likely to get a net economic benefit from doing so. Because these alternatives are intended to reduce effort in the long-term, their cumulative effects on the resource will likely be positive. Alternatives 1, 2, 3 and 4 are volunatry programs, making their impacts uncertain. Cumulative effects of Alternatives 5 and 6 on the resource are likely to be positive, since these options will reduce available DAS. Any of the alternatives will be more effecitve in controlling mortality if combined with Alternative 5 or another approach to reduce or control latent, unused DAS. If not, capacity reduction alternatives may increase effort in the short term, however, diminishing the positive value of their long-term cumulative effects. Cumulative effects on habitat are unknown, though most likely negligible unless effort is sharply reduced in regions of particularly sensitive habitat.

The impact of the Capacity Reduction alternatives, such as Permit Absorption, Permit Transfer, DAS Transfer and Freeze on Unused DAS, range from none to slightly positive due to the facts that these four are voluntary and may reduce latent effort, which would be beneficial to protected species. Since these measures are voluntary, no benefit will necessarily accrue if no one participates. The no action alternative assumes a generally negative impact due to little or no control of fleet size. The assumption is here that effects on protected species would be negative without any control on the fleet size. However, there would be a more positive effect when more permanent measures are adopted to recover large whales by reducing takings as the forthcoming Atlantic Large Whale Take Reduction Plan get developed and implemented. For the Permit Absorption alternative, the overall positive effect may be reduced for turtles if the permits that are transferred are combined with scallop permits, which may have negative additional consequences for sea turtles that are caught in scallop dredges. Similarly, the Permit Transfer alternative allows limited access permits holders to transfer to another vessel. This reactivation of latent effort which could result in changes in the gear used by a permit. If this results in a a shift from trawls to gillnets, it may further impact large whales, harbor porpoise, dolphin and seals. This is not a likely result, however, given the relative economic performance of these sectors in recent years – the change in gear is likely to be in the other direction. The net cumulative effects to these species is unknown. The same is true for DAS Transfer and Freeze on unused DAS. The remaining alternatives, DAS Reserve and Mandatory latent Effort, have mandatory controls on latent effort and therefore have offer more benefit to protected resources in comparison to the no action and the other alternatives and therefore have more positive cumulative effects.

The proposed action adopts the DAS transfer and the DAS reserve capacity options.

5.7.7.3 Management Alternatives to Address Rebuilding Requirements

Relative to the no action alternative, the most likely cumulative effects of the proposed action and four management alternatives to address rebuilding requirements are expected to be positive for the resource and its environment, negative in the short-term but positive in the long-term for the fishery participants, and are designed to create long-term sustainability of both the resource and the directed fishery. Cumulative effects of recreational measures are similar, but of a smaller magnitude.

Each of these rebuilding alternatives approaches the issue of stock rebuilding in a different way; all of the alternatives are designed to meet the goals of stock rebuilding. However, some of the rebuilding alternatives will only be successful in meeting the requirements of formal rebuilding programs for certain stocks when considered in a cumulative sense, in conjunction with other measures in Amendment 13 as well as previous and potential future measures. For example, Rebuilding Alternative 3 – Area Management – requires that hard TACs be implemented in conjunction with the measures outlined in this alternative to ensure its success. As a stand-alone alternative, area management has a positive effect on the groundfish stocks but does not meet the requirements of rebuilding programs for most of the stocks. The cumulative effects of area management in conjunction with additional effort controls that currently exist as well as future output controls (hard TACs) are strongly positive for groundfish stocks.

With respect to the four alternatives to rebuild the groundfish stocks and the proposed action, the impacts are all positive to protected resources in comparison to the no action. The no action here assumes that the existing closed areas are beneficia l to whales since they overlap with high use areas (Cashes Ledge, WGOM, and Right Whale critical habitat). Despite the negative effects of the threats discussed above, the existing closures are beneficial to large whales and other protected species. The 65 % reduction in used DAS, reduction in allocated DAS (with a hard TAC), Area Management (also with a hard TAC) and the Hard TAC alternatives all reduce the fishing mortality by reducing effort and gear in the water, thereby reducing potential for adverse effects to protected resources. It is unknown whether one of these alternatives would have a greater benefit to some or all the species. However, since there is a reduced effort and gear, there is likely less chance for gear entanglement by all species. Therefore, the four alternatives provide a net positive effect to protected species over and beyond the existing measures. This protection should further improve for large whales when the forthcoming Large Atlantic Whale Take Reduction plan goes into effect in the future.

The rebuilding alternatives in Amendment 13 employ many of the same types of measures. These basic management measures are discussed in terms of their cumulative effects, below.

<u>Area Closures (Year-round)</u>
Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 4
Alternative 3 not specified

All of the management measures to address rebuilding incorporate the current year-round area closures. Area closures alone are not likely to have significant effects on stock rebuilding, except for species of limited mobility, such as sea scallops. However, the effects of these closures over the long term are positive for the groundfish resource, since they protect areas of EFH for many of the stocks. There are no cumulative effects of year-round closures in the rebuilding alternatives in Amendment 13, since they are identical to the existing closures.

Seasonal/Rolling Closures
Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 4
Alternative 3 not specified

Like area closures, seasonal/rolling closures protect habitat and benefit groundfish stocks. These closures may, however, redirect effort, intensifying it in other areas. The cumulative effects of new seasonal and rolling closures are positive for the resource and habitat across the range of the fishery. The effects on communities may be negative and unequally distributed. Closures in the inshore Gulf of Maine may particularly impact smaller vessels, resulting in long-term negative cumulative effects on the inshore fleet.

Possession Limits
Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 3
Alternative 4

All of the rebuilding alternatives incorporate possession limits. If appropriate possession limits are chosen, they will have a positive cumulative effect on the resource. Possession limits may increase regulatory discards in some areas, although additional measures in Amendment 13 including special access programs and running the DAS clock, are intended to address this potential problem. Possession limits have no direct cumulative effects on habitat. They may have negative cumulative effects on fishers in the short-term, with long-term benefits resulting from successful stock rebuilding.

Effort Controls (Days-at-Sea)
Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 4

Most of the rebuilding alternatives utilize effort controls in the form of days-at-sea. Alternative 1 is the most restrictive in terms of DAS reductions, with a 65% decrease in active days across the fishery. DAS restrictions are among the most beneficial effort reduction tools, and result in a direct positive cumulative effect on the resource. By reducing the amount of time fishing gear is contacting the seafloor, DAS reductions also result in an indirect positive cumulative effect on habitat. The severe DAS reductions proposed in Alternative 1 will have a negative cumulative effect on communities, as vessels with too few days-at-sea to remain productive may be forced to retire from the fishery. The DAS leasing program and some of the capacity reduction alternatives are intended to alleviate some of the negative effects of DAS reductions.

Gear Restrictions

Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 4
Alternative 3 not specified

Gear restrictions are a component of nearly all of the rebuilding alternatives. Alternative 2, which uses gear modifications as primary tool for stock rebuilding, implements the most gear requirements and restrictions of any of the rebuilding alternatives. In general, increases in minimum mesh size, use of more selective gear to reduce the catch of incidental species and species of particular concern, net limits and other gear restrictions have a positive cumulative effect on the resource, particularly due to the protection of juveniles. Gear restrictions may have a positive cumulative effect on habitat if they reduce bottom contact time or introduce gear modifications that cause less damage to sensitive benthic structures. The cumulative effects of gear restrictions on communities are difficult to measure, although it is likely that these measures will have different effects across gear sectors.

Minimum Fish Sizes
Alternatives that incorporate measure:
Proposed action
NAA
Alternative 1
Alternative 2
Alternative 4
Alternative 3 not specified

Minimum fish sizes help protect juvenile fish, and have a positive cumulative effect on groundfish stocks. Establishing minimum sizes may have a greater impact on recreational fishers than those engaged in the commercial fishery, but the cumulative effects of minimum sizes in Amendment 13 are negligible. Minimum sizes have no cumulative effect on habitat.

VMS Requirements
Alternatives that incorporate measure:
Alternative 2
Alternative 4

The cumulative effects of VMS requirements are described under the fishery program administration section, above.

Long-term Cumulative Effects
Long-term effects of each of these rebuilding alternatives on the multispecies stocks are clear: stocks will rebuild as a result of the accumulated effects of measures applied over time and in response to these specific measures in Amendment 13 targeted at stock rebuilding. Effects of these alternatives in the long term are less clear or quantifiable from a social and economic perspective.

5.7.7.4 Alternatives to Minimize the Adverse Effects of Fishing on Habitat

5.7.7.4.1 Habitat Alternative 1, No Action Alternative – No Action

This alternative was not selected. This alternative retains management measures in place during fishing year 2001 that serve to protect habitat and minimize impacts associated with fishing. These include groundfish closed areas, effort controls, prohibition on the brush sweep or “streetsweeper” trawl, and the inshore Gulf of Maine 12 inch roller gear limit. In addition, for the purposes of this assessment, the No Action alternative includes the cumulative benefits of the other past management actions described in the previous section.

The three areas on Georges Bank and in southern New England were closed in December 1994 to trawls and dredges; the western GOM area was closed in May 1998. Shrimp trawls and clam dredges are exempted from the closed area regulations, and portions of the two closed areas on GB were opened to scallop dredging in June 2000. Because these closures are temporary and do not exclude all types of bottom-tending gear, they are not directly comparable to proposed habitat closed areas. As such, they do not benefit benthic habitat to the same degree as would permanent habitat closures that would exclude all gears that have a potential adverse effect on benthic habitat. These closures have, nevertheless, had a positive habitat effect during the past 4-8 years.

Fishing effort in the Northeast multi-species fishery has increased since the implementation of days-at-sea limitations in the fishery in 1995, but is well below levels that prevailed during the 1970s and 1980s. In contrast, bottom contact time in the scallop fishery has declined in recent years as the resource has grown and dredging has concentrated in areas with high biomass. Even if total bottom contact time has remained fairly stable in recent years, the displacement of effort from the closed areas has undoubtedly increased habitat disturbance in certain open areas, particularly in previously undisturbed or lightly disturbed areas. Restrictions on the use of "streetsweeper" trawls could have had beneficial effects on rocky bottom habitats in the GOM, although it is not clear that this type of gear was ever used to any great degree before it was prohibited.

The amount of bottom area included in the four existing groundfish closed areas is considerably more (5,847 nm^2) than in any of the habitat closed area alternatives, but they contain a smaller percentage of gravel substrate than alternatives 3, 4, and 6. Scaled for area, the percentage of EFH area for moderately and highly vulnerable species is relatively low. The predominant substrate is sand. Four of the five biomass indices (benthivores, amphipod feeders, principal groundfish, and principal demersal finfish) are high. The percentage of total biomass for six species with strong benthic habitat associations was moderate and the overall benthic biomass index was high.

5.7.7.4.2 Alternative 2 – Incidental Benefits of Stock Re-Building Measures

This alternative was selected. Proposed Amendment 13 management measures that are not directly habitat-related fall into eight categories. There are no habitat benefits, or no significant benefits, of fishery administration or sector allocation measures. Measures designed to control capacity (e.g., permit and days-at-sea transfers) will have long-term habitat benefits because they will limit the utilization of latent fishing effort that would otherwise increase effort. Days-at-sea (DAS) reductions that are implemented in Amendment 13 could be large (as much as 65% for certain stocks) and would reduce fishing effort and bottom contact time, as would possession limits – at least in certain areas and times of year. Rolling seasonal closures would only have temporary habitat benefits that would be lost as soon as fishing began again. Gear modifications that reduced gear contact with the bottom (e.g., raised footrope trawls) would have positive habitat benefits in areas where the gear is used. Habitat benefits that would result when certain areas are closed to fishing when a maximum catch (TAC) is reached would also be short-term and not very effective unless the area remained closed to all bottom-tending mobile gear for months at a time and/or the recovery time of benthic communities and seabed features was rapid. Measures that would allow unused DAS to be transferred to reduced impact gears would mitigate mobile gear effects.

Gear effects without any management measures are described as moderate to high. The implementation of fishery management measures have had incidental benefits as described above in the No Action alternative. The impact of any of the proposed Amendment 13 would add further benefits to offshore habitat. These benefits of the proposed alternatives are described in Section 5.3.6 of this document. The non-fishing impacts described above are generally considered in the low to moderate range in the offshore areas. The incremental effect of low non-fishing activities would not likely cause cumulative effects in these offshore fishing areas. The moderate level impacts that might occur would be localized in nature and therefore would not appreciably accumulate to enhance the negative effects of gear described above. Considering the incidental beneficial impacts of any of the above-described alternatives combined with the non-fishing and fishery management measures, the resultant effect will generally be a net positive effect on fish habitat in the offshore area. Since the effects of any of these alternatives do not occur in inshore or riverine areas, the beneficial effects would not accumulate in these areas. This would be true for negative effects, which also would not accumulate in these areas.

5.7.7.4.3 Alternative 3 – Modified Groundfish Closed Areas

This alternative was not selected. The proposed modifications to the boundaries of existing closed areas are intended to expand the area of complex hard-bottom habitat (gravel-cobble-boulder) and protect it from any adverse effects associated with fishing, particularly by mobile, bottom-tending gear (trawls and dredges). There are slight differences in the proposed western boundary of the western GOM closed area in the two versions of this alternative (3a and b). The area that would be closed is 2,727 (3a) or 2,637 nmi^2 (3b). These two alternatives rank high in terms of EFH area contained within the modified closed areas for 43 moderately and highly vulnerable species and life stages. More hard-bottom habitat (bedrock and gravel) would be protected than in any of the other six proposed closed are alternatives. The predominant substrates are sand and gravelly sand. Biomass indices for these two alternatives were high for benthivores, eleven principal groundfish species, and for six species that are closely associated with benthic habitats, and moderate for amphipod-feeding fish and a large group of demersal finfish species. The total benthic biomass index was high.

As with the previous alternative, the proposed modifications to the closed area boundaries under this alternative, combined with benefits of past manage measures, would have beneficial effects to EFH as a result of the additional hard-bottom protected areas. Thus, the negative effects of fishing offshore outside the closed areas would not accumulate and would be offset by the protection of the high quality hard-bottom areas. The slight difference in area between the two options would not result in any significantly different cumulative effects. No cumulative effects would occur in inshore/riverine areas as they are not affected by the closure.

5.7.7.4.4 Alternative 4 – Habitat Sub-Sets Within Modified Groundfish Closed Areas

This alternative was not selected. Areas within modified closed areas that would specifically protect hard-bottom habitats were selected. The area that would be closed is 2,241 nmi^2. This alternative ranks just as high as alternative 3 in terms of EFH area for 43 moderately and highly vulnerable species and life stages. This alternative ranked second to #3 (a or b) in terms of the percent bedrock and gravel it contains. The predominant substrates are sand and gravelly sand. The biomass indices for this alternative were the same as alternative #3, i.e., high for benthivores, eleven principal groundfish species, and six species that are closely associated with benthic habitats, moderate for amphipod-feeding fish and a large group of demersal finfish species. The total benthic biomass index was high.

As with the previous alternative, the proposed modifications to the closed area boundaries under this alternative, combined with benefits of past manage measures would have beneficial effects to EFH as a result of the additional hard-bottom protected areas. As with the previous alternative, the negative effects of fishing offshore outside the closed areas would be offset by the protection of the high quality hard-bottom areas. No cumulative effects would occur in inshore/riverine areas as they are not affected by the closure.

5.7.7.4.5 Alternative 5 – Closed Areas Designed to Balance EFH AREA Protection and Fishery Productivity

This alternative was not selected.

5a (2,870 nm^2) – Scaled for area, the five closed areas in this alternative contain a fairly high percentage of EFH area for 43 moderately and highly vulnerable species and life stages in the Northeast region. The percentage of gravel substrate is very low and there is no bedrock. The predominant substrates are sand and mud. Biomass indices for this alternative were low for benthivores and principal groundfish species, and moderate for amphipod-feeding fish, demersal finfish, and six species that are closely associated with benthic habitats. The total benthic biomass index was moderate.

5b (2,972 nm^2) – Scaled for area, the five closed areas in this alternative contain a fairly high percentage of EFH area for 43 moderately and highly vulnerable species and life stages in the Northeast region. The area of gravel substrate is very low and there is no bedrock. The predominant substrate is sand. Biomass indices for this alternative were high for moderate for demersal finfish, moderate for benthivores and amphipod-feeding fish, and low for principal groundfish species and six benthic species. The total biomass index is moderate.

5c (2,803 nm^2) – Scaled for area, the five closed areas in this alternative contain a high percentage of EFH area for 43 moderately and highly vulnerable species and life stages in the Northeast region. The percentage of gravel substrate is low and there is a very small amount of bedrock. The predominant substrates are sand and mud. Biomass indices for this alternative were low for principal groundfish species and moderate for benthivores, amphipod-feeding fish, demersal finfish species, and for six benthic species. The total benthic biomass index is moderate.

5d (2,918 nm^2) – Scaled for area, the five closed areas in this alternative would contain a relatively low percentage of EFH area for 43 moderately and highly vulnerable species and life stages in the Northeast region. The percentage of gravel substrate is low and there is no bedrock. The predominant substrate is sand. Biomass indices for this alternative were low for benthivores, amphipod-feeding fish, principal groundfish, and benthic species, and moderate demersal finfish. The total benthic biomass index was low.

The four closed area options (a-d) included in this alternative, combined with benefits of past manage measures, would have beneficial effects to EFH as a result of the additional protected areas. However, gains in the amount of hard-bottom habitat would be considerably less than alternatives 3 or 4. Furthermore, the biomass of species associated with the bottom would be less per unit area than in any of the other alternatives. Nevertheless, the negative effects of fishing in un-protected offshore areas would be offset by the five area closures proposed in any one of these alternatives. No cumulative effects would occur in inshore/riverine areas as they are not affected by the closures.

5.7.7.4.6 Alternative 6 – Existing Groundfish Closed Areas Except for Areas Opened Under Scallop FW13 Closed Area Access Program (No Modifications to Closed Area Boundaries)

This alternative was not selected. This is the largest of the proposed closed areas (4,038 nm^2). Scaled for area, the five closed areas in this alternative would contain a relatively low percentage of EFH area for 43 moderately and highly vulnerable species and life stages in the Northeast region. Some gravel substrate would be protected, but not as much as in the closed areas proposed in alternatives 3 and 4.. The predominant substrate is sand. Biomass indices for this alternative were high for benthivores, principal groundfish species, demersal finfish species, and for six species that are closely associated with benthic habitats, and moderate for amphipod-feeding fish. Total benthic biomass ranked high.

This closed area option would have beneficial cumulative effects to EFH as a result of closing such a large area that includes some hard-bottom substrate. As was the case for alternatives 3 and 4, this area supports a high biomass of benthic species, including 11 principal groundfish species. However, scaled for area, EFH gains would be slightly less than all the other alternatives except 5d. The negative effects of fishing in offshore areas that remained accessible to trawling would be offset by the protection afforded by the closed areas. No cumulative effects would occur in inshore/riverine areas as they are not affected by the closures.

5.7.7.4.7 Alternative 7 – Expand List of Gears Prohibited in Existing Closed Areas

This alternative was selected in part. This measure would exclude bottom-tending mobile gears such as shrimp trawls and hydraulic clam dredges from the existing groundfish closed areas. These gears are known to adversely effect benthic marine habitats, so there would be a positive habitat benefit associated with this alternative. This would probably not be the case for other gears that contact the bottom, but have negligible effects on benthic habitat (e.g., pots, gill nets, and long lines). The proposed action only applies this restriction to hydraulic clam dredges.

The cumulative effect for this alternative, combined with benefits of past manage measures, would be to reduce gear effects by prohibiting a more inclusive list of gear types within the existing closed areas that adversely affect benthic habitats. This would have a net benefit to habitat within these areas and no cumulative negative effects within the areas would occur. Since the areas are offshore, this alternative should have no cumulative effects to inshore and riverine areas.

5.7.7.4.8 Alternative 8 – Restrictions on the Use of Rockhopper and/or Roller Gear

This alternative was not selected. There are five options for this management measure. The first would involve an immediate prohibition on the use of roller gear with a diameter greater than the current maximum size (31-36 inches). This would be the least effective option, since it would allow large roller gear to be used: trawling would be more difficult only in areas with large rocks that the smaller diameter rollers could not get over. Options (b), (c), and (d) would prohibit the use of roller gear larger than 22, 12, and 5 inches, either immediately or in a stepwise fashion over several years. The smaller the maximum size, the greater the area that could potentially become inaccessible to trawling.

These restrictions would indirectly reduce trawling effort in rocky bottom areas, but probably not eliminate it completely. Reducing the size of rockhopper and roller gear increases the probability that the gear will hang up and be damaged, thus increasing the risks of trawling in rocky bottom areas and encouraging fishermen to avoid them.

The cumulative effect of this alternative, combined with benefits of past manage measures, would be to reduce trawling in rocky bottom areas that remain open to mobile bottom-tending gear. The benefits of this alternative would increase as the maximum size of the prohibited roller gear decreases. Habitat benefits would also be greater if any of these options were implemented immediately as opposed to being phased in over several years (as many as six years in 8(e)), and, more importantly, if they applied in a larger versus a smaller area. Because nearshore habitats have already been compromised by coastal pollution and habitat development, the beneficial effects of reducing trawling in rocky bottom areas may be limited by the physical disturbance that has already occurred in these areas. However, when trawl gear does hang up in rocky bottom, habitat damage may be more severe in local areas.

5.7.7.4.9 Alternative 9 – Require Vessel Monitoring Systems On All Groundfish Vessels

This alternative was not selected. Use of VMS on all groundfish vessels will improve the quality of data needed to determine the amount of fishing activity that takes place in certain areas and habitat types at certain times of year. This information will improve our understanding of habitat disturbance patterns in the NE region and facilitate future management decisions.

There are no cumulative effects negative or positive associated with this alternative since there is no associated impact. However, the information provided will enable fishery managers to better relate management actions to fishing effort and thus make more informed decisions on future habitat actions.

5.7.7.4.10 Alternative 10 – Habitat Closed Areas that are Modifications of Existing Mortality Closures and Other Proposed Habitat Closures *(Preferred Alternative)*

This alternative was selected, in part. Alternative 10b is part of the proposed action as a Level 3 habitat protection area. Alternative 10a is the second largest habitat alternative (3,050 nmi2). Additionally, both 10a and 10b have a very high percentage of overlap with the existing groundfish closed areas (82% and 81%, respectively). For this reason, the vast majority of bottom area contained within this alternative has been relatively un-disturbed by mobile, bottom-tending gear for 5-8 years. The areas are between 58-60% sand, but there is a modest amount of gravel and gravelly sand as well. While alternative 10a protects more habitat than 10b, the cumulative effects of both alternatives are positive for habitat.

5.7.8 Social and Economic Effects of Habitat Measures

This cumulative impact assessment characterizes the magnitude of social and economic impacts likely to result from the alternatives considered in the Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 to the Northeast Multispecies Fishery Management Plan.

5.7.8.1 Social and Economic Conditions of Communities and Businesses

General Revenue Loss Impacts

Alternative 5b level 1 will result in the most significant revenue losses nearing 38 million dollars. The revenue impacts of Alternatives 6, 10a and 10b, which approach 4 million dollars, are significantly less than all other alternatives and is 33 million less than the losses likely to be experienced under alternative 5b, the most restrictive. The smallest losses are expected for Alternative 10b.

Port Community and Regional Impacts

The concentration of revenue loss for Level 1 EFH alternatives 3a, 3b, and 4 are localized in the New Bedford, Gloucester, and Cape Cod regions with a minimum of approximately 2/3 of the revenue loss coming from the community of New Bedford. A level 3 closure generally reduces overall revenue losses across ports except for New Bedford for which revenue loss remains constant for both closure levels. This results in an increase in the relative proportion (> 80%) of impact for New Bedford for these alternatives. Smaller impacts were found for the communities of Gloucester followed by Harwichport, and Chatham which were generally lower for level 3 closures. This contrasts with alternatives 5a, 5b, 5c, 5d, 10a and 10b, for which smaller revenue losses were more evenly distributed across five regions (New Bedford, Gloucester, New Jersey, Cape Cod, and Boston).

<u>Surf Clam and Ocean Quahog Fishery</u>**:** Alternatives 3a, 3b and 4 would have no impact on the surf clam/ocean quahog fishery. Alternative 6 would mitigate impacts for the most states but would have the largest overall impact and would affect the state of Massachusetts exclusively. Of the Alternatives that would affect the fishery, Alternative 5a would have aggregate impacts similar to that of Alternatives 5b and 5d but these impacts would be more broadly distributed across states in the Northeast region.

State	Total Bushels	Alternative 3a, 3b, & 4	Alternative 5a	Alternative 5b	Alternative 5c	Alternative 5d	Alternative 6	Alternative 10A & 10B
MA	936,236	0	4.1%	11.0%	11.0%	8.8%	40.7%	4.8%
MD	622,065	0	5.1%	0.0%	5.1%	0.0%	0.0%	0.0%
ME	108,590	0	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
NJ	3,788,123	0	2.4%	0.4%	2.4%	0.0%	0.0%	0.0%
RI	175,920	0	0.9%	0.9%	0.9%	44.6%	0.0%	2.1%
Totals	5,630,934	0	2.9%	2.1%	4.0%	2.9%	6.8%	0.9%

Table 362 - Proportional Loss of Surf Clam/Ocean Quahog Landings (bushels) by State and Alternative

Vessel leng th class
Alternative 5b has the greatest over-all impact across all vessel sectors for level 1 EFH closures ranging from income impacts of 10% for large and medium vessels to 23% for small vessels. Level 3 impacts remain the same for large vessels and fall below 10% for medium and small vessels. Alternative 6 has the least impact on revenue across all vessel categories, all of which are less than 3%. Revenue impacts for small and medium vessels are most affected by alternatives 5a - 5d while large vessels are more affected by alternatives 3a and 3b. Level 3 revenue impacts are generally lessened for medium and small vessels while large vessel impacts remain constant.

Number of affected vessels
The number of small vessels impacted is substantially less for a level 3 closure while the number of vessels impacted for large and medium vessel classes is not significantly different between level 1 and 3 closure alternatives. The number of boats affected and the average revenue loss of impacted vessels is greater for alternatives 5a, 5b, 5c, and 5d as compared to other alternatives.

Gear
The hook, gillnet, and trap gear sectors are consistently impacted across all alternatives for level one closures. These impacts are eliminated for level 3 closures. Scallop dredge and trawl gear sectors impacts remain the same for level 1 and level 3 closures.

5.7.8.2 Anticipated Revenue Losses for Habitat Alternatives Based on Input/Output Analysis

The impacts on gross sales, income and employment in the New England coastal would be greatest for Alternative 5b while either Alternative 6, 10A or 10B would reduce these impacts by nearly ten-fold. The impacts are likely to be an upper bound estimate since the potential impacts of Level 3 vis à vis Level 1 were not estimated. In between these extremes, the remaining alternatives form two clusters each having similar impacts within a cluster. Specifically, Alternatives 3a, 3b and 5c form one of these clusters with gross sales impacts of about $100 million; income losses of about $30 million; and employment losses of up to 1,400 jobs. Alternatives 4, 5a, and 5d form a second cluster with lower impacts of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs. Alternative 10b results in the lowest employment impact, with a loss of only 175 jobs.

Across sub-region the Massachusetts sub-regions of New Bedford, Gloucester, Cape and Islands, and Boston account for between 70 and 90% of economic impacts regardless of alternative. The New Bedford sub-region would be particularly affected followed by Gloucester and the Cape and Islands sub-region. For New Bedford the Level 3 habitat closure may not provide substantial relief because of the importance of scallops, monkfish, and groundfish in the New Bedford seafood economy.

5.7.8.3 Cumulative Effect on Communities and Businesses

In general, impacts across all forms of analysis identified habitat alternative 5b as having the greatest impact and alternatives 6, 10a, and 10b as having the least. In between these extremes, more severe impacts (gross sales impacts of about $100 million; income losses of about $30 million; and employment losses of up to 1,400 jobs) will result from alternatives 3a, 3b, and 5c. Less severe impacts (losses of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs) will result from alternatives 4, 5a, and 5d. The cumulative effects of habitat alternatives on communities are negative, and are evident in the predicted loss of income and jobs. Cumulative effects of alternatives 4, 5a, 5d, 10a and 10b will be less severe and long-lasting than those resulting from alternatives 5b, 5c, 3a, and 3b. Generally speaking, the amount of area closed to fishing does not predict the severity of cumulative effects of these closure measures on communities. Location and timing of closures are more important factors in determining how these alternatives will affect the fishery.

For all VTR records retained for analysis, the total estimated gross revenue from all species reported during calendar year 2001 was $296.3 million. For a Level 1 habitat closure the relative change in total gross revenues ranged from a low of 1.3% for Alternative 6 to a high of 12.8% for Alternative 5b. The remaining alternatives all ranged between 5 and 8% in total revenue impact with little appreciable difference between Alternatives 3a (7.8%) and 3b (7.4%) or between Alternatives 4 (5.3%) and 5d (5.6%).

Revenue impacts across species were more varied across alternatives than total revenue impacts. The impact on monkfish revenue was between 11 and 18% under any of the variants of Alternative 5 a-d. By contrast, scallop revenue impacts were largest under Alternative 5b (10.8%) but were less than 1.5% for Alternatives 5a, c, and d. Revenue losses for small mesh fisheries for whiting and squid were similar (about 3%) for Alternatives 5a, b, and c but were less than 1% for all others. Revenue losses for combined "other" species (dogfish, skates, lobster, shrimp, herring, mackerel, tunas, and clams) were greatest for Alternatives 5b (12.7%) and 5c (11.4%) but were similar all other habitat alternatives (from 3.5 to 6.5%). Revenue losses for groundfish were highest for Alternative 5b (21.6%) and lowest for Alternative 6 (1.7%). With only two exceptions revenue losses for groundfish exceeded that of all other species across all alternatives. Revenue losses for combined summer flounder, black sea bass, and scup were 0.1% for all alternatives other than the variants of Alternative 5. Among these alternatives, revenue losses were similar for Alternatives 5a, c, and d.

A Level 3 habitat closure would mitigate revenue impacts on stationary bottom tending gear, and as a result, total revenue impacts would be lessened. The revenue losses for a Level 3 closure ranged from 8.1% (Alternative 5b) to 0.5% (Alternative 6). Compared to the Level 1 closure effects, the revenue losses for the remaining alternatives were about 1 to 2% lower. However, revenue losses for specific species groups were substantially reduced. Since a large proportion of monkfish are landed with gillnet gear the Level 3 closure would mitigate a substantial proportion of estimated monkfish revenue losses. Similarly, revenue losses for the "other" species group would be mitigated under a Level 3 closure because a significant proportion of these revenues are comprised of lobster using trap gear. Revenue losses for groundfish would be partially offset by a Level 3 closure since gillnet and hook segments of the groundfish fishery would not be affected. However, trawl gear accounts for the majority of groundfish effort so groundfish revenue losses would still range between 9 and 14% for all alternatives except Alternative 6.

Overall, the relative difference between a Level 1 and Level 3 habitat closure mitigates about 22% of total revenue losses for Alternatives 3a, 3b, and 4. For the Alternative 5 variants the revenue losses are reduced by as much as 46% (Alternative 5c). Much of this reduction in revenue impact is associated with savings of monkfish gillnet and lobster trap fishery revenues.

As a share of total revenue loss, groundfish losses for a Level 1 closure range from a low of 27% for Alternative 6 to a high of 54% for Alternative 4. Revenue losses for scallops represent about one-quarter of revenues loss for Alternative 4 and nearly one-third of total losses for Alternatives 3a, 3b, and 5b. Monkfish revenue losses were 7% or less of total revenue losses for Alternatives 3a, 3b, and 4 but were at least 12% of revenue losses for all other alternatives.

Since a Level 3 habitat closure does not provide any relief to fisheries using mobile bottom-tending gear the share of revenue impact for fisheries that are dominated by these mobile gears increases relative to other fishery impacts. For example, the combined share of groundfish and scallop revenue losses is at least 70% for all Alternatives and is as much as 90% of revenue impact for Alternative 4.

5.7.8.4 Habitat Alternative Impacts on Protected Species

The Habitat alternatives also have a generally slightly positive to positive cumulative impact to protected resources in comparison to No Action. Again without the habitat alternatives, positive impacts to protected resources would result from the existing closed areas in the short term. However, the threats to large whales discussed above would likely continue until specific measures identified in the ongoing and future recovery plans and the forthcoming Atlantic Large Whale Take Reduction Plan are implemented through some future action or regulation, as appropriate. The overall cumulative effect of the rebuilding alternatives (Alternative 2) is considered positive to protected species, as discussed above. However, since the closures are made for fishery management purposes, they are subject to change by future management actions, for example, when the stocks are rebuilt. Closed area alternatives 3, 4, 5, 6 and 10 would be more permanent since they are for the purpose of habitat protection. Since the concern here is mobile bottom-tending gear such as trawls, the benefits to large whales, which will still interact with gillnets may be less positive for those species. Such closures would still reduce effort and gear in these areas and therefore reduce gear interaction with small mammals and turtles. Additional benefits would incur if habitat closures were chosen in addition to Alternative 2. Alternatives 2, 6 and 10 were identified as preferred alternatives. It is difficult to assess the impact of Alternative 7, since the gear that would be proposed for exclusion is not specified. Thus, the effects are unknown. It is not likely that Alternatives 8 (Restrictions on Rockhopper/roller gear) and Alternative 9 (VMS on all groundfish vessels) will have much positive effect and thus cumulative benefit to protected species. The latter may have positive indirect effects since it will provide accurate data on gear use and area identifying where effort is in relation to species distribution data. However, the overall cumulative effect would likely be negligible to none.

5.7.9 Other Foreseeable Local, State, and Federal Actions

While the measures to achieve rebuilding are expected to result in economic benefits to the industry over the long term, some effects of short term declines in revenues and jobs may be irreversible, restricting the economic growth of the industry during later years when the resource has been rebuilt. Two such effects are gentrification and delocalization. The process of gentrification transforms working harbors into upscale areas primed for recreation and tourism, replacing infrastructure that supports the commercial fishing industry with waterfront housing, entertainment and dining establishments, or other facilities. Among the businesses and industry support structures that may be eliminated are vessel maintenance and repair facilities, equipment manufacturers and retailers, fish processing plants, fish auctions, and provisioners of food, ice, fuel, oil, and other goods. As the industry is restricted in their ability to catch fish, the related land-based infrastructure is also constrained. With increasing shoreline property prices and an economically strained industry, this infrastructure may be permanently replaced by new entities with alternative functions. Hall-Arber et al. (2001) noted that "if the facilities as well as the stocks are not protected, once the biophysical capital rebounds, communities dependent on [these] facilities…will not be able to take advantage of the improved stock conditions to generate fisheries capital for the region and nation." These structural changes to the economy and physical composition of fishing communities are accompanied by delocalization, or the loss of localized community character and culture (Hall-Arber et al. 2001). Long-standing traditions and close-knit alliances that unite fishing communities and families may cease to exist.

Amendment 13 does not introduce measures that specifically seek to mitigate these problems of infrastructure loss and the changing culture of fishing communities in New England. This may have serious long-term economic and social effects. However, it can be assumed that if such reductions in land-based infrastructure are significant, the income, revenue and employment trajectories will be more depressed in later years than predicted by the quantitative economic analyses in this document. Hall-Arber et al. suggest that fishing community sites at greatest risk of gentrification and delocalization are those that are most "industrial" in appearance and closest to centers of urban activity, such as Gloucester and New Bedford.

Accompanying de-localization and gentrification is a change in the composition of fishery participants. Certain individuals who currently participate in the groundfish fishery may be forced to retire from fishing or move into another fishery. The implications of this are that long-term economic gains may not apply to current fishery participants if these individuals have left the groundfish fishery.

The impacts of possible future state and local community actions are difficult to evaluate, given the complexity and geographic range of the groundfish industry. In some communities, actions have been taken to preserve shoreline access for fishing businesses, through restrictions on use or through tax advantages. Such measures help slow gentrification and loss of the waterfront, helping to preserve infrastructure. Other communities have been less committed to maintaining a commercial fishing presence, and have encouraged increased use of waterfront property for tourist, recreational boating, or residential uses.

States have partnered with the federal government in the past to administer emergency relief to fishermen affected by restrictive groundfish regulations. State universities have initiated several programs to educate fishermen about options to groundfishing, including the use of fishing vessels to participate in scientific research projects funded by a variety of sources. In some cases, states have altered regulations for fishing in state waters to provide additional opportunities to fishermen coping with strict federal regulations. These direct interactions with the fishing industry are only one possible source of future impacts. State decisions on permitting of power plants, coastal wind farms, or other shoreside development could impact groundfishing in the future, though near-coast actions will have less impact on those groundfish species that do not rely on estuaries for a significant part of their life-cycle.

Reasonably foreseeable federal actions include additional or revised fishing regulations, both for the groundfish fleet and for other target species. Amendment 13 clearly contemplates adjustments in the future to make sure that target fishing mortalities are met, and provides room for special access programs if fishing mortality is too low. But many vessels depend on groundfish for only a portion of their fishing income. Revised regulations to cope with changing stock conditions for these other species could either positively or adversely impact fishing communities, depending on whether revenues increase or decline as a result. Any federal efforts to mitigate impacts of the regulations, such as through direct assistance to fishing vessels or through the funding of job retraining programs, etc., could mitigate some of the impacts of this action on communities. Federal support for an industry-funded buyout, if sufficient in magnitude, could help reduce the capacity of the groundfish fleet and improve the profitability of the industry. Some federal actions could have indirect effects. Federal decisions on offshore petroleum access, for example, could have either a positive or negative effect on the habitat and groundfish, and, as a result, the fishing communities dependent on those resources.

6.0 Data and Research Needs

In November, 2000 the Groundfish Oversight Committee identified the following research needs for the groundfish fishery and resource:

1. Investigations into stock definition, stock movements, mixing, and migration, such as through tagging studies, DNA markers, morphological characteristics, etc. Effect of assumptions on stock definition, movements, mixing, and migration on stock assessments.

2. Methods to improve sampling of commercial catch at age data, such as through cooperative NMFS/industry programs to supplement port agents.

3. Investigations into relationships between stocks, including predator/prey relationships and evaluation of whether stock status of some species is slowing rebuilding of groundfish stocks.

4. Comparative studies on the impacts (positive and negative) of gear on habitat, such as the different impacts between chain nets, roller gear, and rockhopper gear, etc. Studies on whether limiting roller or rockhopper gear, or specifying other aspects of trawl gear, results in areas of complex habitat that are not used by trawl fishermen.

5. Development of appropriate programs to collect information required for social and economic impact analysis.

6. Research on extent and composition of discards and bycatch in the groundfish fishery.

7. Research fishing practices or gear modifications that may change the ratio of component catch species or improve selectivity of gear. As an example, research should consider ways to catch flatfish and not roundfish, or ways to target haddock and not cod.

8. Research on bycatch and discards of groundfish in other fisheries, including small mesh fisheries, and fishing practices or gear modifications that may reduce bycatch or improve selectivity of gear.

9. Quantify the impacts of closed areas, and evaluate the effectiveness timing closures to coincide with spawning activity (e.g. Gulf of Maine rolling closures).

10. Development of industry–based information collection systems to improve information used for groundfish management.

Section 9.3.4 of the SEIS describes EFH research needs identified by the Habitat Technical Team.

7.0 Applicable Law

7.1 Magnuson-Stevens Act

The Magnuson-Stevens Act, implemented Oct 11, 1996, changed the standards for fisheries management. Perhaps the most significant of these changes is the establishment of strict criteria for determining the status of stocks based in large measures on maximum sustainable yield (MSY), and for rebuilding overfished stocks to biomass levels that can produce MSY on a continuing basis. This new requirement has taken several years to implement, primarily because the NEFMC has had to first revise all overfishing definitions to comply with the new standard, conduct assessments of all stocks to determine the status relative to the new overfishing definitions, and modify the management plans to achieve the stock rebuilding that is necessary.

7.1.1 Consistency with National Standards

Section 301 of the Magnuson-Stevens Act requires that regulations implementing any fishery management plan or amendment be consistent with the ten national standards listed below.

1. *Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery for the United States fishing industry.*

   The proposed management measures are designed to end overfishing on the eight groundfish stocks that are currently subject to excessive fishing pressure. In addition, the proposed action implements formal rebuilding programs for all overfished stocks. For overfished fisheries, the Magnuson-Stevens Act defines optimum yield as the amount of fish which provides for rebuilding to a level consistent with producing the maximum sustainable yield from the fishery. The measures are designed to achieve the fishing mortality rates, and yields, necessary to rebuild the overfished stocks.

   Because of the multispecies nature of this fishery, the measures necessary to rebuild overfished stocks also reduce fishing mortality on healthy stocks. This could prevent harvesting the opimtum yiled from those stocks while rebuilding programs are being followed for the overfished stocks. The proposed action includes measures that are designed to allow increased harvests of healthy stocks. These measures include the provision for special access programs to target healthy stocks, as well as the provision for additional fishing time, in the form of a different category of DAS, in order to target healthy stocks. While many of the details of these programs have yet to be developed, the proposed action etabslishes the structure that can be used to access healthy stocks in order that optimum yield can be harvested from them during the period that other stocks are being rebuilt.

2. *Conservation and management measures shall be based on the best scientific information available.*

   The proposed action is based on the most recent estimates of stock status available. These estimates are in the form of unpublished information provided by the Northeast Fisheries Science Center. Stock size and fishing mortality in calendar year 2002 was estimated based on landings information for that period. In addition, the amendment used information from the most recent stock assessments: either the updated assessments in November 2002 for the groundfish complex as a whole, or assessments published during 2003 for five stocks (witch flounder, SNE/MA yellowtail flounder, CC/GOM yellowtail flounder, SNE/MA winter flounder, and GOM winter flounder).

   Management targets for this action are based on NEFSC 2002a, a comprehensive review of fishing mortality thresholds and biomass targets for the groundfish complex.

With respect to bycatch information, the action uses bycatch information from the most recent assessments. Bycatch data from observer report , vessel logbooks, or other sources must be rigoroulsy reviewed before conclusions can be drawn on the extent and amount of bycatch. While additional observer data has been collected since the most recent assessments were completed, it has not been analyzed or reviewed through the stock assessment process and thus cannot be used.

The Gear Effects Evaluation and Adverse Impacts Determinations for the Final Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 satisfy these requirements. The SFA requires the NEFMC to minimize, to the extent practicable, the adverse impacts of fishing on the EFH associated with any federally regulated fishing activities in the Northeast region. To do this, this amendment must evaluate the effects of all fishing gears used in the region on groundfish EFH, following the guidelines indicated above. The potential impacts of groundfish fishing on the EFH of other species in the region must be evaluated as well.

Since the implementation of the Council's Omnibus EFH Amendment of 1998 (NEFMC 1998), NMFS, NEFMC and MAFMC conducted a Gear Effects Workshop that evaluated the effects of fishing gears used in the Northeast region on mud, sand, and gravel habitats (NEREFHSC 2002). Additional sources of information include work done by the NEFMC Essential Fish Habitat Technical Team, and a National Research Council report on the Effects of Trawling and Dredging on Seafloor Habitat (NRC 2002). Additional information is included in this document.

Gear Descriptions
Specifically, to describe gears, information from the NMFS VTR database and an ASMFC gear report was used. The primary source of information for gear descriptions was the EFH Omnibus Amendment (1998). Additionally, gear descriptions are provided using the Northeast Regional EFH Steering Committee's 2002 report from the Gear Effects Workshop in addition to several articles published in peer reviewed journals.

Distribution of Fishing Activity by Gear
The data used to perform this analysis were extracted from vessel trip report and clam logbook databases maintained at the U.S. National Marine Fisheries Service (NMFS) Northeast (NE) Regional Office in Gloucester, MA. Days absent calculations for trawl and dredge vessels are clearly preferable to simply summing the number of trips, but over-estimate actual fishing time since they include travel time and any other non-fishing-related activity while vessels are away from port. Thus, the GIS plots and analyses presented here do not represent fishing effort. They were only used to indicate the relative, not the absolute, distribution of fishing activity by geographical area and sediment type. Toward this end, all GIS input data were compiled and sorted into three categories: low, medium, and high degrees of activity that corresponded to cumulative percentages of 90, 75, and 50% of the total number of days at sea, or days spent fishing for each gear type during the seven-year time period. Data reported from ten minute squares (TMS) south of Cape Hatteras, North Carolina (35° N) and north of 45° N latitude in the Gulf of Maine were excluded from analysis, as were TMS-binned data from the low end (cumulative percentages >90%) of the frequency distribution. Exclusion of "low end" data (TMS with only a few trips or days) eliminated a large number of spatially misreported trips from analysis. Also included in this section are GIS plots of fishing activity for scallop dredge vessels operating in the limited access fishery during 1998, 1999, and 2000 which were derived from vessel monitoring systems (VMS) placed aboard each vessel. These plots provide a much more detailed depiction of fishing activity for dredge vessels during these three years than VTR data since they are collected at much higher spatial and temporal resolutions. Data were collected at 20-minute intervals during the time when vessel speed was less than 5 knots in order to differentiate between fishing activity and steaming time and then binned into one nautical mile squares. It is recognized that fishing activity includes other activities besides dredging, e.g., shucking time.

Types of Gear Effects

A number of authors have reviewed, to varying extents, existing scientific literature on the effects of fishing on habitat (e.g., Auster et al. 1996, Cappo et al. 1998, Collie 1998, Jennings and Kaiser 1998, Rogers et al. 1998, Auster and Langton 1999, Hall 1999, Collie et al. 2000, Lindeboom and de Groot 2000, Barnette 2001, National Research Council 2002). The conclusions reached by these authors are extracted from a recent NOAA report (Johnson 2002). A number of review papers have focused specifically on the physical effects of bottom trawls (e.g. ICES 1973). A working committee of the International Council for the Exploration of the Seas (ICES) issued, in November 2000, a report on the "Effects of Different Types of Fisheries on North Sea and Irish Sea Benthic Ecosystems." This report (ICES 2000) was a summary of findings based on a comprehensive report of the same title edited by Lindeboom and de Groot (1998). Alteration of physical structure, sediment suspension, changes in chemistry, and changes to benthic community are documented and described in the FEIS using peer reviewed literature and two reports (NRC and Gear Effects Workshop).

A Review of Fishing Gear Effects Literature Relevant to the U.S. Northeast Region was conducted and included in the FEIS that included the review of forty-four publications. They included all known studies (written in English) that examined the effects of the three principal mobile, bottom-tending fishing gears used in the Northeast U.S. on benthic marine habitats. Only publications that evaluated the direct habitat effects of fishing by these gears were reviewed (i.e., modifications to the physical structure of the seafloor or effects on benthic organisms that live in or on the seafloor). Effects of fishing on resource populations were not included, nor were studies that evaluated the indirect effects of fishing on marine ecosystems caused by the selective removal of species targeted by the gear or which are caught incidentally (as by-catch) during fishing. Both peer-reviewed and non-peer-reviewed publications were included, but most were peer-reviewed. To be included, accounts of research projects had to be complete and describe methods and results. Abstracts and poster presentations were not included. The summaries in this document are, in all cases, based on primary source documents. Two bottom-tending mobile gear types that are widely used in other parts of the world, but not in the Northeast U.S. – beam trawls and toothed scallop dredges – were not included even though considerable research has been conducted on their habitat effects. Also excluded were studies done on the effects of other gear types used strictly in inshore state waters in habitats where sea scallops are not found (e.g., escalator dredges in submerged aquatic vegetation) and any research relating to fixed and pelagic gear effects.

Vulnerability of Benthic EFH to Bottom-Tending Fishing Gears and Adverse Impacts Determinations

To evaluate the vulnerability of benthic EFH to bottom-tending fishing gears, information used included: 1) the EFH designations adopted by the NEFMC and MAFMC; 2) the results of a fishing gear effects workshop convened in Fall 2001 (NEREFHSC 2002); 3) an evaluation of the information provided in this gear effects evaluation section of this document, including the effects of fishing gear on habitat from existing scientific studies, and the geographic distribution of fishing gear use in the Northeast Region; and 4) the habitats utilized by each species and life stage as indicated in their EFH designation and supplemented by other references. A matrix (was developed for each benthic life stage for each species to determine the vulnerability of its EFH to effects from bottom tending mobile gear. Six criteria were qualitatively evaluated for each life stage based upon existing information. Each evaluation consisted of a score based upon a predefined threshold. The methods used to rank vulnerability were subject to a peer review by the NMFS Northeast Fisheries Science Center's review process for publications. The thresholds for adverse impact determinations were developed and reviewed by the Council's Essential Fish Habitat Technical Team. The adverse impact determinations are based on conclusions in the Gear Effects Evaluation in section 09.3.1.2 and is substantiated by two recent reports. The first of these (NREFHSC 2002) is the report of a workshop held in October 2001 that examined the habitat effects of gears used in the Northeast region on three substrate types (gravel, sand, and mud). The second report (Morgan and Chuenpagdee 2003) evaluated the effects of ten different commercial fishing gears on marine ecosystems in U.S. waters.

Evaluation of the potential adverse effects of groundfish fishing on EFH
From the vulnerability analysis, it was determined that the EFH of some species in the region may be adversely impacted from groundfish fishing. Thus, alternatives were developed in Amendment 13 to minimize, to the extent practicable, the adverse impacts of groundfish fishing on EFH. Many of the alternatives designed to minimize the adverse impacts of fishing on EFH include closed areas for EFH protection. These alternatives were evaluated using a strategy developed by the Essential Fish Habitat Technical Team of the New England Fishery Management Council. Using the best available science for the entire region, the habitats within the management area were described. More specifically, the amount of various sediment types, the aerial extent of EFH designations, and biomass indices for various species were analyzed using several sources of data and methods (See Appendix XI for a detailed description of the methods used in the habitat evaluation). All of the data were analyzed using GIS, a mapping program that enables data to be analyzed geographically.

The sediments inside each alternative were evaluated based on a digitized US Geological Survey map (Poppe et al, published in 1986 and 1989), which is the only source of sediment data available that includes the entire management area. The amount and percent coverage of bedrock, gravel, gravelly sand, sand, muddy sand, and mud bottoms in each area was described. The amount and percent coverage of EFH area in square nautical miles was calculated for species with EFH vulnerable to bottom tending gear. EFH area was calculated as the number of square nautical miles included in designated ten-minute squares of longitude and latitude, as defined in the EFH Omnibus Amendment (1998) and other sources. Lastly, the Habitat Technical Team identified several trophic guilds, species assemblages, and individual benthic species that are indicators of the ecosystem characteristics of each proposed habitat closed area. Biomass data were obtained from the 1995-2001 NMFS bottom trawl survey data. As illustrated in the document, there are limitations to each of these data sets and methods, however the Council has used the best available science to describe the affected environment and evaluate the potential habitat impacts from the various alternatives under consideration.

3. *To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.*

The proposed action manages each individual groundfish stock as a unit throughout its range. In general, management measures specifically designed for one stock are applied to the entire range of the stock. There are minor exceptions, such as when a trip limit is applied to an area slighlty different than the stock area to facilitate management and enforcement concerns. In addition, the groundfish complex as a whole is managed in close coordination. Many of the management measures are applied to all groundfish stocks, They are desinged and evaluated for their impact on the fishery as a whole.

4. *Conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be (A) fair and equitable to all such fishermen; (B) reasonably calculated to promote conservation; and (C) carried out in such a manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.*

The proposed management measures do not discriminate between residents of different states. They are applied equally to all permit holders, regardless of homeport or location. While the measures do not discriminate between permit holders, they do have different impacts on different participants. This is because of the differences in the distribution of fish and the varying stock levels in the complex. For example, the measures designed to rebuild GB cod have more impacts on fishermen who target that stock. Some of these impacts may be localized, as often communities near the stock may have developed small boat fisheries that target it. These distributive impacts are difficult to avoid given the requirement to rebuild overfished stocks. Even if the measures are designed to treat all permit holders the same, the fact that fish stocks are not distributed evenly, and that individual vessels may target specific stocks, means that distirbutive impacts cannot be avoided.

The proposed action does include some measures designed to mitigate these distributive impacts. The sector allocation and special access programs are specifically designed to foster ways to target healthy stocks to mitigate some of these distributional impacts. In addition, the use of Category B DAS may create similar opportunities in the future, though many of the details of this program have yet to be defined.

The proposed action does allocate fishing priviliges under Amendment 13 based on a permit's fishing history during the period fishing years 1996 through 2001. Active groundfish fishermen during this period receive a higher percentage of their DAS that can be used when the amendment is implemented. The proposed action in effect reduces currently active groundfish effort while preventing inactive effort from re-entering the fishery until stocks rebuild. In the extreme, a vessel that was did not actively fish for groundfish during this period will not be able to fish at all when the amendment is implemented, though as stocks rebuild there may be opportunities provided in the future. The impacts of this measure for each state are described in section 5.4.9.4.5. The impacts are roughly similar for vessels that are homported in Maine, Massachusetts, Rhode Island, and New Hampshire. These impacts are greater for for vessels homeported in Connecticut, New York, New Jersey, and other states. This proposal, however, is reasonably calculated to promote conservation. By reducing active fishing activity, fishing mortality on groundfish stocks will be reduces and stocks will rebuild more quickly. At the same time, by controlling the opportunty for effort that has not been used to target grouindfsh in recent years, the proposed action prevents the reintroduction of new fishing effort that could slow stock growth.

One specific allocation of resources contained in the proposed action will occur through the sector allocation proposal. Allocations to a voluntary self-selecting sector will be based on the recent fishing history of the sector participants. The proposed action includes a limit so that a voluntary sector cannot acquire an excessive share of the TAC for any stock.

5. *Conservation and management measures shall, where practicable consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.*

The proposed management program relies primarily on restrictions in time fishing – days-at-ea (DAS) – to control fishing mortality. While there are measures included that tend to reduce economic efficiency of vessels, they are generally required for sound management reasons. For example, restrictions on minimum mesh size reduce catches, but benefit the resource by targeting larger fish that have had an opportunity to spawn. Closed areas also reduce efficiency by preventing fishermen from fishing in high cath areas, but provide benefits to both habitat protection and spawning aggregatioins of fish. Some of the measures in this amendment will improve economic efficiency. The increase in th GOM cod trip limit will make each day more profitable, and the reduction in the number of seasonal closures in the Gulf of Maine will enable fishermen more opportunities to fish in an economic manner. Specific proposals that address economic concerns include the DAS leasing and DAS transfer provisiosn of the amendment. These measures allow for fishermen to consolidate DAS on fewer vessels, making each active fishing vessel more economically viable.

6. *Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.*

The measures allow for the use of different gear, vessel size, and fishing practices. While there are many restrictions included with respect to minimum mesh size, quantity of gear, closed areas, and fishing time, there are no restrictions preventing the use of a specific gear in an open area, and few restrictions on the deployment of that gear. The proposed action includes programs desgined to encourage innovation in fishing practices in order to target healthy stocks. These programs include the special access programs, sector allocation, and the use of Cateogry B DAS.

7. *Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.*

   The Council considered the costs and benefits of a range of alternatives to achieve the goals and objectives of this FMP. It considered the costs to the industry of taking no action relative to adopting a rebuilding program. The expected benefits are greater in the long-term if stocks are rebuilt, though it is clear there are significant short-term declines in revenue that can be expected.

   Some management alternatives were not selected in part because of concerns over the costs and burdens of administering the program. The area management proposal, recreational fishing permits, periodic review of closed areas and certified bycatch/exempted fisheries, requirement for a vessel monitoring system on all vessels, flexible area action system – these are all examples of management measures whose costs were deemed to outweigh the benefits expected.

   The management program does not duplicate other regulatory efforts. Management of multispecies in federal waters is not subject to coordinate regulatoin by any other management body. Absent Council action, a coordinated rebuilding effort would not occur to restore the health of the overfished stocks.

8. *Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse impacts on such communities.*

   Consistent with the requirements of the Magnuson-Stevens Act to prevent overfishing and rebuild overfished stocks, the proposed action will restrict fishing activity through the imposition of additional restrictions on fishing time, possession limits, and other measures. In addition, it adopts additional measures intended to minimize, to the extent practicable, the adverse effects of fishing on essential fish habitat. Analyses of the impacts of these measures show that landings and revenues are likely to decline for many participants in th early years of the rebuilding program. These declines will probably have negative impacts on fishing communities throughout the region, but particularly on those ports that rel heavily on groundfish.

   The action, however, includes measures that are intended to both provide for sustained participation and minimze the adverse impacts of the measures. The proposed action is based on a combination of a phased and adaptive rebuilding strategies.Economic analyses of this approach shows that in the short term the economic impacts are less than under other approaches that were considered. Over the long term, the economic benefits may not be as great. The reason for choosing this approach was concern that the the other alternatives were so draconian that they would eliminate many ports from the fishery and as a result these ports would not be able to benefit when stocks rebuild. Both the strategy and the measures adopted are intended to provide for a higher level of sustained participation so that these ports will still be involved in the fishery when stocks rebuild.

   Other measures are included that are designed to foster continued participation. As previously discussed, the sector allocation, special access program, and Category B DAS programs are designed to provide avenues for fishermen to continue to participate while stocks rebuild. The proposed action reduces the number of seasonal closed areas in the Gulf of Maine (compared to FY 2001), reducing the periods when small boat fishermen from some ports are excluded from access to the fisheries.

9. *Conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.*

   The proposed action includes a number of measures that are designed to minimize bycatch. These are described in detail in section 5.2.8.

10. *Conservation and management measures shall, to the extent practicable, promote safety of human life at sea.*

   The primary control on fishing mortality use in this plan is limiations on the number of DAS that vessels can fish. These DAS can be used at any time, subject to limitations imposed by closed areas. Reductions in DAS could affect vessel safety if vessels are unable to remain economically viable. Comments received suggested that vessel maintenance and safety equipment are often two major costs that are trimmed when vessel revenues decline. In the early years of the rebuilding program, vessel revenues are expected to decline for many vessels under the proposed action. If operators are unable to afford maintenance or safety equipment, there could be an increased number of accidents. While reduced fishing time means that vessels are on the water for less time and subject to fewer hazards, it is not clear that this will compensate for the lack of spending on safety and maintenance equipement. Reduced time fishing could also lead to less experience for crew and vessel captains, which could adversely affect safety.

   The proposed action, however, does include some measures that may help mitigate these problems. Both DAS leasing and the DAS transfer provision will help some vessels obtain more DAS so that they can remain profitable. Indeed, public comments received highlighted that some owners who currently operate two vessels will be able to combine DAS on one vessel, saving some maintenance costs and enabling them to operate more safely. While DAS are being reduced, for some areas the action includes some measures to make each DAS more profitable. The GOM cod trip limit is raised to 800 pounds, for example. The proposed action also reduces the number of seasonal closed areas in the Gulf of Maine by two months, creating more opportunities for fishermen to choose to fish.

7.1.2 Other M-SFCMA requirements

Section 303 (a) of FCMA contains 14 required provisions for FMPs. These are discussed below. Any fishery management plan that is prepared by any Council, or by the Secretary, with respect to any fishery, shall—

(1) contain the conservation and management measures, applicable to foreign fishing and fishing by vessels of the United States, which are-- (A) necessary and appropriate for the conservation and management of the fishery to prevent overfishing and rebuild overfished stocks, and to protect, restore, and promote the long-term health and stability of the fishery; (B) described in this subsection or subsection (b), or both; and (C) consistent with the national standards, the other provisions of this Act, regulations implementing recommendations by international organizations in which the United States participates (including but not limited to closed areas, quotas, and size limits), and any other applicable law;

Optimum yield from this fishery is harvested entirely by U.S. vessels. There is no opportunity and no provisions for foreign fishing in this management plan.

(2) contain a description of the fishery, including, but not limited to, the number of vessels involved, the type and quantity of fishing gear used, the species of fish involved and their location, the cost likely to be incurred in management, actual and potential revenues from the fishery, any recreational interest in the fishery, and the nature and extent of foreign fishing and Indian treaty fishing rights, if any;

An updated desription of the fishery is included in the Affected Human Environment section of the document, section 9.4.

(3) assess and specify the present and probable future condition of, and the maximum sustainable yield and optimum yield from, the fishery, and include a summary of the information utilized in making such specification;

Maximum sustainable yield is described in section 3.1.5, with a short explanation of the source of this estimate. Optimum yield continues to be defined as in Amendment 9 (see section 3.1.4). The condition of the fishery, including a summary of changes in stock status, is included in section 9.2.1.1, while information on landings and revenues form the fishery is in section 9.4. Probable future stock conditions are estimated in section 5.2.1.1. The future economic condition of the fishery is described in section 5.4.

(4) assess and specify-- (A) the capacity and the extent to which fishing vessels of the United States, on an annual basis, will harvest the optimum yield specified under paragraph (3), (B) the portion of such optimum yield which, on an annual basis, will not be harvested by fishing vessels of the United States and can be made available for foreign fishing, and (C) the capacity and extent to which United States fish processors, on an annual basis, will process that portion of such optimum yield that will be harvested by fishing vessels of the United States;

Fishing vessels of the U.S. will harvest the optimum yield from th fishery and none will be available to foreign fishing.

(5) specify the pertinent data which shall be submitted to the Secretary with respect to commercial, recreational, and charter fishing in the fishery, including, but not limited to, information regarding the type and quantity of fishing gear used, catch by species in numbers of fish or weight thereof, areas in which fishing was engaged in, time of fishing, number of hauls, and the estimated processing capacity of, and the actual processing capacity utilized by, United States fish processors;

Reporting requirements are defined in section 3.4.14.

(6) consider and provide for temporary adjustments, after consultation with the Coast Guard and persons utilizing the fishery, regarding access to the fishery for vessels otherwise prevented from harvesting because of weather or other ocean conditions affecting the safe conduct of the fishery; except that the adjustment shall not adversely affect conservation efforts in other fisheries or discriminate among participants in the affected fishery;

The proposed action continues to allow the carry-over of a small number of DAS from one fishing year to the next. If a fisherman is unable to fish because of weather or other ocean conditions, this measure allows his available fishing time to be used in the next fishing year. This practice does not require a consultation with the Coast Guard.

(7) describe and identify essential fish habitat for the fishery based on the guidelines established by the Secretary under section 305(b)(1)(A), minimize to the extent practicable adverse effects on such habitat caused by fishing, and identify other actions to encourage the conservation and enhancement of such habitat;

Essential fish habitat was defined in an earlier action. This amendment does not change those definitions.

(8) in the case of a fishery management plan that, after January 1, 1991, is submitted to the Secretary for review under section 304(a) (including any plan for which an amendment is submitted to the Secretary for such review) or is prepared by the Secretary, assess and specify the nature and extent of scientific data which is needed for effective implementation of the plan;

Additional research needs are specified in sections and 6.0 and 9.3.4.

(9) include a fishery impact statement for the plan or amendment (in the case of a plan or amendment thereto submitted to or prepared by the Secretary after October 1, 1990) which shall assess, specify, and describe the likely effects, if any, of the conservation and management measures on--(A) participants in the fisheries and fishing communities affected by the plan or amendment; and (B) participants in the fisheries conducted in adjacent areas under the authority of another Council, after consultation with such Council and representatives of those participants;

Fishery impacts are described in several sections. Economic impacts of the proposed measures to minimize the adverse impacts of fishing on essential fish habitat (to the extent practicable) are described in section 5.4.8. Other economic impacts, including the economic impacts of the meaures to achieve rebuilding requirements, are described in section 5.4. These impacts are described based on numerous categories, including homeport state and major groundfihs ports. Impacts of this action on other fisheries are described in section 5.4.13. Finally, section 5.6 analyzes the expected social impacts on a community/port level.

(10) specify objective and measurable criteria for identifying when the fishery to which the plan applies is overfished (with an analysis of how the criteria were determined and the relationship of the criteria to the reproductive potential of stocks of fish in that fishery) and, in the case of a fishery which the Council or the Secretary has determined is approaching an overfished condition or is overfished, contain conservation and management measures to prevent overfishing or end overfishing and rebuild the fishery;

The proposed action revises the criteria for identifying when a fishery is overfished. These revised criteria are described in section 3.1. By reference, the analysis of the criteria and the relationship to reproductive potential of a stock is detailed in NEFSC 2002a. The proposed action includes management measures (section 3.6) to end overfishing and rebuild overfished stocks identified in sections 3.2.1 and 3.2.3.1.3.

(11) establish a standardized reporting methodology to assess the amount and type of bycatch occurring in the fishery, and include conservation and management measures that, to the extent practicable and in the following priority--

(A) minimize bycatch; and

(B) minimize the mortality of bycatch which cannot be avoided;

Standardized reporting methodologies have been defined in previous actions for this management plan. They are modified by the proposed measures in section 3.4.14.2. In addition, the management plan includes guidance for an acceptable level of observer coverage (section 3.4.10) to supplement required vessel bycatch reporting. Conservation and management measures that, to the extent practicable, minimize bycatch and bycatch mortality are described in section 5.2.8.

(12) assess the type and amount of fish caught and released alive during recreational fishing under catch and release fishery management programs and the mortality of such fish, and include conservation and management measures that, to the extent practicable, minimize mortality and ensure the extended survival of such fish;

This management plan does not include any catch and release recreational management measures.

(13) include a description of the commercial, recreational, and charter fishing sectors which participate in the fishery and, to the extent practicable, quantify trends in landings of the managed fishery resource by the commercial, recreational, and charter fishing sectors; and

Descriptions of the commercial, recreational, and charter fishing sectors which participate in the fishery, including trends in landings by these sectors, are in section 9.4.

(14) to the extent that rebuilding plans or other conservation and management measures which reduce the overall harvest in a fishery are necessary, allocate any harvest restrictions or recovery benefits fairly and equitably among the commercial, recreational, and charter fishing sectors in the fishery.

Proposed management meaures restrict harvest levels for all sectors of the fishery. Recovery benefits have been allocated equitably, most notably with respect to haddck: commercial trip limits have been relaxed, and the proposed action removes the haddock bag limit for recreational vessels.

(15) The EFH Provisions of the SFA (50 CFR Part 600.815) require the inclusion of the following components of FMPs. The Council has fully met these obligations as detailed below each mandatory component.

(A) Identify and description of EFH
(B) Fishing activities that adversely affect EFH
  (i) Evaluation of potential adverse effects
  (ii) Minimizing adverse effects
(C) Identification of non-Magnuson-Stevens Act fishing activities that may adversely affect EFH
(D) Identification of non-fishing related activities that may adversely effect EFH.
(E) Cumulative impacts analysis
(F) Identification of conservation and enhancement actions.
(G) List the major prey species and discussion the location of the prey species' habitat
(H) Identification of habitat areas of particular concern
(I) Recommendations for research and information needs
(J) Review and revision of EFH components of FMPs.

(A) Identify and description of EFH
EFH for the management unit of the Northeast Multispecies FMP has been identified and described in Amendment 10. The Council plans to update these EFH designations through an omnibus amendment that will be initiated in early 2004 and will become Amendment 11 to the Northeast Multispecies FMP.

(B) Fishing activities that adversely affect EFH

(i) Evaluation of potential adverse effects

The EFH Final Rule (50 CFR Part 600) provides guidance to the Regional Fishery Management Councils for identifying fishing activities that adversely impact essential fish habitat (EFH). In addition to the EFH Final Rule, guidance provided by the Habitat Conservation Division (HCD) headquarters office in the form of a memo dated October 2002 was followed in the preparation of this section of Amendment 13. This evaluation should primarily include the impacts of activities associated with the fishery that is the subject of the management action, as well as other federally-managed and state-managed fishing activities. Based on the guidance provided by the EFH Final Rule and the HCD office, this determination focuses on the effects of fishing activities in the New England multi-species fishery on groundfish EFH. It also includes information on the effects of other federally-managed fishing activities on groundfish EFH, and identifies gears used in state-managed fisheries that could affect groundfish EFH. Most of the information needed to complete this determination is provided in more detail in previous sub-sections of Section 9.3.1.

Section 9.3.1.2 describes commercial fishing gears used in the Northeast region of the U.S. and the geographic distribution and use of the principal bottom-tending gears in three broadly-defined habitat types. It also evaluates the effects of bottom trawls and dredges on benthic marine habitats in the region. Most of this information is derived from the NMFS, NEFMC and MAFMC-sponsored Gear Effects Workshop that evaluated the effects of fishing gears used in the Northeast region on mud, sand, and gravel habitats (NREFHSC 2002) and from an extensive review of relevant gear effects studies (Stevenson et al. 2003). Additional sources of information include work done by the NEFMC Habitat Technical Team and NEFMC and NMFS staff, and a National Research Council report on the Effects of Trawling and Dredging on Seafloor Habitat (NRC 2002). The information in this section serves as the basis for evaluating which gear types, if any, are most likely to have an adverse impact on essential fish habitat for federally-managed species in the NE region.

Section 9.3.1.3 evaluates the vulnerability of all 37 federally-managed species' to gear types found to have potential adverse impacts on EFH. Vulnerability was evaluated according to four broad categories: none (0); low (L); moderate (M); and high (H), based upon a matrix analysis of habitat function, habitat sensitivity and gear use. Results are summarized by species and life stage.

Specifically, species and life stages were ranked according to the vulnerability of their EFH to the effects of mobile, bottom-tending gear. EFH for those ranked as moderately or highly vulnerable were included in this adverse impacts evaluation. For this determination, fishing activities are interpreted to mean fishing gears, since there is not enough information available to support a more detailed determination based on different fishing practices used with each gear type. Adverse impacts associated with each gear type are assessed for specific habitat types that make up groundfish EFH. Only benthic habitats are considered, since the gears used to catch groundfish are bottom-tending gears. Habitat type is based on type of substrate, and, to some extent, depth and degree of exposure to natural disturbance. These simplifications were made in order to allow maximum use of the information available and to provide an evaluation that encompasses as broad a range of the relevant fisheries and affected habitats as possible.

EFH for those ranked as moderately or highly vulnerable were included in this adverse impacts evaluation. For the purposes of this action, EFH vulnerability that is ranked as low is considered to have a potential adverse effect to EFH that is minimal and temporary in nature. Therefore, the Council will eliminate from further consideration any EFH that has a low vulnerability to scallop dredges, otter trawls and clam dredges. Refer to 9.3.1.6 for a detailed look at the vulnerability rankings based on shelter, food, reproduction, habitat sensitivity, habitat rank, gear distribution and gear rank. Background on how vulnerability was determined in this exercise is useful for understanding how EFH could be adversely affected as a result of fishing with different gear types. Vulnerability was divided into four broad categories, including: none (0); low (L); moderate (M); and high (H), based upon a matrix analysis of habitat function, habitat sensitivity and gear use. Several criteria were qualitatively evaluated for each life stage based upon existing information. Each evaluation consisted of a score based upon a predefined threshold. The criteria used and the key describing what each ranking stands for is described in 9.3.1.6. Depth range and substrates that are included in the EFH designations for those species that have been determined to be adversely impacted indicate that, as a group, they occupy a wide range of depths and bottom types.

Section 9.3.1.8 summarizes the results and findings of this section, identifying the potential adverse impacts of the three principal mobile, bottom-tending gears on three principal bottom types in the region. These results serve as the basis for analyzing proposed alternatives to minimize the adverse impacts of these gears on EFH.

(ii) Minimizing adverse effects

The EFH Final Rule also stipulates that "each FMP must minimize to the extent practicable the adverse effects of fishing on EFH that is designated under other federal FMPs". Federally-managed species that could be affected by the New England groundfish fishery are listed in 9.3.1.7. In order to minimize and mitigate the adverse effects of the fishery on EFH the Council will implement Habitat Alternative 2 (Benefits of other Amendment 13 alternatives), Alternative 7 (Expand the list of gears prohibited in year-round closed areas to include clam dredges), and Alternative 10b (Compromise Habitat Closure Areas). Habitat Alternative 10b will prohibit bottom-tending mobile gear, with the exception of shrimp trawls from the Western Gulf of Maine Closed Area, from fishing in vulnerable areas containing the above benthic habitat types. Alternative 7 will prohibit clam dredges from accessing groundfish closed. Additionally, Alternatives 2 will be implemented to further mitigate the adverse effects of the fishery on EFH. The proposed action is further described in Section 3.7 and the environmental consequences and practicability analysis of these alternatives can be found in Section 5.3.8, 5.3.9 and 5.3.10. The Council has determined that the combination of these gear restrictions, effort reductions and area closures minimizes, to the extent practicable, the adverse effects of fishing on EFH. This includes the adverse effects of the groundfish fishery on all federally-designated EFH as well as the adverse effects of other federally-managed fisheries on groundfish EFH.

(C) Identification of non-Magnuson-Stevens Act fishing activities that may adversely affect EFH
Section 9.3.1.9 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(D) Identification of non-fishing related activities that may adversely effect EFH.
Section 9.3.1.10 addresses the requirements of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(E) Cumulative impacts analysis
Section 5.7.7.4 addresses the requirement of this component.

(F) Identification of conservation and enhancement actions.
Section 9.3.2 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(G) List the major prey species and discussion the location of the prey species' habitat
Section 9.3.3 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(H) Identification of habitat areas of particular concern
Section 9.3.5 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(I) Recommendations for research and information needs
Section 9.3.4 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

(J) Review and revision of EFH components of FMPs.
Section 9.3.6 addresses the requirement of this component. This section will be thoroughly updated in the upcoming omnibus habitat amendment (to be Amendment 14 to the NE Multispecies FMP).

7.2 National Environmental Policy Act (NEPA)

7.2.1 Executive Summary

See page I-iii.

7.2.2 Background and Purpose

The background and purpose for this action, including a statement of the problem , purpose and need for action, and goals and objectives are in Section 2.0. The problem and need for action were initially defined during the Council's scoping process. A summary of this process and the comments received during that time follows.

During the spring of 1999 the Council initiated a scoping process to solicit suggestions and information on the range of issues that should be addressed and alternatives that should be considered in Amendment 13. A list of issues were generated through scoping and additional meetings of the groundfish committee and advisory panel. These are summarized below.

Multispecies Stock Rebuilding

- The multispecies FMP must address the SFA requirement for maximum ten-year rebuilding schedules for all groundfish stocks.
- The fishery management cycle is not coordinated well with stock assessment cycle.
- Management measures to rebuild weaker stocks in a geographical region often preclude fishing for stronger stocks, resulting in more significant economic dislocation for the fleet as a whole.

Fishing Effort and Capacity

Latent effort

- With the current number of active vessels, allocated DAS cannot be increased without jeopardizing stock rebuilding.
- Only about 1/3 of the allocated multispecies DAS were used during the 1998 fishing year. Unused allocations could be re-activated, countering rebuilding efforts whenever catch rates increase. This demonstrates the challenge of matching groundfish fleet capacity to sustainable harvest capacity.

Days At Sea (DAS) effort reduction program

- DAS are not being used as the primary management tool to reduce fishing effort in the multispecies fishery because of very strong resistance to reducing DAS below current levels.

Inequities associated with DAS allocations and DAS usage

- Dayboats can make more than one trip per 24-hour DAS.
- "Catchability" (catch rates) of gear is difficult to coordinate with fishing effort/DAS allocations between gear sectors (For example, DAS are not counted for gillnet soak time.)

DAS "running clock"

- Both "frontloading" (beginning the DAS clock before leaving the dock) and running the clock after landing an overage decrease the ability to estimate true fishing effort through DAS usage.
- The "running clock" renders trip limits virtually unenforceable.

Allocation and Equity Issues

- Equal application of a regulation often results in unequal distribution of impacts on different fleet sectors.
- Conversely, application of different regulations to various fleet sectors is often perceived as an unfair allocation of fishing privileges.
- Management measures are often tied to specific gear sectors, yet there are no harvest allocations for any gear sectors.
- There is a significant perception of inequity due to exemptions/exceptions made for recreational vessels regarding trip limits and closed areas.

Closed Area Management

- It is very difficult to spread the conservation burden evenly across fleet sectors using area closures as a management tool.
- It is difficult to make closed areas less polarizing and less economically disruptive.
- Problems minimizing socio-economic impacts on communities are most directly affected by area closures

- Closed areas force vessels to concentrate their effort and fish less efficiently in remaining open areas, intensifying competition and increasing gear conflicts.
- Short-term area closures may not achieve intended results as areas open and effort re-enters the area.
- It is difficult to identify appropriate exemptions within the closed areas to minimize negative impacts on other fisheries.

Trip Limits

- When used as a primary mortality reduction tool (as they have been), they often result in significant discards and do not reduce fishing mortality as intended.
- Species-specific trip limits in a multispecies fishery often result in discarding of that species above the trip limit as vessels continue to fish for other multispecies.
- It is difficult to design a trip limit that adequately constrains both small and large vessels without inequitably affecting one or the other.
- “Backstops” often create incentive for derby-style fishing.
- In general, trip limits are very difficult to enforce.

Experimental and Exempted Fisheries

- Experimental and exempted fisheries are required to demonstrate that 5% or less of their catch is composed of non-target species. This five percent standard will become increasingly difficult to meet as groundfish stocks recover and may preclude several fisheries, offering few alternatives to fishing for multispecies even though regulated species bycatch may not be as important a concern as the stocks rebuild.
- The process for obtaining an exempted experimental fishing permit difficult and time-consuming.
- The challenges of this process provide no mechanism for encouraging conservation engineering.

Fishing Gear and Selectivity

- The multispecies FMP does not provide incentives for fishermen to use more selective, less destructive fishing gear (except for large-mesh exemptions).
- No mechanism exists in the multispecies plan for improving accountability for discarded bycatch.
- It is difficult to match minimum fish sizes with the appropriate minimum mesh size.
- There is a lack of adequate mesh/gear selectivity information for all multispecies stocks/fisheries.

7.2.3 Summary of the SEIS

Refer to Executive Summary, page I-iii.

7.2.4 Description of the Proposed Management Measures

The management measures under consideration are described in section 3.0. Descriptions of the measures not selected are in section 4.0.

7.2.5 Description of the Affected Environment

The Affected Environment is described in Volume II.

7.2.6 Impacts of the Management Measures Under Consideration

The impacts of the alternatives under consideration are described in section 5.0.

7.2.7 Cumulative Impacts of the Proposed Action

The National Environmental Policy Act (NEPA) requires that cumulative effects of “past, present, and reasonably foreseeable future actions” (40 CFR § 1508.7) be evaluated along with the direct effects and indirect effects of each proposed alternative. Cumulative impacts result from the combined effect of the proposed action's impacts and the impacts of other past, present, and reasonably foreseeable future actions. These impacts can result from individually minor but collectively significant actions taking place over a period of time. The Council on Environmental Quality (CEQ) directs federal agencies to determine the significance of cumulative effects by comparing likely changes to the environmental baseline. On a more practical note, the CEQ (1997) states that the range of alternatives considered must include the "no-action alternative as a baseline against which to evaluate cumulative effects." Therefore, the analyses in this document, referenced in the following cumulative impacts discussion, compare the likely effects of the proposed actions to the effects of the no-action alternative.

Cumulative effects are evaluated in section 5.7.

7.2.8 Determination of Significance

Section 6.02 of the NOAA Administrative Order 216-6, Environmental Review Procedures for Implementing the National Environmental Policy Act, provides specific guidance on determining the significance of fishery management actions. The nine criteria to be addressed are as follows:

1. May the proposed action be reasonably expected to jeopardize the sustainability of any target species that may be affected by the action?
2. May the proposed action be reasonably expected to jeopardize the sustainability of any non-target species?
3. May the proposed action be reasonably expected to cause substantial damage to the ocean and coastal habitats and/or essential fish habitat as defined under the Magnuson-Stevens Act and identified in FMPs?
4. May the proposed action be reasonably expected to have a substantial adverse impact on public health or safety?
5. May the proposed action be reasonably expected to adversely affect endangered or threatened species, marine mammals, or critical habitats of these species?
6. May the proposed action be reasonably expected to result in cumulative adverse effects that could have a substantial effect on the target species or non-target species?
7. May the proposed action be reasonably expected to have a substantial impact on biodiversity and ecosystem function within the affected area?
8. Are significant social or economic impacts interrelated with significant natural or physical environmental effects?
9. What is the degree to which the effects on the quality of the human environment are likely to be highly controversial?

The Council has reviewed the nine criteria relative to the action proposed in Amendment 13 to the Multispecies FMP. Based on these criteria the Council has determined that the proposed action represents a significant action and has prepared an EIS in accordance with the National Environmental Policy Act.

7.2.9 Response to Comments

Approximately 5,000 written comments were received during the comment period. Responses to comments are in Appendix XVII.

7.2.10 Rationale for the Proposed Action

Because of current stock status and the requirements of the Magnuson-Stevens Act, additional management measures are needed for the multispecies fishery to end overfishing and rebuild overfished stocks. These measures must comply with the specific requirements of the M-S Act as well as other applicable law. The Council believes the proposed management action is the appropriate way to meet these requirements. In order end to overfishing and rebuild overfished stocks, this amendment proposes extensive restrictions on the commercial and recreational fishing industries. For the commercial industry, the measures rely almost entirely on the use of effort controls to reduce fishing mortality. Effort controls – restrictions on the number of days that can be fished, requirements to use specific gear, closed areas, etc. – have proven successful in managing this fishery in the recent past. Fishing mortality has been reduced on a number of stocks in the multispecies fishery, and overall stock status has improved (see section 9.2.1.1 for specific details). In 1996, seventeen stocks were overfished; in 2002, only ten stocks are overfished, and five of those are projected to leave that status in the near future. Clearly recent experience shows that the use of effort controls can achieve reductions in fishing mortality if correctly designed and applied. These accomplishments are even greater if measures against the standards that guided previous management decisions rather than the recently updated esimates of target stock size. At the same time, however, it is clear that the application of these effort controls has not succeeded in meeting the stringent requirements of the M-S Act to end overfishing and rebuild overfished stocks. While many groundfish stocks are growing, there are still eight stocks subject to overfishing and roughly half the stocks are in an overfished status (many are expected to grow out of the overfished status in short order). Rather than abandon the use of effort controls, the Council has chosen a management program which will make them more stringent in order to address these problematic stocks.

The Council did consider three management alternatives that were based, at least in part, on quota or "hard" total allowable catches (TACs). These alternatives were not selected for a variety of reasons. A common element, however, is a hesitancy to replace a successful management program – effort controls - with a system that was tried in the early 1980's and failed miserably by both biological and economic measures. The application of a hard TAC in the multispecies fishery, with stocks that have overlapping geographic ranges, proved impossible to administer and enforce. Preliminary attempts to craft a hard TAC program based on directed and incidental fisheries proved impossible given the mix of species, gear, and seasons used to prosecute the groundfish fishery in New England. Experience in other regions has been similar when there has been a "global" quota – that is, one that is not allocated to individual vessels. Market disruption often occurs, as vessesl participate in a race to fish in order to harvest their share of the resource before the full quota is caught.

The use of effort controls, however, is not without problems. Effort controls tend to be blunt instruments, reducing mortality on both healthy and ailing stocks at the same time. Yield is sacrificed from healthy stocks in order to reduce mortality on stocks in poor condition. Reductions in days-at-sea, the primary control, reduce opportunities to fish on healthy stocks. For this reason, the proposed commerial fishery measures identify specific opportunities that can be used to target those healthy stocks. While some of the details of these programs remain to be specified, this proposal will both help mitigate the economic impacts of the proposed action and help realize the benefits of stocks that are rebuilding.

While over the long-term the expected benefits of the rebuilding program are positive, in the short-term harvesters are likely to experience reduced revenues. In addition to the opportunities that may be available to target healthy stocks, the proposed action includes measures to help the industry adapt to these short-term reductions and remain economically viable. By allowing vessels to lease fishing time, vessels that do not have enough time to fish can either lease their limited days to other vessels – earning revenues at reduced cost – or they can lease days from other vessels to make up for the shortfall. Either choice wil help improve the profitability of the fishery. Another program allows a vessel leaving all fisheries to transfer fishing time to another permit, subject to a conservation "tax" on fishing time so that the overall pool of allocated time is reduced.

The use of effort controls has also been complicated by the allocation of excessive effort to the industry as a whole. In recent years, the amount of time spent fishing has increased, but still was only a fraction of the allocated days available. In this action the Council has chosen to reduce the pool of allocated days that can be used by basing allocations on recent fishing history. This choice is controversial, but is intended to help current participants remain economically viable during rebuildng by limiting the amount of effort that can re-enter the fishery.

Other opportunities have been created to ensure a viable fishing industry. The proposed action will allow the formation of volunatry, self-selecting sectors. These sectors may be able to develop more efficient means to harvest their portion of the resource. Permit provisiosn for hand-gear permits have also been revised so that this small group of fishermen remain economically viable and continue to participate in the fishery.

While much of this discussion focuses on the need to end overfishing and rebuild overfished stocks, the proposed action also addresses other M-S Act requirements. The Council has selected alternatives that will minimize, to the extent practicable, the adverse effects of fishing on essential fish habitat. The selection of these alternatives is complicated by the nascent state of knowledge of the sea floor and the impacts fishing gear on habitat and fisheries production. The Council has carefully balanced these concerns and chosen alternatives that minimize the adverse effects of fishing while providing opportunties for the fishery to remain viable.

7.2.11 List of Preparers

Doug Beach, NEFMC Contractor
Anne Beaudreau, NEFMC Staff
Deirdre Boelke, NEFMC Staff
Dr. Jon Brodziak, NMFS NEFSC
Lou Chiarella, NMFS NERO
Woneta Cloutier, NEFMC Staff

This Amendment and SEIS were prepared without any federal/state/local cooperating agencies as defined by 40 CFR 1501.6. Federal agencies represented on the New England Fishery Management Council include the U.S. Coast Guard and the U.S. Fish and Wildlife Service. State agencies represented on the Council include the fisheries management divisions of the states of Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut.

7.2.12 List of Persons Receiving Copies of the DSEIS

The Council distributes the Draft FMP/DSEIS to members of the Groundfish PDT and the Groundfish Advisory Panel, and the Recreational Advisory Panel. These individuals include:

Tom Nies, Lori Steele, Leslie-Ann McGee, Anne Beaudreau, Deirdre Valentine, Chad Demarest, NEFMC Staff
Thomas Warren and Susan Murphy, NMFS Northeast Regional Office
Jon Brodziak, NEFSC (Population Dynamics)
Phil Logan, Eric Thunberg, John Walden, and Lisa Colburn, NEFSC Social Sciences
Steve Correia, Massachusetts Division of Marine Fisheries
Kevin Kelly, Maine Department of Marine Resources
Vincent Balzano, Saco, ME
Carl Bouchard; Exeter, NH
Joseph Branin, Highlands, NJ
Sima Freierman, Montauk, NY
Randy Gauron, Hampton, NH
Willam Gerencer, Bowdoin, ME
David Marciano, Beverly, MA
Frank Mirarchi, Scituate, MA
Paul Parker, No. Chatham, MA
Geoffrey Smith, South Portland, ME
Bud Brown, Georgetown, ME
Charles Cassels, Georgetown MA
Frederick Christian, Salem, MA
Bradley Cook, Hampton, NH
Philip Desfosses, Portsmouth, NH
Anthony Dilernia, Fresh Meadows, NY
Barry Gibson, Beverly, MA
Joseph Grady, Hampton Falls, NH
John Groff, Hartford, CT
Alan Hill, Manchester, MA
Bruce Munson, Beverly, MA
Edward Mowak, Needham, MA
Michael Sosik, Jr. Sturbridge, MA
Donald Swanson, Derry, NH
James Velleca, Cranston, RI

As part of the review process for consistency with applicable laws such as the CZMA and the ESA, the Council distributes this Draft FMP/DSEIS to the following individuals:

Ms. Kathleen Leydon, Maine Coastal Program
Mr. David Hartman, New Hampshire Coastal Program
Mr. Tom Skinner, Massachusetts Coastal Zone Management
Mr. Grover Fugate, Rhode Island Coastal Resources Council
Mr. Tom Oullette, Connecticut Office of Long Island Sound Programs
Mr. George Stafford, New York Division of Coastal Resources
Mr. Lawrence Torok, New Jersey Division of Coastal Resources

Mr. Nicholas Di Pasquale, Delaware DNREC
Ms. Gwynne Schultz, Maryland Coastal Zone Management Division
Ms. Laura McKay, Virginia Coastal Resources Management Program
Ms. Donna Moffitt, North Carolina Division of Coastal Management
Mr. E. James Tabor, Pennsylvania Department of Environmental Protection
Mr. Chris Brooks, South Carolina Ocean and Coastal Resources Management
Mr. Daniel Furlong, Mid-Atlantic Fishery Management Council
Mr. Robert Mahood, South Atlantic Fishery Management Council
Captain Vincent O'Shea, Atlantic States Marine Fisheries Commission

In addition, the Council prepares a notice to its "Interested Party" list for groundfish that announces the availability of the DSEIS and public hearing document and announces the schedule for public hearings. A Notice of Availability of the DSEIS is also published in the *Federal Register.* At that time, anyone on the "Interested Party" list or any other member of the public may call the Council office and request a copy of the DSEIS for their review. There are approximately 830 individuals on the "Interested Party" mailing list for groundfish. The Council also intends to make this Draft FMP/DSEIS available for downloading through its website (www.nefmc.org).

7.2.13 Index

The index can be found at the end of Volume I, section 8.5.

7.3 Other Existing Applicable Laws

7.3.1 Fishery Management Plans

There are many FMPs implemented in the U.S. EEZ within the same general geographic area as the management area for the Groundfish FMP. The following list identifies all known approved FMPs developed for the U.S. EEZ along the Atlantic Coast:

New England Council:	Atlantic Herring FMP; Atlantic Salmon FMP; Monkfish FMP; Northeast Multispecies FMP; Sea Scallop FMP; Red Crab FMP; Northeast Skate Complex FMP.
Mid-Atlantic Council:	Atlantic Mackerel, Squid and Butterfish FMP; Bluefish FMP; Dogfish FMP; Summer Flounder, Scup and Black Sea Bass FMP; Surfclam and Ocean Quahog FMP; Tilefish FMP.
South Atlantic Council:	Atlantic Coast Red Drum FMP; Coastal Migratory Pelagics FMP; Coral, Coral Reef and Live/Hard Bottom Habitats FMP; Golden Crab FMP; Shrimp FMP; Snapper Grouper FMP; Spiny Lobster FMP.
Secretarial Plans (NMFS):	American Lobster FMP; Atlantic Billfish FMP; Atlantic Tunas, Swordfish and Sharks FMP.

7.3.2 Treaties and International Agreements

Foreign fishing is prohibited within the U.S. EEZ for anadromous species and continental shelf fishery resources beyond the EEZ out to the limit of U.S. jurisdiction under the Convention of the Continental Shelf, unless authorized by an international agreement existing prior to passage of the Magnuson-Stevens Act and still in force or authorized by a Governing International Fishery Agreement issued subsequent to the Magnuson-Stevens Act. There are no pre- or post-Magnuson-Stevens Act agreements affecting the Northeast Multispecies Complex.

7.3.3 Federal Laws and Policies

All applicable Federal laws and policies, including the Endangered Species Act (ESA) and the Marine Mammal Protection Act (MMPA) are identified and discussed in this section. The National Environmental Policy Act (NEPA) is discussed in Section 7.2.

7.3.3.1 Administrative Procedures Act

Sections 551-553 of the Federal Administrative Procedures Act establish procedural requirements applicable to informal rulemaking by federal agencies. The purpose is to ensure public access to the federal rulemaking process, and to give the public notice and an opportunity to comment before the agency promulgates new regulations.

The APA requires solicitation and review of public comments on actions taken in the development of a fishery management plan and subsequent amendments and framework adjustments. Development of this amendment provided many opportunities for public review, input, and access to the rulemaking process. During its scoping period the Council requested suggestions and information from the public on the range of issues that should be addressed and alternatives that should be considered in Amendment 13. Comments received during scoping are summarized in Section 7.2.2. Public comments were also received during the public comment period, in both written form and at a series of public hearings. See Section 8.4 for a list of public meetings at which proposed measures in Amendment 13 to the Northeast Multispecies FMP were discussed.

7.3.3.2 Coastal Zone Management Act

The Council has reviewed the coastal zone management programs for states whose coastal waters are within the range of areas affected by the proposed actions, including: Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware and Maryland. It has determined that the proposed action is consistent with the CZM programs of those states and will send a notification of this determination, along with a copy of the amendment document, for their concurrence. Copies of the correspondence are on file at the Council office.

State Contacts

For a list of individuals contacted regarding the CZMA consistency determination for Amendment 13 to the Northeast Multispecies FMP, see Section 7.2.12.

7.3.3.3 Endangered Species Act

Section 7 of the Endangered Species Act requires federal agencies conducting, authorizing, or funding activities that may affect threatened or endangered species to ensure that those impacts do not jeopardize the continued existence of listed species. A discussion of the potential impacts of Amendment 13 is found in Section 5.2.11 of this document. The discussion concludes that the Amendment 13 measures will result in significant reductions in effort largely through a DAS reduction plan, that will not change the basis for the previous no jeopardy determinations for threatened or endangered species found in the FMP's management area. In addition, it is reasonable to assume that Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region so that the current assessment of jeopardy to right whales could be revaluated.

For information on the ESA-listed species that will potentially be affected and a discussion of the potential impacts of the existing fishery and new Amendment 13 measures, see sections 5.2.9 (Volume I) and section 9.2.2 (Volume II).

7.3.3.4 Executive Order 12612 (Federalism)

The Executive Order on Federalism was established to restore the division of governmental responsibilities between the national government and the States and to ensure that the principles of federalism established in the E.O. guide federal departments and agencies in the formulation and implementation of policies. Nine fundamental federalism principles were established in the E.O. to guide federal legislation and policy development. The primary of these principles states that "federalism is rooted in the knowledge that political liberties are best assured by limiting the size and scope national government." In addition, federal departments and agencies that are developing policies that will affect the States must adhere to four policy-making criteria established in the E.O. which promote the authority and autonomy of the States.

While the policies established in Amendment 13 will affect certain States, they do not imply federalism implications sufficient to warrant preparation of an assessment under E.O. 12612. The affected states have been closely involved in the development of the proposed management measures through their involvement in the Regional Fishery Management Council process (i.e., all affected states are represented as voting members on at least one Council). This amendment was developed with the full participation and cooperation of the state representatives of the New England Council, and the Draft Amendment 13 will be provided to the Mid-Atlantic Council for their review and consideration. No comments were received from any state officials relative to any federalism implications of the proposed Amendment 13 to the multispecies FMP.

7.3.3.5 Executive Order 12630 (Property Rights)

The Executive Order on Property Rights was established to assist Federal departments and agencies in proposing, planning and implementing actions with due regard for the Fifth Amendment which provides that private property shall not be taken for public use without just compensation. Because this amendment addresses management of a public resource, it does not contain policies that have takings implications, as defined in the E.O.

7.3.3.6 Executive Order 12898 (Environmental Justice)

Executive Order (E.O.) 12898 requires that, "to the greatest extent practicable and permitted by law… each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations in the United States and its territories and possessions…" Due to data constraints and other concerns the means for conducting this analysis are not yet available at this stage of the public hearing process. Nonetheless, many of the participants in the groundfish industry may come from lower income and/or ethnic minority populations. These populations may be more vulnerable to more restrictive management measures. For example, in many ports crew may be comprised of ethnic minorities, and many regions in which fishing is an important livelihood can also be economically impoverished.

7.3.3.7 Regulatory Impact Review

This section provides the information necessary for the Secretary of Commerce to address the requirements of Executive Order 12866 and the Regulatory Flexibility Act. The amendment document contains all the elements of the RIR/RFA, and the relevant sections are identified by reference to the document.

The purpose and need for management (statement of the problem) is described in section 2.2 of this document. The proposed action is described in section 3.0 of the amendment document. The economic impacts are described in section 5.4 and summarized below under the discussion of how the proposed action is characterized under Executive order 12866 and the Regulatory Flexibility Act.

7.3.3.7.1 Executive Order 12866 (Regulatory Planning and Review)

The Executive Order on Regulatory Planning and Review was established to make the process of federal regulation more accessible and open to the public. In accordance with this E.O., the Council has:

- identified and assessed the issues requiring regulatory action and available alternatives to address these issues in Amendment 13;
- considered the degree and nature of risks posed by activities within its jurisdiction as well as the costs and benefits associated with the intended regulations;
- designed these regulations with consideration for flexibility, enforcement costs, distributive impacts and equity;
- based its decisions on the best reasonably obtainable scientific, technical, economic and other information;
- identified and assessed alternative forms of regulation;
- sought the views of State and local governmental entities to harmonize Federal regulations with relevant State regulations;
- avoided duplicative regulations with those of other Federal agencies;
- taken into account the costs of regulations on society;
- and drafted these regulations in a comprehensive and comprehensible manner.

E.O. 12866 requires a review of proposed regulations to determine whether or not the expected effects would be significant, where a significant action is any regulatory action that may

-
- Have an annual effect on the economy of $100 million or more, or adversely affect in a material way the economy, a sector of the economy, productivity, jobs, the environment, public health or safety, or State, local, or tribal governments or communities;

- Create a serious inconsistency or otherwise interfere with an action taken or planned by another agency;
- Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or
- Raise novel legal or policy issues arising out of legal mandates, the President's priorities, of the principles set forth in the Executive Order.

Of these four criteria, the discussion to follow focuses only on the expected magnitude and duration of the economic impacts of the Proposed Action.

The Proposed Action would implement a management program that would achieve rebuilding of all groundfish stocks within 10 years for most stocks and within a longer time period for three stocks. The Proposed Action would be implemented in 2004 and would reach all rebuilding objectives by 2026 (with the exception of redfish). The Proposed Action would produce net benefits (the sum of consumer surplus, income payments, and profit) of $2.6 billion at a 7% discount rate. Compared to returning to regulatory measures that were in place in fishing year 2001 the Proposed Action produces higher net present value by $51 million and produces net present value $93 million higher than what current regulations would produce over the same time period. However, returning to fishing year 2001regulations or retaining current regulatory measures would result in fishing mortality rates that would be inconsistent with statutory obligations under the Sustainable Fisheries Act.

Economic analysis of the Proposed Action and all non-selected alternatives is reported in 5.4. These analyses include assessment of both long term economic benefits of different rebuilding strategies and short term impacts of the specific regulatory measures needed to achieve rebuilding targets in fishing year 2004. Based on these analyses, the Proposed Action would produce lower present value of net benefit than alternative rebuilding strategies but would implement a suite of management measures that would result in lower short term impacts on fishing and fishing related businesses, communities, and on the New England economy as a whole. Specifically, the Proposed Action would yield net present value of economic benefit $50 million lower than other rebuilding alternatives but would reduce overall gross sales impacts on the New England economy by between $18 and $82 million as compared to other non-selected alternatives with larger DAS reductions or hard TAC's.

Even though the Proposed Action would have generally lower short-term impacts, the estimated impact on the New England economy would still be substantial. Relative to 1998-2001 average conditions, gross sales for the New England economy as a whole were estimated to be reduced by $135 million. Note that this estimate of economic impact is likely to be overestimated for several reasons. First, the impact assessment did not take into account all possible adaptations or regulatory measures that would tend to offset predicted losses in sales. Second, changes in productivity associated with 1998-2001 average stock conditions as compared to the projected higher 2004 stock levels were not taken into account. Such changes in productivity would mean that at least some portion of DAS reductions would be offset by increases in catches by commercial fishing vessels and would make higher supplies of seafood available to dealers, processors, and consumers. Last, the $135 million reduction in gross sales represents a cumulative loss compared to 2001 and is not necessarily equal to an annual loss. These considerations make it difficult to determine whether or not realized economic impacts will exceed the $100 million level in 2004. Further, as long as access to stocks that may be fished at higher levels is realized, projected landings and revenues may actually increase under the Proposed Action compared to 2002 and 2003 levels. Even if possible landings are not realized in 2004, projected changes in resource conditions indicate that recovery to current levels will be relatively rapid and would be much higher over the longer term. This means that while the Proposed Action could have a $100 million or greater impact on the economy, it would not have a sustained adverse annual $100 million impact as landings hence gross fishing revenues and their attendant benefits to fishing related industries and communities are expected to recover quickly. Nevertheless, available economic impact estimates indicate that the Proposed Action will have an adverse economic impact on the New

England economy and the fishing and fishing related sectors in particular that may be cumulative for at least 2004 and for some years thereafter. Therefore, the Proposed Action is determined to be significant for purposes of the Executive Order. The following provides additional summary information on long term and short term impacts.

Long Term Economic Benefits
The choice of long term strategy to achieve rebuilding involves selection of a time frame and an overall approach to rebuilding. Economic analysis of a 2009 as compared to a 2014 rebuilding time frame for most stocks shows a net gain of between $12 and $40 million depending on the selected rebuilding strategy (see 5.4.3, Comparison of Economic Benefit of Alternative Rebuilding Times). Therefore, the Proposed Action implements a 2014 rebuilding time frame.

Economic analysis of alternative rebuilding strategies shows that the net present value of the Proposed Action would be $2,624 million (See 5.4.1) while net present value of the Constant fishing mortality rate approach (section 5.4.2.6), the Phased approach (section 5.4.2.7) and the Adaptive approach (section 5.4.2.8) would be $2,671 million, $2,625 million, and $2,680 million respectively. Thus, the Proposed Action would not produce the highest net benefit among all rebuilding alternatives. However, the Proposed Action does provide nearly equivalent net benefits to any other alternative from 2004 to 2008 and from 2015 to 2026. From 2009 to 2014 fishing mortality rates need to be comparatively lower than that of other rebuilding approaches for some stocks because of higher mortality rates that would result from 2004 to 2008.

The Proposed Action landings were estimated to be 146 million pounds in 2004 and rise to nearly 300 million pounds in 2014 (Table 368). Landings would continue to increase before reaching an equilibrium level of approximately 320 million pounds in 2026. Over the entire time frame the present value of accumulated revenues would be $2.8 billion. Adding $421 million in consumer's surplus to total revenues results in a gross benefit of $3.2 billion. The estimated present value of total costs was $607 million consisting of $374 million in fixed cost and $233 million in operating costs. Deducting these estimates of fishing cost from fishing revenues leaves $2.2 billion in present value of payments to fishing crew and captains and vessel owner profits. Adding consumer surplus to fishing returns in excess of costs results in a total net benefit of $2.6 billion.

The present value of each rebuilding alternative was evaluated using a discount rate of 7%. Sensitivity analysis using a range of discount rates indicates that all rebuilding alternatives would still yield superior net benefits compared to either maintaining current regulations or reverting back to the 2001 regulatory environment at all interest rates up to and including 10%. Further, the relative ranking of rebuilding alternatives was robust at interest rates below 7% but that the ranking of the Proposed Action in terms of net present value would fall below the Phased Alternative for interest rates above 7%.

Economic benefits were only measured for commercial fishing but the rebuilding program would also provide increased fishing opportunities to recreational anglers. Of the groundfish species targeted by recreational anglers cod and haddock are the most important. Economic effects on anglers are manifested in a change in the value or satisfaction that they derive from taking a recreational fishing trip. If the primary motivation for fishing is based on merely catching fish, then changes in measures that affect keep rates without change catch may have relatively little impact on recreational values. By contrast, if the primary motivation for fishing is keeping fish then measures that affect keep rates would result in a change in recreational values. Research indicates that recreational anglers are motivated by a variety of factors but neither cod nor haddock are noted "game" fish so it may be assumed that recreational values will be affected predominantly by increasing keep opportunities.

The Proposed Action would liberalize recreational regulations for GOM cod by changing the bag limit and by reducing the size limit for haddock. This means that anglers would benefit from greater keep opportunities upon implementation and would gain additional value over time as groundfish resources are restored.

Year	Landings	Total Revenue	Consumer Surplus	Gross Benefit	Fixed Costs	Variable Costs	Total Cost	Producer Surplus	Net Benefit
2003	130	128	11	139	31	29	59	68	79
2004	146	129	15	145	29	23	51	78	93

Table 368 - Summary of Projected Landings (millions of pounds) and Discounted Economic Benefits (Benefits and Costs measured in millions of dollars discounted at 7%)

Short Term Impacts

Economic analysis of short term impacts included evaluation of comparative changes in gross fishing revenues (section 5.4.4), DAS needed in order to break-even (section 5.4.5), and total impacts on the New England economy (section 5.4.6). Additionally, analysis of potential business failure rates and relative change in profitability were examined for the Proposed Action (see section 7.3.3.7.2).

The Proposed Action would result in lowest impact in terms of relative change in total fishing revenues regardless of vessel size, gear, level of dependence on groundfish, home state, or port. However, the Proposed Action would still have significant impacts and may not appreciably change some of the distributive effects that may be expected to occur under one or more of the non-selected alternatives. For example, the Proposed Action would still have disproportional impacts on vessels with high dependence on groundfish. Across gear categories the Proposed Action would have similar impacts for 10% of the most impacted vessels regardless of gear but would still have an overall disproportionate impact on trawl vessels than either gillnet or hook vessels. With respect to vessel size (LOA), the Proposed Action would not have disproportionate impacts on vessels that are more than 70 feet as compared to vessels that are between 50 and 70 feet. However, vessels that were less than 50 feet in length were less impacted than either of the larger length categories. Vessel impacts among gear group and size categories indicate that small hook vessels will be disproportionately impacted compared to large hook vessels but would not be significantly more disadvantaged relative to other segments of the groundfish fleet. Unlike small hook vessels, small gillnet vessels would be less disadvantaged in terms of revenue loss compared to larger gillnet vessels. The same may be said for small as compared to medium and large trawl vessels. Revenue impacts among vessels from different home port states were largest for states that border the Gulf of Maine. Among these states, revenue impacts on Massachusetts vessels disproportionately affected compared to either Maine or New Hampshire vessels. Impacts on Maine vessels were similar to that of New Hampshire.

Since the Proposed Action would result in lower DAS reductions and in lower gross sales losses vessels would be more likely to have sufficient DAS allocations to remain above break-even and would result in lower overall impacts on the New England economy than any of the non-selected alternatives. As noted above, while the Proposed Action does reduce overall impacts, the potential DAS reductions are still likely to result in some vessels without enough DAS to break-even. Based on analysis of potential business failure rates (see IRFA) between 200 and 260 vessels may not be able to remain in business depending on levels of debt. Note that the analysis also indicated that the potential failure rate was highest for large trawl vessel than nay other gear or size class.

The short term impacts were evaluated based on empirical models and data that made it impossible to develop a comprehensive quantitative treatment of all management measures contemplated in the Proposed Action. Therefore, there are several measures that would be implemented under the Proposed Action that would offer the opportunity to mitigate the estimated short-term impacts.

The Proposed Action would implement a DAS leasing and a DAS transfer program. These programs both provide vessels with the opportunity to acquire additional DAS that may be used to offset DAS reductions. Economic analysis of DAS leasing (see section 7.3.3.7.2) indicates that profitability for both lessor and lessee would be improved. The analysis also indicates that leased DAS may flow from larger to smaller vessels and from Maine vessels to Massachusetts vessels. The former effect may be due to two factors. First, upgrade restrictions means that it is much easier to move DAS from larger to smaller vessels while large vessels may find it difficult to find trading partners. Second, the profitability analysis indicates that larger vessels may be less profitable than smaller vessels due to higher fixed cost payments, crew size requirements, and higher debt levels. This finding that leased DAS may flow from large to smaller vessels may be a reflection of differences in relative profitability indicating that leasing of DAS may be more driven by profit levels and will not necessarily go to vessels that land the most fish. The finding that leased DAS may flow out of Maine may not be surprising since the Gulf of Maine has more species of concern as compared to Georges Bank. However, as discussed below, the opportunity for using anything other than Category A DAS may be limited in the Gulf of Maine. This means that either DAS transfer or DAS leasing may be the most important programs available to Maine vessels to offset the Proposed Action DAS reduction. Thus, the demand for leasing may be greater in Maine than elsewhere so the net flow away from Maine may not be as large as predicted.

In addition to leasing, the Proposed Action would partition DAS into Category A, B, and C DAS, where the latter would not be available for use at least until all stocks have been rebuilt. Category A DAS would be available for general use upon implementation of the Proposed Action. The short-term impacts were estimated based only on the expected use of these Category A DAS. However, Category B DAS would also be allocated to fishing vessels that would be available for use in Special Access Programs (Reserve B days) or under specific circumstances (Regular B days) where stocks that may be fished at higher levels with low incidental catches of stocks of concern. The availability of these additional DAS will provide vessels an opportunity to increase total fishing time and income. At this time, identified Special Access Programs are limited to Georges Bank meaning that until other programs have been developed, the opportunity to use either Reserve or Regular B DAS will be limited to vessels that operate on Georges Bank. Generally, these programs may realistically be limited to larger vessels that have sufficient range and seaworthiness to take advantage of these programs (U.S./Canada resource sharing area and the Closed Area II Georges Bank Yellowtail Access program). A Special Access Program for hook gear in Closed Area I may provide an opportunity for some smaller vessels to use B DAS. As noted above, given the fact that the Gulf of Maine has a larger number of stocks of concern, the opportunity to use B DAS may be limited for vessels that fish in this area.

The Proposed Action would implement a process whereby groups of vessels owners may obtain a sector allocation. It also proposes a specific Georges Bank cod hook sector for implementation. While not implemented by the proposed action, a Georges Bank cod gillnet sector was considered and may be implemented in the future. The number of sector participants is not known at this time, nor are the specific details of how these sectors will operate. However, sector allocation may be used to design fishing rules that allow member vessels to land the same amount of fish, but do so in the least costly manner possible.

Compared to other non-selected alternatives, the Proposed Action would eliminate the raised footrope trawl proposed under Alternative 1. The Proposed Action would also delay use of differential DAS counting in the Southern New England yellowtail flounder stock area. The Proposed Action would provide for credit from steaming time to specific Special Access Programs, and would allow vessels to turn off VMS systems under certain circumstances.

7.3.3.7.2 Regulatory Flexibility Act (RFA)

The purpose of the Regulatory Flexibility Analysis (RFA) is to reduce the impacts of burdensome regulations and record-keeping requirements on small businesses. To achieve this goal, the RFA requires government agencies to describe and analyze the effects of regulations and possible alternatives on small business entities. On the basis of this information, the Regulatory Flexibility Analysis determines whether the proposed action would have a "significant economic impact on a substantial number of small entities."

The RFA applies to any rule or regulation that must undergo "notice and comment" under the Administrative Procedures Act (APA), specifically those rules published as proposed rules. When RFA applies, the Council must assess the impacts of the regulations to determine if they will have a "significant economic impact on a substantial number of small entities." See Sections 3.0, the description of the proposed action and section 5.4 impacts on the proposed action on vessels of different sizes and gear types. The Council also considered a large amount of input from the regulated entities and will evaluate the effectiveness and impacts of the proposed action on a continuing basis.

The Regulatory Flexibility Act (RFA) recognizes and defines three kinds of small entities: small businesses, small organizations, and small governmental jurisdictions. The established standards are:

- Any fish harvesting or hatchery business is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates) and if it has annual receipts of not in excess of $3.0 million.
- For related industries involved in canned and cured fish and seafood or prepared fish or frozen fish and seafoods, a small business is one that employs 500 employees or fewer.
- For the wholesale industry, a small business is one that employs 100 or fewer.
- For marinas and charter/party boats, a small business is one with annual receipts not in excess of $5.0 million.
- A small organization is any not-for-profit enterprise that is independently owned and operated and not dominant in its field.

- A small governmental jurisdiction is any government or district with a population of less than 50,000.

In practice, although some firms own more than one vessel, the number of vessels is a reasonable proxy for the number of small business entities. The groundfish industry directly affected by the proposed action is composed primarily of small business entities. In 2001, about 549 otter trawls, 187 gillnet and 176 longline vessels participated in the Northeast fishery, including the Gulf of Maine and Georges Bank areas. The average annual revenues of these vessels were less than $3 million for the period 1994-2001. The tuna purse seine industry consists of five vessels with average annual revenues of less than $3 million in 1998 and 1999.

The RFA requires government agencies to evaluate the financial impacts of regulations on small entities. If NMFS can certify if a proposed or final rule will not have a "significant economic impact on a substantial number of small entities," it is not required to conduct a full RFAA or a periodic review of the resulting rules. Any certification statement should include the following:

- A statement of basis and purpose of the rule.

- A description and estimate of the number of small entities to which the rule applies.

- An estimate of economic impacts on small entities, by entity size and industry.

- An explanation of the criteria used to evaluate whether the rule would impose "significant economic impacts." Two criteria are considered for determining significance:

    - Disproportionality. Do the regulations place a substantial number of small entities at a significant competitive advantage to large entities?
    - Profitability: Does the regulations significantly reduce profit for a substantial number of small entities?

        - An explanation of the criteria used to evaluate whether the rule would impose impacts on a "substantial number of small entities." The term "substantial number" has no specific statutory definition and the criterion does not lend itself to objective standards.

- A description of, and an explanation of the basis for, assumptions used.

The purposed and basis for the proposed action are described in Section 2.0.

The Proposed Action would implement changes affecting any vessel holding a limited access groundfish permit, an open access hand gear-only permit, and vessels that hold an open access party/charter permit. Based on fishing year 2002 (FY2002) data the total number of small entities that may be affected would be 1,442 limited access permit holders, 1,994 hand gear permits, and 685 party/charter permits. However, since an open access permit holder may hold more than one permit, the total number of unique entities holding either a hand gear or a party/charter permit was 2,250 of which 1,565 held only a hand gear permit, 306 held only a party/charter permit, and 379 held both a hand gear and a party/charter permit.

The SBA size standard for small commercial fishing entities is $3.5 million in gross sales while the size standard for small party/charter operators is 100 employees. The commercial fishing size standard would apply to limited access permit holders as well as open access hand-gear only permits. Available data based on 1998-2001 average gross sales show that the maximum gross for any single commercial fishing vessel was $1.3 million. While an entity may own multiple vessels, available data make it difficult to determine which vessels may be controlled by a single entity. For this reason, each vessel is treated as a single entity for purposes of size determination and impact assessment. This means that all commercial fishing entities would fall under the SBA size standard.

Available vessel trip report data for party/charter operators indicate that vessels typically employ two or three crew per trip. While some operators are likely to have additional employees to arrange bookings and other business related activities the known scale of operations in the Northeast region make it very unlikely that any one entity would have more than 100 employees. Therefore, all party/charter businesses would fall under the SBA size standard. Note that vessels that may engage in both party/charter and commercial fishing activity are also considered small since neither gross sales or number of employees would be above the size standard for either type of activity.

Impacts on Limited Access Permit Holders
The Proposed Action would implement both a change in baseline DAS allocations and a number of management measures that would affect the manner in which available DAS allocations may be used. The latter would principally affect vessels that participate in the groundfish fishery while the latter would affect all vessels whether they are current participants or not.

Impact of DAS Allocation Baseline
The Settlement Agreement assigned baseline DAS allocations based solely on DAS that had been called-in during fishing years 1996 to 2000 and granted a minimum allocation of 10 DAS to all limited access permit holders. The Proposed Action would change this baseline by adding FY2001 to the qualification period but would also require that only years in which at least 5,000 pounds of regulated groundfish would count toward qualification. Vessels that either called in no DAS at all or never landed more than 5,000 pounds in a single year would receive a baseline allocation of zero although their full pre-settlement agreement allocation would be placed in Category C DAS.

Preliminary analysis of the Proposed Action indicates that the majority (599) of vessels would see no change in their effective effort baseline while 272 vessels would receive a higher allocation than their Settlement Agreement baseline. However, 52 vessels would have a lower baseline and 519 vessels would receive a zero baseline allocation. Of the vessels with a zero baseline, 394 were vessels that had received a minimum allocation and 125 were vessels whose baseline allocation was more than 10 DAS under the Settlement Agreement.

In effect, the Proposed Action places greater weight on providing for continued participation in the groundfish fishery to those vessels that may be comparatively more active and that may be more dependent on the groundfish fishery for business income. That is, reducing the potential pool of qualifying DAS makes it possible to achieve the same conservation objective with a lower DAS reduction to all remaining vessels that will receive a baseline allocation.

Vessels that receive no baseline allocation in FY2004 would not be able to fish for regulated groundfish until all stocks have been rebuilt and all Category B DAS have been converted to Category A DAS. While this prohibition may not have an immediate impact on fishing income (i.e. vessels that received no allocation have either not participated in the groundfish fishery over a five-year period or did participate but at a very low level), a loss of DAS does mean that the equity value of the business would be reduced. A loss in equity would affect the resale value of the vessel and may affect the ability to obtain business loans.

A total of 923 vessels would receive a non-zero baseline allocation; approximately the annual average number of vessels that have participated in the groundfish fishery since 1996. For these qualifying vessels the Proposed Action would have no affect on economic opportunities for the 519 vessels with no change in baseline DAS. It would increase economic opportunity for 272 vessels, while 57 boats with DAS allocations receive lower allocations. Approximately 500 vessels will receive zero DAS.

Economic Impact of Management Measures
In making a determination of whether any regulatory action will have a significant impact on a substantial number of small entities NMFS guidelines requires consideration of whether or not the proposed measure will have a disproportionate impact on small as compared to large entities and/or whether the action would have a significant impact on profitability for a substantial number of small entities.

Disproportionality
Since all entities were deemed to fall under the SBA size standard for small commercial fishing entities disproportionality does not apply as a standard against which small entity impacts would be compared to large entity impacts. Nevertheless, in section 5.4.4 of the FSEIS revenue impacts were estimated for several different vessel categories including total value of groundfish sales where groundfish sales classes were broken into four intervals based on quartiles of the distribution of 1998-2001 average groundfish sales for participating vessels. The findings in section 5.4.4 indicate that relative changes in total fishing income would have lower impact on vessels with total groundfish sales of less than $35,000 but would be similar for the most impacted vessels at all other sales intervals. Overall, vessels with the highest groundfish sales may be expected to be more affected by Amendment 13 management measures but that the Proposed Action would have lower revenue impact than any of the non-selected alternatives. To examine whether the Proposed Action would have disproportionate impacts based on total sales the revenue impacts were summarized by gross sales intervals where intervals were established as the quartiles of the distribution of 1998-2001 average gross sales.

Relative changes in total fishing revenues was not markedly different across all sales intervals at least among the 55 most impacted vessels in each sales interval, although the estimated impact at the 10^{th} percentile was greatest (-44.7%) for vessels with sales less than $65,000 (Table 369). However, revenue impacts on remaining 150 or so vessels in this sales category were generally lower and were even positive for some vessels as compared to vessels with higher gross sales. In fact, the overall impact was generally most burdensome on vessels with highest gross sales ($300,000 or more). Note that these estimated impacts would be higher for all sales intervals for any of the non-selected alternatives. Based on the estimated changes in gross fishing revenue the Proposed Action would have higher impact on vessels with highest total sales and would not, therefore, have a disproportionate impact on vessels with smallest total sales.

		Proposed Action	
Gross Groundfish Sales Intervals	Number of Vessels	Lower	Upper
$65,000 or less (n = 205)			
10th Percentile and Below	21	Minimum	-44.7%
10th to 25th Percentile	31	-44.7%	-28.8%
25th to 50th Percentile	51	-28.8%	-11.4%
50th to 75th Percentile	51	-11.4%	-0.3%
75th to 90th Percentile	31	-0.3%	12.7%
Above 90th Percentile	21	12.7%	Maximum
$65,001 to $150,000 (n = 218)			
10th Percentile and Below	22	Minimum	-38.0%
10th to 25th Percentile	33	-38.0%	-30.9%
25th to 50th Percentile	55	-30.9%	-17.7%
50th to 75th Percentile	55	-17.7%	-2.3%
75th to 90th Percentile	33	-2.3%	2.0%
Above 90th Percentile	22	2.0%	Maximum
$150,001 to $300,000 (n = 211)			
10th Percentile and Below	21	Minimum	-40.2%
10th to 25th Percentile	32	-40.2%	-33.8%
25th to 50th Percentile	53	-33.8%	-20.7%
50th to 75th Percentile	53	-20.7%	-8.9%
75th to 90th Percentile	32	-8.9%	-0.4%
Above 90th Percentile	21	-0.4%	Maximum
$300,001 or more (n = 214)			
10th Percentile and Below	21	Minimum	-41.5%
10th to 25th Percentile	32	-41.5%	-37.4%
25th to 50th Percentile	54	-37.4%	-26.0%
50th to 75th Percentile	54	-26.0%	-11.1%
75th to 90th Percentile	32	-11.1%	-3.9%
Above 90th Percentile	21	-3.9%	Maximum

Table 369 - Revenue Impacts by Fishing Vessel Gross Sales Size Classes

Profitability

Change in gross revenues provides an incomplete picture of the impact of the Proposed Action on vessel profitability making it difficult to determine whether any given vessel may cease business operations. Unfortunately, while available data permit tracking landings and revenues by vessel no comparable data collection system exists to collect a comprehensive set of operating, fixed, and debt service costs for the groundfish fleet. This means that it is not possible to directly provide a reliable numerical estimate of current profit levels or how many vessels may not able to remain profitable once the Proposed Action is implemented. However, a relative measure of profitability change and percent of possible business failures was estimated by simulating vessel costs and returns by using a combination of the cost data developed for the break-even DAS analysis (see section 5.4.5), available data, and the estimated reduction in effective effort. Specifically, empirical data were used to fit theoretical probability distributions for fixed costs, costs per day, annual revenue on groundfish trips, annual revenue on trips where groundfish were not landed, days absent on groundfish trips, and days absent on trips where groundfish were not landed. A Monte Carlo simulation was then run using 1,000 iterations to produce 1,000 different possible financial profiles or equivalently profit levels for each gear and size class developed for the break-even analysis. By simultaneously simulating a baseline scenario and the Proposed Action (the baseline groundfish days absent reduced by 45%) each realization produces a paired estimate of profit for the baseline and the Proposed Action. In this manner, groundfish revenue is directly linked to the DAS reduction but so too are the operating cost savings associated with a reduction in groundfish effort.

Calculations

The calculations used to estimate profitability for each iteration of the Monte Carlo simulation are reported in Table 370 where a single random draw from the probability distributions shown in row 2 (variable costs per day), row 3 (annual fixed costs), row 10 (annual trip revenue when groundfish are landed), row 11 (annual trip revenue when not landing groundfish), row 14 (total days absent), and row 15 (the proportion of groundfish days absent to total days absent). Data used to estimate these probability distributions came from several sources. Cost data come from the cost surveys described in Section 4.4.5. Since the break-even data were developed in FY2000 constant dollars, revenue data came from dealer reports for FY2000 while days absent data come from vessel trip reports. Note that, where appropriate, probability distributions were truncated at zero to assure that random draws would come only from the positive portion of the probability distribution. Also, annual groundfish trip revenue (row 10) was forced to be positively correlated with the proportion of groundfish days absent (row 15) while annual non-groundfish trip revenue (row 11) was forced to be negatively correlated with groundfish days absent. In this manner, random draws of groundfish revenue are sampled from the higher portion of groundfish revenue distribution when the proportion of groundfish days absent to total days absent is high. Conversely, random draws of non-groundfish revenues are sampled from the lower portion of the non-groundfish revenue distribution when the proportion of groundfish days absent to total days absent is high.

Rows 5 – 8 show differences among different gear-size groupings in terms of total gross sales but are not used in any calculations. Rows 18 – 21 show annual principal and interest payments to debt service. These values were determined by using the cost survey data. The cost survey data show that many vessels have no debt while others have high levels of debt payments. However, since there were so few observations with reported debt payments a probability distribution could not be estimated. Instead, four classes of debt (zero, low, medium, and high) were developed using quartiles for observations that did reported debt payments.

Rows 25 and 26 are the crux of the analysis of profitability analysis. Row 25 calculates total revenue per day on groundfish trips based on realized groundfish revenue (row 10) and groundfish days absent (row 12). Row 26 adjusts the realized groundfish days absent from row 12 by an adjustment factor reflecting the effective groundfish effort change (row 23). A value of 1.0 in row 23 would return the realized groundfish days absent in row 12 whereas a value of 0.55 (i.e. a 45% reduction from the baseline) would return 55% of the row 12 realization. Whereas total revenue and trip costs for trips that do not land any regulated groundfish are unaffected by a reduction in groundfish effort (see calculations in rows 34 and 35), total groundfish revenue and trip costs are dependent on groundfish days. This makes it possible to estimate changes in trip costs as groundfish effort changes and assures that a simulated reduction in groundfish revenue is derived from the same average revenue per day. In concept this is equivalent to simulating the impact on a single hypothetical vessel by assuring any change in realized profit is based on the same cost structure and the same average groundfish productivity.

Rows 37 and 38 sums total trip revenue from all sources (row 31 plus row 34), total trip costs (row 32 plus row 35) while row 39 is set equal to the realized fixed costs from the fixed cost distribution (row 3). These cost and returns are subdivided between crew (rows 42 to 46) and the boat (rows 49 to 52) based on the lay system identified in row 41. For all but medium and large otter trawl vessels the lay system is assumed to be what is known as a "clear" lay where revenues are split between the crew and the boat according in a fixed proportion and all trip costs are paid by the crew. For example, a 60/40 clear lay means that crew are paid 60% of total revenue received on the trip and trip costs are deducted from this amount. The remaining 40% share goes to the boat from to cover fixed costs, debt service, and owner profit. Medium and large trawls are assumed to use a "broken" lay in which crew receive a fixed proportion of trip revenue but trip costs are not deducted from crew share. In a broken lay system trip costs are paid by the boat as are all other costs.

Returns to debt service and owner profit (row 54) is determined as the difference between the gross revenue to the boat (row 50) and the sum of trip costs paid by the boat (row 51) and fixed costs (row 52). Owner profit depends on the magnitude of debt payments. Profit levels for vessels with no debt, low, medium, and high debt are calculated in rows 57 to 60 by deducting the corresponding debt values in rows 17 to 21 from row 54.

The Monte Carlo simulation results in 1,000 different paired profit levels with and without a 45% reduction in effective groundfish effort. As a combination of possible revenue and cost realizations the resulting profit estimates may be positive while others are negative. To construct a baseline, it was assumed that only realizations that resulted in positive profit (greater than or equal to zero) would be operating in the without effort reduction condition. Estimates of business failure rates and relative change in profit levels were then based on the paired comparisons where baseline profit was at or above zero.

Results

The potential business failure rate ranged from 25 to 35% for small vessels using long-line gear depending on debt levels (Table 371). For vessels that may remain above break-even, median reduction in profit level ranged from 47% to 56% for vessels with no debt and high debt respectively. Across all vessels, reductions in profit levels could exceed 80% while some vessels may experience more modest changes in profitability (between 8.0 and 25% depending on debt level). Available data does not make it possible to determine the mix of small long-line vessels by debt level. However, assuming a medium debt level represents a fleet average, 17 out of a total of 51 small long-line vessels (see Table 187 for total vessels by size-gear groupings) may be expected to cease business operations.

Larger long-line vessels had higher overall fishing revenues in FY2000 than small long-line vessels but also had higher estimated costs but these costs represented a small overall proportion of total fishing revenues which also means that business failure rates are also likely to be lower. Failure rates were estimated to range from a low of 9% for vessels with no debt and a high of 15% for vessels with high annual debt payments (Table 372). Median estimated reduction in profit level was also lower than small long-line vessels but still exceeded 37% regardless of debt level. At the medium debt failure rate, a total of 3 of 24 large long-line vessels may cease business operations under the Proposed Action.

Business failure rates for small gillnet vessels may range from 19 to 24% depending on debt level (Table 373). Median reduction in profit would be about 35% but may be much higher (more than 80%) for some vessels or may be less than 1% for others. Assuming a medium debt failure rate, 14 of 63 small gillnet vessels may be expected to cease business operations.

As was the case for larger hook vessels, larger gillnet vessels had higher overall fishing revenues but costs were not higher by the same proportion. For this reason, failure rates for large gillnet vessels were somewhat lower (from 15 to 21%) than for small gillnet vessels (Table 374). However, potential reductions in profit levels for vessels that would still be above break-even may be higher for large as compared to small gillnet vessels. Specifically, median profit reduction may be at least 50%; about 15 percentage points greater than estimated median impacts on small gillnet vessels. Using the medium debt level failure rate, a total of 23 of 118 large gillnet vessels may be expected to cease business operations.

Small trawl vessels (less than 50 feet in length) may have business failure rates between 27 and 33% depending on level of debt payments (Table 375). Median losses in profit levels for vessels that may still be able to break-even may be between 50 and 60% with some vessels experiencing much larger reduction in profitability (90% or greater for vessels with high debt) while others may experience much lower reductions in profit. Assuming that medium debt is consistent with a fleet average, about 55 of 187 small trawl vessels may go out of business under the Proposed Action.

The business failure rate for medium trawl vessels was estimated to range between 18 and 27% (Table 376). This failure rate was lower than that of small trawl vessels suggesting that these vessels may be able to take advantage of economies of scale that make them somewhat more resilient to adverse economic conditions. Median reduction in profit level ranged within a narrow interval of from 45 to 48%. Based on the medium debt failure rate, 48 of 218 trawl vessels would not be able to remain in business after Amendment 13 is implemented.

Large trawl vessels had the highest debt levels and generally had higher trip and fixed costs than any other vessel size or gear category. These higher costs were not offset by proportionally higher revenue that tends to produce lower profit margins than other vessel gear/size classes. For this reason the estimated business failure rate (between 31 and 43%) was the highest for large trawl vessels (Table 377). Similarly, median reductions in profit were also generally higher (53 to 61%) as were reductions in profitability for both the most affected and least affected vessels. Applying the medium debt failure rate to the 187 large trawl vessels included in the economic analysis in Section 4.4.4 results in a potential for 68 business failures.

Discussion

Based on the above analysis a total of 228 vessels of varying sizes and gear groups may not be able to remain in business under the Proposed Action. This estimate was based on the assumption that all vessels had a medium level of debt and may range from 190 to 260 depending upon which debt level best represent a fleet-wide average. These estimates are also contingent on the extent to which the simulated cost and returns reflect actual financial conditions in the groundfish fleet. Unfortunately, not enough cost data particularly on fixed costs and debt payments has been collected to evaluate the veracity of these results. This difficulty aside, the profitability analysis did not take into account differences in potential revenue generation that may exist for vessels that fish predominately in the Gulf of Maine as compared to elsewhere. The analysis also does not account for differences in how area closures may affect vessels particularly small as compared to large vessels. Finally, the analysis only took into account the potential effort reduction associated with the expected use of Category A DAS.

The Proposed Action contains a number of measures that would provide small entities with some degree of flexibility to be able to offset at least some portion of the estimated losses in profit. The major offsetting measures include the opportunity to use additional "B" DAS, leasing of DAS, DAS transfer, and sector allocation. As designed the Proposed Action would achieve target fishing mortality rates for most stocks but would achieve higher then necessary reduction for others. Category B DAS would be subdivided into two categories one which would be used in Special Access Programs (reserve B DAS) while the use of the remaining B days or Regular B DAS will be determined in a Framework Action. The primary purpose of B DAS is to provide access to and increased yield from stocks that may be fished at higher levels. These opportunities would enhance profitability for vessels that may be able to participate in any one or more of these special fisheries.

Particularly for vessels with few alternative fisheries, reductions in profit may be offset by the ability to acquire more DAS either through leasing or DAS transfer. The former would make DAS available to a vessel for a single fishing season whereas the latter would be a permanent transfer of DAS from one vessel to another. Transferred DAS would be subject to a 40% conservation tax on the transfer but vessels would be able to acquire both Category A and Category B DAS. By contrast, a DAS lease would not be subject to a conservation tax but vessels would be only allowed to acquire Category A DAS. Which option any given vessels may choose to pursue is not known but analysis clearly suggests that making DAS available in some form of exchange can improve overall profitability for both buyer and seller. The following discussion describes this analysis.

Economic Analysis of Days at Sea Leasing Program

The economic impact of a DAS leasing program was estimated by simulating a quota market using a mathematical programming model. The model maximized industry profits by choosing the days each vessel will fish (if any) of their own allocation, days they will lease from other vessels, and the number of their days they will lease to other vessels. Each vessel can only fish a maximum number of days at sea, which is the sum of their Category A DAS and their FY 2001 allocation. Days fished above their allocation of Category A DAS must be leased from other vessels. Vessels were also not allowed to be both a lessee and lessor, although in reality this could happen. Restrictions were placed on the model that did not allow days to be leased by larger vessels from smaller vessels, which were consistent with the restrictions passed by the Council. Results from the model yielded a very efficient outcome in terms of maximizing industry profit with as few vessels as possible. In reality, the actual leasing of quota among industry participants may not be as profitable as projected by the model. An individual vessel's activity level chosen by the model is determined by its productivity, the maximum allowable days it can fish, the lease price for days at sea, daily fishing costs, and the prices of each species, and a restriction which prohibit leasing of days from smaller vessels by bigger vessels. The model does not differentiate between areas fished, where vessels land their fish, and a variety of other factors that will influence the amount of quota leased, including other fisheries in which the vessel can participate, and it assumes perfect information among participants.

Vessels were grouped together regardless of gear type, and then stratified into fleets of 100 vessels[8]. Each fleet was then paired with itself, and then with every other fleet to simulate trades between all 1,345 vessels that could potentially lease quota. For each sector pair, the model was run fifty times in order to incorporate a stochastic lease price, which was generated based on results from a previous linear programming model. Lease prices used in the model ranged from $218 to $2,093, with a mean of $1,029. Results from the simulations were used to examine changes in profitability that would occur from allowing days at sea leasing.

Results

Results from the simulation runs were stratified by gear type and length of vessel. Class 1 vessels were less than 50 feet; class 2 vessels were between 50 and 69 feet, and class 3 vessels were 70 feet and greater. The

[8] The size of the non-linear programming model limited the maximum fleet size which could be analyzed, while incorporating a stochastic lease price.

three gear types examined were hook (50 vessels), trawl (1,126 vessels) and gillnet (169 vessels). There were more vessels in the model than had Category A DAS in the proposed action. Because vessels can fish up to the total of their Category A DAS and their FY 2001 allocation, vessels with zero Category A DAS can still lease days at sea, and therefore need to be included in the model. Because the model is attempting to maximize industry profit, under a DAS sea leasing scheme, fewer vessels will fish (Table 378). However, mean profits for all vessels will be higher than if days at sea trading were not allowed, and all vessels fished their allocation (Table 379). Mean profits are also higher than the mean profit levels generated during calendar year 2002 by vessels actually fishing.

Vessels which choose to lease all their quota can greatly enhance their profit since the owner is getting all the revenue from the lease without incurring any costs, and in particular not having to pay labor costs. The decision from a vessel perspective on whether to lease quota *to* other vessels is based on whether they can lease their quota for more then they would earn after paying crew share and covering other expenses[9]. If a vessel decides to lease quota *from* other vessels, it is based on whether they can earn more from a leased day at sea than what they will pay for the lease plus what they will pay to the crew, and to cover other expenses.

Model results generally showed the flow of lease days going from larger vessels to smaller vessels. Trawl and Gillnet vessels less than 50 feet in length were projected to use more days at sea than in 2002 under a DAS leasing scheme (Table 380). Trawl and Gillnet Vessels greater than 50 feet saw their days at sea usage decline from 2002 levels. Hook vessels were also projected to see their days at sea increase. Restrictions on DAS trading make it difficult for larger vessels to lease from smaller vessels, but the opposite does not hold. Small vessels have a large potential number of vessels that they can lease from, which is what model results show. Examination of both tables 2 and 3 show that larger vessels can profit by leasing their days to smaller vessels. For example, length class 2 trawl vessels average profit was $68,387 using an average of 36.92 days of effort under a DAS leasing scheme, while their average profit was $31,428 using 46.13 days of effort in 2002. Small trawl vessels average profit was $41,111 using 31.9 days of effort under days at sea leasing, while their 2002 average profit was $12,271, and their average days at sea was 25.13. This demonstrates that both sectors would be better off with a DAS leasing program than fishing at their calendar year 2002 effort levels.

Additionally, the average profit levels were projected to be higher under days at sea leasing than if the vessels fished at their allocated 2004 levels. This demonstrates days at sea leasing provides substantial regulatory relief to vessels compared with no leasing.

[9] The particular costs faced by each vessel depend on the particular lay system they employ. For the purposes of this model, it was assumed the vessel paid the variable operating costs such as fuel and ice, and then paid the crew. This simplified the model slightly, but may underestimate the profit that each vessel owner would earn under a days at sea leasing program if they decide to fish.

Table 380 - Average Days Fished and Leased by Gear Type and Length Class

Impact on Party/Charter Operators

The Proposed Action would relax current restrictions on the bag limit for Gulf of Maine party/charter passengers and would permit passengers to retain a two-day equivalent of the daily bag limit on trips that take place over two calendar days and that are at least 15-hours in duration. These measures would affect any vessel that chose to take passengers for-hire in the Gulf of Maine where cod were caught. While there are a large number of vessels that hold a party/charter groundfish permit there have only been about 120 vessels that have actually reported landing Gulf of Maine cod when taking passengers for hire. Of these vessels, the majority earn at least 75% of fishing income from passenger fees. Although the impact of a relaxation of the Proposed Action recreational measures cannot be estimated using available data there is little doubt that the higher bag limit will be more attractive to party/charter customers which should result in higher passenger loads and an overall improvement in party/charter business profits.

Impact on Hand-Gear Only Permit Holders

The Proposed Action would convert the existing open access hand-gear permit into a limited access category and an open access category. Vessels that qualify for a limited access permit would benefit from a relaxation on the cod trip limit and would not be subject to trip limits on any other species. Vessels that do not qualify for limited access would still be able to obtain and open access permit but the cod trip limit would be much lower than current hand-gear only permit holders may retain. Available data show that even though a large number of open access hand-gear permits have been issued in the past not much more than 10% of these permits actually report landings of any amount of either cod or haddock. A preliminary assessment of qualification indicates that approximately 150 vessels would qualify for a limited access hand-gear only permit which just about as many vessels with documented landings in any given year since 1997. Thus, the conversion to a limited access permit with the potential to achieve higher landings and higher incomes overall also may permit the majority of small entities currently participating in the fishery to continue operating.

7.3.3.8 Executive Order 13158 (Marine Protected Areas)

The Executive Order on Marine Protected Areas requires each federal agency whose actions affect the natural or cultural resources that are protected by an MPA to identify such actions, and, to the extent permitted by law and to the extent practicable, avoid harm to the natural and cultural resources that are protected by an MPA. The E.O. defines a Marine Protected Area as “any area of the marine environment that has been reserved by Federal, State, territorial, tribal, or local laws or regulations to provide lasting protection for part or all of the natural and cultural resources therein.”

The Departments of Commerce and the Interior are jointly developing a list of MPAs that meet the definition of MPA for the purposes of this E.O. As of the date of submission of the FSEIS, the list of MPA sites has not been developed by the departments. However, it is likely that when the list is available the Stellwagen Bank National Marine Sanctuary and the Council’s year-round groundfish closed areas (Closed Area I, Closed Area II, Nantucket Lightship Closed Area, and Western Gulf of Maine Closed Area), at a minimum, will meet criteria for an MPA and will likely be listed.

The E.O. promotes the development of MPAs by enhancing or expanding the protection of existing MPAs and establishing or recommending new MPAs. Amendment 13 proposes modifying and expanding existing year-round groundfish closures to afford more protection to sensitive benthic habitat as well as establishing new area closures for habitat protection. This is consistent with the goals of E.O. 13158, which support the use of closed areas as management tools for habitat protection.

7.3.3.9 Marine Mammal Protection Act

The NEFMC has reviewed the impacts of Amendment 13 on marine mammal species and has concluded that the management actions contained in Amendment 13 are consistent with the provisions of the MMPA. The take of harbor porpoise under the existing FMP have been reduced to the point that would allow the stocks to achieve optimum levels. The level of take for the remaining odontocetes and seals that are affected by this fishery are low enough, in relation to the size of their populations, that it has been determined that the stocks would be allowed to achieve optimum levels. Therefore, since the mortality and serious injury that is likely to occur under the existing FMP has been assessed relative to the PBR allowed for each species under the MMPA and found to be below those levels, the NEFMC concludes that Amendment 13 will further reduce effort providing additional protection to these species.

7.3.3.10 Paperwork Reduction Act

Materials and analysis required under the PRA will be submitted under separate cover after the final SEIS is prepared.

7.3.3.11 Data Quality Act (P.L. 106-554)

The Data Quality Ac directed the Office of Management and Budget to issue government wide guidelines that "provide policy and procedural guidance to federal agencies for ensuring and maximizing the quality, objectivity, utility, and integrity of information (including statistical information) disseminated by federal agencies." NOAA guidelines are available at http://www.noaanews.noaa.gov/stories/iq.htm and are not repeated here. Amendment 13 falls under the category of a Natural Resource Plan. It is a composite of several different types of information, including scientific, management, and stakeholder input, from a variety of sources. Compliance of this document with NOAA standards is evaluated below.

Utility: The information disseminated by this Amendment is intended to describe proposed management actions and the impacts of those actions. As such, it is intended to be useful to:

-Industry participants so they can provide informed comment on their preferred alternatives
-Managers/policy makers so they can choose alternatives

Section 9.0 provides background information so that the impacts described in section 5.0 can be more fully understood.

Integrity: Confidential information is not reported in this amendment as provided by 50 CFR Subpart E. Sources of data are clearly described and referenced.

Objectivity: Information is provided in an unbiased manner. Where necessary, descriptions of analytic techniques are provided so the limitations of the analyses can be understood. Where possible, variation in scientific information is reported so the uncertainty of estimates can be evaluated. Data sources are clearly described, and citations to referenced documents are included.

This Amendment is developed in accordance with NMFS Operational Guidelines for Fishery Management Plans. A wide range of information has been incorporated. The information is presented in such a way that clear policy choices can be made for the major issues. Information included has been reviewed prior to incorporation through a wide range of processes, including formal peer reviews, informal reviews by the Groundfish Plan Development Team, and public review through participation in Council meetings. In addition, before this plan is final, additional public and private reviewers will be afforded an opportunity to comment, and the comments will be considered in the preparation of the final SEIS.

7.3.4 State and Local Laws and Policies

Federal fisheries permit holders fishing in state waters must adhere to federal fisheries regulations unless they are specifically exempted or the state regulations are more restrictive. The following is a summary of state regulations relevant to groundfish.. Most states are in the process of adjusting their groundfish regulations to reflect changes made by NMFS to federal groundfish reulgations in July, 2003. These changes are not shown below.

MAINE

Licensing and Reporting Requirements

- Non-resident commercial fishermen in the groundfish fishery must report time and location of fishing, gear used, and species and catch information by phone or written report to the Bureau of Marine Patrol.

Seasonal/Area Closures

- No fishing, taking or possession of federally regulated groundfish species in Sheepscot Bay and Boothbay from May 1-June 30.

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size
Atlantic cod	22”	23”
haddock	19”	23”
pollock	19”	19”
witch flounder	14”	14”
yellowtail flounder	13”	13”
American plaice	14”	14”
Atlantic halibut	36”	36”
winter flounder	12”	12”
redfish	9”	9”

Gear Restrictions

Recreational—

- Charter, party and recreational vessels are prohibited from fishing for groundfish with more than 2 hooks per line and more than 1 line per angler, and must stow all other fishing gear on board the vessel.

Commercial—

Gear type	Mesh size	Net Limit	Hook type	Hook Limit
trawl net, sink gillnet, Scottish seine, mid-water trawl	≥ 6” diamond/square in body and wings; ≥ 6.5” diamond/square in cod end	not specified	N/A	N/A
stand-up gillnet	≥ 6.5”	max. 50 nets	N/A	N/A
tie-down gillnet	≥ 7”	max. 100 nets; for mesh ≥ 10”, max. 150 nets	N/A	N/A
tub trawl, longline	N/A	N/A	size 12/0 or greater circle hooks only	2000

- Use of crucifiers with less than 6” spacing between fairlead rollers is prohibited.

Possession Limits

Atlantic cod

Commercial- maximum 500 lbs. landed/possessed daily

Atlantic halibut
See "Species-specific Regulations" section, below.

<u>Species-specific Regulations</u>
Atlantic halibut
Open seasons—

- Sunrise May 1-Sunset July 31 east of line from Schoodic point due south (magnetic) in territorial waters; Sunrise April 1-Sunset June 30 west of above line.

Minimum size— 36"
Possession limit—

- Possession of other species is prohibited while fishing for Atlantic halibut.
- Commercial- 4 fish/day
- Recreational/Party/Charter- 1 fish/day

Quota—

- Commercial/Recreational- No more than 50 fish/season

Gear restrictions—

- Size "14oo" or greater circle hooks up to a maximum of 450 circle hooks/day

License—

- Licensed commercial fishermen must receive an Atlantic halibut endorsement on a fishing license issued by the ME Department of Marine Resources. To receive this endorsement, a fisherman must contact the DMR before March 1 and participate in a tagging and release training program.

Additional requirements—

- Those fishing for halibut are required to maintain a log of halibut catches with specific information about each fish and may also be asked to take observers on board and preserve certain halibut organs for laboratory examination.

NEW HAMPSHIRE

<u>Size Limits</u>

Species	Commercial Minimum Size	Recreational Minimum Size
Atlantic cod	22"	23"
haddock	19"	23"
pollock	19"	none
yellowtail flounder	13"	13"
American plaice	14"	14"
winter flounder	12"	12"
redfish	9"	9"

- Cod/haddock must have head and tail intact or as fillets with skin intact, no less than 14" long.

<u>Gear Restrictions</u>
Hook Gear—

- Cod, haddock, pollock, white hake, redfish, American plaice, windowpane flounder, witch flounder, winter flounder, and yellowtail flounder may not be taken during the months of April, May and June.
- Only circle hooks size 12/0 when using bait
- No more than 800 circle hooks
- Fairlead rollers must have 6" spaces between each

Gillnets—

- Cod, haddock, pollock, white hake, redfish, American plaice, windowpane flounder, witch flounder, winter flounder, and yellowtail flounder may not be taken during the months of April, May and June.
- No more than 25 nets, each no greater than 300 feet long
- Gillnets used to take the above species from the Great Bay estuarine system inland of Memorial Bridge in Portsmouth, Little Harbor and tributaries inland of its most seaward jetty, Rye Harbor and tributaries inland of its most seaward jetty, and inland of Hampton Harbor Bridge may be used April 16-October 31 only, 2 hours before sunrise until 2 hours after sunset. Gillnets must be within eyesight (unaided by binoculars and other such magnification instruments) of the fishing vessel at all times and must adhere to the following specific ations:
    - = 3" mesh
    - = 100 feet long, = 7 feet wide

Possession Limits
- Cod and haddock may only be taken recreationally during the months of April, May and June.
- Recreational daily limit
    - 10 cod/haddock combined, April 1-Nov 30
    - 5 cod/haddock combined Dec 1-March 31
- Commercial daily limit
    - 500 lbs. cod by gillnet
    - 200 lbs. cod, haddock or yellowtail flounder combined by hook gear

MASSACHUSETTS

Licensing and Reporting Requirements
- Special permit required for at-sea processing
- Permit required for participation in gillnet fishery

Seasonal/Area Closures
- Month of May— upper Cape Cod Bay and Massachusetts Bay north of 42°, south of 42°30'
- Month of June— north of 42°30' from Marblehead to the New Hampshire border
- April-May and Oct.-Nov.— Cape Cod Bay and Massachusetts Bay from Plymouth north to Marblehead
- April-June— upper Massachusetts Bay and Ipswich Bay from Marblehead to the New Hampshire border
- From May 1 to May 31 it is illegal to possess groundfish species east of Cape Cod south of 42°N and east of 70°W

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size
Atlantic cod	22"	23"
haddock	19"	none
pollock	19"	none
yellowtail flounder	13"	13"

Gear Restrictions

Gear type	Mesh size	Net Limit
trawls	≥ 6½” throughout entire net north and east of Cape Cod, Jan. 1-Dec. 31; ≥ 6½” throughout entire net south of Cape Cod, Nov. 1-April 22; ≥ 4½” throughout entire net in area defined in state regs, June 1-Oct. 31	not specified
sink and flatfish gillnets	≥ 6½” throughout entire net	not specified

- Line-trawling for cod permitted during certain time and area closures with certain hook restrictions, as specified in state regs.
- No disks rollers, or rockhopper gear greater than 18” in diameter
- Vessels over 90 feet in length are prohibited from fishing in MA state waters
- Rod-and-reel, handlines, and longlines may be used in January with written permission of the MA Department of Marine Fisheries director

Gillnets—

- North of Cape Cod— Bottom/sink gillnets prohibited Nov. 1-Nov. 30 and March 1-March 31 in certain designated areas
- South and west of Cape Cod— Gillnets (all types) prohibited April 1-November 15, with few exceptions
- Massachusetts Bay— Bottom gillnets prohibited May 15-November 1 within designated management area

Possession Limits

- Recreational daily limit
  - 10 fish/person/day, April-November
  - 5 fish/person/day December-March
- Commercial daily limit
  - 500 lbs./24-hour day North of Cape Cod
  - 2,000 lbs./24-hour day South of Cape Cod

Atlantic cod

- Gonads may not weigh more than 10% of the total weight of cod aboard vessel
- No removal of gonads from fish smaller than the minimum size

- Small-mesh fishermen in upper Cape Cod Bay Whiting Area may not possess cod, haddock, pollock, redfish, white hake, yellowtail flounder, winter flounder, windowpane flounder, American plaice, witch flounder and ocean pout

Species-specific Regulations

Winter Flounder

Possession limit—

- No possession of winter flounder in Mount Hope Bay and tributaries May 20-Sept. 27 and Oct. 29-April 12
- Daily limit of 4 winter flounder (24-hour period) April 13-May 19 and Sept. 28-Oct. 28
- Commercial- No taking winter flounder from Mount Hope Bay and tributaries
- Recreational- 8 winter flounder/person at one time; reduced during March 1-April 30 to 3 winter flounder/person at one time

RHODE ISLAND

Licensing and Reporting Requirements

- Upon request of the RI Dept. of Environmental Management, every owner/operator and dealer must make either or both a telephone report or written report of activities

Seasonal/Area Closures

- Recreational closed season for winter flounder— April 20-May 27 and Sept. 28-Oct. 28
- Commercial closed season for winter flounder— March 1-Sept. 30 and Oct. 1-Nov. 15

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size
Atlantic cod	19”	20”
haddock	19”	19”
pollock	19”	19”
American plaice	14”	14”
winter flounder	12”	12”
yellowtail flounder	13”	13”
witch flounder	none	14”

Gear Restrictions

- No mechanical trawling device, beam, pair or otter trawl allowed in Narragansett Bay and various associated rivers and ponds in Narragansett Bay watershed except in some designated areas (these areas are described in detail in the state regulations)
- No setting, hauling or maintaining a trawling device in any listed channels, ponds, or rivers (refer to state regs)
- Beam, pair and otter trawls or other mechanical trawling devices are allowed in the upper Narragansett Bay Trawling Area between July 1 and Nov. 1, except on weekends and legal state holidays
- No setting, hauling or maintaining a seine along the shoreline within a half mile in both directions of the seaward entrance of various specified ponds and rivers open to the sea, extending seaward for 300 yards
- Except for menhaden, it is illegal to set, maintain, or haul a gillnet for any species in the Pawcatuck River or Little Narragansett Bay and within 1.5 miles south and west of Napatree Point
- Traps, pots and stationary gear must be marked with the license number, name of owner and a buoy
- Use of explosives as a fishing device prohibited
- Additional gear restrictions apply to certain ponds, described in the state regs.

Gillnets—

- A license is required to fish using a gillnet. Any RI resident is eligible for a license. Cost: $200.
- Near- and off-shore ends of all gillnets must be marked with orange/fluorescent orange bullet shaped buoys with minimum dimensions 9”x16”; buoys must be marked with name/license number of owner and “GN” in letters at least 3” tall
- Each gillnet must be hauled once per day (24 hr. period, midnight to midnight)
- Gillnets may not be set, hauled or maintained within 3,000 ft. of a fish trap licensed by the RI Department of Environmental Management
- Floating gillnets must be constantly tended (operator must remain within 100 ft. of the net at all times)
- Mesh for bottom tending gillnets must be less than 5”

- State regulations specify some additional setting and spacing restrictions and seasonal closures for gillnet use

Species-specific Regulations

Winter Flounder

- Permit required for fishing for winter flounder
- Minimum mesh size of 6” required throughout state waters and across all gear types while fishing for winter flounder
- Harvesting or possession of winter flounder prohibited in Narragansett Bay north of lines from So. Ferry Road in Narragansett to Ft. Getty; Ft. Wetherill to Ft. Adams; Sandy Pt. to High Hill Pt.
- A winter flounder Coastal Marine Life Management Area (CMLMA) is established in all state waters north of a line from Sakonnet Point Light to Pt. Judith Light; no possession of winter flounder while fishing in CMLMA

- Fishing for winter flounder in CMLMA prohibited from 1 hour after sunset until 1 hour before sunrise (except with gill and fyke nets)
- CMLMA annual commercial winter flounder quota, for all gear types, is divided into two seasons:
  - 1st season—March 1 until half of the annual quota is landed
  - 2nd season—October 1-November 15, unless the entire quota is reached before Nov. 15
- Quota overages are subtracted from the next year’s allocation
- Recreational possession limit for winter flounder: 4 fish/person/day
- Commercial trip limit for winter flounder: 100 lbs/day in coastal ponds within the CMLMA, 300 lbs/day in other areas (south end of CMLMA). While fishing in the entire CMLMA, 300 lb. possession limit applies.

CONNECTICUT

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size
winter flounder	12”	12”
Atlantic cod	19”	none
yellowtail flounder	13”	none
haddock	19”	none
pollock	19”	none
witch flounder	14”	none
American plaice	14”	none
redfish	9”	none

NEW YORK

The State of NY is in the process of amending its current groundfish regulations. Current regulations and proposed changes are described separately below. Changes to the current regs will most likely be implemented by the end of September, 2002.

Current

Licensing and Reporting Requirements

- A fishing license must be carried at all times while fishing

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size
Atlantic cod	19”	21”
haddock	19”	21”
pollock	19”	19”
yellowtail flounder	13”	13”
winter flounder	12”	11”

Species-specific Regulations

Winter Flounder

- Recreational open season— 3rd Saturday in March-June 30 and Sept. 15-Nov. 30
- Recreational trip limit— 15 fish/vessel during fishing time (not less than 24 hours)
- Commercial open season, by gear-type—
    - pound and trap nets: July 26-June 14
    - fyke nets: Oct. 1-March 22
    - all other gear: Dec. 1-June 13

Proposed Additions

- At-sea transfer of any species with a possession limit is prohibited
- Some new reporting requirements are proposed
- Possession of winter flounder is prohibited in recreational and commercial fisheries.
- Fish pots/traps must be tagged (color coded) indicating year issued by the NY Dept. of Environmental Conservation

Fish Trap Specifications	**Circular Vents**	**Rectangular Vents**
Max. Number Vents	1	1
Max. Size of Opening	diameter: 23/8”	dimensions: 11/8” x 5¾”

NEW JERSEY

Licensing and Reporting Requirements

- An individual applying for a gillnet license must have possessed a gillnet license for at least one of the two previous years. Otherwise, the applicant must file an application in person for two consecutive years.

Open Recreational Seasons

Species	Season
winter flounder	March1-May 31; Sept. 15-Dec. 31
Atlantic cod	Jan. 1-Dec. 31
haddock	Jan. 1-Dec. 31
pollock	Jan. 1-Dec. 31

Size Limits

Species	Commercial Minimum Size	Recreational Minimum Size	Minimum Fillet Size
Atlantic cod	21”	21”	14”
haddock	21”	21”	14”
pollock	19”	19”	13”
winter flounder	12”	11”	none

Gear Restrictions

- All gear must be legibly, indelibly marked with the gear ID number of the owner
- Stakes to mark various nets must stand at least 2 feet above mean high water, and must be visible from all sides:
  - reflectors may not be less than 2” in diameter
  - reflective tape may not be less than 2” wide
  - light colored squares may not be less than 2’ square
  - light colored jugs/buoys may not be less than 12” in diameter
- No unattended overnight staked/anchored gillnets June 15-Oct. 31 (operator must be less than 1500 ft. from the nearest portion of the net)
- Gillnet mesh must be =2.75” stretched in tributaries of Delaware Bay or =3.25” stretched Jan. 1-Feb. 29

Species-specific Regulations

Winter Flounder

- Use of fyke net for capturing winter flounder prohibited Feb. 20-Oct. 31
- Use of other commercial gear for capturing winter flounder prohibited June 1-Nov. 30

Other

- Removal of head, tail, skin or mutilation which prevents accurate identification of the species is prohibited.
- A party boat owner may apply for a Special Fillet Permit for a specific vessel, subject to the following restrictions:
  - Once fishing commences, no parts or carcasses of Atlantic cod, haddock, pollock, winter flounder and other flatfish (as well as some species not managed under the Northeast Multispecies FMP) may be discarded overboard; only whole or live fish may be returned to the water.
  - No fillet of any flounder or other flatfish shall be less than 8 inches in length between May 1 and Oct. 31 or less than 5 inches in length from Nov. 1 to April 30.
  - See minimum fillet sizes in “Size Limits” section, above.

8.2 Glossary

Adult stage: One of several marked phases or periods in the development and growth of many animals. In vertebrates, the life history stage where the animal is capable of reproducing, as opposed to the juvenile stage.

Adverse effect: Any impact that reduces quality and/or quantity of EFH. May include direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to, benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality and or quantity of EFH. Adverse effects to EFH may result from actions occurring within EFH or outside of EFH and may include sites-specific of habitat wide impacts, including individual, cumulative, or synergistic consequences of actions.

Aggregation: A group of animals or plants occurring together in a particular location or region.

Anadromous species: fish that spawn in fresh or estuarine waters and migrate to ocean waters

Amphipods: A small crustacean of the order Amphipoda, such as the beach flea, having a laterally compressed body with no carapace.

Anaerobic sediment: Sediment characterized by the absence of free oxygen.

Anemones: Any of numerous flowerlike marine coelenterates of the class Anthozoa, having a flexible cylindrical body and tentacles surrounding a central mouth.

Annual total mortality: Rate of death expressed as the fraction of a cohort dying over a period compared to the number alive at the beginning of the period (# total deaths during year / numbers alive at the beginning of the year). Optimists convert death rates into annual survival rate using the relationship S=1-A.

ASPIC (A Surplus Production Model Incorporating Covariates): A non-equilibrium surplus production model developed by Prager (1995). ASPIC was frequently used by the Overfishing Definition Panel to define B_{MSY} and F_{MSY} reference points. The model output was also used to estimate rebuilding timeframes for the Amendment 9 control rules.

Bay: An inlet of the sea or other body of water usually smaller than a gulf; a small body of water set off from the main body; e.g. Ipswich Bay in the Gulf of Maine.

Benthic community: *Benthic* means the bottom habitat of the ocean, and can mean anything as shallow as a salt marsh or the intertidal zone, to areas of the bottom that are several miles deep in the ocean. *Benthic community* refers to those organisms that live in and on the bottom. (A*In*@ meaning they live within the substrate; e.g, within the sand or mud found on the bottom. See *Benthic infauna*, below)

Benthic infauna: See *Benthic community*, above. Those organisms that live *in* the bottom sediments (sand, mud, gravel, etc.) of the ocean. As opposed to *benthic epifauna*, that live *on* the surface of the bottom sediments.

Benthivore: Usually refers to fish that feed on benthic or bottom dwelling organisms.

Berm: A narrow ledge typically at the top or bottom of a slope; e.g. a berm paralleling the shoreline caused by wave action on a sloping beach; also an elongated mound or wall of earth.

Biogenic habitats: Ocean habitats whose physical structure is created or produced by the animals themselves; e.g, coral reefs.

Biomass: The total mass of living matter in a given unit area or the weight of a fish stock or portion thereof. Biomass can be listed for beginning of year (Jan-1), Mid-Year, or mean (average during the entire year). In addition, biomass can be listed by age group (numbers at age * average weight at age) or summarized by groupings (e.g., age 1^+, ages 4+ 5, etc). See also spawning stock biomass, exploitable biomass, and mean biomass.

B_{MSY}: The stock biomass that would produce MSY when fished at a fishing mortality rate equal to F_{MSY}. For most stocks, B_{MSY} is about ½ of the carrying capacity. The proposed overfishing definition control rules call for action when biomass is below ¼ or ½ B_{MSY}, depending on the species.

$B_{threshold}$: 1) A limit reference point for biomass that defines an unacceptably low biomass i.e., puts a stock at high risk (recruitment failure, depensation, collapse, reduced long term yields, etc). 2) A biomass threshold that the SFA requires for defining when a stock is overfished. A stock is overfished if its biomass is below $B_{threshold}$. A determination of overfished triggers the SFA requirement for a rebuilding plan to achieve B_{target} as soon as possible, usually not to exceed 10 years except certain requirements are met. In Amendment 9 control rules, $B_{threshold}$ is often defined as either $1/2B_{MSY}$ or 1/4 B_{MSY}. $B_{threshold}$ is also known as $B_{minimum}$.

B_{target}: A desirable biomass to maintain fishery stocks. This is usually synonymous with B_{MSY} or its proxy.

Biomass weighted F: A measure of fishing mortality that is defined as an average of fishing mortality at age weighted by biomass at age for a ranges of ages within the stock (e.g., ages 1^+ biomass weighted F is a weighted average of the mortality for ages 1 and older, age 3^+ biomass weighted is a weighted average for ages 3 and older). Biomass weighted F can also be calculated using catch in weight over mean biomass. See also fully-recruited F.

Biota: All the plant and animal life of a particular region.

Bivalve: A class of mollusks having a soft body with platelike gills enclosed within two shells hinged together; e.g., clams, mussels.

Bottom roughness: The inequalities, ridges, or projections on the surface of the seabed that are caused by the presence of bedforms, sedimentary structures, sedimentary particles, excavations, attached and unattached organisms, or other objects; generally small scale features.

Bottom tending mobile gear: All fishing gear that operates on or near the ocean bottom that is actively worked in order to capture fish or other marine species. Some examples of bottom tending mobile gear are otter trawls and dredges.

Bottom tending static gear: All fishing gear that operates on or near the ocean bottom that I snot actively worked; instead, the effectiveness of this gear depends on species moving to the gear which is set in a particular manner by a vessel, and later retrieved. Some examples of bottom tending static gear are gillnets, traps, and pots.

Boulder reef: An elongated feature (a chain) of rocks (generally piled boulders) on the seabed.

Bryozoans: Phylum aquatic organisms, living for the most part in colonies of interconnected individuals. A few to many millions of these individuals may form one colony. Some bryozoans encrust rocky surfaces, shells, or algae others form lacy or fan-like colonies that in some regions may form an abundant

component of limestones. Bryozoan colonies range from millimeters to meters in size, but the individuals that make up the colonies are rarely larger than a millimeter. Colonies may be mistaken for hydroids, corals or seaweed.

Burrow: A hole or excavation in the sea floor made by an animal (as a crab, lobster, fish, burrowing anemone) for shelter and habitation.

Bycatch: (v.) the capture of nontarget species in directed fisheries which occurs because fishing gear and methods are not selective enough to catch only target species; (n.) fish which are harvested in a fishery but are not sold or kept for personal use, including economic discards and regulatory discards but not fish released alive under a recreational catch and release fishery management program.

Capacity: the level of output a fishing fleet is able to produce given specified conditions and constraints. Maximum fishing capacity results when all fishing capital is applied over the maximum amount of available (or permitted) fishing time, assuming that all variable inputs are utilized efficiently.

Catch: The sum total of fish killed in a fishery in a given period. Catch is given in either weight or number of fish and may include landings, unreported landings, discards, and incidental deaths.

Coarse sediment: Sediment generally of the sand and gravel classes; not sediment composed primarily of mud; but the meaning depends on the context, e.g. within the mud class, silt is coarser than clay.

Commensalism: See *Mutualism*. An interactive association of two species where one benefits in some way, while the other species is in no way affected by the association.

Continental shelf waters: The waters overlying the continental shelf, which extends seaward from the shoreline and deepens gradually to the point where the sea floor begins a slightly steeper descent to the deep ocean floor; the depth of the shelf edge varies, but is approximately 200 meters in many regions.

Control rule: A pre-determined method for determining fishing mortality rates based on the relationship of current stock biomass to a biomass target. Amendment 9 overfishing control rules define a target biomass (B_{MSY} or proxy) as a management objective. The biomass threshold ($B_{threshold}$ or B_{min}) defines a minimum biomass below which a stock is considered overfished.

Cohort: see yearclass.

Crustaceans: Invertebrates characterized by a hard outer shell and jointed appendages and bodies. They usually live in water and breathe through gills. Higher forms of this class include lobsters, shrimp and crawfish; lower forms include barnacles.

Diatoms: Small mobile plants (algæ) with silicified (silica, sand, quartz) skeletons. They are among the most abundant phytoplankton in cold waters, and an important part of the food chain.

Days absent: an estimate by port agents of trip length. This data was collected as part of the NMFS weighout system prior to May 1, 1994.

Days-at-sea (DAS): the total days, including steaming time that a boat spends at sea to fish.

Demersal species: Most often refers to fish that live on or near the ocean bottom. They are often called benthic fish, groundfish, or bottom fish.

Discards: animals returned to sea after being caught; see Bycatch (n.)

Dissolved nutrients: Non-solid nutrients found in a liquid.

Echinoderms: A member of the Phylum Echinodermata. Marine animals usually characterised by a five-fold symmetry, and possessing an internal skeleton of calcite plates, and a complex water vascular system. Includes echinoids (sea urchins), crinoids (sea lillies) and asteroids (starfish).

Ecosystem-based management: a management approach that takes major ecosystem components and services—both structural and functional—into account, often with a multispecies or habitat perspective

Egg stage: One of several marked phases or periods in the development and growth of many animals. The life history stage of an animal that occurs after reproduction and refers to the developing embryo, its food store, and sometimes jelly or albumen, all surrounded by an outer shell or membrane. Occurs before the *larval* or *juvenile stage.*

Elasmobranch: Any of numerous fishes of the class Chondrichthyes characterized by a cartilaginous skeleton and placoid scales: sharks; rays; skates.

Embayment: A bay or an indentation in a coastline resembling a bay.

Emergent epifauna: See *Epifauna*. Animals living upon the bottom that extend a certain distance above the surface.

Epifauna: See *Benthic infauna. Epifauna* are animals that live on the surface of the substrate, and are often associated with surface structures such as rocks, shells, vegetation, or colonies of other animals.

Essential Fish Habitat (EFH): Those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity. The EFH designation for most managed species in this region is based on a legal text definition and geographical area that are described in the Habitat Omnibus Amendment (1998).

Estuarine area: The area of an estuary and its margins; an area characterized by environments resulting from the mixing of river and sea water.

Estuary: A water passage where the tide meets a river current; especially an arm of the sea at the lower end of a river; characterized by an environment where the mixing of river and seawater causes marked variations in salinity and temperature in a relatively small area.

Eutrophication: A set of physical, chemical, and biological changes brought about when excessive nutrients are released into the water.

Euphotic zone: The zone in the water column where at least 1% of the incident light at the surface penetrates.

Exclusive Economic Zone (EEZ): a zone in which the inner boundary is a line coterminous with the seaward boundary of each of the coastal States and the outer boundary is line 200 miles away and parallel to the inner boundary

Exempt fisheries: Any fishery determined by the Regional Director to have less than 5 percent regulated species as a bycatch (by weight) of total catch according to 50 CFR ?648.80(a)(7).

Exploitable biomass: The biomass of fish in the portion of the population that is vulnerable to fishing.

Exploitation pattern: Describes the fishing mortality at age as a proportion of fully recruited F (full vulnerability to the fishery). Ages that are fully vulnerable experience 100% of the fully recruited F and are termed fully recruited. Ages that are only partially vulnerable experience a fraction of the fully recruited F and are termed partially recruited. Ages that are not vulnerable to the fishery (including discards) experience no mortality and are considered pre-recruits. Also known as the partial recruitment pattern, partial recruitment vector or fishery selectivity.

Exploitation rate (u): The fraction of fish in the exploitable population killed during the year by fishing. This is an annual rate compared to F, which is an instantaneous rate. For example, if a population has 1,000,000 fish large enough to be caught and 550,000 are caught (landed and discarded) then the exploitation rate is 55%.

Fathom: A measure of length, containing six feet; the space to which a man can extend his arms; used chiefly in measuring cables, cordage, and the depth of navigable water by soundings.

Fishing mortality (F): A measurement of the rate of removal of fish from a population caused by fishing. This is usually expressed as an instantaneous rate (F) and is the rate at which fish are harvested at any given point in a year. Instantaneous fishing mortality rates can be either fully recruited or biomass weighted. Fishing mortality can also be expressed as an exploitation rate (see exploitation rate) or less commonly, as a conditional rate of fishing mortality (m, fraction of fish removed during the year if no other competing sources of mortality occurred. Lower case m should not be confused with upper case M, the instantaneous rate of natural mortality).

$F_{0.1}$: a conservative fishing mortality rate calculated as the F associated with 10 percent of the slope at origin of the yield-per-recruit curve.

F_{MAX}: a fishing mortality rate that maximizes yield per recruit. F_{MAX} is less conservative than $F_{0.1}$.

F_{MSY}: a fishing mortality rate that would produce MSY when the stock biomass is sufficient for producing MSY on a continuing basis.

$F_{threshold}$: 1) The maximum fishing mortality rate allowed on a stock and used to define overfishing for status determination. Amendment 9 frequently uses F_{MSY} or F_{MSY} proxy for $F_{threshold.}$ 2) The maximum fishing mortality rate allowed for a given biomass as defined by a control rule.

Fishing effort: the amount of time and fishing power used to harvest fish. Fishing power is a function of gear size, boat size and horsepower.

Fluidized: When a normally non-fluid material is made to act like a fluid; e.g. gravity, shaking or injection of a fluid.

Framework adjustments: adjustments within a range of measures previously specified in a fishery management plan (FMP). A change usually can be made more quickly and easily by a framework adjustment than through an amendment. For plans developed by the New England Council, the procedure requires at least two Council meetings including at least one public hearing and an evaluation of environmental impacts not already analyzed as part of the FMP.

Furrow: A trench in the earth made by a plow; something that resembles the track of a plow, as a marked narrow depression; a groove with raised edges.

Glacial moraine: A sedimentary feature deposited from glacial ice; characteristically composed of unsorted clay, sand, and gravel. Moraines typically are hummocky or ridge-shaped and are located along the sides and at the fronts of glaciers.

Glacial till: Unsorted sediment (clay, sand, and gravel mixtures) deposited from glacial ice.

Grain size: the size of individual sediment particles that form a sediment deposit; particles are separated into size classes (e.g. very fine sand, fine sand, medium sand, among others); the classes are combined into broader categories of mud, sand, and gravel; a sediment deposit can be composed of few to many different grain sizes.

Growth overfishing: Fishing at an exploitation rate or at an age at entry that reduces potential yields from a cohort but does not reduce reproductive output (see recruitment overfishing).

Halocline: The zone of the ocean in which salinity increases rapidly with depth.

Habitat complexity: Describes or measures a habitat in terms of the variability of its characteristics and its functions, which can be biological, geological, or physical in nature. Refers to how complex the physical structure of the habitat is. A bottom habitat with *structure-forming organisms*, along with other three dimensional objects such as boulders, is more complex than a flat, featureless, bottom.

Highly migratory species: tuna species, marlin, oceanic sharks, sailfishes, and swordfish

Hydroids: Generally, animals of the Phylum Cnidaria, Class Hydrozoa; most hydroids are bush-like polyps growing on the bottom and feed on plankton, they reproduce asexually and sexually.

Immobile epifaunal species: See *epifauna*. Animals living on the surface of the bottom substrate that, for the most part, remain in one place.

Individual Fishing Quota (IFQ): federal permit under a limited access system to harvest a quantity of fish, expressed by a unit or units representing a percentage of the total allowable catch of a fishery that may be received or held for exclusive use by an individual person or entity

Juvenile stage: One of several marked phases or periods in the development and growth of many animals. The life history stage of an animal that comes between the *egg* or *larval stage* and the *adult stage*; juveniles are considered immature in the sense that they are not yet capable of reproducing, yet they differ from the larval stage because they look like smaller versions of the adults.

Landings: The portion of the catch that is harvested for personal use or sold.

Land runoff: The part of precipitation, snowmelt, or irrigation water that reaches streams (and thence the sea) by flowing over the ground, or the portion of rain or snow that does not percolate into the ground and is discharged into streams instead.

Larvae stage: One of several marked phases or periods in the development and growth of many animals. The first stage of development after hatching from the *egg* for many fish and invertebrates. This life stage looks fundamentally different than the juvenile and adult stages, and is incapable of reproduction; it must undergo metamorphosis into the juvenile or adult shape or form.

Lethrinids: Fish of the genus *Lethrinus*, commonly called emperors or nor'west snapper, are found mainly in Australia's northern tropical waters. Distinctive features of Lethrinids include thick lips, robust canine teeth at the front of the jaws, molar-like teeth at the side of the jaws and cheeks without scales. Lethrinids are carnivorous bottom-feeding fish with large, strong jaws.

Limited-access permits: permits issued to vessels that met certain qualification criteria by a specified date (the "control date").

Lutjanids: Fish of the genus of the Lutjanidae: snappers. Marine; rarely estuarine. Some species do enter freshwater for feeding. Tropical and subtropical: Atlantic, Indian and Pacific Oceans.

Macrobenthos: See *Benthic community* and *Benthic infauna*. Benthic organisms whose shortest dimension is greater than or equal to 0.5 mm.

Maturity ogive: A mathematical model used to describe the proportion mature at age for the entire population. A_{50} is the age where 50% of the fish are mature.

Mean biomass: The average number of fish within an age group alive during a year multiplied by average weight at age of that age group. The average number of fish during the year is a function of starting stock size and mortality rate occurring during the year. Mean biomass can be aggregated over several ages to describe mean biomass for the stock. For example the mean biomass summed for ages 1 and over is the 1^+ mean biomass; mean biomass summed across ages 3 and over is 3^+ mean biomass.

Megafaunal species: The component of the fauna of a region that comprises the larger animals, sometimes defined as those weighing more than 100 pounds.

Mesh selectivity ogive: A mathematical model used to describe the selectivity of a mesh size (proportion of fish at a specific length retained by mesh) for the entire population. L_{25} is the length where 25% of the fish encountered are retained by the mesh. L_{50} is the length where 50% of the fish encountered are retained by the mesh.

Meter: A measure of length, equal to 39.37 English inches, the standard of linear measure in the metric system of weights and measures. It was intended to be, and is very nearly, the ten millionth part of the distance from the equator to the north pole, as ascertained by actual measurement of an arc of a meridian.

Metric ton: A unit of weight equal to a thousand kilograms (1kgs = 2.2 lbs.). A metric ton is equivalent to 2,205 lbs. A thousand metric tons is equivalent to 2.2 million lbs.

Microalgal: Small microscopic types of algae such as the green algae.

Microbial: Microbial means of or relating to microorganisms.

Minimum spawning stock threshold: the minimum spawning stock size (or biomass) below which there is a significantly lower chance that the stock will produce enough new fish to sustain itself over the long term.

Mobile organisms: organisms that are not confined or attached to one area or place, that can move on their own, are capable of movement, or are moved (often passively) by the action of the physical environment (waves, currents, etc.).

Molluscs: Common term for animals of the phylum Mollusca. Includes groups such as the bivalves (mussels, oysters etc.), cephalopods (squid, octopus etc.) and gastropods (abalone, snails). Over 80,000 species in total with fossils back to the Cambrian period.

Mortality: see Annual total mortality (A), Exploitation rate (u), Fishing mortality (F), Natural mortality (M), and instantaneous total mortality (Z).

Motile: Capable of self-propelled movement. A term that is sometimes used to distinguish between certain types of organisms found in water.

Multispecies: the group of species managed under the Northeast Multispecies Fishery Management Plan. This group includes whiting, red hake and ocean pout plus the regulated species (cod, haddock, pollock, yellowtail flounder, winter flounder, witch flounder, American plaice, windowpane flounder, white hake and redfish).

Mutualism: See *Commensalism*. A symbiotic interaction between two species in which both derive some benefit.

Natural disturbance: A change caused by natural processes; e.g. in the case of the seabed, changes can be caused by the removal or deposition of sediment by currents; such natural processes can be common or rare at a particular site.

Natural mortality: A measurement of the rate of death from all causes other than fishing such as predation, disease, starvation, and pollution. Commonly expressed as an instantaneous rate (M). The rate of natural mortality varies from species to species, but is assumed to be M=0.2 for the five critical stocks. The natural mortality rate can also be expressed as a conditional rate (termed n and not additive with competing sources of mortality such as fishing) or as annual expectation of natural death (termed v and additive with other annual expectations of death).

Nearshore area: The area extending outward an indefinite but usually short distance from shore; an area commonly affected by tides and tidal and storm currents, and shoreline processes.

Nematodes: a group of elongated, cylindrical worms belonging to the phylum Nematoidea, also called thread-worms or eel-worms. Some non-marine species attack roots or leaves of plants, others are parasites on animals or insects.

Nemerteans: Proboscis worms belonging to the phylum Nemertea, and are soft unsegmented marine worms that have a threadlike proboscis and the ability to stretch and contract.

Nemipterids: Fishes of the Family Nemipteridae, the threadfin breams or whiptail breams. Distribution: Tropical and sub-tropical Indo-West Pacific.

Northeast Shelf Ecosystem: The Northeast U.S. Shelf Ecosystem has been described as including the area from the Gulf of Maine south to Cape Hatteras, extending from the coast seaward to the edge of the continental shelf, including the slope sea offshore to the Gulf Stream.

Northwest Atlantic Analysis Area (NAAA): A spatial area developed for analysis purposes only. The boundaries of this the area are within the 500 fathom line to the east, the coastline to the west, the Hague line to the north, and the North Carolina/ South Carolina border to the south. The area is approximately 83,550 square nautical miles, and is used as the denominator in the EFH analysis to determine the percent of sediment, EFH, and biomass contained in an area, as compared to the total NAAA.

Nutrient budgets: An accounting of nutrient inputs to and production by a defined ecosystem (e.g., salt marsh, estuary) versus utilization within and export from the ecosystem.

Observer: any person required or authorized to be carried on a vessel for conservation and management purposes by regulations or permits under this Act

Oligochaetes: See *Polychaetes*. Oligochaetes are worms in the phylum Annelida having bristles borne singly along the length of the body.

Open access: describes a fishery or permit for which there is no qualification criteria to participate. Open-access permits may be issued with restrictions on fishing (for example, the type of gear that may be used or the amount of fish that may be caught).

Opportunistic species: Species that colonize disturbed or polluted sediments. These species are often small, grow rapidly, have short life spans, and produce many offspr ing.

Optimum Yield (OY): the amount of fish which A) will provide the greatest overall benefit to the nation, particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems; B) is prescribed as such on the basis of the maximum sustainable yield from the fishery, as reduced by any relevant economic, social, or ecological factor; and C) in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery

Organic matter: Material of, relating to, or derived from living organisms.

Overfished: A conditioned defined when stock biomass is below minimum biomass threshold and the probability of successful spawning production is low.

Overfishing: A level or rate of fishing mortality that jeopardizes the long-term capacity of a stock or stock complex to produce MSY on a continuing basis.

Peat bank: A bank feature composed of partially carbonized, decomposed vegetable tissue formed by partial decomposition of various plants in water; may occur along shorelines.

Pelagic gear: Mobile or static fishing gear that is not fixed, and is used within the water column, not on the ocean bottom. Some examples are mid-water trawls and pelagic longlines.

Phytoplankton: Microscopic marine plants (mostly algae and diatoms) which are responsible for most of the photosynthetic activity in the oceans.

Piscivore: A species feeding preferably on fish.

Planktivore: An animal that feeds on plankton.

Polychaetes: Polychaetes are segmented worms in the phylum Annelida. Polychaetes (poly-chaetae = many-setae) differ from other annelids in having many setae (small bristles held in tight bundles) on each segment.

Porosity: The amount of free space in a volume of a material; e.g. the space that is filled by water between sediment particles in a cubic centimeter of seabed sediment.

Possession-limit-only permit: an open-access permit (see above) that restricts the amount of multispecies a vessel may retain (currently 500 pounds of "regulated species").

Pre-recruits: Fish in size or age groups that are not vulnerable to the fishery (including discards).

Prey availability: The availability or accessibility of prey (food) to a predator. Important for growth and survival.

Primary production: The synthesis of organic materials from inorganic substances by photosynthesis.

Recovery time: The period of time required for something (e.g. a habitat) to achieve its former state after being disturbed.

Recruitment: the amount of fish added to the fishery each year due to growth and/or migration into the fishing area. For example, the number of fish that grow to become vulnerable to fishing gear in one year would be the recruitment to the fishery. "Recruitment" also refers to new year classes entering the population (prior to recruiting to the fishery).

Recruitment overfishing: fishing at an exploitation rate that reduces the population biomass to a point where recruitment is substantially reduced.

Regulated groundfish species: cod, haddock, pollock, yellowtail flounder, winter flounder, witch flounder, American plaice, windowpane flounder, white hake and redfish. These species are usually targeted with large-mesh net gear.

Relative exploitation: an index of exploitation derived by dividing landings by trawl survey biomass. This measure does not provide an absolute magnitude of exploitation but allows for general statements about trends in exploitation.

Retrospective pattern: A pattern of systematic over-estimation or underestimation of terminal year estimates of stock size, biomass or fishing mortality compared to that estimate for that same year when it occurs in pre-terminal years.

Riverine area: The area of a river and its banks.

Saurids: Fish of the family Scomberesocidae, the sauries or needlefishes. Distribution: tropical and temperate waters.

Scavenging species: An animal that consumes dead organic material.

Sea whips: A coral that forms long flexible structures with few or no branches and is common on Atlantic reefs.

Sea pens: An animal related to corals and sea anemones with a featherlike form.

Sediment: Material deposited by water, wind, or glaciers.

Sediment suspension: The process by which sediments are suspended in water as a result of disturbance.

Sedentary: See *Motile* and *Mobile organisms*. Not moving. Organisms that spend the majority of their lives in one place.

Sedimentary bedforms: Wave-like structures of sediment characterized by crests and troughs that are formed on the seabed or land surface by the erosion, transport, and deposition of particles by water and wind currents; e.g. ripples, dunes.

Sedimentary structures: Structures of sediment formed on the seabed or land surface by the erosion, transport, and deposition of particles by water and wind currents; e.g. ripples, dunes, buildups around boulders, among others.

Sediment types: Major combinations of sediment grain sizes that form a sediment deposit, e.g. mud, sand, gravel, sandy gravel, muddy sand, among others.

Spawning adult stage: See *adult stage*. Adults that are currently producing or depositing eggs.

Spawning stock biomass (SSB): the total weight of fish in a stock that sexually mature, i.e., are old enough to reproduce.

Species assemblage: Several species occurring together in a particular location or region

Species composition: A term relating the relative abundance of one species to another using a common measurement; the proportion (percentage) of various species in relation to the total on a given area.

Species diversity: The number of different species in an area and their relative abundance

Species richness: See *Species diversity*. A measurement or expression of the number of species present in an area; the more species present, the higher the degree of species richness.

Species with vulnerable EFH: If a species was determined to be "highly" or "moderately" vulnerable to bottom tending gears (otter trawls, scallop dredges, or clam dredges) then it was included in the list of species with vulnerable EFH. Currently there are 23 species and life stages that are considered to have vulnerable EFH for this analysis.

Status Determination: A determination of stock status relative to $B_{threshold}$ (defines overfished) and $F_{threshold}$ (defines overfishing). A determination of either overfished or overfishing triggers a SFA requirement for rebuilding plan (overfished), ending overfishing (overfishing) or both.

Stock: A grouping of fish usually based on genetic relationship, geographic distribution and movement patterns. A region may have more than one stock of a species (for example, Gulf of Maine cod and Georges Bank cod). A species, subspecies, geographical grouping, or other category of fish capable of management as a unit.

Stock assessment: determining the number (abundance/biomass) and status (life-history characteristics, including age distribution, natural mortality rate, age at maturity, fecundity as a function of age) of individuals in a stock

Structure-forming organisms: Organisms, such as corals, colonial bryozoans, hydroids, sponges, mussel beds, oyster beds, and seagrass that by their presence create a three-dimensional physical structure on the bottom. See *biogenic habitats*.

Submerged aquatic vegetation: Rooted aquatic vegetation, such as seagrasses, that cannot withstand excessive drying and therefore live with their leaves at or below the water surface in shallow areas of estuaries where light can penetrate to the bottom sediments. SAV provides an important habitat for young fish and other aquatic organisms.

Surficial sediment: Sediment forming the sea floor or land surface; thickness of the surficial layer may vary.

Surplus production: Production of new stock biomass defined by recruitment plus somatic growth minus biomass loss due to natural deaths. The rate of surplus production is directly proportional to stock biomass and its relative distance from the maximum stock size at carrying capacity (K). B_{MSY} is often defined as the biomass that maximizes surplus production rate.

Surplus production models: A family of analytical models used to describe stock dynamics based on catch in weight and CPUE time series (fishery dependent or survey) to construct stock biomass history. These models do not require catch at age information. Model outputs may include stock biomass history, biomass weighted fishing mortality rates, MSY, F_{MSY}, B_{MSY}, K, (maximum population biomass where stock growth and natural deaths are balanced) and r (intrinsic rate of increase).

Survival rate (S): Rate of survival expressed as the fraction of a cohort surviving the a period compared to number alive at the beginning of the period (# survivors at the end of the year / numbers alive at the beginning of the year). Pessimists convert survival rates into annual total mortality rate using the relationship A=1-S.

Survival ratio (R/SSB): an index of the survivability from egg to age-of-recruitment. Declining ratios suggest that the survival rate from egg to age-of-recruitment is declining.

TAC: Total allowable catch. This value is calculated by applying a target fishing mortality rate to exploitable biomass.

Taxa: The plural of taxon. Taxon is a named group or organisms of any rank, such as a particular species, family, or class.

Ten-minute- "squares" of latitude and longitude (TMS): Are a measure of geographic space. The actual size of a ten-minute-square varies depending on where it is on the surface of the earth, but in general each square is approximately 70-80 square nautical miles in this region. This is the spatial area that EFH designations, biomass data, and some of the effort data have been binned into for analysis purposes in various sections of this document.

Topography: The depiction of the shape and elevation of land and sea floor surfaces.

Total mortality: The rate of mortality from all sources (fishing, natural, pollution) Total mortality can be expressed as an instantaneous rate (called Z and equal to F + M) or Annual rate (called A and calculated as the ratio of total deaths in a year divided by number alive at the beginning of the year)

Trophic guild: Trophic is defined as the feeding level within a system that an organism occupies; e.g., predator, herbivore. A guild is defined as a group of species that exploit the same class of environmental resources in a similar way. The trophic guild is a utilitarian concept covering both structure and organization that exists between the structural categories of trophic groups and species.

Turbidity: Relative water clarity; a measurement of the extent to which light passing through water is reduced due to suspended materials.

Two-bin (displacement) model: a model used to estimate the effects of area closures. This model assumes that effort from the closed areas (first bin) is displaced to the open areas (second bin). The total effort in the system is then applied to the landings-per-unit-effort (LPUE) in open areas to obtain a projected catch. The percent reduction in catch is calculated as a net result.

Vulnerability: In order to evaluate the potential adverse effects of fishing on EFH, the vulnerability of each species EFH was determined. This analysis defines vulnerability as the likelihood that the functional value of EFH would be adversely affected as a result of fishing with different gear types. A number of criteria were considered in the evaluation of the vulnerability of EFH for each life stage including factors like the function of habitat for shelter, food and/or reproduction.

Yield-per-recruit (YPR): the expected yield (weight) of individual fish calculated for a given fishing mortality rate and exploitation pattern and incorporating the growth characteristics and natural mortality.

Yearclass: also called cohort. Fish that were spawned in the same year. By convention, the "birth date" is set to January 1st and a fish must experience a summer before turning 1. For example, winter flounder that were spawned in February-April 1997 are all part of the 1997 cohort (or year-class). They would be considered age 0 in 1997, age 1 in 1998, etc. A summer flounder spawned in October 1997 would have its birth date set to the following January 1 and would be considered age 0 in 1998, age 1 in 1999, etc.

Z: instantaneous rate of total mortality. The components of Z are additive (i.e., Z = F+M)

Zooplankton: See *Phytoplankton*. Small, often microscopic animals that drift in currents. They feed on detritus, phytoplankton, and other zooplankton. They are preyed upon by fish, shellfish, whales, and other zooplankton.

8.3 Table of Acronyms

The table of acronyms can be found after the table of contents.

8.4 List of Public Meetings

Amendment 13 issues were discussed at the following meetings.

	Meeting Type	Meeting Location	Meeting Dates
2000	Council Meeting	Tavern on Harbor, Gloucester	3/22/2000
	Council Meeting	Providence Biltmore, PVD, RI	5/3 & 5/4/2000
	Council Meeting	Sheraton, Portsmouth, NH	6/14 & 6/15/2000
	Council Meeting	DoubleTree Hotel, Portland, ME	7/26 & 7/27/2000
	Council Meeting	Seaport Inn, Fairhaven, MA	9/25 - 9/27/2000

FINAL

Amendment 13

To the

Northeast Multispecies Fishery Management Plan

VOLUME II
Affected Environment

Prepared by the
New England Fishery Management Council
National Marine Fisheries Service

INTENTIONALLY BLANK

9.0 Description of the Resource and the Affected Environment

A full description of the affected environment was prepared for the Environmental Assessment (EA) that accompanied Amendment 11 to the Northeast Multispecies Fishery Management Plan, Amendment 9 to the Atlantic Sea Scallop Fishery Management Plan, Amendment 1 to the Monkfish FMP, Amendment 1 to the Atlantic Salmon FMP and Sections of the Atlantic Herring FMP (NEFMC 1998a) (heretofore referred to as the "Omnibus EFH Amendment"). This Amendment also contained essential fish habitat (EFH) designations for all groundfish species managed by the New England Fishery Management Council (NEFMC). Amendment 9 to the Northeast Multispecies FMP (NEFMC 1998b) added halibut to the list of managed groundfish stocks; information for this species was updated in the accompanying Environmental Assessment (EA).

The description of the affected environment is presented to provide sufficient background information on the various resources and entities likely to be affected by the actions proposed or under consideration in the SEIS. While there has been little change in the biological or physical components of the environment since the implementation of the Omnibus EFH Amendment, other than changes in stock status that are summarized in Section 9.2.1.1, several reports have since been published which add to our understanding of the physical and biological environment of this region. Although this section deals with the *affected* environment, it does not present the effects of the proposed management program.

9.1 Physical Environment

This section contains a description of the physical environment of the Northeast multispecies fishery, including oceanographic and physical habitat conditions in the Gulf of Maine – Georges Bank region and the area south of New England. Some of the information presented in this section was originally included in the EA for the Omnibus EFH Amendment (NEFMC 1998a).

9.1.1 Physical Characteristics of Regional Systems

The Northeast Shelf Ecosystem (Figure 220) has been described as including the area from the Gulf of Maine south to North Carolina, extending from the coast seaward to the edge of the continental shelf, including the slope sea offshore to the Gulf Stream (Sherman et al. 1996). The continental slope of this region includes the area east of the shelf, out to a depth of 2000 m. A number of distinct sub-systems comprise the region, including the Gulf of Maine, Georges Bank, the Mid-Atlantic Bight, and the continental slope. Occasionally another subsystem, Southern New England, is described; however, we incorporated the distinctive features of this region into the descriptions of Georges Bank and the Mid-Atlantic Bight.

The Gulf of Maine is an enclosed coastal sea, characterized by relatively cold waters and deep basins, with a patchwork of various sediment types. Georges Bank is a relatively shallow coastal plateau that slopes gently from north to south and has steep submarine canyons on its eastern and southeastern edge. It is characterized by highly productive, well-mixed waters and strong currents. The Mid-Atlantic Bight is comprised of the sandy, relatively flat, gently sloping continental shelf from southern New England to Cape Hatteras, NC. The continental slope begins at the continental shelf break and continues eastward with increasing depth until it becomes the continental rise. It is fairly homogenous, with exceptions at the shelf break, some of the canyons, the Hudson Shelf Valley and in areas of glacially rafted hard bottom. Pertinent aspects of the physical characteristics of each of these systems are described in sections that follow. This review is based on several summary reviews (Abernathy 1989, Backus 1987, Beardsley et al. 1996, Brooks 1996, Cook 1988, Dorsey 1998, Kelley 1998, Wiebe et al. 1987, Mountain 1994, NEFMC 1998, Schmitz et al. 1987, Sherman et al. 1996, Steimle et al. 1999b, Stumpf and Biggs 1988, Townsend 1992, Tucholke 1987). Literature citations are not included for generally accepted concepts; however, new research and specific results of research findings are cited.

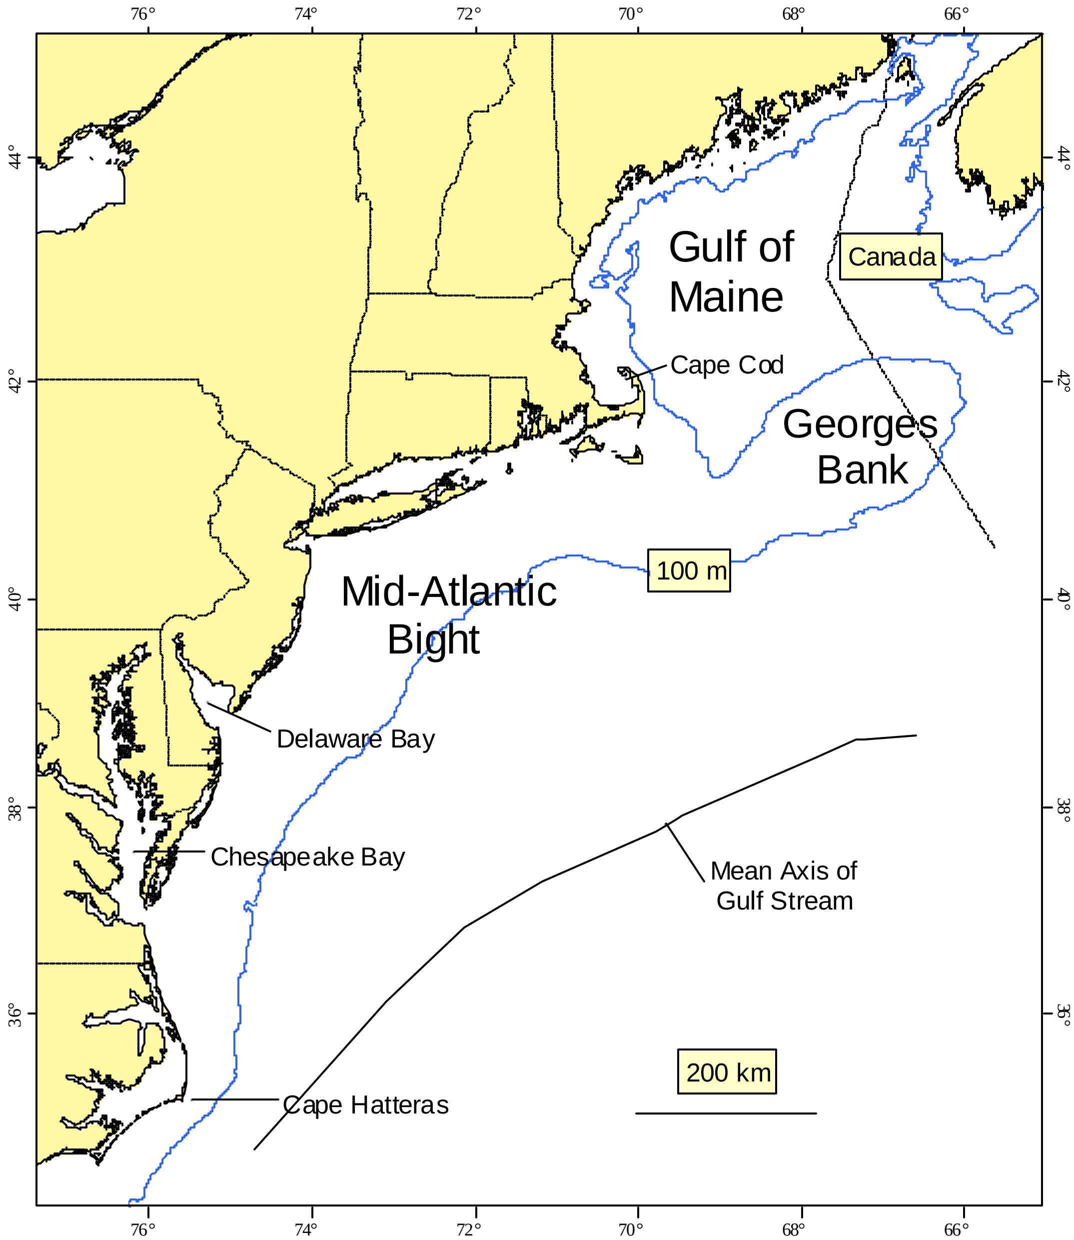

Figure 220 - U.S. Northeast shelf ecosystem.

9.1.1.1 Gulf of Maine

Although not obvious in appearance, the Gulf of Maine is actually an enclosed coastal sea, bounded on the east by Browns Bank, on the north by the Nova Scotian (Scotian) Shelf, on the west by the New England states and on the south by Cape Cod and Georges Bank (Figure 220). The Gulf of Maine (GOM) was glacially derived, and is characterized by a system of deep basins, moraines and rocky protrusions with limited access to the open ocean. This geomorphology influences complex oceanographic processes which result in a rich biological community.

The Gulf of Maine is topographically unlike any other part of the continental border along the U.S. east coast. It contains 21 distinct basins separated by ridges, banks, and swells. The three largest basins are Wilkinson, Georges, and Jordan (Figure 220). Depths in the basins exceed 250 m, with a maximum depth of 350 m in Georges Basin, just north of Georges Bank. The Northeast Channel between Georges Bank and Browns Bank, leads into Georges Basin, and is one of the primary avenues for exchange of water between the GOM and the North Atlantic Ocean.

High points within the gulf include irregular ridges, such as Cashes Ledge, which peaks at 9 m below the surface, as well as lower flat-topped banks and gentle swells. Some of these rises are remnants of the sedimentary shelf left after the glaciers removed most of it. Others are glacial moraines and a few, like Cashes Ledge, are out-croppings of bedrock. Very fine sediment particles created and eroded by the glaciers have collected in thick deposits over much of the Gulf of Maine, particularly in its deep basins (Figure 221**)**. These mud deposits blanket and obscure the irregularities of the underlying bedrock, forming topographically smooth terrains. Some shallower basins are covered with mud as well, including some in coastal waters. In the rises between the basins, other materials are usually at the surface. Unsorted glacial till covers some morainal areas, as on Sewell Ridge to the north of Georges Basin and on Truxton Swell to the south of Jordan Basin. Sand predominates on some high areas and gravel, sometimes with boulders, predominates on others.

Coastal sediments exhibit a high degree of small-scale variability. Bedrock is the predominant substrate along the western edge of the Gulf of Maine north of Cape Cod in a narrow band out to a depth of about 60 m. Rocky areas become less common with increasing depth, but some rock outcrops poke through the mud covering the deeper sea floor. Mud is the second most common substrate on the inner continental shelf. Mud predominates in coastal valleys and basins that often border abruptly on rocky substrates. Many of these basins extend without interruption into deeper water. Gravel, often mixed with shell, is common adjacent to bedrock outcrops and in fractures in the rock. Large expanses of gravel are not common, but do occur near reworked glacial moraines and in areas where the seabed has been scoured by bottom currents. Gravel is most abundant at depths of 20-40 m, except in eastern Maine where a gravel-covered plain exists to depths of at least 100 m. Bottom currents are stronger in eastern Maine where the mean tidal range exceeds 5 m. Sandy areas are relatively rare along the inner shelf of the western Gulf of Maine, but are more common south of Casco Bay, especially offshore of sandy beaches.

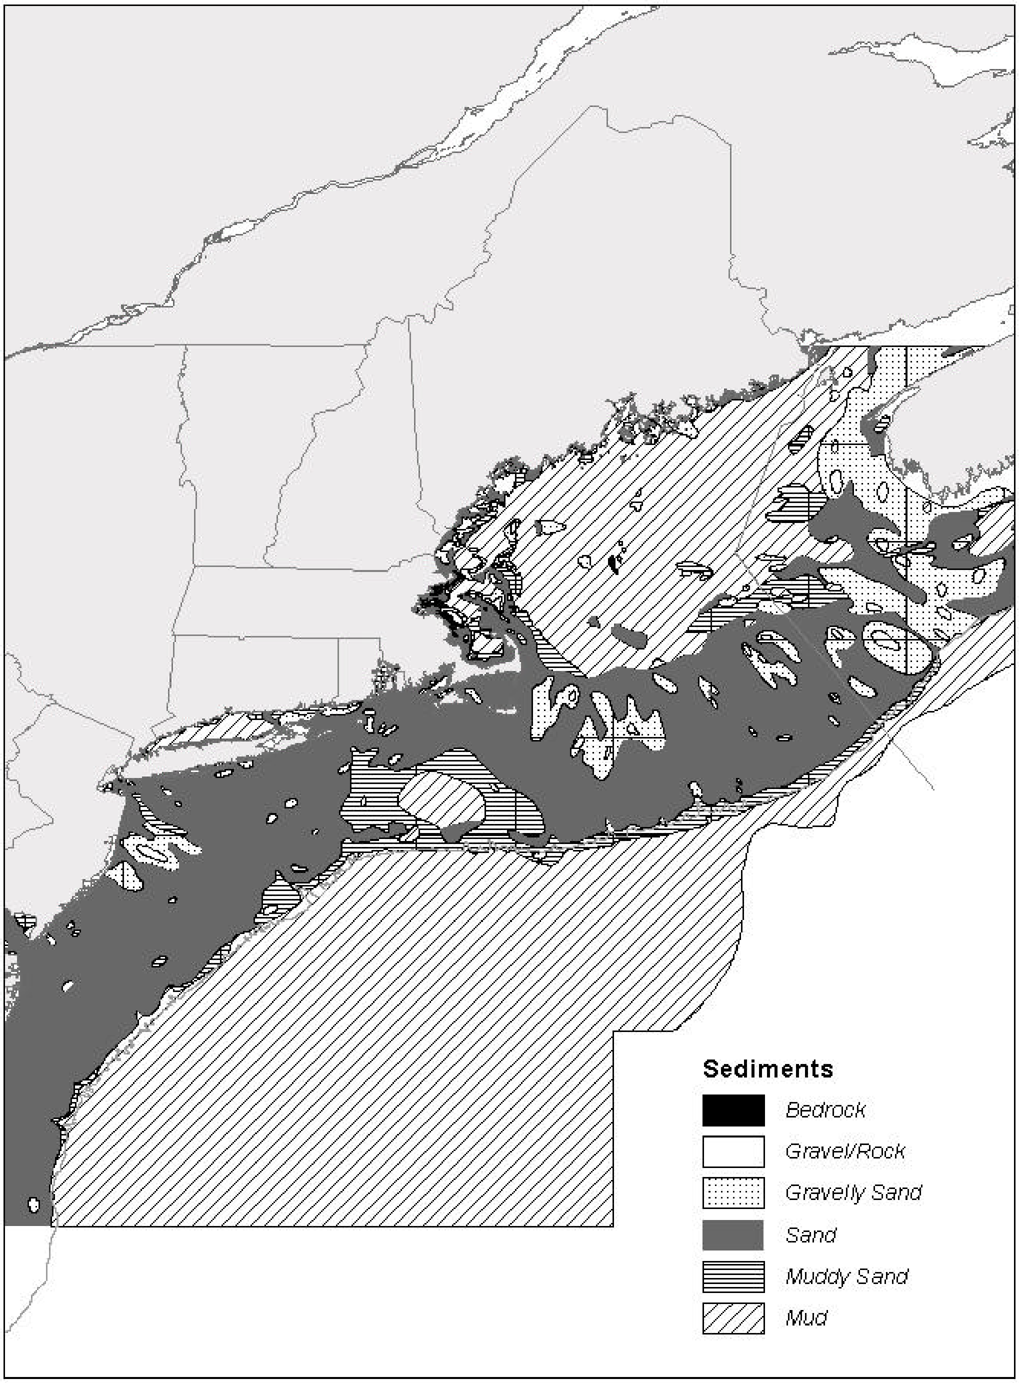

Figure 221- Map showing distribution of surficial sediments, Gulf of Maine, Georges Bank, and the Mid-Atlantic Bight (modified from original map by Poppe *et al.* 1989).

An intense seasonal cycle of winter cooling and turnover, springtime freshwater runoff, and summer warming influences oceanographic and biologic processes in the Gulf of Maine. The Gulf has a general counterclockwise nontidal surface current that flows around its coastal margin. It is primarily driven by fresh, cold Scotian Shelf water that enters over the Scotian Shelf and through the Northeast Channel, and freshwater river runoff, which is particularly important in the spring. Dense relatively warm and saline slope water entering through the bottom of the Northeast Channel from the continental slope also influences gyre formation. Counterclockwise gyres generally form in Jordan, Wilkinson, and Georges Basins and the Northeast Channel as well. These surface gyres are more pronounced in spring and summer; with winter, they weaken and become more influenced by the wind.

Stratification of surface waters during spring and summer seals off a mid-depth layer of water that preserves winter salinity and temperatures. This cold layer of water is called "Maine intermediate water" (MIW) and is located between more saline Maine bottom water and the warmer, stratified Maine surface water. The stratified surface layer is most pronounced in the deep portions of the western GOM. Tidal mixing of shallow areas prevents thermal stratification and results in thermal fronts between the stratified areas and cooler mixed areas. Typically, mixed areas include Georges Bank, the southwest Scotian Shelf, eastern Maine coastal waters, and the narrow coastal band surrounding the remainder of the Gulf.
The Northeast Channel provides an exit for cold MIW and outgoing surface water while it allows warmer more saline slope water to move in along the bottom and spill into the deeper basins. The influx of water occurs in pulses, and appears to be seasonal, with lower flow in late winter and a maximum in early summer.

Gulf of Maine circulation and water properties can vary significantly from year to year. Notable episodic events include shelf-slope interactions such as the entrainment of shelf water by Gulf Stream rings (see *Gulf Stream and Associated Features*), and strong winds that can create currents as high as 1.1 meters/second over Georges Bank. Warm core Gulf Stream rings can also influence upwelling and nutrient exchange on the Scotian shelf, and affect the water masses entering the GOM. Annual and seasonal inflow variations also affect water circulation.

Internal waves are episodic and can greatly affect the biological properties of certain habitats. Internal waves can shift water layers vertically, so that habitats normally surrounded by cold MIW are temporarily bathed in warm, organic-rich surface water. On Cashes Ledge, it is thought that deeper nutrient rich water is driven into the photic zone, providing for increased productivity. Localized areas of upwelling interaction occur in numerous places throughout the Gulf.

9.1.1.2 Georges Bank

Georges Bank is a shallow (3-150 m depth), elongate (161 km wide by 322 km long) extension of the continental shelf which was formed by the Wisconsinian glacial episode and is characterized by a steep slope on its northern edge and a broad, flat, gently sloping southern flank. The Great South Channel lies to the west. Natural processes continue to erode and rework the sediments on Georges Bank. It is anticipated that erosion and reworking of sediments will reduce the amount of sand available to the sand sheets, and cause an overall coarsening of the bottom sediments (Valentine et al. 1993).

Glacial retreat during the late Pleistocene deposited the bottom sediments currently observed on the eastern section of Georges Bank, and the sediments have been continuously reworked and redistributed by the action of rising sea level, and by tidal, storm and other currents. The strong, erosive currents affect the character of the biological community. Bottom topography on eastern Georges Bank is characterized by linear ridges in the western shoal areas; a relatively smooth, gently dipping sea floor on the deeper, easternmost part; a highly energetic peak in the north with sand ridges up to 30 m high and extensive gravel pavement, and steeper and smoother topography incised by submarine canyons on the southeastern margin (see *Continental Slope* for more on canyons). The nature of the seabed sediments varies widely, ranging from clay to gravel (Figure 221). The gravel-sand mixture is usually a transition zone between coarse gravel and finer sediments.

The central region of the bank is shallow; shoals and troughs characterize the bottom, with sand dunes superimposed upon them. The two most prominent elevations on the ridge and trough area are Cultivator and Georges Shoals. This shoal and trough area is a region of strong currents, with average flood and ebb tidal currents greater than 4 km per hour, and as high as 7 km per hour. The dunes migrate at variable rates, and the ridges may move, also. In an area that lies between the central part and northeast peak, Almeida et al. (2000) identified high energy areas as between 35 – 65 m deep, where sand is transported on a daily basis by tidal currents; and a low energy area at depths > 65 m that is affected only by storm currents. The area west of the Great South Channel, known as Nantucket shoals (Figure 220), is similar in nature to the central region of the bank. Currents in these areas are strongest where water depth is shallower than 50 m. This type of traveling dune and swale morphology is also found in the mid-Atlantic bight.

The Great South Channel separates the main part of Georges Bank from Nantucket Shoals. Sediments in this region include gravel pavement and mounds, some scattered boulders, sand with storm generated ripples, scattered shell and mussel beds. Tidal and storm currents may range from moderate to strong, depending upon location and storm activity (Valentine, pers. comm.).

Oceanographic frontal systems occur between water masses from the Gulf of Maine and Georges Bank. These water masses differ in temperature, salinity, nutrient concentration, and planktonic communities, which influence productivity and may influence fish abundance and distribution. Currents on Georges Bank include a weak, persistent clockwise gyre around the bank, a strong semidiurnal tidal flow predominantly northwest and southeast, and very strong, intermittent storm-induced currents, which can all occur simultaneously. Tidal currents over the shallow top of Georges Bank can be very strong, and keep the waters over the bank well mixed vertically. This results in a tidal front that separates the cool waters of the well-mixed shallows of the central bank from the warmer, seasonally stratified shelf waters on the seaward and shoreward sides of the bank. The clockwise gyre is instrumental in distribution of the planktonic community, including larval fish. For example, Lough and Potter (1993) describe passive drift of Atlantic cod and haddock eggs and larvae in a southwest residual pattern around Georges Bank. Larval concentrations are found at varying depths along the southern edge between 60 – 100 m.

9.1.1.3 Mid Atlantic Bight

The Mid-Atlantic Bight includes the shelf and slope waters from Georges Bank south to Cape Hatteras, and east to the Gulf Stream (Figure 220). Like the rest of the continental shelf, the topography of the Mid-Atlantic Bight was shaped largely by sea level fluctuations caused by past ice ages. The shelf's basic morphology and sediments derive from the retreat of the last ice sheet, and the subsequent rise in sea level. Since that time, currents and waves have modified this basic structure.

Shelf and slope waters of the Mid-Atlantic Bight have a slow southwestward flow that is occasionally interrupted by warm core rings or meanders from the Gulf Stream. On average, shelf water moves parallel to bathymetry isobars at speeds of 5-10 cm/second at the surface and 2 cm/second or less at the bottom. Storm events can cause much more energetic variations in flow. Tidal currents on the inner shelf have a higher flow rate of 20 cm/second that increases to 100 cm/second near inlets.

Slope water tends to be warmer than shelf water because of its proximity to the Gulf Stream, and also tends to be more saline. The abrupt gradient where these two water masses meet is called the shelf-slope front. This front is usually located at the edge of the shelf and touches bottom at about 75-100 m depth of water, and then slopes up to the east toward the surface. It reaches surface waters approximately 25-55 km further offshore. The position of the front is highly variable, and can be influenced by many physical factors. Vertical structure of temperature and salinity within the front can develop complex patterns because of the interleaving of shelf and slope waters – for example cold shelf waters can protrude offshore, or warmer slope water can intrude up onto the shelf.

The seasonal effects of warming and cooling increase in shallower, near shore waters. Stratification of the water column occurs over the shelf and the top layer of slope water during the spring-summer and is usually established by early June. Fall mixing results in homogenous shelf and upper slope waters by October in most years. A permanent thermocline exists in slope waters from 200-600 m. Temperatures decrease at the rate of about 0.02º C per meter and remain relatively constant except for occasional incursions of Gulf stream eddies or meanders. Below 600 m, temperature declines, and usually averages about 2.2º C at 4000 m. A warm, mixed layer approximately 40 m thick resides above the permanent thermocline.

The "cold pool" is an annual phenomenon particularly important to the Mid-Atlantic Bight. It stretches from the Gulf of Maine along the outer edge of Georges Bank and then southwest to Cape Hatteras. It becomes identifiable with the onset of thermal stratification in the spring and lasts into early fall until normal seasonal mixing occurs. It usually exists along the bottom between the 40 m and 100 m isobaths and extends up into the water column for about 35 m, to the bottom of the seasonal thermocline. The cold pool usually represents about 30% of the volume of shelf water. Minimum temperatures for the cold pool occur in early spring and summer, and range from 1.1º C to 4.7º C.

The shelf slopes gently from shore out to between 100 and 200 km offshore where it transforms to the slope (100 – 200 m water depth) at the shelf break. In both the Mid-Atlantic and on Georges Bank, numerous canyons incise the slope, and some cut up onto the shelf itself (see section on *Continental Slope*). The primary morphological features of the shelf include shelf valleys and channels, shoalmassifs, scarps, and sand ridges and swales (Figure 222, Figure 223).

Most of these structures are relic except for some sand ridges and smaller sand-formed features. Shelf valleys and slope canyons were formed by rivers of melted glacier that deposited sediments on the outer shelf edge as they entered the ocean. Most valleys cut about 10 m into the shelf, with the exception of the Hudson Shelf Valley, which is about 35 m deep. The valleys were partially filled as the glacier melted and egressed across the shelf. The glacier also left behind a lengthy scarp near the shelf break from Chesapeake Bay north to the eastern end of Long Island. Shoal retreat massifs were produced by extensive deposition at a cape or estuary mouth. Massifs were also formed as estuaries retreated across the shelf.

The sediment type covering most of the shelf in the Mid-Atlantic Bight is sand, with some relatively small, localized areas of gravel and gravelly sand (Figure 221). On the slope, muddy sand and mud predominate. Sediments are fairly uniformly distributed over the shelf in this region. A sheet of sand and gravel varying in thickness from 0 to 10 m covers most of the shelf. The mean bottom flow from the constant southwesterly current is not fast enough to move sand, so sediment transport must be episodic. Net sediment movement is in the same southwesterly direction as the current. The sands are mostly medium to coarse grains, with finer sand in the Hudson Shelf Valley and on the outer shelf. Mud is rare over most of the shelf, but is common in the Hudson Shelf Valley. Occasionally relic estuarine mud deposits are re-exposed in the swales between sand ridges. Fine sediment content increases rapidly at the shelf break, which is sometimes called the "mud line," and sediments are 70-100% fines on the slope.

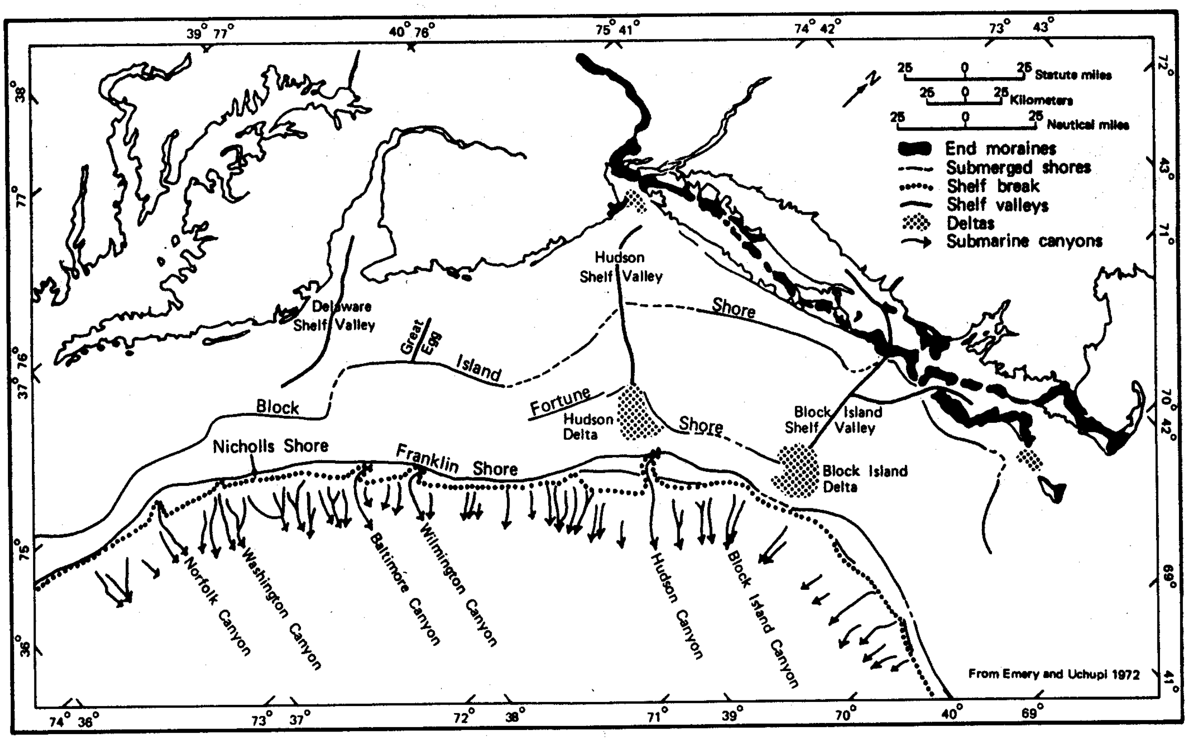

Figure 223 - Major features of the Mid-Atlantic and Southern New England continental shelf. Source: Stumpf and Biggs (1988).

In addition to sand ridges that were formed by the glaciers, some sand ridges have been formed since the end of the last ice age. Their formation is not well understood; however, they appear to develop from the sediments that erode from the shore face. They maintain their shape, so it is assumed that they are in equilibrium with modern current and storm regimes. They are usually grouped, with heights of about 10 m, lengths of 10-50 km and spacing of 2 km. Ridges are usually oriented at a slight angle towards shore, running in length from northeast to southwest. The seaward face usually has the steepest slope. Sand ridges are often covered with smaller similar forms such as sand waves, megaripples, and ripples. Swales occur between sand ridges. Since ridges are higher than the adjacent swales, they are exposed to more energy from water currents, and experience more sediment mobility than swales. Ridges tend to contain less fine sand, silt and clay while relatively sheltered swales contain more of the finer particles. Swales have greater benthic macrofaunal density, species richness and biomass, due in part to the increased abundance of detrital food and the physically less rigorous conditions.

Sand waves are usually found in patches of 5-10 with heights of about 2 m, lengths of 50-100 m and 1-2 km between patches. Sand waves are primarily found on the inner shelf, and often observed on sides of sand ridges. They may remain intact over several seasons. Megaripples occur on sand waves or separately on the inner or central shelf. During the winter storm season, they may cover as much as 15% of the inner shelf. They tend to form in large patches and usually have lengths of 3-5 m with heights of 0.5-1 m. Megaripples tend to survive for less than a season. They can form during a storm and reshape the upper 50-100 cm of the sediments within a few hours. Ripples are also found everywhere on the shelf, and appear or disappear within hours or days, depending upon storms and currents. Ripples usually have lengths of about 1-150 cm and heights of a few centimeters.

The northern portion of the mid-Atlantic bight is sometimes referred to as southern New England. Some of the features of this area were described earlier (see *Georges Bank*); however, one other formation of this region that deserves note is the “mud patch” which is located just southwest of Nantucket Shoals and southeast of Long Island. Tidal currents in this area slow significantly, which allows silts and clays to settle out. The mud is mixed with sand, and is occasionally re-suspended by large storms. This habitat is an anomaly of the outer continental shelf.

Artificial reefs are another significant mid-Atlantic habitat, formed much more recently on the geologic time-scale than other regional habitat types. These localized areas of hard structure have been formed by shipwrecks, lost cargoes, disposed solid materials, shoreline jetties and groins, submerged pipelines, cables, and other materials (Steimle and Zetlin 2000). While some of materials have been deposited specifically for use as fish habitat, most have an alternative primary purpose; however, they have all become an integral part of the coastal and shelf ecosystem. It is expected that the increase in these materials has had an impact on living marine resources and fisheries, but these effects are not well known. In general, reefs are important for attachment sites, shelter, and food for many species, and fish predators such as tunas may be attracted by prey aggregations, or may be behaviorally attracted to the reef structure.

9.1.1.4 Continental Slope

The continental slope extends from the continental shelf break, at depths between 60 m and 200 m, eastward to a depth of 2000 m. The width of the slope varies from 10-50 km, with an average gradient of 3-6°; however, local gradients can be nearly vertical. The base of the slope is defined by a marked decrease in seafloor gradient where the continental rise begins.

The morphology of the present continental slope appears largely to be a result of sedimentary processes that occurred during the Pleistocene, including:

1) slope upbuilding and progradation by deltaic sedimentation principally during sea-level low-stands;
2) canyon-cutting by sediment mass movements during and following sea-level low-stands;
3) sediment slumping.

The slope is cut by at least 70 large canyons between Georges Bank and Cape Hatteras (Figure 224) and numerous smaller canyons and gullies, many of which may feed into the larger canyon systems. The New England Seamount Chain including Bear, Mytilus, Balanus, etc. occurs on the slope southwest of Georges Bank. A smaller chain (Caryn, Knauss, etc.) occurs in the vicinity in deeper water.

A "mud line" occurs on the slope at a depth of 250 m – 300 m, below which fine silt and clay-size particles predominate (Figure 221). Localized coarse sediments and rock outcrops are found in and near canyon walls, and occasional boulders occur on the slope as a result of glacial rafting. Sand pockets may also be formed as a result of downslope movements.

Gravity induced downslope movement is the dominant sedimentary process on the slope, and includes slumps, slides, debris flows, and turbidity currents, in order from thick cohesive movement to relatively non-viscous flow. Slumps are localized blocks of sediment that may involve short downslope movement. However, turbidity currents can transport sediments thousands of kilometers.

Submarine canyons are not spaced evenly along the slope, but tend to decrease in areas of increasing slope gradient. Canyons are typically "v"-shaped in cross section and often have steep walls and outcroppings of bedrock and clay. The canyons are continuous from the canyon heads to the base of the continental slope. Some canyons end at the base of the slope, but others continue as channels onto the continental rise. Larger and more deeply incised canyons are generally significantly older than smaller ones, and there is also evidence that some older canyons have experienced several episodes of filling and re-excavation. Many, if not all, submarine canyons may first form by mass-wasting processes on the continental slope, although there is evidence that some canyons formed as a result of fluvial drainage (i.e., Hudson Canyon).

Canyons can alter the physical processes in the surrounding slope waters. Fluctuations in the velocities of the surface and internal tides can be large near the heads of the canyons, leading to enhanced mixing and sediment transport in the area. Shepard et al. (1979) concluded that the strong turbidity currents initiated in study canyons were responsible for enough sediment erosion and transport to maintain and modify those canyons. Since surface and internal tides are ubiquitous over the continental shelf and slope, it can be anticipated that these fluctuations are important for sedimentation processes in other canyons as well. In Lydonia Canyon, Butman et al. (1982) found that the dominant source of low-frequency current variability was related to passage of warm core Gulf Stream rings rather than the atmospheric events that predominate on the shelf.

The water masses of the Atlantic continental slope and rise are essentially the same as those of the North American Basin (defined in Wright and Worthington 1970). Worthington (1976) divided the water column of the slope into three vertical layers: deep water (colder than 4°C), the thermocline (4°-17°C), and warm water (warmer than 17°C). In the North American Basin the deep water accounts for two-thirds of all the water, the thermocline for about one quarter, and the warm water the remainder. In the slope water north of Cape Hatteras, the only warm water occurs in the Gulf Stream and seasonally influenced summer waters.

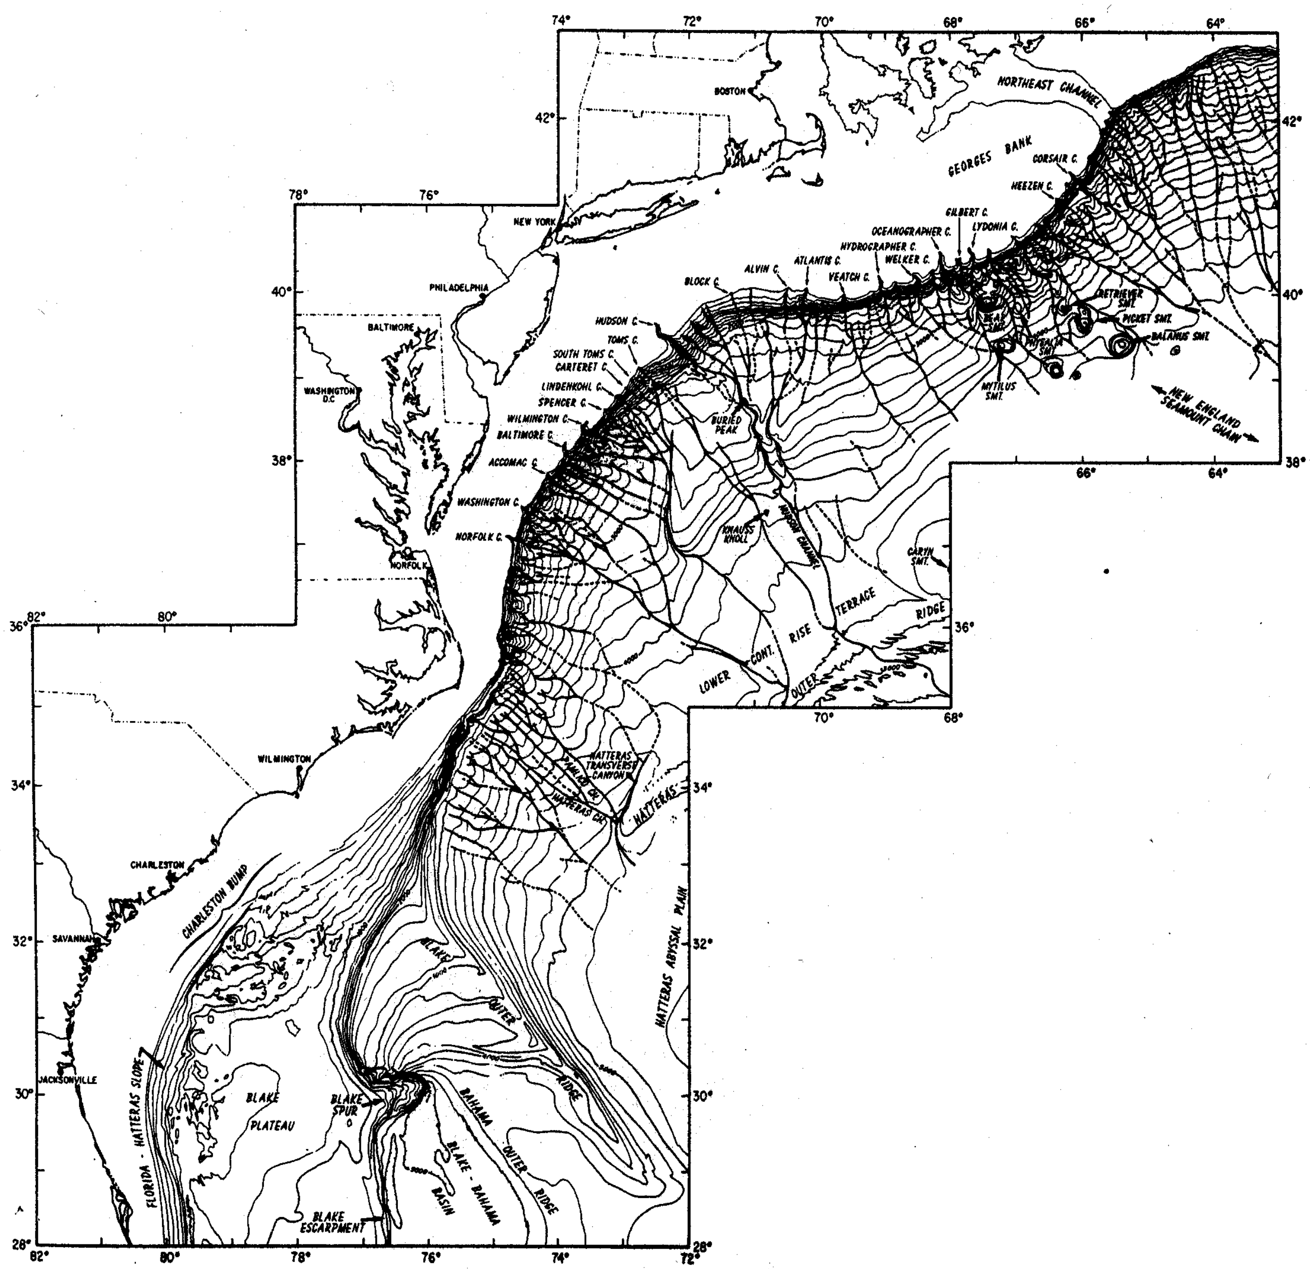

Figure 224 - Bathymetry of the U.S. Atlantic continental margin. Contour interval is 200 m below 1000 m water depth and 100 m above 1000 m. Axes of principal canyons and channels are shown by solid lines (dashed where uncertain or approximate). Source: Tucholke (1987).

The principal cold-water mass in the region is the North Atlantic Deep Water. North Atlantic Deep Water is comprised of a mixture of five sources: Antarctic Bottom Water, Labrador Sea Water, Mediterranean Water, Denmark Strait Overflow Water, and Iceland-Scotland Overflow Water. The thermocline represents a fairly straightforward water mass compared with either the deep water or the surface water. Nearly 90% of all thermocline water comes from the water mass called the Western North Atlantic Water. This water mass is slightly less saline northeast of Cape Hatteras due to the influx of southward flowing Labrador Coastal Water.

Seasonal variability in slope waters penetrates only the upper 200 m of the water column. In the winter months, cold temperatures and storm activity create a well-mixed layer down to about 100-150 m, but summer warming creates a seasonal thermocline overlain by a surface layer of low-density water. The seasonal thermocline, in combination with reduced storm activity in the summer, inhibits vertical mixing and reduces the upward transfer of nutrients into the photic zone.

Two currents found on the slope, the Gulf Stream and Western Boundary Undercurrent, together represent one of the strongest low frequency horizontal flow systems in the world. Both currents have an important influence on slope waters. Warm and cold core rings that spin off the Gulf Stream are a persistent and ubiquitous feature of the Northwest Atlantic Ocean (see section on *Gulf Stream*). The Western Boundary Undercurrent flows to the southwest along the lower slope and continental rise in a stream about 50 km wide. The boundary current is associated with the spread of North Atlantic Deep Water, and it forms part of the generally westward flow found in slope water. North of Cape Hatteras it crosses under the Gulf Stream in a manner not yet completely understood.

9.1.1.5 Gulf Stream and Associated Features

Shelf and slope waters of the Northeast are intermittently but intensely affected by the Gulf Stream. The Gulf Stream begins in the Gulf of Mexico and flows northeastward at an approximate rate of 1 m/second (2 knots), transporting warm waters north along the eastern coast of the United States, and then east towards the British Isles. Conditions and flow of the Gulf Stream are highly variable on time scales ranging from days to seasons. The principal sources of variability in slope waters off the northeastern shelf are intrusions from the Gulf Stream.

The location of the Gulf Stream's shoreward, western boundary is variable because of meanders and eddies. Gulf Stream eddies are formed when extended meanders enclose a parcel of seawater and pinch off. These eddies can be cyclonic, meaning they rotate counterclockwise and have a cold-core formed by enclosed slope water (cold core ring), or anticyclonic, meaning they rotate clockwise and have a warm core of Sargasso Sea water (warm core ring). The rings are shaped like a funnel, wider at the top and narrower at the bottom, and can have depths of over 2000 m. They range in size from approximately 150-230 m in diameter. There are 35% more rings and meanders in the vicinity of Georges Bank than in the Mid-Atlantic region. A net transfer of water on and off the shelf may result from the interaction of rings and shelf waters. These warm or cold core rings maintain their identity for several months until they are reabsorbed by the Gulf Stream. The rings and the Gulf Stream itself have a great influence over oceanographic conditions all along the continental shelf.

9.1.1.6 Coastal Features

Coastal and estuarine features such as salt marshes, mud flats, rocky intertidal zones, sand beaches, and submerged aquatic vegetation are critical to inshore and offshore habitats and fishery resources of the Northeast. For example, coastal areas and estuaries are important for nutrient recycling and primary production, and certain features serve as nursery areas for juvenile stages of economically important species. Salt marshes are found extensively throughout the region. Tidal and subtidal mud and sand flats are general salt marsh features and are also occur in other estuarine areas. Salt marshes provide nursery and spawning habitat for many finfish and shellfish species. Salt marsh vegetation can also be a large source of organic material that is important to the biological and chemical processes of the estuarine and marine environment.

Rocky intertidal zones are periodically submerged, high-energy environments found in the northern portion of the Northeast system. Sessile invertebrates and some fish inhabit rocky intertidal zones. A variety of algae, kelp, and rockweed are also important habitat features of rocky shores. Fishery resources may depend upon particular habitat features of the rocky intertidal that provide important levels of refuge and food.

Sandy beaches are most extensive along the Northeast coast. Different zones of the beach present suitable habitat conditions for a variety of marine and terrestrial organisms. For example, the intertidal zone presents suitable habitat conditions for many invertebrates, and transient fish find suitable conditions for foraging during high tide. Several invertebrate and fish species are adapted for living in the high-energy subtidal zone adjacent to sandy beaches.

9.1.1.7 Recent Oceanographic Conditions

The broad-scale hydrography of the Gulf of Maine – Georges Bank region is strongly influenced by variation in the major water mass fluxes into the Gulf of Maine. The two key sources of inflows to the Gulf of Maine are Scotian Shelf water, which is relatively cool and fresh, and slope water, which is relatively warm and more saline. The volume ratio of Scotian Shelf water to slope water was roughly 1:2 during the 1980s, while during the 1990s, the volume ratio has been roughly 2:1 (Pers. Comm. Dr. David Mountain, Northeast Fisheries Science Center, 166 Water Street, Woods Hole, MA 02543). As a result of these broad-scale changes in inputs, water salinity has been lower in the Gulf of Maine during the 1990s.

Changes in the relative salinity of the Gulf of Maine have been indexed by salinity anomalies on the northwest flank of Georges Bank during 1975-2001. The observed salinity anomaly index shows cyclic variation on a 3-5 year time scale. During the 1990s, the salinity anomaly index has been low. In particular, salinity was very low during the 1996-1999 period. Since 1999, the salinity index has returned to normal levels. Based on some recent research, it appears that when salinity is low during autumn, chlorophyll levels in the subsequent spring tend to be higher than average, indicating higher primary production in the Gulf of Maine. Whether this higher primary production funnels upward through the food web to improve growth of commercially-exploited fishes is not known, however.

During 1998, there was an unusual influx of Labrador slope water (LSW) into the Gulf of Maine (Pers. Comm. Dr. David Mountain, Northeast Fisheries Science Center, 166 Water Street, Woods Hole, MA 02543). The event began in January and was detectable through the autumn of 1998. Labrador slope water is cooler and fresher than the “normal” water mass of slope water that flows into the Gulf. Thus, the influx of LSW reduced water temperatures, on average, in 1998. This event was also notable because it was the first time since the 1960s that a LSW mass was observed in the Gulf of Maine. The unusual influx of LSW likely corresponds to a delayed response of local ocean conditions to the dramatic change in the North Atlantic Oscillation Index, a broad-scale measure of winter atmospheric pressure, during 1995-1996.

Interestingly, recruitment of several groundfish stocks in the Gulf of Maine was above recent average levels in 1998. In particular, the 1998 year classes of white hake, American plaice, witch flounder, and Gulf of Maine cod were larger than might be expected given recent low levels of recruitment. In addition, the 1998 and 1999 year classes of Georges Bank haddock were large in comparison to recent levels. Overall, it appears that the LSW event of 1998 may have had a positive effect on larval survival of several groundfish stocks, as measured by recruitment estimates taken from stock assessments.

9.2 Biological Environment

This section contains a description of the biological environment of the Northeast multispecies fishery, including biological habitat conditions in the Gulf of Maine – Georges Bank region and the area south of New England. Some of the information presented in this section was originally included in the EA for the Omnibus EFH Amendment (NEFMC 1998a).

Fish pass through a gamut of process and conditions throughout their life histories. The probability of successfully surviving and reproducing subsequent generations varies from species to species and for individuals of a species. One of the main values of habitat lies in the provision of adequate food for all metabolic considerations of fish, ultimately for both individual and population growth. Habitat can also provide refugia from predation, aggregation of prey for more effective feeding (i.e., minimized foraging costs), aggregation of individuals to enhance spawning, shelter from extreme physio-chemical events, adequate physio-chemical environment (e.g., oxygen production, detritus conversion, etc.), cycling of nutrients into "packaged" forms amenable for propagation up through the food web, etc. Thus, available habitat can improve the probabilities of successful survival and reproduction of fish.

Additionally, the degree of habitat complexity and utilization can mitigate some of the effects of predatory losses of fishes, particularly for juvenile stages. However, competition is another major biological consideration facing fish that is difficult to directly demonstrate in marine ecosystems. Knowing patterns of shared prey use (e.g., diet similarities) and spatio-temporal overlap can provide some insight into the potential competitors of a given fish species. Other biotic concerns such as parasitism, commensalim, or mutualism are recognized as factors but are effectively infeasible to assess on the broad oceanographic and fish community scales at which fish are typically sampled.

Below is a compilation of the general biological setting or "environment" within which many of the fish that are the principal subject of this document are found. This mosaic of biota is not intended to provide conclusive specific details regarding ecological processes that effect a particular fish species or life stage, rather a general background of the biological community surrounding these fish.

9.2.1 Description of the Species

The management unit is described in Amendments 7 and 9 to the FMP. No changes are proposed. Life history and habitat characteristics of the stocks managed in this FMP can be found in the Essential Fish Habitat Source documents (series) published as NOAA Technical Memorandums and available at http://www.nefsc.noaa.gov/nefsc/habitat/efh/.

9.2.1.1 Stock Status

Since implementation of Amendment 5 in 1994, the management program has succeeded in increasing the biomass of most groundfish stocks and, in general, reduced fishing mortality on most stocks. Estimated biomass tripled from 1995 to 2001, as shown in Figure 225 for twelve stocks with biomass estimates. While overall biomass has increased rapidly, some stocks – such as GB cod, SNE/MA yellowtail flounder, and CC/GOM yellowtail flounder – have only shown gradual improvement. Progress has also been made in controlling fishing mortality for many stocks. Fishing mortality for Gulf of Maine cod has been reduced in half since 1990, plaice mortality has been held nearly constant, and CC/GOM yellowtail flounder mortality has been reduced by about one-fourth. More dramtic success is obvious on Georges Bank, where the mortality of all key stocks has declined significantly since 1990. In the Southern New England area, winter flounder mortality has been cut in half while that of yellowtail flounder has been reduced by about a third (Figure 226).

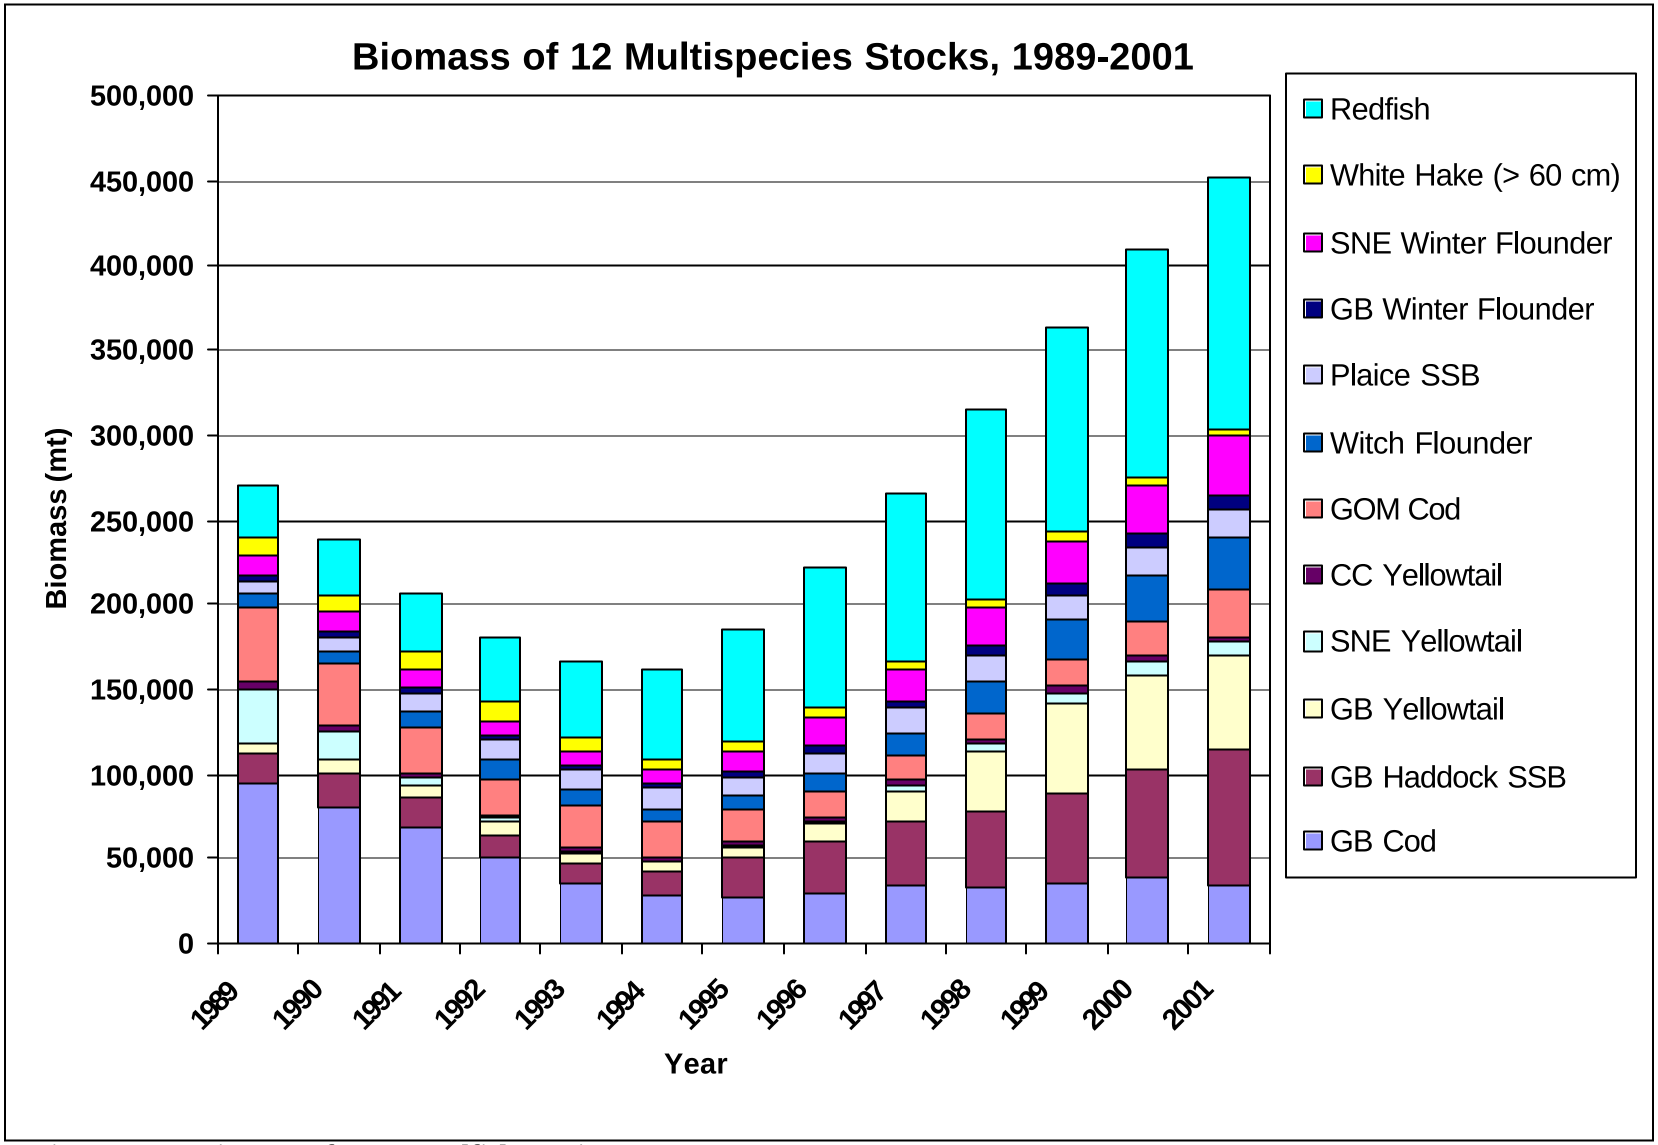

Figure 225 – Biomass of 12 groundfish species, 1989 – 2001

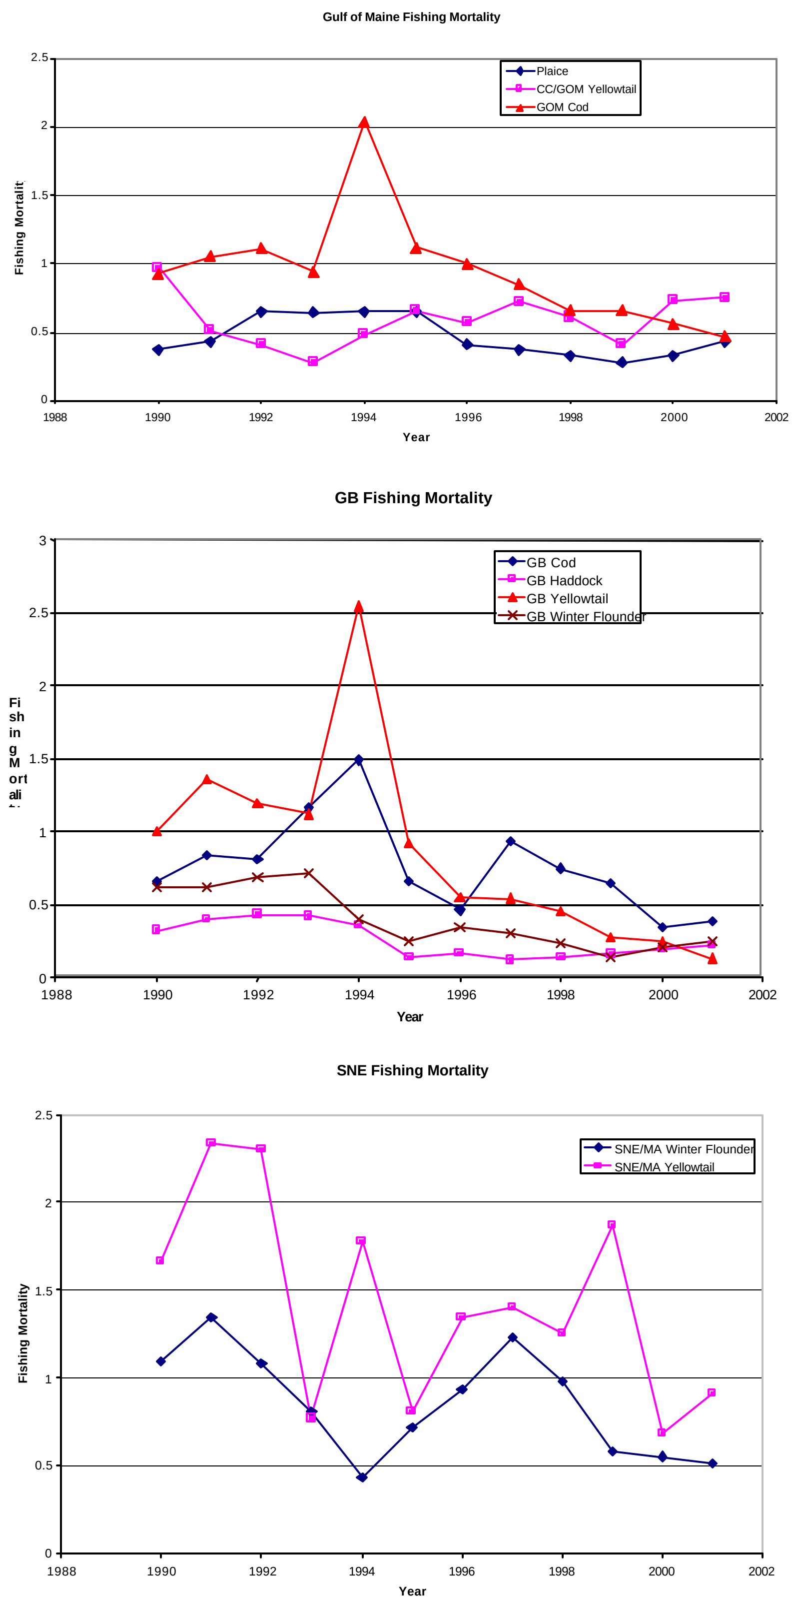

Figure 226 – Trends in fishing mortality by area

In terms of stock determinations – whether a stock is overfished or overfishing is occurring – there have also been improvements since 1996. In 1996, only one groundfish stock was not overfished, and overfishing was not occurring on only six stocks (Figure 227). Based on projected estimates of mortality and biomass provided by the Northeast Fisheries Science Center, in 2002 eight stocks were not overfished and overfishing was not occurring on ten stocks. The number of stocks that were both overfished and overfishing was occuring dropped from eleven in 1996 to six in 2002. In 1996, fishing mortality on eight stocks was more than twice F_{MSY}, while by 2002 only three stocks were subject to fishing mortality rates that were twice this threshold. The overall complex has not only seen an increase in biomass, but has experienced a decline in fishing mortality.

While increasing biomass and declining fishing mortality reflect improvements in stock conditions, the M-S Act requires that action be taken based on current conditions. This amendment is based on regulated groundfish stock status through calendar year 2001. The primary sources are the report of the Groundfish Assessment Review Meeting (GARM) (NEFSC 2002b), SAW 36 (NEFSC 2003a) and SAW 37 (NEFSC 2003b). The GARM updated assessments for all groundfish stocks. Groundfish assessments are usually prepared by the Stock Assessment Workshop (SAW) and reviewed by the Stock Assessment Review Committee (SARC). Assessments focus on individual stocks with a gap of several years common between updates. Georges Bank cod, haddock, and yellowtail flounder are assessed annually by the Trans-boundary Resource Assessment Committee (TRAC) which is prepared by NEFSC scientists to provide information to managers. On an annual basis, the Council's Multi-Species Monitoring Committee compiles available assessment information, conducts projections if necessary to estimate stock status between assessment cycles, and reports to the Council on the status of all groundfish stocks. The GARM report published in October 2002 supercedes the information from previous assesments and the MSM. SAW 36 updated the assessment for SNE/MA winter flounder and included assessments for Cape Cod/Gulf of Maine yellowtail flounder, SNE/MA winter flounder, and GOM winter flounder.

In the spring of 2002, the *Final Report of the Working Group on re-Evaluation of Biological Reference Points for New England Groundfish* (NEFSC 2002a) was prepared. While the focus of this working group was to re-estimate B_{MSY} and F_{MSY}, the group also estimated biomass and fishing mortality for groundfish stocks through calendar year 2001. This was done through projecting forward stock status based on the 2001 landings for age-based stocks, rather than through updating assessment models. Survey indices were examined and exploitation rates calculated for index –based stocks. There are differences between stock conditions reported by the working group and the GARM. The most significant are for SNE/MA yellowtail flounder, plaice, SNE/MA winter flounder, and witch flounder. The GARM determined that significant mortality reductions are necessary for these stocks, while the Working Group report concluded that only minor reductions were necessary. In addition, the GARM determined that pollock was not overfished and that plaice was overfished, while the Working Group concluded the opposite. The Council is relying on the GARM results since this was an assessment – not a reference point – exercise and it provids the best available science for decision makers.

Subsequent to preparation of the draft amendment and in response to comments received at public hearings, the NEFSC provided estimates of fishing mortality and stock size in 2003. These estimates were based on landings in calendar year 2003 are were projected forward from the GARM 2002. They were not developed through either a baseline or updated assessment and thus are subject to additional uncertainty. While these estimates were used in developing the rebuilding strategy, the impact of the proposed management action is still compared to the 2001 fishing mortality rates throughout the document. The 2002 estimates are provided below.

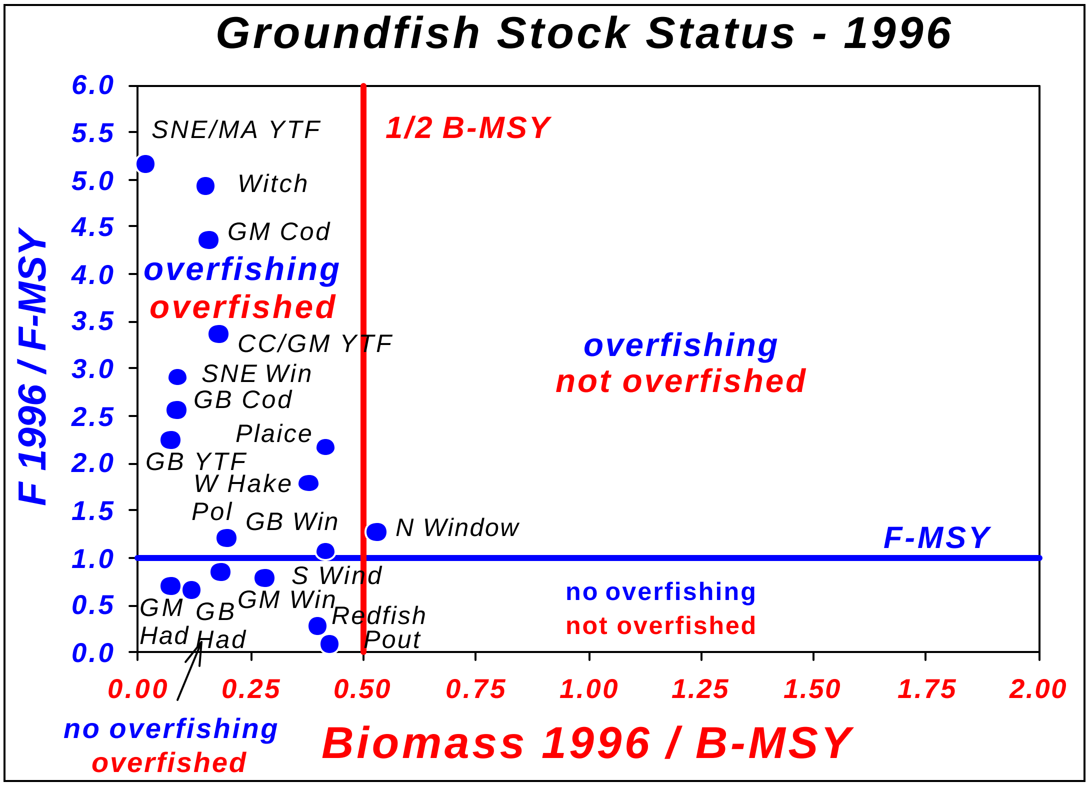

Figure 227 – Groundfish stock status, 1996 (NEFSC, unpublished data)

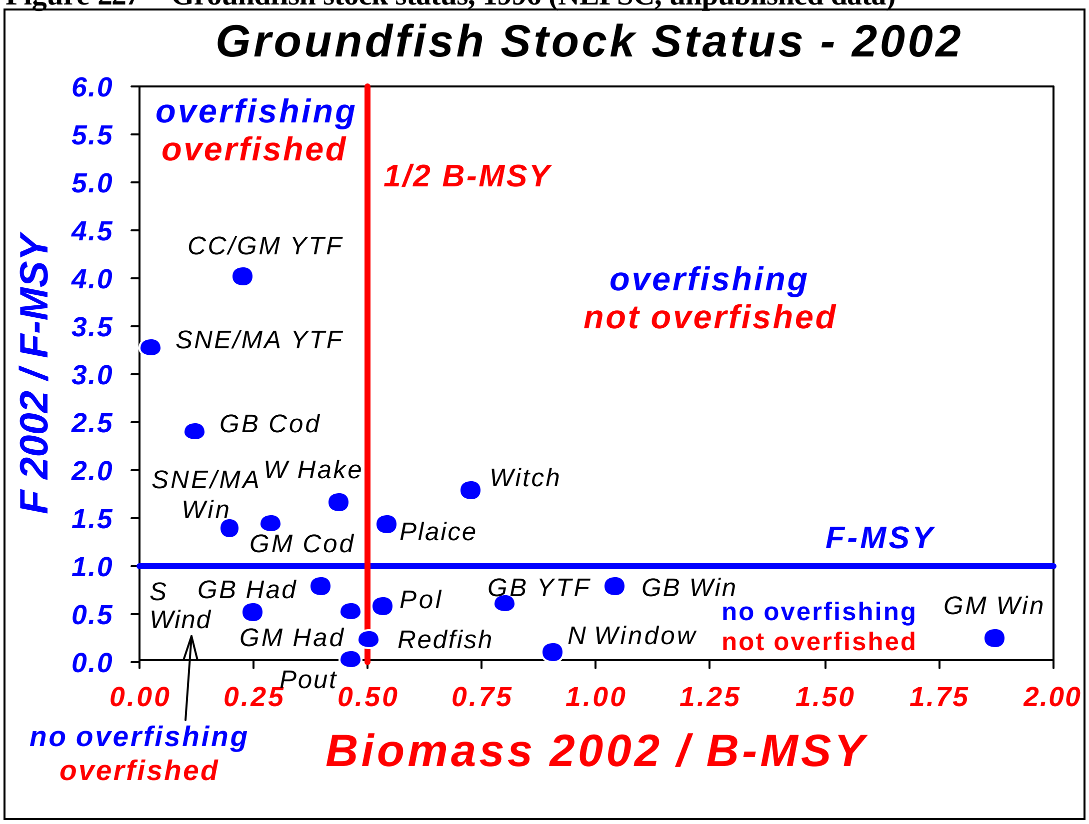

Figure 228 - Groundfish stock status, 2002 (NEFSC, unpublished data)

	Biomass		Fishing Mortality	
Stock	**2001**	**2002 (Projected)**	**2001**	**2002 (Projected)**
GOM Cod	22,000 mt	23,850	0.47	0.33
GB Cod	29,170 mt	26,560	0.38	0.43
GB Haddock	74,400 mt	99,570	0.22	0.20
GOM Haddock(1)	10.31	10.28	0.12	0.12
GB Yellowtail Flounder	39,000 mt	47,100	0.13	0.15
Cape Cod/GOM Yellowtail Flounder	3,200 mt	2,840	0.75	0.68
SNE/MA yellowtail flounder	1,900 mt	1,540	0.91	0.85
American Plaice	13,822 mt	15,570	0.43	0.27
Witch Flounder(3)	12,300 mt	18,300	0.76	0.41
GOM Winter Flounder	5.37	7,690	0.14	0.10
GB Winter Flounder(2)	9,805	9,805	0.25	0.25
SNE/MA Winter Flounder	7,600 mt	5,970	0.51	0.44
Acadian Redfish	119,600 mt (2000)	119,600	0.01	0.01
White Hake(1)	2.35	3.37	1.36	0.91
Pollock(1)	1.60	1.74	3.55	3.30
Windowpane Flounder (North)(1)	0.79	0.85	0.1	0.09
Windowpane Flounder (South)(1)	0.21	0.23	0.69	0.50
Ocean Pout(1)	2.46	2.28	0.007	0.01
Atlantic Halibut	0.2		Unknown	Unknown

Table 381 – Stock biomass and fishing mortality (2001). Units are SSB and fully-recruited fishing mortality unless noted. Sources: 2001 estimates based on GARM 2002, SAW 35, and SAW 37; 2002 estimates from NEFSC (unpublished data) and SAW 37.

(1) Biomass based on fall survey index, mortality based on relative exploitation rate (multi-year average)
(2) Total biomass and biomass weighted fishing mortality
(3) Witch flounder assessed in SAW 37. Estimates of 2001 fishing mortality were 57 percent higher than the 0.45 estimated by the GARM. This information was not provided to the Council until July, 2003.

9.2.1.2 Stock Status Uncertainty

The Council's understanding of current stock status is complicated by errors that may have been introduced due to problems in the conduct of the NEFSC trawl survey. NEFSC trawl surveys provide a fishery-independent measure of stock biomass. The NEFSC reported to the Council in September, 2002, that the trawl warps used on one of the survey vessels were inaccurately marked when installed in 2000. As the amendment was developed, there was a concern that this error may have affected the performance of the trawl net, as the marks are used to set equal amounts of cable on each leg of the trawl. For age-based assessments, the trawl survey is only on piece of data used to estimate stock size. It does, however, influence the terminal year estimates of stock size and fishing mortality. For index-based assessments, the trawl survey is the only data used to estimate stock size. Generally, a three year moving average is used.

The timing of the cable installation raised a concern that the survey index may need to be adjusted for two of the three most recent years, which will affect not only stock size estimates, but the relative exploitation rate that is calculated.

The GARM report (NEFSC 2002b) included sensitivity analyses for three different assumptions about the impact of the trawl warp problem on the survey index. For most stocks, assuming a change in the trawl survey index as a result of the warp problem did not result in a change in management advice. The exceptions were for plaice, GOM haddock, white hake, and SNE/MA yellowtail. The status of these stocks changes based on different assumptions of the impact of the warp error on survey indices.

A panel of experts reviewed the trawl warp issue – including experiments conducted to evaluate the impacts of the errors and the GARM sensitivity analyses – and concluded that the GARM analysis was sound (Payne et al. 2003). The Panel also recommended continuing to use the trawl survey data for New England groundfish, while recommending additional analyses of the performance of the surveys. The overall conclusion of the Panel was that the scientific information provided by the NEFSC (including stock status and estimates of status determination criteria) was accurate and should be used as the basis for management actions. For this reason, the amendment is based on the information provided by NEFSC 2002a and NEFSC 2002b and subsequent assessments.

9.2.2 Endangered Species and Marine Mammals

The Council has determined that the following species that are listed under the Endangered Species Act of 1973 (ESA) as endangered, threatened, or candidate species are found in the environment utilized by the fisheries regulated through proposed Amendment 13 to the Multispecies FMP. The Council has also included in the list below a number of species that are identified as protected under either the Marine Mammal Protection Act of 1972 (MMPA) or the Migratory Bird Act of 1918, as well as two right whale critical habitat designations that are found in the same area.

Cetaceans

Northern right whale (*Eubalaena glacialis*)	Endangered
Humpback whale (*Megaptera novaeangliae*)	Endangered
Fin whale (*Balaenoptera physalus*)	Endangered
Blue whale (*Balaenoptera musculus*)	Endangered
Sei whale (*Balaenoptera borealis*)	Endangered
Sperm whale (*Physeter macrocephalus*)	Endangered
Minke whale (*Balaenoptera acutorostrata*)	Protected
Harbor porpoise (*Phocoena phocoena*)	Protected
Risso's dolphin (*Grampus griseus*)	Protected
Pilot whale (*Globicephala* spp.)	Protected
White-sided dolphin (*Lagenorhynchus acutus*)	Protected
Common dolphin (*Delphinus delphis*)	Protected
Spotted and striped dolphins (*Stenella* spp.)	Protected
Bottlenose dolphin (*Tursiops truncatus*)	Protected

Seals

Harbor seal (*Phoca vitulina*)	Protected
Gray seal (*Halichoerus grypus*)	Protected
Harp seal (*Phoca groenlandica*)	Protected

Sea Turtles

Leatherback sea turtle (*Dermochelys coriacea*)	Endangered
Kemp's ridley sea turtle (*Lepidochelys kempii*)	Endangered

Green sea turtle (*Chelonia mydas*)	Endangered
Hawksbill sea turtle (*Eretmochelys imbricata*)	Endangered
Loggerhead sea turtle (*Caretta caretta*)	Threatened

Fish

Shortnose sturgeon (*Acipenser brevirostrum*)	Endangered
Atlantic salmon (*Salmo salar*)	Endangered
Barndoor skate (*Dipturus laevis*)	Candidate Species

Birds

Roseate tern (*Sterna dougallii dougallii*)	Endangered
Piping plover (*Charadrius melodus*)	Endangered

Critical Habitat Designations

Right whale	Cape Cod Bay Great South Channel

Although all of the protected species listed above may be found in the general geographical area covered by the Multispecies FMP, not all are affected by the fishery for several reasons. Some protected species may inhabit more inshore or offshore areas than those utilized by the groundfish species, prefer a different depth or temperature zone than multispecies or may migrate through the area at different times than the species regulated by the FMP. In addition, certain protected species may not be vulnerable to capture or entanglement in certain fishing gear used in the multispecies fishery. The above species list is divided into two groups. The first group contains those species not likely to be affected by Amendment 13 to the Multispecies FMP. The second group contains a more detailed assessment for the species that may be affected by Amendment 13 to the Multispecies FMP.

9.2.2.1 Protected Species Not Likely Affected by this FMP

The Council has reviewed the current information available on the distribution and habitat needs of the endangered, threatened, and otherwise protected species listed above in relation to the action being considered in the proposed Amendment 13 to the Multispecies FMP. Following this review, the Council has made an assessment that multispecies fishing operations, as managed by the proposed Amendment 13 to the Multispecies FMP, are not expected to affect the shortnose sturgeon *(Acipenser brevirostrum*), the Gulf of Maine distinct population segment (DPS) of Atlantic salmon (*Salmo salar*), the roseate tern (*Sterna dougallii dougallii*), the piping plover (*Charadrius melodus*) or the hawksbill sea turtle (*Eretmochelys imbricata*), all of which are listed species under the Endangered Species Act of 1973.

There are several cetaceans protected under the Marine Mammal Protection Act of 1972 (MMPA) that are found in the waters fished by the multispecies fishery, namely the Risso's dolphin (*Grampus griseus*), spotted and striped dolphins (*Stenella* spp.), and coastal forms of Atlantic bottlenose dolphin (*Tursiops truncatus*). Although these species may occasionally become entangled or otherwise entrapped in certain fishing gear such as pelagic longline and mid-water trawls, these gear types are not used in the multispecies fishery.

In addition, the Council believes that multispecies fishing operations will not adversely affect the right whale critical habitat areas listed above. The Council will be asking the NMFS and USFWS for concurrence in these assessments.

Shortnose Sturgeon

The shortnose sturgeon is benthic fish that mainly occupies the deep channel sections of several Atlantic coast rivers. They can be found in most major river systems from St. Johns River, Florida to the Saint John River in New Brunswick, Canada. The species is considered truly anadromous in the southern portion of its range (*i.e.*, south of Chesapeake Bay). However, they spend the majority of their life history within the fresh water sections of the northern rivers with only occasional forays into salt water, and are thus considered to be "freshwater amphidromous" (NMFS 1998a). There have been no documented cases of shortnose sturgeon taken in gear used in the multispecies fishery.

The multispecies fishery in the Northeast Region may extend to shallow water, but not into the intertidal zone of major river systems where shortnose sturgeon are likely to be found. Therefore, there appears to be adequate separation between the two species making it highly unlikely that the multispecies fisheries will affect shortnose sturgeon.

Atlantic Salmon

The wild populations of Atlantic salmon found in rivers and streams from the lower Kennebec River north to the U.S.-Canada border are considered to be endangered. These rivers include the Dennys, East Machias, Machias, Pleasant, Narraguagus, Ducktrap, and Sheepscot Rivers and Cove Brook. Atlantic salmon are an anadromous species with spawning and juvenile rearing occurring in freshwater rivers followed by migration to the marine environment. Juvenile salmon in New England rivers typically migrate to sea in May after a two to three year period of development in freshwater streams, and remain at sea for two winters before returning to their U.S. natal rivers to spawn from mid October through early November. While at sea, salmon generally undergo an extensive northward migration to waters off Canada and Greenland. Data from past commercial harvest indicate that post-smolts overwinter in the southern Labrador Sea and in the Bay of Fundy. The numbers of wild Atlantic salmon that return to these rivers are perilously small, with total run sizes of approximately 150 spawners occurring in 1999 (Baum 2000).

Capture of Atlantic salmon have occurred in U.S. commercial fisheries or by research/survey vessels. However, none have been documented after 1992. No multispecies landings have been recorded for the areas adjacent to the Atlantic salmon rivers. In addition, the NMFS fishery research surveys have rarely found multispecies in the nearshore regions adjacent to the Atlantic salmon rivers. Therefore, it is unlikely that operation of the multispecies fisheries occurs in or near the rivers where concentrations of Atlantic salmon are most likely to be found. Furthermore, bottom-tending gear used in the multispecies fishery is not likely to encounter salmon in the open water environment, making it is highly unlikely that the fisheries occurring under the proposed Amendment 13 to the Multispecies FMP will affect the endangered runs of Atlantic salmon in the Gulf of Maine.

Roseate Tern and Piping Plover

The roseate tern and piping plover inhabit coastal waters and nest on coastal beaches within the Northeast Region. The terns prey on small schooling fishes, and the plovers prey on shoreline invertebrates and other small fauna. Foraging activity for these species occurs either along the shoreline (plovers) or within the top several meters of the water column (terns). Bottom-tending otter trawl, sink gillnet, and longline gear that are used in the multispecies fishery pose no threat to these species or their forage species.

Hawksbill Sea Turtle

The hawksbill turtle is relatively uncommon in the waters of the Northeast Region. Hawksbills prefer coral reefs, such as those found in the Caribbean and Central America where they feed primarily on a wide variety of sponges and mollusks. There are accounts of small hawksbills stranded as far north as Cape Cod, Massachusetts. However, many of these strandings were observed after hurricanes or offshore storms. No takes of hawksbill sea turtles have been recorded in northeast or Mid-Atlantic fisheries where observers have been deployed in the otter trawl (including the Mid-Atlantic) and sink gillnet fisheries that catch multispecies.

Hawksbills may occur in the southern range of the area (i.e., North Carolina and South Carolina), but their distribution is not known to overlap with those waters fished by vessels that may catch multispecies. Therefore, it is unlikely that interactions between hawksbill sea turtles and vessels that catch multispecies will occur.

Risso's Dolphin

The Risso's dolphin is distributed along the continental shelf edge of North America from Cape Hatteras to Georges Bank. The minimum population estimate for the Risso's dolphin that was derived from limited survey estimates that took place in U.S. waters is 22,916 (Waring et al. 2001). This species has been observed taken in the pelagic drift gillnet, pelagic longline, and mid-water trawl fisheries, but have never been reported in gear capable of catching multispecies. Although the Risso's dolphin feeding habitat overlaps with the distribution of the multispecies fishery, their pelagic prey species (squid and schooling fishes) would make it unlikely that they would encounter the bottom tending gear used in the multispecies fishery. Therefore, it is unlikely that the take in this fishery will occur at levels that compromise their ability to maintain optimum sustainable population levels, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Pelagic Delphinids (Spotted and Striped Dolphins)

The pelagic delphinid complex is made up of small odontocete species that are broadly distributed along the continental shelf edge where depths range from 200 - 400 meters. They are commonly found in large schools feeding on schools of fish. The minimum population estimates for each species number in the tens of thousands. They are known to be taken in pelagic and sink gillnets gear as well as mid-water trawl gear. Their pelagic prey species suggest they do not forage near the bottom, making it unlikely that they would encounter the bottom tending gear used in the multispecies fishery. Therefore, it is unlikely that the take in this fishery will be at levels that compromise their ability to maintain optimum sustainable population levels, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Coastal Bottlenose Dolphins

The coastal form of the bottlenose dolphin occurs in the shallow, relatively warm waters along the U.S. Atlantic coast from New Jersey to Florida and the Gulf of Mexico. They rarely range beyond the 25-meter depth contour north of Cape Hatteras. Although they are known to be taken in coastal sink gillnet operations, these fisheries do not overlap multispecies fishery areas. Waring et al. (2001) described the estimated total take of coastal bottlenose dolphins in all fisheries (including those that catch multispecies) to be below the PBR established for that stock. As described above, the proposed Amendment 13 to the Multispecies FMP will not increase the gillnet effort in the Northeast Region, and is not expected to extend into the more shallow range of the coastal bottlenose dolphin. Therefore, the proposed Amendment 13 to the Multispecies FMP will not further inhibit the ability of the bottlenose dolphin to achieve the optimum sustainable population level for the coastal stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Right Whale Critical Habitat

NMFS evaluated the potential effects of the federal multispecies fisheries on the two critical habitats that have been designated in the Great South Channel and Cape Cod Bay in the Opinion issued on June 14, 2001. NMFS evaluated the potential effects of the proposed fisheries operations on both prey availability and quality and nursery protection in the critical habitat. There was concern that the operation of these fisheries could diminish the value of the habitat by altering trophic dynamics that could reduce the availability of right whale prey within the critical habitat areas. However, right whales feed primarily on zooplankton that live in the mid-water zone, which are not likely adversely affected by bottom-tending multispecies gear directly. Therefore, the Council does not believe the multispecies fishery, as operated under the proposed Amendment 13 to the Multispecies FMP, will affect right whale critical habitat.

9.2.2.2 Status of Protected Species Potentially Affected by this FMP

The potential impacts to protected species that may result from the management alternatives and measures being considered under this Amendment are described in Section 4.2.6 of this document. The section below will focus on the status of the various species listed above that are found in the multispecies management area (Northeast Region) and may be affected by the fishing operations occurring under the proposed Amendment 13 to the Multispecies FMP. Additional background information on the range-wide status of these species and a description of right whale critical habitat can be found in a number of published documents, including sea turtle status reviews (NMFS and USFWS 1995, Marine Turtle Working Group - TEWG, 1998, 2000) and biological reports (USFWS 1997), recovery plans for the humpback whale (NMFS 1991a), right whale (NMFS 1991b), Kemp's Ridley sea turtle (USFWS and NMFS 1992), Atlantic green sea turtle (NMFS and USFWS 1991a), leatherback sea turtle (NMFS and USFWS 1992) and loggerhead sea turtle (NMFS and USFWS 1991b); and the 2001 Marine Mammal Stock Assessment Reports (Waring et al. 2001).

Right Whale

Right whales were found historically in all the world's oceans within the temperate to subarctic latitudes. There are three major subdivisions of right whales: North Pacific, North Atlantic, and Southern Hemisphere; with eastern and western subunits found in the North Atlantic (Perry et al. 1999). Because of our limited understanding of the genetic structure of the species, the conservative approach to conservation of this species has been to treat the subunits as separate groups whose survival and recovery is critical to the health of the species.

The northern right whale has the highest risk of extinction of all large whales. Scarcity of right whales is the result of an 800-year history of whaling that continued into the 1960s (Klumov 1962). Records indicate that right whales were subject to commercial whaling in the North Atlantic as early as 1059, with an estimated 25,000-40,000 right whales believed to have been taken between the 11^{th} and 17^{th} centuries. The size of the western North Atlantic right whale population at the termination of whaling is unknown. The stock was first recognized as seriously depleted as early as 1750. However, right whales continued to be taken in shore-based operations or opportunistically by whalers in search of other species as late as the 1920s. By the time the species was internationally protected in 1935 there may have been fewer than 100 North Atlantic right whales in the western North Atlantic (Hain 1975; Reeves et al. 1992; Kenney et al. 1995).

Intense whaling was also the cause of the critically endangered status of the North Pacific right whale. Currently, the North Pacific population is so small that no reliable estimate can be given. In the Atlantic, the eastern subpopulation of the North Atlantic population may already be extinct. The fact that the western North Atlantic subpopulation is the most numerous right whale population in the northern hemisphere, and is only estimated to number approximately 300 animals, is testimony to the severely depleted status of this species in the northern hemisphere. In contrast, the southern right whale is recovering with a growth rate of 7% in many areas.

Right whales appear to prefer shallow coastal waters, but their distribution is also strongly correlated to zooplankton prey distribution (Winn et al. 1986). In both northern and southern hemispheres, right whales are observed in the lower latitudes and more coastal waters during winter, where calving takes place, and then migrate to higher latitudes during the summer. In the western North Atlantic, they are found west of the Gulf Stream and are most commonly associated with cooler waters (<21º C). They are not found in the Caribbean and have been recorded only rarely in the Gulf of Mexico.

NMFS designated three right whale critical habitat areas on June 3, 1994 (59 FR 28793) to help protect important right whale foraging and calving areas within the U.S. These areas are: Cape Cod Bay; the Great South Channel (both off Massachusetts); and the waters adjacent to the southern Georgia and northern Florida coast. In 1993, Canada's Department of Fisheries declared two conservation areas for right whales;

one in the Grand Manan Basin in the lower Bay of Fundy, and a second in Roseway Basin between Browns and Baccaro Banks (Canadian Recovery Plan for the North Atlantic Right Whale 2000).

Right whales feed on zooplankton through the water column, and in shallow waters may feed near the bottom. In the Gulf of Maine, they have been observed feeding primarily on copepods, by skimming at or below the water's surface with open mouths (NMFS 1991b; Kenney et al. 1986; Murison and Gaskin 1989; and Mayo and Marx 1990). Research suggests that right whales must locate and exploit extremely dense patches of zooplankton to feed efficiently (Waring et al. 2001). New England waters include important foraging habitat for right whales and at least some portion of the right whale population is present in these waters throughout most months of the year. They are most abundant in Cape Cod Bay between February and April (Hamilton and Mayo 1990; Schevill et al. 1986; Watkins and Schevill 1982) and in the Great South Channel in May and June (Kenney et al. 1986; Payne et al. 1990) where they have been observed feeding predominantly on copepods, largely of the genera *Calanus* and *Pseudocalanus* (Waring et al. 2001). Right whales also frequent Stellwagen Bank and Jeffrey's Ledge, as well as Canadian waters including the Bay of Fundy and Browns and Baccaro Banks, in the spring and summer months. Mid-Atlantic waters are used as a migratory pathway from the spring and summer feeding/nursery areas to the winter calving grounds off the coast of Georgia and Florida.

However, much about right whale movements and habitat use are still unknown. Approximately 85% of the population is unaccounted for during the winter (Waring et al. 2001). Radio and satellite tagging has been used to track right whales, and has shown lengthy and somewhat distant excursions into deep water off the continental shelf (Mate et al. 1997). In addition photographs of identified individuals have documented movements of the western North Atlantic right whales as far north as Newfoundland, the Labrador Basin and southeast of Greenland (Knowlton et al. 1992). Sixteen satellite tags were attached to right whales in the Bay of Fundy, Canada, during summer 2000 in an effort to further elucidate the movements and important habitat for North Atlantic right whales. The movements of these whales varied, with some remaining in the tagging area and others making periodic excursions to other areas before returning to the Bay of Fundy. Several individuals were observed to move along the coastal waters of Maine, while others traveled to the Scotian Shelf off Nova Scotia. One individual was successfully tracked throughout the fall, and was followed on her migration to the Georgia/Florida wintering area.

Recognizing the precarious status of the right whale, the continued threats present in its coastal habitat throughout its range, and the uncertainty surrounding attempts to characterize population trends, the International Whaling Commission (IWC) held a special meeting of its Scientific Committee from March 19-25, 1998, in Cape Town, South Africa, to conduct a comprehensive assessment of right whales worldwide. The workshop's participants reviewed available information on the North Atlantic right whale. The conclusions of Caswell et al. (1999) were particularly alarming. Using data on reproduction and survival through 1996, Caswell determined that the western North Atlantic right whale population was declining at a rate of 2.4% per year, with one model suggesting that the mortality rate of the right whale population had increased five-fold in less than one generation. According to Caswell, if the mortality rate as of 1996 does not decrease and the population's reproductive performance does not improve, extinction could occur in 191 years and would be certain within 400 years.

The IWC Workshop participants expressed "considerable concern" in general for the status of the western North Atlantic right whales. This concern was based on recent (1993-1995) observations of near-failure of calf production, the significantly high mortality rate, and an observed increase in the calving interval. It was suggested that the slow but steady recovery rate published in Knowlton et al. (1994) may not be continuing. Workshop participants urgently recommended increased efforts to reduce the human-caused mortality factors affecting this right whale population.

As stated in the IWC Workshop, there has been concern over the decline in birth rate. In the three calving seasons following Caswell's analysis, only 10 calves are known to have been born into the population, with only one known right whale birth in the 1999/2000 season. However, the 2000/2001 calving season had 31 right whale calves sighted, with 27 surviving. Although these births are encouraging, biologists recognize that there may be some additional natural mortality with the 2000/2001 calves and cautious optimism is necessary because of how close the species is to extinction. In addition, efforts to reduce human-caused mortality must be accelerated if these individuals are to survive to sexual maturity and help reverse the population decline.

One question that has repeatedly arisen regarding the western North Atlantic population of right whales is the effect that "bottlenecking" may have played on the genetic integrity of right whales. Several genetics studies have attempted to examine the genetic diversity of right whales. Results from a study by Schaeff et al. (1997) indicate that North Atlantic right whales are less genetically diverse than southern right whales; a separate population that numbers at least four times as many animals with an annual growth rate of nearly seven percent. A recent study compared the genetic diversity of North Atlantic right whales with the genetic diversity of southern right whales. The researchers found only five distinct haplotypes (a maternal genetic marker) exist amongst 180 different North Atlantic right whales sampled, versus 10 haplotypes among just 16 southern right whales sampled. In addition, one of the five haplotypes found in the North Atlantic right whales was observed in only four animals; all males born prior to 1982 (Malik et al. 2000). Because this genetic marker can be passed only from female to offspring, there is an expectation that it will be lost from the population. Two interesting facts about this haplotype are: (1) the last known female with this type was an animal killed by the shore fishery at Amagansett, Long Island in 1907; and (2) this haplotype is basal to all others worldwide (i.e., it is the most ancient of all right whales).

Low genetic diversity is a general concern for wildlife populations. It has been suggested that North Atlantic right whales have been at a low population size for hundreds of years and, while the present population exhibits very low genetic diversity, the major effects of harmful genes are thought to have occurred well in the past, effectively eliminating those genes from the population (Kenney 2000). To determine how long North Atlantic right whales have exhibited such low genetic diversity, researchers have analyzed DNA extracted from museum specimens. Rosenbaum et al. (2000) found these samples represented four different haplotypes, all of which are still present in the current population, suggesting there has not been a significant loss of genetic diversity within the last 191 years. Although this sample size (n=6) was small, it supports the theory that significant reduction in genetic diversity likely occurred prior to the late 19^{th} century.

The role of contaminants or biotoxins in reducing right whale reproduction has also been raised. Contaminant studies have confirmed that right whales are exposed to and accumulate contaminants, but the effect that such contaminants might be having on right whale reproduction or survivability is unknown.

Competition for food resources is another possible factor impacting right whale reproduction. Researchers have found that North Atlantic right whales appear to have thinner blubber than right whales from the South Atlantic (Kenney, 2000). It has also been suggested that oceanic conditions affecting the concentration of copepods may in turn have an effect on right whales since they rely on dense concentrations of copepods to feed efficiently (Kenney 2000). However, evidence is lacking to demonstrate either that a decline in birth rate is related to depleted food resources or that there is a relationship between oceanic conditions and copepod abundance to right whale fitness and reproduction rates.

General Human Impacts and Entanglement

Right whales may be adversely affected by habitat degradation, habitat exclusion, acoustic trauma, harassment, or reduction in prey resources due to trophic effects resulting from a variety of activities including the operation of commercial fisheries. However, the major known sources of anthropogenic mortality and injury of right whales clearly are ship strikes and entanglement in commercial fishing gear such as the sink gillnet gear used to catch multispecies.

Based on photographs of catalogued animals from 1959 and 1989, Kraus (1990) estimated that 57% of right whales exhibited scars from entanglement and 7% from ship strikes (propeller injuries). Hamilton et al. (1998) updated this work using data from 1935 through 1995. The new study estimated that 61.6% of right whales exhibit injuries caused by entanglement, and 6.4% exhibit signs of injury from vessel strikes. These data may be misleading, as a ship strike may be less of a "recoverable" event than entanglement in rope. It is also known that several whales have apparently been entangled on more than one occasion, and that some right whales that have been entangled were subsequently involved in ship strikes. Furthermore, these numbers are based on sightings of free-swimming animals that initially survive the entanglement or ship strike. Therefore, the actual number of interactions may be higher as some animals are likely drowned or killed immediately, and the carcass never recovered or observed.

The most recent data describing the observed entanglements of right whales is found in Table 126. It should be noted that no information is currently available on the response of the right whale population to recent (1997-1999) efforts to mitigate the effects of entanglement and ship strikes. However, as noted above, both entanglements and ship strikes have continued to occur. Therefore, it is not possible to determine whether the trend through 1996, as reported by Caswell, is continuing. Furthermore, results reported by Caswell suggest that it is not possible to determine that anthropogenic mortalities alone are responsible for the decline in right whale survival. However, the IWC concluded that reduction of anthropogenic mortalities would significantly improve the species' survival probability.

The best available information makes it reasonable to conclude that the current death rate exceeds the birth rate in the western North Atlantic right whale population. The nearly complete reproductive failure in this population from 1993 to 1995 and again in 1998 and 1999 suggests that this pattern has continued for almost a decade. Because no population can sustain a high death rate and low birth rate indefinitely, this combination places the North Atlantic right whale population at high risk of extinction. On a positive note, the 2000/2001 calving season was the most promising in the past 5 years. However, these young animals must be provided with protection so that they can mature and contribute to future generations in order to be a factor in stabilizing of the population.

Humpback Whale

Humpback whales calve and mate in the West Indies and migrate to feeding areas in the northwestern Atlantic during the summer months. Six separate feeding areas are utilized in northern waters (Waring et al. 2001). Only one of these feeding areas, the Gulf of Maine, lies within U.S. waters contained within the management unit of the FMP (Northeast Region). Most of the humpbacks that forage in the Gulf of Maine visit Stellwagen Bank and the waters of Massachusetts and Cape Cod Bays. Sightings are most frequent from mid-March through November between 41º N and 43º N, from the Great South Channel north along the outside of Cape Cod to Stellwagen Bank and Jeffreys Ledge (CeTAP 1982), and peak in May and August. However, small numbers of individuals may be present in this area year-round. They feed on a number of species of small schooling fishes, particularly sand lance and Atlantic herring, by filtering large amounts of water through their baleen to capture prey (Wynne and Schwartz 1999).

Data from a photographic identification catalogue of over 600 individual humpback whales have described the majority of the habitats used by this species (Barlow and Clapham 1997; Clapham et al. 1999). The photographic data have identified that reproductively mature western North Atlantic humpbacks winter in tropical breeding grounds in the Antilles, primarily on Silver and Navidad Banks north of the Dominican Republic. The primary winter range where calving and copulation is believed to take place also includes the Virgin Islands and Puerto Rico (NMFS 1991a). Calves are born from December through March and are about 4 meters at birth. Sexually mature females give birth approximately every 2 to 3 years. Sexual maturity is reached between 4 and 6 years of age for females and between 7 and 15 years for males. Size at maturity is about 12 meters.

Humpback whales use the mid-Atlantic as a migratory pathway. However, observations of juvenile humpbacks since 1989 in the mid-Atlantic have been increasing during the winter months, peaking January through March (Swingle et al. 1993). Biologists theorize that non-reproductive animals may be establishing a winter-feeding range in the mid-Atlantic since they are not participating in reproductive behavior in the Caribbean. The whales using this mid-Atlantic area were found to be residents of the Gulf of Maine and Atlantic Canada (Gulf of St. Lawrence and Newfoundland) feeding groups, suggesting a mixing of different feeding stocks in the mid-Atlantic region. Strandings and entanglements of humpback whales have increased between New Jersey and Florida during the same period (Wiley et al. 1995).

New information has become available on the status and trends of the humpback whale population in the North Atlantic that indicates the population is increasing. However, it has not yet been determined whether this increase is uniform across all six feeding stocks (Waring et al. 2001). For example, although the overall rate of increase has been estimated at 9.0% (CV=0.25) by Katona and Beard (1990), Barlow and Clapham (1997) reported a 6.5% rate through 1991 for the Gulf of Maine feeding group.

A variety of methods have been used to estimate the North Atlantic humpback whale population. However, the photographic mark-recapture analyses from the Years of the North Atlantic Humpback (YONAH) project gave a North Atlantic basin-wide estimate of 10,600 (95% c.i. = 9,300 - 12,100) is regarded as the best available estimate for that population.

General Human Impacts and Entanglement

The major known sources of anthropogenic mortality and injury of humpback whales include entanglement in commercial fishing gear such as the sink gillnet gear used to catch multispecies, and ship strikes. Based on photographs of the caudal peduncle of humpback whales, Robbins and Mattila (1999) estimated that between 48% and 78% of animals in the Gulf of Maine exhibit scarring caused by entanglement. Several whales have apparently been entangled on more than one occasion. These estimates are based on sightings of free-swimming animals that initially survive the encounter. The most recent data describing the observed entanglements of humpback whales is found in Table 126. Because some whales may drown immediately, the actual number of interactions may be higher. In addition, the actual number of species-gear interactions is contingent on the intensity of observations from aerial and ship surveys.

Humpback whales may also be adversely affected by habitat degradation, habitat exclusion, acoustic trauma, harassment, or reduction in prey resources due to trophic effects resulting from a variety of activities including the operation of commercial fisheries.

Fin Whale

Fin whales inhabit a wide range of latitudes between 20-75° N and 20-75° S (Perry et al. 1999). Fin whales spend the summer feeding in the relatively high latitudes of both hemispheres, particularly along the cold eastern boundary currents in the North Atlantic and North Pacific Oceans and in Antarctic waters (IWC 1992). Most migrate seasonally from relatively high-latitude Arctic and Antarctic feeding areas in the summer to relatively low-latitude breeding and calving areas in the winter (Perry et al. 1999).

As was the case for the right and humpback whales, fin whale populations were heavily affected by commercial whaling. However, commercial exploitation of fin whales occurred much later than for right and humpback whales. Wide-scale commercial exploitation of fin whales did not occur until the 20th century when the use of steam power and harpoon-gun technology made exploitation of this faster, further offshore species feasible. In the southern hemisphere, over 700,000 fin whales were landed in the 20th century. More than 48,000 fin whales were taken in the North Atlantic between 1860 and 1970 (Perry et al. 1999). Fisheries existed off of Newfoundland, Nova Scotia, Norway, Iceland, the Faroe Islands, Svalbard (Spitsbergen), the British isles, Spain and Portugal. Fin whales were rarely taken in U.S. waters, except when they ventured near the shores of Provincetown, MA, during the late 1800s (Perry et al. 1999).

In the North Atlantic today, fin whales are widespread and occur from the Gulf of Mexico and Mediterranean Sea northward to the edges of the arctic pack ice (NMFS 1998b). A number of researchers have suggested the existence of fin whale subpopulations in the North Atlantic. Mizroch et al. (1984) suggested that local depletions resulting from commercial over harvesting supported the existence of North Atlantic fin whale subpopulations. Others have used genetic information to support the existence of multiple subpopulations of fin whales in the North Atlantic and Mediterranean (Bérubé et al. 1998). Although the IWC's Scientific Committee proposed seven stocks for North Atlantic fin whales, it is uncertain whether these stock boundaries define biologically isolated units (Waring et al. 2001). NMFS has designated one stock of fin whale for U.S. waters of the North Atlantic (Waring et al. 2001) where the species is commonly found from Cape Hatteras northward.

Various estimates have been provided to describe the current status of fin whales in western North Atlantic waters. Based on the history and trends of whaling catch, an estimate of 3,590 to 6,300 fin whales was obtained for the entire western North Atlantic (Perry et al. 1999). Hain et al. (1992) estimated that about 5,000 fin whales inhabit the Northeastern United States continental shelf waters. The latest SAR (Waring et al. 2001) gives a best estimate of abundance for fin whales of 2,814 (CV = 0.21). However, this is considered an underestimate, as too little is known about population structure, and the estimate is derived from surveys over a limited portion of the western North Atlantic. There is also not enough information to estimate population trends.

Despite our broad knowledge of fin whales, less is known about their life history as compared to right and humpback whales. Age at sexual maturity for both sexes ranges from 5-15 years. Physical maturity is reached at 20-30 years. Conception occurs during a 5 month winter period in either hemisphere. After a 12-month gestation, a single calf is born. The calf is weaned between 6 and 11 months after birth. The mean calving interval is 2.7 years, with a range of between 2 and 3 years (Agler et al. 1993). Like right and humpback whales, fin whales are believed to use western North Atlantic waters primarily for feeding and migrate to more southern waters for calving. However, the overall pattern of fin whale movement consists of a less obvious north-south pattern of migration than that of right and humpback whales.

Based on acoustic recordings from hydrophone arrays, Clark (1995) reported the fin whale as the most acoustically common whale species heard in the North Atlantic and described a general pattern of fin whale movements in the fall from the Labrador/Newfoundland region, south past Bermuda, and into the West Indies. However, evidence regarding where the majority of fin whales winter, calve, and mate is still scarce.

The overall distribution of fin whales may be based on prey availability. This species preys opportunistically on both zooplankton and fish (Watkins et al. 1984). The predominant prey of fin whales varies greatly in different geographical areas depending on what is locally available. In the western North Atlantic, fin whales feed on a variety of small schooling fish (i.e., herring, capelin, sand lance) as well as squid and planktonic crustaceans (Wynne and Schwartz 1999). As with humpback whales, fin whales feed by filtering large volumes of water for their prey through their baleen plates. Photo identification studies in western North Atlantic feeding areas, particularly in Massachusetts Bay, have shown a high rate of annual return by fin whales, both within years and between years (Seipt et al. 1990).

As discussed above, fin whales were the focus of commercial whaling, primarily in the 20th century. The IWC did not begin to manage commercial whaling of fin whales in the North Atlantic until 1976 and were not given total protection until 1987, with the exception of a subsistence whaling hunt for Greenland. In total, there have been 239 reported kills of fin whales from the North Atlantic from 1988 to 1995.

General Human Impacts and Entanglement

The major known sources of anthropogenic mortality and injury of fin whales include ship strikes and entanglement in commercial fishing gear such as the sink gillnet gear used to catch multispecies. However, many of the reports of mortality cannot be attributed to a particular source. Of 18 fin whale mortality records between 1991 and 1995, four were associated with vessel interactions, although the true cause of mortality was not known. Although several fin whales have been observed entangled in fishing gear, no mortalities have been attributed to gear entanglement.

In general, known mortalities of fin whales are less than those recorded for right and humpback whales. This may be due in part to the more offshore distribution of fin whales where they are either less likely to encounter entangling gear, or are less likely to be noticed when gear entanglements or vessel strikes do occur. Fin whales may also be adversely affected by habitat degradation, habitat exclusion, acoustic trauma, harassment, or reduction in prey resources due to trophic effects resulting from a variety of activities including the operation of commercial fisheries.

Sei Whale

Sei whales are a widespread species in the world's temperate, subpolar and subtropical and even tropical marine waters. However, they appear to be more restricted to temperate waters than other balaenopterids (Perry et al. 1999). The IWC recognized three stocks in the North Atlantic based on past whaling operations: (1) Nova Scotia; (2) Iceland Denmark Strait; (3) Northeast Atlantic (Donovan 1991 *in* Perry et al. 1999). Mitchell and Chapman (1977) suggested that the sei whale population in the western North Atlantic consists of two stocks, a Nova Scotian Shelf stock and a Labrador Sea stock. The Nova Scotian Shelf stock includes the continental shelf waters of the Northeast Region, and extends northeastward to south of Newfoundland. The IWC boundaries for this stock are from the U.S. east coast to Cape Breton, Nova Scotia and east to 42°W longitude (Waring et al. 2001). This is the only sei whale stock within the management unit of this FMP.

Sei whales became the target of modern commercial whalers primarily in the late 19th and early 20th century after stocks of other whales, including right, humpback, fin and blues, had already been depleted. Sei whales were taken in large numbers by Norway and Scotland from the beginning of modern whaling (NMFS 1998b). Small numbers were also taken off of Spain, Portugal, and West Greenland from the 1920's to 1950's (Perry et al. 1999). In the western North Atlantic, a total of 825 sei whales were taken on the Scotian Shelf between 1966-1972, and an additional 16 were by a shore-based Newfoundland whaling station (Perry et al. 1999). The species continued to be exploited in Iceland until 1986 even though measures to stop whaling of sei whales in other areas had been put into place in the 1970s (Perry et al. 1999). There is no estimate for the abundance of sei whales prior to commercial whaling. Based on whaling records, approximately14,295 sei whales were taken in the entire North Atlantic from 1885 to 1984 (Perry et al. 1999).

Sei whales winter in warm temperate or subtropical waters and summer in more northern latitudes. In the North Atlantic, most births occur in November and December when the whales are on the wintering grounds. Conception is believed to occur in December and January. Gestation lasts for 12 months and the calf is weaned at 6-9 months when the whales are on the summer feeding grounds (NMFS 1998b). Sei whales reach sexual maturity at 5-15 years of age. The calving interval is believed to be 2-3 years (Perry et al. 1999).

Sei whales occur in deep water throughout their range, typically over the continental slope or in basins situated between banks (NMFS 1998b). In the northwest Atlantic, the whales travel along the eastern Canadian coast in autumn on their way to and from the Gulf of Maine and Georges Bank where they occur in winter and spring. Within the Northeast Region, the sei whale is most common on Georges Bank and into the Gulf of Maine/Bay of Fundy region during spring and summer. Individuals may range as far south as North Carolina. It is important to note that sei whales are known for inhabiting an area for weeks at a time then disappearing for years or even decades. This has been observed all over the world, including in the southwestern Gulf of Maine in 1986, but the basis for this phenomenon is not clear.

Although sei whales may prey upon small schooling fish and squid in the Northeast Region, available information suggests that calanoid copepods are the primary prey of this species. There are occasional influxes of sei whales further into Gulf of Maine waters, presumably in conjunction with years of high copepod abundance inshore. Sei whales are occasionally seen feeding in association with right whales in the southern Gulf of Maine and in the Bay of Fundy, although there is no evidence of interspecific competition for food resources. There is very little information on natural mortality factors for sei whales. Possible causes of natural mortality, particularly for young, old, or otherwise compromised individuals are shark attacks, killer whale attacks, and endoparasitic helminthes (Perry et al. 1999).

There are insufficient data to determine trends of the sei whale population. Because there are no abundance estimates within the last 10 years, a minimum population estimate cannot be determined for management purposes (Waring et al. 2001). Abundance surveys are problematic because this species is difficult to distinguish from the fin whale and too little is known of the sei whale's distribution, population structure and patterns of movement.

<u>General Human Impacts and Entanglement</u>

Few instances of injury or mortality of sei whales due to entanglement or vessel strikes have been recorded in U.S. waters. Entanglement is not known to impact this species in the U.S. Atlantic, possibly because sei whales typically inhabit waters further offshore than most commercial fishing operations, or perhaps entanglements do occur but are less likely to be observed. However, due to the overlap of this species' observed range with the multispecies fishery areas that use sink gillnet gear, the potential for entanglement does exist. A small number of ship strikes of this species have been recorded, the most recent documented incident occurring in 1994 when a carcass was brought in on the bow of a container ship in Charlestown, Massachusetts. No entanglements in fishing gear have been observed or noted in stranding data. Similar impacts noted above for other baleen whales may also occur. Due to the deep-water distribution of this species, interactions that do occur are less likely to be observed or reported than those involving right, humpback, and fin whales that often frequent areas within the continental shelf.

Blue Whale

Like the fin whale, blue whales occur worldwide and are believed to follow a similar migration pattern from northern summering grounds to more southern wintering areas (Perry et al. 1999). Three subspecies have been identified: *Balaenoptera musculus musculus, B.m. intermedia*, and *B.m. brevicauda* (NMFS 1998c). Only *B. musculus* occurs in the northern hemisphere. Blue whales range in the North Atlantic from the subtropics to Baffin Bay and the Greenland Sea. The IWC currently recognizes these whales as one stock (Perry et al. 1999).

Blue whales were intensively hunted in all of the world's oceans from the turn of the century to the mid-1960s when development of steam-powered vessels and deck-mounted harpoon guns in the late 19th century made it possible to exploit them on an industrial scale (NMFS 1998c). Blue whale populations declined worldwide as the new technology spread and began to receive widespread use (Perry et al. 1999). Subsequently, the whaling industry shifted effort away from declining blue whale stocks and targeted other large species, such as fin whales, and then resumed hunting for blue whales when the species appeared to be more abundant (Perry et al. 1999). The result was a cyclical rise and fall, leading to severe depletion of blue whale stocks worldwide (Perry et al. 1999). In all, at least 11,000 blue whales were taken in the North Atlantic from the late 19th century through the mid-20th century.

Blue whales were given complete protection in the North Atlantic in 1955 under the International Convention for the Regulation of Whaling. There are no good estimates of the pre-exploitation size of the western North Atlantic blue whale stock but it is widely believed that this stock was severely depleted by the time legal protection was introduced in 1955 (Perry et al. 1999). Mitchell (1974) suggested that the stock numbered in the very low hundreds during the late 1960's through early 1970's (Perry et al. 1999). Photo-identification studies of blue whales in the Gulf of St. Lawrence from 1979 to 1995 identified 320 individual whales (NMFS 1998c). The NMFS recognizes a minimum population estimate of 308 blue whales within the Northeast Region (Waring et al. 2001).

Blue whales are only occasional visitors to east coast U.S. waters. They are more commonly found in Canadian waters, particularly the Gulf of St. Lawrence where they are present for most of the year, and in other areas of the North Atlantic. It is assumed that blue whale distribution is governed largely by food requirements (NMFS 1998c). In the Gulf of St. Lawrence, blue whales appear to predominantly feed on a variety of copepod species (NMFS 1998c).

Compared to the other species of large whales, relatively little is known about this species. Sexual maturity is believed to occur in both sexes at 5-15 years of age. Gestation lasts 10-12 months and calves nurse for 6-7 months. The average calving interval is estimated to be 2-3 years. Birth and mating both take place in the winter season (NMFS 1998c), but the location of wintering areas is speculative (Perry et al. 1999). In 1992 the U.S. Navy and contractors conducted an extensive blue whale acoustic survey of the North Atlantic and found concentrations of blue whales on the Grand Banks and west of the British Isles. One whale was tracked for 43 days during which time it traveled 1,400 nautical miles around the general area of Bermuda (Perry et al. 1999).

There is limited information on the factors affecting natural mortality of blue whales in the North Atlantic. Ice entrapment is known to kill and seriously injure some blue whales during late winter and early spring, particularly along the southwest coast of Newfoundland. Habitat degradation has been suggested as possibly affecting blue whales such as in the St. Lawrence River and the Gulf of St. Lawrence where habitat has been degraded by acoustic and chemical pollution. However, there is no data to confirm that blue whales have been affected by such habitat changes (Perry et al. 1999).

<u>General Human Impacts and Entanglement</u>

Entanglements in fishing gear such as the sink gillnet gear used in the multispecies fishery and ship strikes are believed to be the major sources of anthropogenic mortality and injury of blue whales. However, confirmed deaths or serious injuries are few. In 1987, concurrent with an unusual influx of blue whales into the Gulf of Maine, one report was received from a whale watch boat that spotted a blue whale in the southern Gulf of Maine entangled in gear described as probable lobster pot gear. A second animal found in the Gulf of St. Lawrence apparently died from the effects of an entanglement. In March 1998, a juvenile male blue whale was carried into Rhode Island waters on the bow of a tanker. The cause of death was determined to be due to a ship strike that may have occurred outside the U.S. EEZ (Waring et al. 2001).

Sperm Whale

Sperm whales inhabit all ocean basins, from equatorial waters to the polar regions (Perry et al. 1999). In the western North Atlantic they range from Greenland to the Gulf of Mexico and the Caribbean. The sperm whales that occur in the western North Atlantic are believed to represent only a portion of the total stock (Blaylock et al. 1995). Total numbers of sperm whales off the USA or Canadian Atlantic coast are unknown, although eight estimates from selected regions of the habitat do exist for select time periods. The best estimate of abundance for the North Atlantic stock of sperm whales is 4,702 (CV=0.36) (Waring et al. 2001). The IWC recognizes one stock for the entire North Atlantic (Waring et al. 2001).

The IWC estimates that nearly a quarter-million sperm whales were killed worldwide in whaling activities between 1800 and 1900 (IWC 1971). With the advent of modern whaling the larger rorqual whales were targeted. However as their numbers decreased, whaling pressure again focused on smaller rorquals and sperm whales. From 1910 to 1982 there were nearly 700,000 sperm whales killed worldwide from whaling activities (Clarke 1954). Some sperm whales were also taken off the U.S. Mid-Atlantic coast (Reeves and Mitchell 1988; Perry et al. 1999), and in the northern Gulf of Mexico (Perry et al. 1999). Recorded North Atlantic sperm whale catch numbers for Canada and Norway from 1904 to 1972 total 1,995. All killing of sperm whales was banned by the IWC in 1988.

Sperm whales generally occur in waters greater than 180 meters in depth with a preference for continental margins, seamounts, and areas of upwelling, where food is abundant (Leatherwood and Reeves 1983). Sperm whales in both hemispheres migrate to higher latitudes in the summer for feeding and return to lower latitude waters in the winter where mating and calving occur. Mature males typically range to higher latitudes than mature females and immature animals but return to the lower latitudes in the winter to breed (Perry et al. 1999). Waring et al. (1993) suggest sperm whale distribution is closely correlated with the Gulf Stream edge with a migration to higher latitudes during summer months where they are concentrated east and northeast of Cape Hatteras. Distribution extends further northward to areas north of Georges Bank and the Northeast Channel region in summer and then south of New England in fall, back to the mid-Atlantic Bight (Waring et al. 2001).

Mature females in the northern hemisphere ovulate April through August. A single calf is born after a 15-month gestation. A mature female will produce a calf every 4-6 years. Females attain sexual maturity at a mean age of nine years, while males have a prolonged puberty and attain sexual maturity at about age 20 (Waring et al. 2001). Male sperm whales may not reach physical maturity until they are 45 years old (Waring et al. 2001). The sperm whales prey consists of larger mid-water squid and fish species (Perry et al. 1999). Sperm whales, especially mature males in higher latitude waters, have been observed to take significant quantities of large demersal and deep water sharks, multispecies, and bony fishes.

<u>General Human Impacts and Entanglement</u>

Few instances of injury or mortality of sperm whales due to human impacts have been recorded in U.S. waters. Because of their generally more offshore distribution and their benthic feeding habits, sperm whales are less subject to entanglement than are right or humpback whales. However, the multispecies fishery is conducted near the shelf edge and utilizes fixed sink gillnet gear that may pose a threat to sperm whales.

Documented takes primarily involve offshore fisheries such as the offshore lobster pot fishery and pelagic driftnet and pelagic longline fisheries. Ships also strike sperm whales. Due to the offshore distribution of this species, interactions (both ship strikes and entanglements) that do occur are less likely to be reported than those involving right, humpback, and fin whales that more often occur in nearshore areas. Other impacts noted above for baleen whales may also occur.

Due to their offshore distribution, sperm whales tend to strand less often than, for example, right whales and humpbacks. Preliminary data for 2000 indicate that of ten sperm whales reported to the stranding network (nine dead and one injured) there was one possible fishery interaction, one ship strike (wounded with bleeding gash on side) and eight animals for which no signs of entanglement or injury were sighted or reported.

Minke Whale

Minke whales have a cosmopolitan distribution in polar, temperate, and tropical waters. The Canadian east coast population is one of four populations recognized in the North Atlantic. Minke whales off the eastern coast of the U.S. are considered to be part of this population that extends from Davis Strait off Newfoundland to the Gulf of Mexico. The species is common and widely distributed along the U.S. continental shelf. They show a certain seasonal distribution with spring and summer peak numbers, falling off in the fall to very low winter numbers. Like all baleen whales, the minke whale generally occupies the continental shelf proper.

Minke whales are known to be taken in sink gillnet gear used to catch multispecies (see Table 126). Waring et al. (2001) has described the estimated total take of minke whales in all fisheries (including those that catch multispecies) to be below the PBR established for that species. All vessels that utilize sink gillnet gear will be operating under the Multispecies FMP due to the requirement that any gear capable of catching multispecies must obtain a Multispecies permit. Since a sink gillnet cannot be deployed in the Northeast waters without the possibility of catching a species covered under the Multispecies FMP, they will be included in the effort control measures that will be developed under Amendment 13 to the Multispecies FMP. Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region, and will not further inhibit the ability of minke whales to achieve the optimum sustainable population level for the North Atlantic stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Harbor Porpoise

Harbor porpoise are found primarily in the Gulf of Maine in the summer months. However, they migrate seasonally through regions where the multispecies are caught. For example, they move through the southern New England area where the multispecies fishery occurs in the spring (March and April). Harbor porpoise also move through the Massachusetts Bay and Jeffrey's Ledge region in the spring (April and May) and the fall (October November). They are not known to frequent the Georges Bank region where multispecies are also found.

Harbor porpoise are taken in sink gillnet gear used to catch multispecies (see Table 125). The historic level of serious injury and mortality of this species in sink gillnets was known to be high relative to the estimated population level, and was addressed in the Harbor Porpoise Take Reduction Plan (HPTRP) that was developed under the mandates of the MMPA. The HPTRP used a series of time/area closures and required use of acoustical pingers that have reduced the take to acceptable levels. NMFS recently reported in the Federal Register (67FR51234 dated August 7, 2002) that the estimated incidental take of harbor porpoise in U.S. waters for 2001 was 80 animals. The minimum population estimate for 1999 was established at 74,695, and the potential biological removal (PBR) for the harbor porpoise is now set at 747. Although the current mortality estimate is below the latest PBR level, the stock is still considered a strategic stock requiring continued measures to reduce human-caused mortality from commercial fishing. This is due to the fact that there are insufficient data to determine population trends for this species.

The multispecies fisheries that utilize sink gillnet gear operate under the Multispecies FMP that contains effort controls developed in part for protection of this species. Amendment 13 measures will continue, and are likely to increase this effort reduction. The gillnet fishery is also subject to the requirements of the HPTRP implemented by NMFS in December 2, 1998. The combination of measures implemented by the Multispecies FMP and the HTRP have significantly reduced harbor porpoise takes to acceptable levels under the MMPA.

Atlantic White-Sided Dolphin

White-sided dolphins are found in the temperate and sub-polar waters of the North Atlantic, primarily on the continental shelf waters out to the 100-meter depth contour. The species is distributed from central western Greenland to North Carolina, with the Gulf of Maine stock commonly found from Hudson Canyon to Georges Bank and into the Gulf of Maine to the Bay of Fundy. A minimum population estimate for the white-sided dolphin 19,196 has been derived for U.S. waters (Waring et al. 2001) from limited survey estimates. White-sided dolphins have been observed taken in the multispecies sink gillnet, the pelagic drift gillnet, and several mid-water and bottom trawl fisheries. Waring et al. (2001) described the estimated total take of white-sided dolphins in all fisheries (including those that catch multispecies) to be below the PBR established for that species. As described above for the minke whale, the proposed Amendment 13 to the Multispecies FMP will not increase the gillnet effort in the Northeast Region. Therefore, the proposed Amendment 13 to the Multispecies FMP will not further inhibit the ability of white-sided dolphins to achieve the optimum sustainable population level for the North Atlantic stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Pelagic Delphinids (Pilot whales, offshore bottlenose and common dolphins)

The pelagic delphinid complex is made up of small odontocete species that are broadly distributed along the continental shelf edge where depths range from 200 - 400 meters. They are commonly found in large schools feeding on schools of fish. The minimum population estimates for each species number in the tens of thousands. They are known to be taken in pelagic and sink gillnets gear as well as mid-water and bottom trawl gear. Although some takes have been observed in the bottom trawl fishery, their pelagic prey species suggest they do not forage near the bottom, making it unlikely that they would frequently encounter the bottom tending gear used in the multispecies fishery. Therefore, it is unlikely that the take in this fishery will be at levels that compromise their ability to maintain optimum sustainable population levels, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Harbor seal

The harbor seal is found in all nearshore waters of the Atlantic Ocean above about 30 degrees latitude (Waring et al. 2001). In the western North Atlantic they are distributed from the eastern Canadian Arctic and Greenland south to southern New England and New York, and occasionally the Carolinas (Boulva and McLaren 1979; Gilbert and Guldager 1998). It is believed that the harbor seals found along the U.S. and Canadian east coasts represent one population (Waring et al. 2001). Harbor seals are year-round inhabitants of the coastal waters of eastern Canada and Maine, and occur seasonally along the southern New England and New York coasts from September through late-May. However, breeding and pupping normally occur only in waters north of the New Hampshire/Maine border. Since passage of the MMPA in 1972, the number of seals found along the New England coast has increased nearly five-fold with the number of pups seen along the Maine coast increasing at an annual rate of 12.9 percent during the 1981-1997 period (Gilbert and Guldager 1998). The minimum population estimate for harbor seals is 30,990 based on uncorrected total counts along the Maine coast in 1997 (Waring et al. 2001).

Harbor seals are taken in sink gillnet gear used to catch multispecies. Waring et al. (2001) has described the estimated total take of harbor seals in all fisheries to be below the PBR of 1,859 established for that species. All vessels that utilize sink gillnet gear will be operating under the Multispecies FMP due to the requirement that any gear capable of catching multispecies must obtain a multispecies permit. Since a sink gillnet cannot be deployed in the Northeast waters without the possibility of catching a species managed under the Multispecies FMP, they will be included in the effort control measures that will be developed under Amendment 13 to the Multispecies FMP. Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region. Therefore, it will not further inhibit the ability of harbor seals to achieve the optimum sustainable population level for the North Atlantic stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Gray seal

The gray seal is found on both sides of the North Atlantic, with the western North Atlantic population occurring from New England to Labrador. There are two breeding concentrations in eastern Canada - one at Sable Island and one that breeds on the pack ice in the Gulf of St Lawrence. There are several small breeding colonies on isolated islands along the coast of Maine and on outer Cape Cod and Nantucket Island in Massachusetts (Waring et al. 2001). The population estimates for the Sable Island and Gulf of St. Lawrence breeding groups was 143,000 in 1993. The gray seal population in Massachusetts has increased from 2,010 in 1994 to 5,611 in 1999, although it is not clear how much of this increase may be due to animals emigrating from northern areas. Approximately 150 gray seals have been observed on isolated island off Maine.

Gray seals are taken in sink gillnet gear used to catch multispecies. Waring et al. (2001) has described the estimated total take of gray seals from 1959 to 1999 in all fisheries to be between 50 and 155 animals which is well below the PBR of 8,850 established for that species. As stated in the harbor seal discussion above, all vessels that utilize sink gillnet gear will be operating under the Multispecies FMP and thus included in the effort control measures that will be developed under Amendment 13. Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region. Therefore, it will not further inhibit the ability of gray seals to achieve the optimum sustainable population level for the North Atlantic stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Harp seal

The harp seal occurs throughout much of the North Atlantic and Arctic Oceans, and have been increasing off the East Coast of the United States from Maine to New Jersey. Harp seals are usually found off the U.S. from January to May when the western stock of harp seals is at their most southern point of migration (Waring et al. 2001). Harp seals congregate on the edge of the pack ice in February through April when breeding and pupping takes place. The harp seal is highly migratory, moving north and south with the edge of the pack ice. Non-breeding juveniles will migrate the farthest south in the winter, but the entire population moves north toward the Arctic in the summer. The minimum population estimate for the western North Atlantic is 5.2 million seals.

A large number of harp seals are killed in Canada, Greenland and the Arctic. The allowed kill was set at 275,000 in 1997 by the Canada DFO. Mortality in Greenland and the Arctic may exceed 100,000 (Waring et al. 2001). Harp seals are also taken in sink gillnet gear used to catch multispecies. Waring et al. (2001) has described the estimated total take of harp seals from 1959 to 1999 in all fisheries to range between 78 and 694 animals depending on the location of the pack ice edge which drives the seals farther south into the range of the sink gillnet fishery. Even with the highest takes observed, the take is well below the PBR of 156,000 established for that species. As stated in the harbor seal discussion above, all vessels that utilize sink gillnet gear will be operating under the Multispecies FMP and thus included in the effort control measures that will be developed under Amendment 13. Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region. Therefore, it will not further inhibit the ability of harp seals to achieve the optimum sustainable population level for the North Atlantic stock, or cause their serious injury and mortality levels to exceed the PBR levels allowed for commercial fisheries under the MMPA.

Leatherback Sea Turtle

Leatherback turtles are widely distributed throughout the oceans of the world, and are found in waters of the Atlantic, Pacific, Caribbean, and the Gulf of Mexico (Ernst and Barbour 1972). The leatherback sea turtle is the largest living turtle and ranges farther than any other sea turtle species, exhibiting broad thermal tolerances that allow it to forage into the colder Northeast Region waters (NMFS and USFWS, 1995). Evidence from tag returns and strandings in the western North Atlantic suggests that adults engage in routine migrations between boreal, temperate and tropical waters (NMFS and USFWS, 1992). In the U.S., leatherback turtles are found throughout the western North Atlantic during the warmer months along the continental shelf, and near the Gulf Stream edge. A 1979 aerial survey of the outer Continental Shelf from Cape Hatteras, North Carolina to Cape Sable, Nova Scotia showed leatherbacks to be present throughout the area with the most numerous sightings made from the Gulf of Maine south to Long Island (CeTAP 1982). Shoop and Kenney (1992) also observed concentrations of leatherbacks during the summer off the south shore of Long Island and New Jersey. Leatherbacks in these waters are thought to be following jellyfish, their preferred prey.

Compared to the current knowledge regarding loggerhead populations, the genetic distinctness of leatherback populations is less clear. However, genetic analyses of leatherbacks to date indicate female turtles nesting in St. Croix/Puerto Rico and those nesting in Trinidad differ from each other and from turtles nesting in Florida, French Guiana/Suriname and along the South African Indian Ocean coast. Since populations or subpopulations of leatherback sea turtles have not been formally recognized, the conservative approach is to treat leatherback nesting populations as distinct.

Leatherbacks are predominantly pelagic species and feed on jellyfish and other soft-bodied prey. Time-depth-recorder data collected by Eckert et al. (1996) indicate that leatherbacks are night feeders and are deep divers, with recorded dives to depths in excess of 1,000 meters. However, leatherbacks may feed in shallow waters if there is an abundance of jellyfish near shore. For example, leatherbacks occur annually in shallow bays such as Cape Cod and Narragansett Bays during the fall.

Leatherbacks are a long lived species (> 30 years), with an estimated age at sexual maturity reported as about 13-14 years for females, and an estimated minimum age at sexual maturity of 5-6 years, with (Zug and Parham 1996 and NMFS 2001). Leatherbacks nest from March through July and produce 100 eggs or more in each clutch, or a total of 700 eggs or more per nesting season (Schultz 1975). The eggs will incubate for 55-75 days before hatching. The habitat requirements for post-hatchling leatherbacks that reach the ocean are virtually unknown (NMFS and USFWS 1992).

Status and Trends of Leatherback Sea Turtles

Estimated to number approximately 115,000 adult females globally in 1980 (Pritchard 1982) and only 34,500 by 1995 (Spotila et al. 1996), leatherback populations have been decimated worldwide, not only by fishery related mortality but, at least historically, primarily due to exploitation of eggs (Ross 1979). On some beaches nearly 100% of the eggs laid have been harvested (Eckert 1996).

Nest counts are currently the only reliable indicator of population status available for leatherback turtles. The status of the leatherback population in the Atlantic is difficult to assess since major nesting beaches occur over broad areas within tropical waters outside the United States. Recent information suggests that western North Atlantic populations declined from 18,800 nesting females in 1996 (Spotila et al. 1996) to 15,000 nesting females by 2000. In contrast, Eastern Atlantic (i.e., off Africa, numbering ~ 4,700) and Caribbean (4,000) populations appear to be stable. It does appear that the Western Atlantic portion of the population is being subjected to mortality beyond sustainable levels, resulting in a continued decline in numbers of nesting females.

General Human Impacts and Entanglement

Anthropogenic impacts to the leatherback population include fishery interactions as well as exploitation of the eggs (Ross 1979). Eckert (1996) and Spotila et al. (1996) record that adult mortality has also increased significantly, particularly as a result of driftnet and longline fisheries. Zug and Parham (1996) attribute the sharp decline in leatherback populations to the combination of the loss of long-lived adults in fishery related mortality, and the lack of recruitment stemming from elimination of annual influxes of hatchlings because of egg harvesting.

Poaching is not known to be a problem for U.S. nesting populations. However, numerous fisheries that occur in both U.S. state and federal waters are known to negatively impact juvenile and adult leatherback sea turtles. These include incidental take in several commercial and recreational fisheries. Fisheries known or suspected to incidentally capture leatherbacks include those deploying bottom trawls, off-bottom trawls, purse seines, bottom longlines, hook and line, gill nets, drift nets, traps, haul seines, pound nets, beach seines, and surface longlines (NMFS and USFWS 1992).

Leatherback interactions with the southeast shrimp fishery are well documented. Turtle Excluder Devices (TEDs), typically used in the southeast shrimp fishery to minimize sea turtle/fishery interactions, are less effective for the larger leatherbacks. Therefore, the NMFS established a zone to restrict, when necessary, shrimp trawl activities from off the coast of Cape Canaveral, Florida to the Virginia/North Carolina Border.

Leatherbacks are also susceptible to entanglement in lobster and crab pot gear. The probable reasons include: attraction to gelatinous organisms and algae that collect on buoys and buoy lines at or near the surface; attraction to the buoys which could appear as prey; or the gear configuration which may be more likely to wrap around flippers. The total number of leatherbacks reported entangled from New York through Maine from all sources for the years 1980 - 2000 is 119. Entanglements are also common in Canadian waters where Goff and Lien (1988) reported that 14 of 20 leatherbacks encountered off the coast of Newfoundland/Labrador were entangled in fishing gear including salmon nets, herring nets, gillnets, trawl lines and crab pot lines. Prescott (1988) reviewed stranding data for Cape Cod Bay and concluded that for those turtles where cause of death could be determined (the minority), entanglement in fishing gear is the leading cause of death followed by capture by dragger, cold stunning, or collision with boats.

As noted, there are many human-related sources of mortality to leatherbacks. A tally of all leatherback takes anticipated annually under current biological opinions was projected to be as many as 801 leatherback takes, although this sum includes many takes expected to be nonlethal.

Leatherbacks have a number of pressures on their populations, including injury or mortality in fisheries, other federal activities (e.g., military activities, oil and gas development, etc.), degradation of nesting habitats, direct harvest of eggs, juvenile and adult turtles, the effects of ocean pollutants and debris, lethal collisions, and natural disturbances such as hurricanes that are capable of destroying nesting beaches. Spotila et al. (1996) conclude, “stable leatherback populations could not withstand an increase in adult mortality above natural background levels without decreasing the Atlantic population is the most robust, but it is being exploited at a rate that cannot be sustained and if this rate of mortality continues, these populations will also decline.”

Kemp’s Ridley Sea Turtle

The Kemp’s ridley is the most endangered of the world’s sea turtle species. Of the world’s seven extant species of sea turtles, the Kemp's ridley has declined to the lowest population level. Kemp’s ridleys nest in daytime aggregations known as arribadas, primarily on a stretch of beach in Mexico called Rancho Nuevo. Most of the population of adult females nest in this single locality (Pritchard 1969). When nesting aggregations at Rancho Nuevo were discovered in 1947, adult female populations were estimated to be in excess of 40,000 individuals (Hildebrand 1963). By the early 1970s, the world population estimate of mature female Kemp's ridleys had been reduced to 2,500-5,000 individuals. The population declined further through the mid-1980s.

Status and Trends of Kemp’s Ridley Sea Turtles

The TEWG (1998; 2000) indicated that the Kemp's ridley population appears to be in the early stage of exponential expansion. Nesting data, estimated number of adults, and percentage of first time nesters have all increased from lows experienced in the 1970s and 1980s. From 1985 to 1999, the number of nests observed at Rancho Nuevo and nearby beaches has increased at a mean rate of 11.3% per year, allowing cautious optimism that the population is on its way to recovery. For example, nesting data indicated that the number of adults declined from a population that produced 6,000 nests in 1966 to a population that produced 924 nests in 1978 and 702 nests in 1985 then increased to produce 1,940 nests in 1995. Estimates of adult abundance followed a similar trend from an estimate of 9,600 in 1966 to 1,050 in 1985 and 3,000 in 1995. The increased recruitment of new adults is illustrated in the proportion of neophyte, or first time nesters, which has increased from 6% to 28% from 1981 to 1989 and from 23% to 41% from 1990 to 1994.

Kemp’s ridley nesting occurs from April through July each year. Little is known about mating but it is believed to occur before the nesting season in the vicinity of the nesting beach. Hatchlings emerge after 45-58 days. Once they leave the beach, neonates presumably enter the Gulf of Mexico where they feed on available sargassum and associated infauna or other epipelagic species (USFWS and NMFS, 1992). Ogren (1988) suggests that the Gulf coast, from Port Aransas, Texas, through Cedar Key, Florida, represents the primary habitat for subadult ridleys in the northern Gulf of Mexico. However, at least some juveniles will travel northward as water temperatures warm to feed in productive coastal waters off Georgia through New England (USFWS and NMFS, 1992).

Juvenile Kemp’s ridleys use northeastern and Mid-Atlantic coastal waters of the U.S. Atlantic coastline as primary developmental habitat during summer months, with shallow coastal embayments serving as important foraging grounds. Ridleys found in Mid- Atlantic waters are primarily post-pelagic juveniles averaging 40 centimeters in carapace length, and weighing less than 20 kilograms (Terwilliger and Musick

1995). Next to loggerheads, they are the second most abundant sea turtle in Virginia and Maryland waters, arriving in these areas during May and June (Keinath et al., 1987; Musick and Limpus, 1997). Studies have found that post-pelagic ridleys feed primarily on a variety of species of crabs. Mollusks, shrimp, and fish are consumed less frequently (Bjorndal, 1997).

With the onset of winter and the decline of water temperatures, ridleys migrate to more southerly waters from September to November (Keinath et al., 1987; Musick and Limpus, 1997). Turtles who do not head south soon enough face the risks of cold stunning in northern waters. Cold stunning can be a significant natural cause of mortality for sea turtles in Cape Cod Bay and Long Island Sound. For example, in the winter of 1999/2000, there was a major cold-stunning event where 218 Kemp's ridleys, 54 loggerheads, and 5 green turtles were found on Cape Cod beaches. The severity of cold stun events depends on: the numbers of turtles utilizing Northeast waters in a given year; oceanographic conditions; and the occurrence of storm events in the late fall. Cold-stunned turtles have also been found on beaches in New York and New Jersey. Cold-stunning events can represent a significant cause of natural mortality, in spite of the fact that many cold-stunned turtles can survive if found early enough.

<u>General Human Impacts and Entanglement</u>

Like other turtle species, the severe decline in the Kemp's ridley population appears to have been heavily influenced by a combination of exploitation of eggs and impacts from fishery interactions. From the 1940s through the early 1960s, nests from Ranch Nuevo were heavily exploited (USFWS and NMFS, 1992), but beach protection in 1966 helped to curtail this activity (USFWS and NMFS, 1992). Currently, anthropogenic impacts to the Kemp's ridley population are similar to those discussed above for other sea turtle species. Takes of Kemp's ridley turtles have been recorded by sea sampling coverage in the Northeast otter trawl fishery, pelagic longline fishery, and southeast shrimp and summer flounder bottom trawl fisheries.

Kemp's ridleys may also be affected by large-mesh gillnet fisheries. In the spring of 2000, a total of five Kemp's ridley carcasses were recovered from a North Carolina beach where 277 loggerhead carcasses were found. Cause of death for most of the turtles recovered was unknown, but the mass mortality event was suspected to have been from a large-mesh gillnet fishery operating offshore in the preceding weeks. It is possible that strandings of Kemp's ridley turtles in some years have increased at rates higher than the rate of increase in the Kemp's ridley population (TEWG 1998).

Green Sea Turtle

Green turtles are distributed circumglobally. In the western Atlantic they range from Massachusetts to Argentina, including the Gulf of Mexico and Caribbean, but are considered rare north of Cape Hatteras (Wynne and Schwartz, 1999). Most green turtle nesting in the continental United States occurs on the Atlantic Coast of Florida (Ehrhart 1979). Green turtles were traditionally highly prized for their flesh, fat, eggs, and shell, and directed fisheries in the United States and throughout the Caribbean are largely to blame for the decline of the species. In the Gulf of Mexico, green turtles were once abundant enough in the shallow bays and lagoons to support a commercial fishery. However, declines in the turtle fishery throughout the Gulf of Mexico were evident by 1902 (Doughty 1984).

In the continental United States, green turtle nesting occurs on the Atlantic coast of Florida (Ehrhart 1979). Occasional nesting has been documented along the Gulf coast of Florida, at southwest Florida beaches, as well as the beaches on the Florida panhandle (Meylan et al. 1995). The pattern of green turtle nesting shows biennial peaks in abundance, with a generally positive trend during the ten years of regular monitoring, perhaps due to increased protective legislation throughout the Caribbean (Meylan et al., 1995). Increased nesting has also been observed along the Atlantic Coast of Florida, on beaches where only loggerhead nesting was observed in the past). Recent population estimates for the western Atlantic area are not available.

While nesting activity is obviously important in determining population distributions, the remaining portion of the green turtle's life is spent on the foraging and breeding grounds. Juvenile green sea turtles occupy pelagic habitats after leaving the nesting beach. Pelagic juveniles are assumed to be omnivorous, but with a strong tendency toward carnivory during early life stages. At approximately 20 to 25 cm carapace length, juveniles leave pelagic habitats and enter benthic foraging areas, shifting to a chiefly herbivorous diet (Bjorndal 1997). Green turtles appear to prefer marine grasses and algae in shallow bays, lagoons and reefs (Rebel 1974) but also consume jellyfish, salps, and sponges.

As is the case for loggerhead and Kemp's ridley sea turtles, green sea turtles use mid-Atlantic and northern areas of the western Atlantic coast as important summer developmental habitat. Green turtles are found in estuarine and coastal waters as far north as Long Island Sound, Chesapeake Bay, and North Carolina sounds (Musick and Limpus 1997). Like loggerheads and Kemp's ridleys, green sea turtles that use northern waters during the summer must return to warmer waters when water temperatures drop, or face the risk of cold stunning. Cold stunning of green turtles may occur in southern areas as well (*i.e.*, Indian River, Florida), as these natural mortality events are dependent on water temperatures and not solely geographical location.

<u>General Human Impacts and Entanglement</u>

Anthropogenic impacts to the green sea turtle population are similar to those discussed above for other sea turtles species. As with the other species, fishery mortality accounts for a large proportion of annual human-caused mortality outside the nesting beaches, while other activities like dredging, pollution, and habitat destruction account for an unknown level of other mortality. Sea sampling coverage in the pelagic driftnet, pelagic longline, scallop dredge, southeast shrimp trawl, and summer flounder bottom trawl fisheries has recorded takes of green turtles.

Loggerhead Sea Turtle

Loggerhead sea turtles occur throughout the temperate and tropical regions of the Atlantic, Pacific, and Indian Oceans in a wide range of habitats. These include open ocean, continental shelves, bays, lagoons, and estuaries (NMFS and USFWS 1995). Loggerhead sea turtles are primarily benthic feeders, opportunistically foraging on crustaceans and mollusks (Wynne and Schwartz 1999). Under certain conditions they may also scavenge fish (NMFS and USFWS 1991b). Horseshoe crabs are known to be a favorite prey item in the Chesapeake Bay area (Lutcavage and Musick 1985).

<u>Status and Trends of Loggerhead Sea Turtles</u>

The loggerhead sea turtle was listed as threatened under the ESA on July 28, 1978. The species was considered to be a single population in the North Atlantic at the time of listing. However, further genetic analyses conducted at nesting sites indicate the existence of five distinct subpopulations ranging from North Carolina, south along the Florida east coast and around the keys into the Gulf of Mexico, to nesting sites in the Yucatan peninsula and Dry Tortugas (TEWG 2000 and NMFS SEFSC 2001). Natal homing to those nesting beaches is believed to provide the genetic barrier between these nesting aggregations, preventing recolonization of turtles from other nesting beaches.

The threatened loggerhead sea turtle is the most abundant of the sea turtles listed as threatened or endangered in the U.S. waters. In the western North Atlantic, most loggerhead sea turtles nest from North Carolina to Florida and along the gulf coast of Florida. The southeastern U.S. nesting aggregation is the second largest and represents about 35 % of the nests of this species. The total number of nests along the U.S. Atlantic and Gulf coasts between 1989 and 1998, ranged from 53,014 to 92,182 annually, with a mean of 73,751. Since a female often lays multiple nests in any one season, the average adult female population was estimated to be 44,780 (Murphy and Hopkins 1984).

However, the status of the northern loggerhead subpopulation is of particular concern. Based on the above, there are only an estimated 3,800 nesting females in the northern loggerhead subpopulation, and the status of this northern population based on number of loggerhead nests, has been classified declining or stable

(TEWG 2000). Another factor that may add to the vulnerability of the northern subpopulation is that genetics data show that the northern subpopulation produces predominantly males (65%). In contrast, the much larger south Florida subpopulation produces predominantly females (80%) (NMFS SEFSC 2001).

The activity of the loggerhead is limited by temperature. Loggerheads commonly occur throughout the inner continental shelf from Florida through Cape Cod, Massachusetts. Loggerheads may also occur as far north as Nova Scotia when oceanographic and prey conditions are favorable. Surveys conducted offshore as well as sea turtle stranding data collected during November and December off North Carolina suggest that sea turtles emigrating from northern waters in fall and winter months may concentrate in nearshore and southerly areas influenced by warmer Gulf Stream waters (Epperly et al. 1995). This is supported by the collected work of Morreale and Standora (1998) who tracked 12 loggerheads and 3 Kemp's ridleys by satellite. All of the turtles followed similar spatial and temporal corridors, migrating south from Long Island Sound, New York, during October through December. The turtles traveled within a narrow band along the continental shelf and became sedentary for one or two months south of Cape Hatteras.

Loggerhead sea turtles do not usually appear on the most northern summer foraging grounds in the Gulf of Maine until June, but are found in Virginia as early as April. They remain in the mid-Atlantic and northeast areas until as late as November and December in some cases, but the majority leaves the Gulf of Maine by mid-September. Aerial surveys of loggerhead turtles north of Cape Hatteras indicate that they are most common in waters from 22 to 49 meters deep, although they range from the beach to waters beyond the continental shelf (Shoop and Kenney 1992).

All five loggerhead subpopulations are subject to natural phenomena that cause annual fluctuations in the number of young produced. For example, there is a significant overlap between hurricane seasons in the Caribbean Sea and northwest Atlantic Ocean (June to November), and the loggerhead sea turtle nesting season (March to November). Sand accretion and rainfall that result from these storms as well as wave action can appreciably reduce hatchling success. In 1992, Hurricane Andrew affected turtle nests over a 90-mile length of coastal Florida; all of the eggs were destroyed by storm surges on beaches that were closest to the eye of this hurricane (Milton et al. 1994). Other sources of natural mortality include cold stunning and biotoxin exposure.

General Human Impacts and Entanglement

The diversity of the sea turtles life history leaves them susceptible to many human impacts, including impacts on land, in the benthic environment, and in the pelagic environment. Anthropogenic factors that impact the success of nesting and hatching include: beach erosion, beach armoring and nourishment; artificial lighting; beach cleaning; increased human presence; recreational beach equipment; beach driving; coastal construction and fishing piers; exotic dune and beach vegetation; and poaching. An increased human presence at some nesting beaches or close to nesting beaches has led to secondary threats such as the introduction of exotic fire ants, and an increased presence of native species (e.g., raccoons, armadillos, and oppossums) which raid and feed on turtle eggs.

Loggerhead sea turtles originating from the western Atlantic nesting aggregations are believed to lead a pelagic existence in the North Atlantic gyre for as long as 7-12 years before settling into benthic environments. Loggerhead sea turtles are impacted by a completely different set of threats from human activity once they migrate to the ocean. During that period, they are exposed to a series of long-line fisheries that include the U.S. Atlantic tuna and swordfish longline fisheries, an Azorean long-line fleet, a Spanish long-line fleet, and various fleets in the Mediterranean Sea (Aguilar et al. 1995, Bolten et al. 1994, Crouse 1999). Observer records indicate that, of the 6,544 loggerheads estimated to be captured by the U.S. Atlantic tuna and swordfish longline fleet between 1992-1998, an estimated 43 were dead (Yeung 1999). For 1998, alone, an estimated 510 loggerheads (225-1250) were captured in the longline fishery. Aguilar et al. (1995) estimated that the Spanish swordfish longline fleet, which is only one of the many fleets operating in the region, captures more than 20,000 juvenile loggerheads annually (killing as many as 10,700).

Once loggerheads enter the benthic environment in waters off the coastal U.S., they are exposed to a suite of fisheries in federal and State waters including trawl, purse seine, hook and line, gillnet, pound net, longline, and trap fisheries. Loggerhead sea turtles are captured in fixed pound net gear in the Long Island Sound, in pound net gear and trawls in summer flounder and other finfish fisheries in the Mid-Atlantic and Chesapeake Bay, in gillnet fisheries in the Mid-Atlantic and elsewhere, and in multispecies, monkfish, spiny dogfish, and northeast sink gillnet fisheries.

In addition to fishery interactions, loggerhead sea turtles also face other man-made threats in the marine environment. These include oil and gas exploration and coastal development, as well as marine pollution, underwater explosions, and hopper dredging. Offshore artificial lighting, power plant entrainment and/or impingement, and entanglement in debris or ingestion of marine debris are also seen as possible threats. Boat collisions and poaching are two direct impacts that affect loggerheads.

9.2.2.3 Other Species of Concern

Barndoor Skate

Barndoor skate is considered a candidate species under the ESA as a result of two petitions to list the species as endangered or threatened that were received in March and April 1999. In June 1999, the agency declared the petitioned actions to be warranted and requested additional information on whether or not to list the species under the ESA. At the 30th Stock Assessment Workshop (SAW 30) held in November 1999, the Stock Assessment Research Committee (SARC) reviewed the status of the barndoor skate stock relative to the five listing criteria of the ESA. The SARC provided their report to the NMFS in the SAW 30 document (NEFSC 2000). NMFS published a decision on the petitions on September 27, 2002 (67FR61055-61061) that the petitioned actions are not warranted at this time. However, NMFS is leaving barndoor skate on the agency's list of candidate species due to remaining uncertainties regarding the status and population structure of the species

The barndoor skate occurs from Newfoundland, the Gulf of St. Lawrence, off Nova Scotia, the Gulf of Maine, and the northern sections of the Mid-Atlantic Bight down to North Carolina. It is one of the largest skates in the Northwest Atlantic and is presumed to be a long-lived, slow growing species. Barndoor skates inhabit mud and sand/gravel bottoms along the continental shelf, generally at depths greater than 150 meters. They are believed to feed on benthic invertebrates and fishes (Bigelow and Schroeder 1953).

The barndoor skate is often caught as a bycatch species in the offshore trawl and sink gillnet fisheries that target multispecies. When landed, barndoor skate are often used in the skate wing fishery.

The abundance of barndoor skate declined continuously through the 1960's. Since 1990, their abundance has increased slightly on Georges Bank, the western Scotian shelf, and in Southern New England, although the current NEFSC autumn survey biomass index is less than 5% of the peak observed in 1963. The species was identified as an overfished species at the SAW 30 (NEFSC 2000). Skates are sensitive to overutilization generally because of their limited reproductive capacity. This is a characteristic of all of the larger species in the Northeast skate complex that are relatively slow-growing, long-lived, and late maturing.

The bulk of the measures being considered in Amendment 13 to the Multispecies FMP are designed to achieve specific fishing mortality reductions for cod, haddock and yellowtail flounder. The tools being considered include effort reduction in all components of the fleet through DAS and TAC restrictions as well as closed areas. Many of these measures are likely to reduce the bycatch of barndoor skate as well.

Therefore, pending the Council's successful achievement of these goals, barndoor skate should not be further depleted by management actions taken under the proposed Amendment 13 to the Multispecies FMP.

9.2.3 Essential Fish Habitat

The area affected by the proposed action has been identified as EFH for species managed under the NE Multispecies; Atlantic Sea Scallop; Atlantic Monkfish; Summer Flounder; Scup and Black Sea Bass; Squid, Atlantic Mackerel and Butterfish; Atlantic Surf Clam and Ocean Quahog; Atlantic Bluefish; Atlantic Billfish; and Atlantic Tuna, Swordfish and Shark Fishery Management Plans. In general, EFH for these species includes pelagic and demersal waters, saltmarsh creeks, seagrass beds, mudflats and open bay areas, as well as mud, sand, gravel and shell sediments over the continental shelf, and structured habitat containing sponges and other biogenic organisms (NMFS 2002). Specific text descriptions and accompanying maps detailing EFH by species and life stage are included in the Omnibus EFH Amendment.

9.2.4 Habitat Associations and Functions

From a biological perspective, habitats provide living things with the basic life requirements of nourishment and shelter. Habitats may also provide a broader range of benefits to the ecosystem. An illustration of the broader context is the way seagrasses physically stabilize the substrate and help recirculate oxygen and nutrients. In this general discussion, we will focus on the primary, direct value of habitats to federally managed species—feeding and shelter from predation.

The spatial and temporal variation of prey abundance influences the survivorship, recruitment, development, and spatial distribution of organisms at every trophic level. For example, phytoplankton abundance and distribution are a great influence on ichthyoplankton community structure and distribution. In addition, the migratory behavior of juvenile and adult fish is directly related to seasonal patterns of prey abundance and changes in environmental conditions, especially water temperature. Prey supply is particularly critical for the starvation-prone early life history stages of fish.

The availability of food for planktivores is highly influenced by oceanographic properties. The seasonal warming of surface waters in temperate latitudes produces vertical stratification of the water column, which isolates sunlit surface waters from deeper, nutrient-rich water, leading to reduced primary productivity. In certain areas, upwelling, induced by wind, storms, and tidal mixing, inject nutrients back into the photic zone, stimulating primary production. Changes in primary production from upwelling and other oceanographic processes affect the amount of organic matter available for other organisms higher up in the food chain, and thus influence their abundance and distribution. Some of the organic matter produced in the photic zone sinks to the bottom and provides food for benthic organisms. In this way, oceanographic properties can also influence the food availability for sessile benthic organisms. In shallower water, benthic macro and microalgae also contribute to primary production. Recent research on benthic primary productivity indicates that benthic microalgae may contribute more to primary production than has been originally estimated (Cahoon 1999).

Benthic organisms provide an important food source for many managed species. Populations of bottom-dwelling sand lance are important food sources for many piscivorous species, and benthic invertebrates are the main source of nutrition for many demersal fishes. Temporal and spatial variations in benthic community structure affect the distribution and abundance of bottom-feeding fish. Likewise, the abundance and species composition of benthic communities are affected by a number of environmental factors including temperature, sediment type, and the amount of organic matter.

A number of recent studies illustrate the research that has addressed habitat associations for demersal juvenile fish. In shallow, nearshore coastal and estuarine waters of the northeast region, effects of physical habitat factors and prey availability on the abundance and distribution of young-of-the-year flounder (various species) have been investigated in nearshore and estuarine habitats in Connecticut, New Jersey, and North Carolina (Phelan et al. 2001, Stoner et al. 2001, Manderson et al. 2000, Howell et al. 1999, Walsh et al. 1999, and Rountree and Able 1992). There are few comparable studies of more open, continental shelf environments. In the northeast U.S., Steves et al. (1989) identified depth, bottom temperature, and time of year as primary factors delineating settlement and nursery habitats for juvenile silver hake and yellowtail flounder in the mid-Atlantic Bight. Also, in a series of publications, Auster et al. (1991, 1995, 1997) correlated the spatial distributions of benthic juvenile fish (e.g. silver hake) with changes in microhabitat type on sand bottom at various open shelf locations in southern New England. In addition to providing food sources, another important functional value of benthic habitat is the shelter and refuge from predators provided by structure. Three dimensional structure is provided by physical features such as boulders, gravel and cobble, sand waves and ripples, and mounts, burrows and depressions created by organisms. Structure is also provided by emergent epifauna.

The importance of benthic habitat complexity was discussed by Auster (1998a) and Auster and Langton (1999) in the context of providing a conceptual model to visualize patterns in fishing gear impacts across a gradient of habitat types. Based on this model, habitat value increases with increased structural complexity, from the lowest value in flat sand and mud to the highest value in piled boulders. The importance of habitat complexity to federally managed species is a key issue in the Northeast region.

9.2.4.1 Biological Characteristics of Regional Systems

9.2.4.1.1 Gulf of Maine

The Gulf of Maine's geologic features, when coupled with the vertical variation in water properties, result in a great diversity of habitat types. The greatest number of invertebrates in this region are classified as mollusks, followed by annelids, crustaceans, echinoderms and other (Theroux and Wigley 1998). By weight, the order of taxa changes to echinoderms, mollusks, other, annelids and crustaceans. Watling (1998) used numerical classification techniques to separate benthic invertebrate samples into seven types of bottom assemblages. These assemblages are identified in Table 382 and their distribution is depicted in Figure 229. This classification system considers benthic assemblage, substrate type and water properties.

An in-depth review of GOM habitat types has been prepared by Brown (1993). Although still preliminary, this classification system is a promising approach. It builds on a number of other schemes, including Cowardin et al. (1979), and tailors them to Maine's marine and estuarine environments. A significant factor that is included in this review (but has been neglected in others) is a measure of "energy" in a habitat. Energy could be a reflection of wind, waves, or currents present. This is a particularly important consideration in a review of fishing gear impacts since it indicates the natural disturbance regime of a habitat. The amount and type of natural disturbance is in turn an indication of the habitat's resistance to and recoverability from disturbance by fishing gear. Although this work appears to be complete in its description of habitat types, unfortunately, the distribution of many of the habitats are unknown.

Demersal fish assemblages for the Gulf of Maine and Georges Bank were part of broad scale geographic investigations conducted by Mahon et al. (1998) and Gabriel (1992). Both these studies and a more limited study by Overholtz and Tyler (1985) found assemblages that were consistent over space and time in this region. In her analysis, Gabriel found that the most persistent feature over time in assemblage structure from Nova Scotia to Cape Hatteras was the boundary separating assemblages between the Gulf of Maine and Georges Bank, which occurred at approximately the 100 m isobath on northern Georges Bank.

Overholtz & Tyler (1985) identified five assemblages for this region (Table 383). The Gulf of Maine-deep assemblage included a number of species found in other assemblages, with the exception of American plaice and witch flounder, which was unique to this assemblage. Gabriel's approach did not allow species to co-occur in assemblages, and also classified these two species as unique to the deepwater Gulf of Maine-Georges Bank assemblage. Results of these two studies are compared in Table 383. Auster et al. (2001) went a step further, and related species clusters on Stellwagen Bank to reflectance values of different substrate types in an attempt to use fish distribution as a proxy for seafloor habitat distribution. They found significant reflectance associations for twelve of 20 species, including American plaice (fine substrate), and haddock (coarse substrate). Species clusters and associated substrate types are given in Table 384.

Benthic Assemblage	Benthic Community Description
1	Comprises all sandy offshore banks, most prominently Jeffreys Ledge, Fippennies Ledge, and Platts Bank; depth on top of banks about 70 m; substrate usually coarse sand with some gravel; fauna characteristically sand dwellers with an abundant interstitial component.
2	Comprises the rocky offshore ledges, such as Cashes Ledge, Sigsbee Ridge and Three Dory Ridge; substrate either rock ridge outcrop or very large boulders, often with a covering of very fine sediment; fauna predominantly sponges, tunicates, bryozoans, hydroids, and other hard bottom dwellers; overlying water usually cold Gulf of Maine Intermediate Water.
3	Probably extends all along the coast of the Gulf of Maine in water depths less than 60 m; bottom waters warm in summer and cold in winter; fauna rich and diverse, primarily polychaetes and crustaceans; probably consists of several (sub-) assemblages due to heterogeneity of substrate and water conditions near shore and at mouths of bays.
4	Extends over the soft bottom at depths of 60 to 140 m, well within the cold Gulf of Maine Intermediate Water; bottom sediments primarily fine muds; fauna dominated by polychaetes, shrimp, and cerianthid anemones.
5	A mixed assemblage comprising elements from the cold water fauna as well as a few deeper water species with broader temperature tolerances; overlying water often a mixture of Intermediate Water and Bottom Water, but generally colder than 7° C most of the year; fauna sparse, diversity low, dominated by a few polychaetes, with brittle stars, sea pens, shrimp, and cerianthid also present.
6	Comprises the fauna of the deep basins; bottom sediments generally very fine muds, but may have a gravel component in the offshore morainal regions; overlying water usually 7 to 8° C, with little variation; fauna shows some bathyal affinities but densities are not high, dominated by brittle stars and sea pens, and sporadically by a tube-making amphipod.
7	The true upper slope fauna that extends into the Northeast Channel; water temperatures are always above 8° and salinities are at least 35 ppt; sediments may be either fine muds or a mixture of mud and gravel.

Table 382 - Gulf of Maine benthic assemblages as identified by Watling (1998).

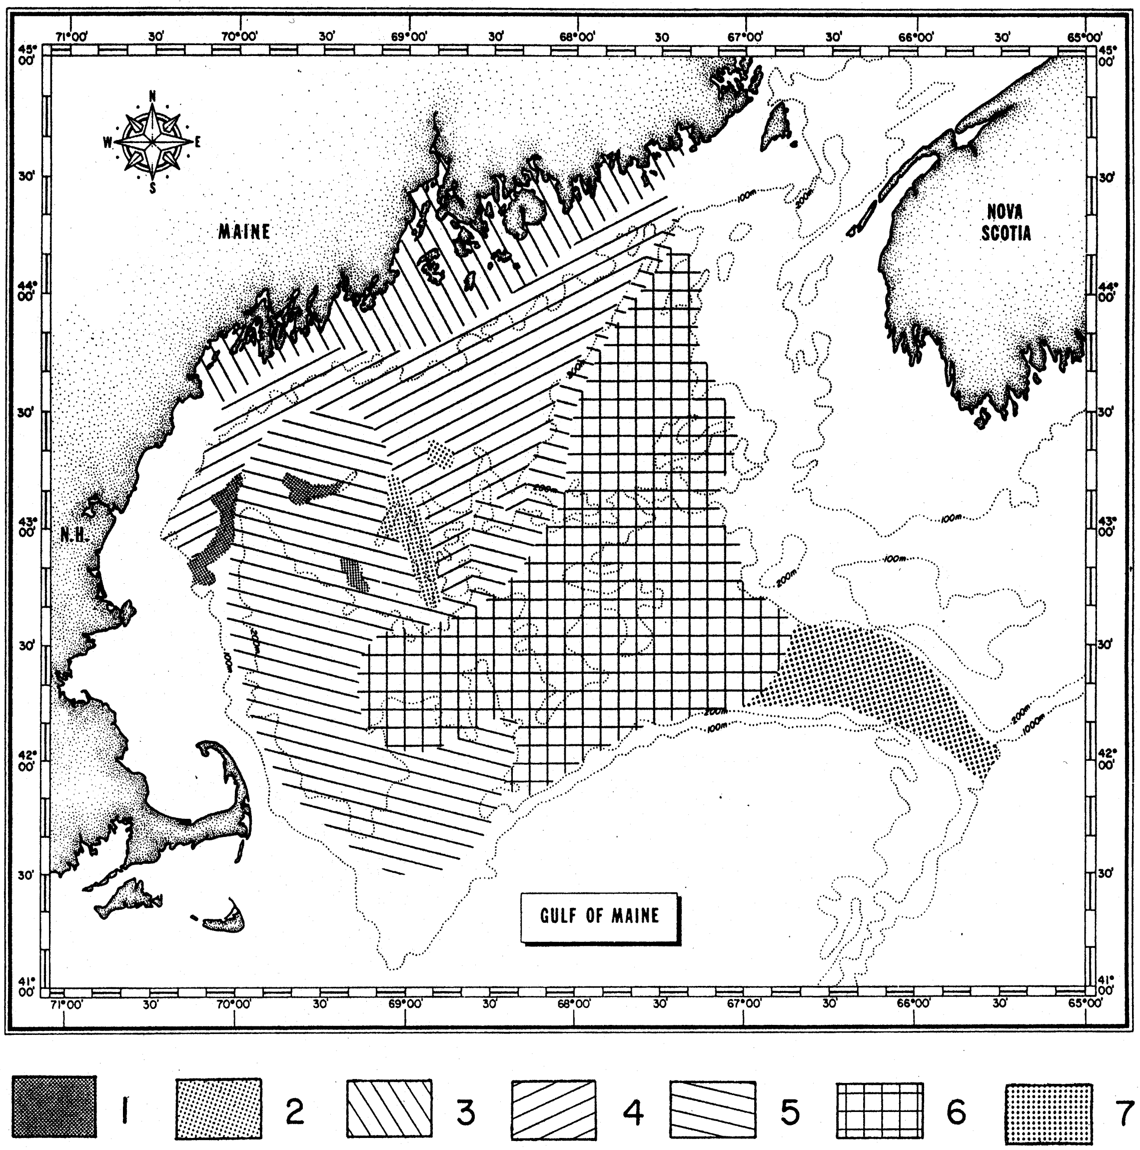

Figure 229 - Distribution of the seven major benthic assemblages in the Gulf of Maine as determined from both soft bottom quantitative sampling and qualitative hard bottom sampling.
The assemblages are characterized as follows: 1. Sandy offshore banks; 2. Rocky offshore ledges; 3. Shallow (<50 m) temperate bottoms with mixed substrate; 4. Boreal muddy bottom, overlain by Maine Intermediate Water, 50 – 160 m (approx.); 5. Cold deep water, species with broad tolerances, muddy bottom; 6. Deep basin warm water, muddy bottom; 7. Upper slope water, mixed sediment. Source: Watling 1998.

9.2.4.1.2 Georges Bank

The interaction of several environmental factors including availability and type of sediment, current speed and direction, and bottom topography have been found to combine to form seven sedimentary provinces on eastern Georges Bank (Valentine et al. 1993), which are outlined in Table 385 and depicted in Figure 230.

Theroux and Grosslein (1987) identified four macrobenthic invertebrate assemblages that corresponded with previous work in the geographic area. They noted that it is impossible to define distinct boundaries between assemblages because of the considerable intergrading that occurs between adjacent assemblages; however, the assemblages are distinguishable. Their assemblages are associated with those identified by Valentine et al. (1993) in Table 385.

The Western Basin assemblage (Theroux and Grosslein 1987) is found in the upper Great South Channel region at the northwestern corner of the bank, in comparatively deep water (150-200 m) with relatively slow currents and fine bottom sediments of silt, clay and muddy sand. Fauna are comprised mainly of small burrowing detritivores and deposit feeders, and carnivorous scavengers. Representative organisms include bivalves (*Thyasira flexuosa, Nucula tenuis, Musculus discors*), annelids (*Nephtys incisa, Paramphinome pulchella, Onuphis opalina, Sternaspis scutata*), the brittle star (*Ophiura sarsi*), the amphipod *Haploops tubicola*, and red crab (*Geryon quedens*). Valentine et al. 1993 did not identify a comparable assemblage; however, this assemblage is geographically located adjacent to Assemblage 5 as described by Watling (1998) (Table 382**,** Figure 229).

The Northeast Peak assemblage is found along the Northern Edge and Northeast Peak, which varies in depth and current strength and includes coarse sediments, mainly gravel and coarse sand with interspersed boulders, cobbles and pebbles. Fauna tend to be sessile (coelenterates, brachiopods, barnacles, and tubiferous annelids) or free-living (brittlestars, crustaceans and polychaetes), with a characteristic absence of burrowing forms. Representative organisms include amphipods (*Acanthonotozoma serratum, Tiron spiniferum*), the isopod *Rocinela americana*, the barnacle *Balanus hameri*, annelids (*Harmothoe imbricata, Eunice pennata, Nothria conchylega,* and *Glycera capitata*), sea scallops (*Placopecten magellanicus*), brittlestars (*Ophiacantha bidentata, Ophiopholis aculeata*), and soft corals (*Primnoa resedaeformis, Paragorgia arborea*).

The Central Georges assemblage occupies the greatest area, including the central and northern portions of the bank in depths less than 100 m. Medium grained shifting sands predominate this dynamic area of strong currents. Organisms tend to be small to moderately large in size with burrowing or motile habits. Sand dollars (*Echinarachnius parma*) are most characteristic of this assemblage. Other representative species include mysids (*Neomysis americana, Mysidopsis bigelowi*), the isopod *Chiridotea tuftsi*, the cumacean *Leptocuma minor*, the amphipod *Protohaustorius wigleyi*, annelids (*Sthenelais limicola, Goniadella gracilis, Scalibregma inflatum*), gastropods (*Lunatia heros*, *Nassarius trivittatus*), the starfish *Asterias vulgaris*, the shrimp *Crangon septemspinosa* and the crab *Cancer irroratus*.

The Southern Georges assemblage is found on the southern and southwestern flanks at depths from 80 m to 200 m, where fine grained sands and moderate currents predominate. Many southern species exist here at the northern limits of their range. Dominant fauna include amphipods, copepods, euphausiids and starfish genus *Astropecten*. Representative organisms include amphipods (*Ampelisca compressa, Erichthonius rubricornis, Synchelidium americanum*), the cumacean *Diastylis quadrispinosa*, annelids (*Aglaophamus circinata, Nephtys squamosa, Apistobranchus tullbergi*), crabs (*Euprognatha rastellifera, Catapagurus sharreri*) and the shrimp *Munida iris*.

Sedimentary Province	Depth (m)	Description	Benthic Assemblage
Northern Edge / Northeast Peak (1)	40-200	Dominated by gravel with portions of sand, common boulder areas, and tightly packed pebbles. Representative epifauna (bryozoa, hydrozoa, *anemones,*and *calcareous* worm tubes) are abundant in areas of boulders. *Strong tidal and storm currents.*	Northeast Peak
Northern Slope & Northeast Channel (2)	200-240	Variable sediment type (gravel, gravel-sand, and sand) scattered bedforms. This is a transition zone between the northern edge and southern slope. *Strong tidal and storm currents.*	Northeast Peak
North / Central Shelf (3)	60-120	Highly variable sediment type (ranging from gravel to sand) with rippled sand, large bedforms, and patchy gravel lag deposits. *Minimal epifauna on gravel due to sand movement. Representative epifauna in sand areas include amphipods, sand dollars, and burrowing anemones.*	Central Georges
Central & Southwestern Shelf - *shoal ridges* (4)	10-80	Dominated by sand (fine and medium grain) with large sand ridges, dunes, waves, and ripples. Small bedforms in southern part. *Minimal epifauna on gravel due to sand movement. Representative epifauna in sand areas include amphipods, sand dollars, and burrowing anemones.*	Central Georges
Central & Southwestern Shelf - *shoal troughs* (5)	40-60	Gravel (including gravel lag) and gravel-sand between large sand ridges. Patch large bedforms. Strong currents. (Few samples – submersible observation noted presence of gravel lag, rippled gravel-sand, and large bedforms.) *Minimal epifauna on gravel due to sand movement. Representative epifauna in sand areas include amphipods, sand dollars, and burrowing anemones.*	Central Georges
Southeastern Shelf (6)	80-200	Rippled gravel-sand (medium and fine-grained sand) with patchy large bedforms and gravel lag. Weaker currents; *ripples are formed by intermittent storm currents. Representative epifauna include sponges attached to shell fragments and amphipods.*	Southern Georges
Southeastern Slope (7)	400-2000	Dominated by silt and clay with portions of sand (medium and fine) with rippled sand on shallow slope and smooth silt-sand deeper.	none

Table 385 - Sedimentary provinces of Georges Bank, as defined by Valentine *et al.* (1993) and Valentine and Lough (1991) with additional comments by Valentine (personal communication) and Benthic Assemblages assigned from Theroux and Grosslein (1987).

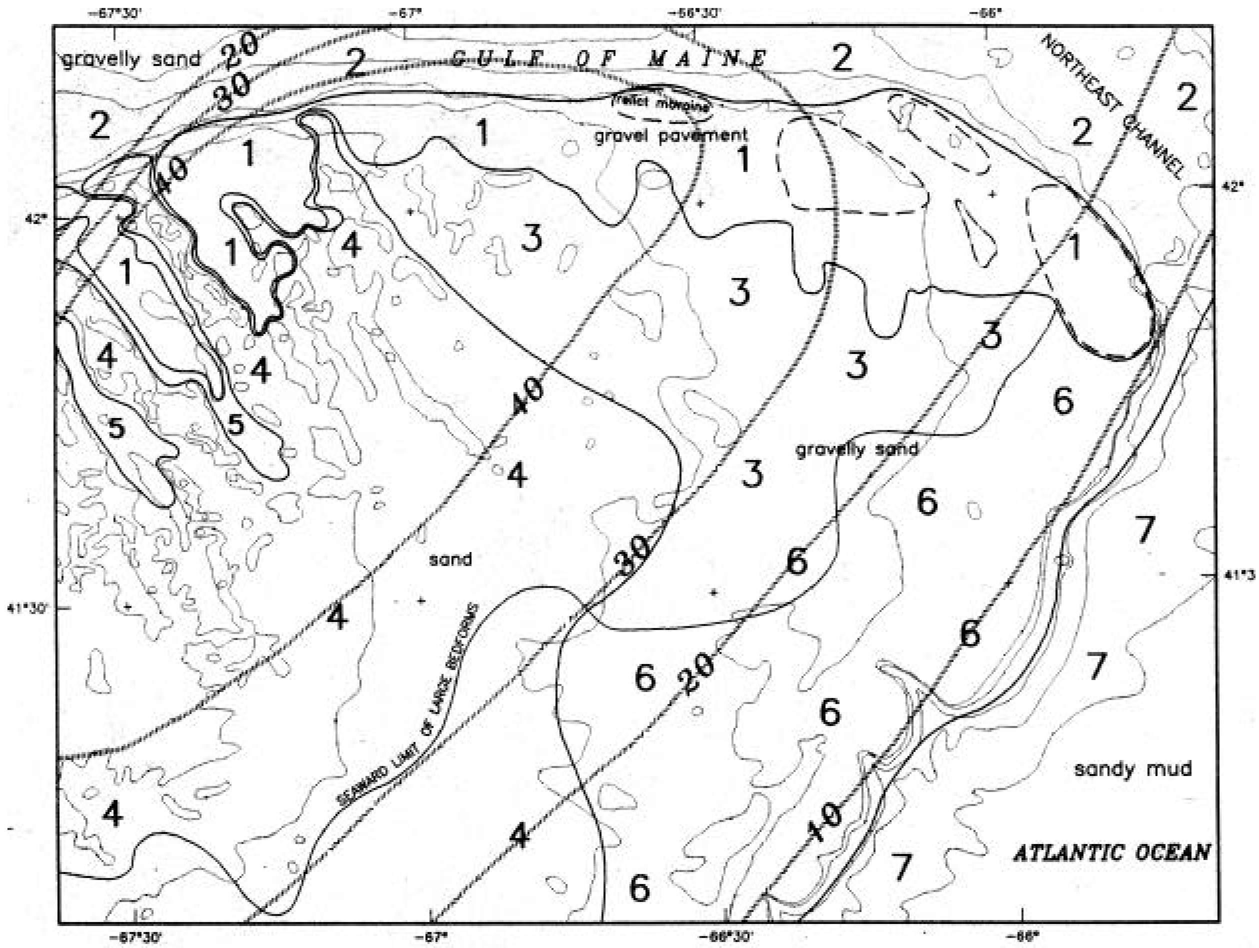

Figure 230 - Sedimentary provinces of eastern Georges Bank based on criteria of sea floor morphology, texture, sediment movement and bedforms, and mean tidal bottom current speed (cm/sec).

Relict moraines (bouldery sea floor) are enclosed by dashed lines. Source: Valentine and Lough (1991).

Along with high levels of primary productivity, Georges Bank has been historically characterized by high levels of fish production. Several studies have attempted to identify demersal fish assemblages over large spatial scales. Overholtz and Tyler (1985) found five depth-related groundfish assemblages for Georges Bank and the Gulf of Maine that were persistent temporally and spatially. Depth and salinity were identified as major physical influences explaining assemblage structure. Gabriel identified six assemblages, which are compared with the results of Overholtz & Tyler (1984) in Table 383. Mahon et al. (1998) found similar results.

A few recent studies (Garrison 2000, Garrison and Link 2000, Garrison 2001) demonstrate the persistence of spatio-temporal overlap among numerically dominant, commercially valuable and /or ecologically important species. The studies by Garrison and associates utilized an index of spatial overlap based on the NOAA spring and fall surveys. He found that among the community of fish species on Georges Bank, only a very few species have high spatial overlaps with other species. The most notable example is silver hake (whiting), which had a very high overlap with most other species, suggestive of a broad distribution. Trends in spatial overlap over time generally reflect changes in species abundance. During the 1960s, haddock and yellowtail flounder were both widely distributed and had high spatial overlaps with other species. As abundance of these species declined through the 1970s into the 1990s, their spatial range contracted and their overlaps with other species subsequently declined. In contrast to this, species whose abundance has increased through time show an expansion of ranges and increased spatial overlap with other species. Interestingly and to confirm other studies of fish assemblages, the major species assemblages have been generally consistent across time given the changes in relative abundance.

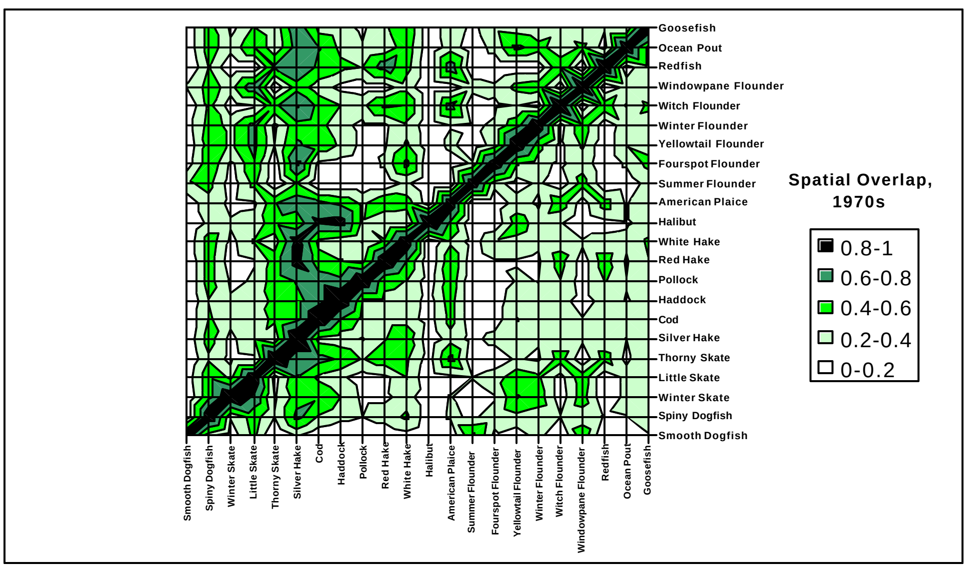

Figure 231 - Spatial overlap of primary finfish species on Georges Bank, 1970s (as modified from Garrison and Link 2000)

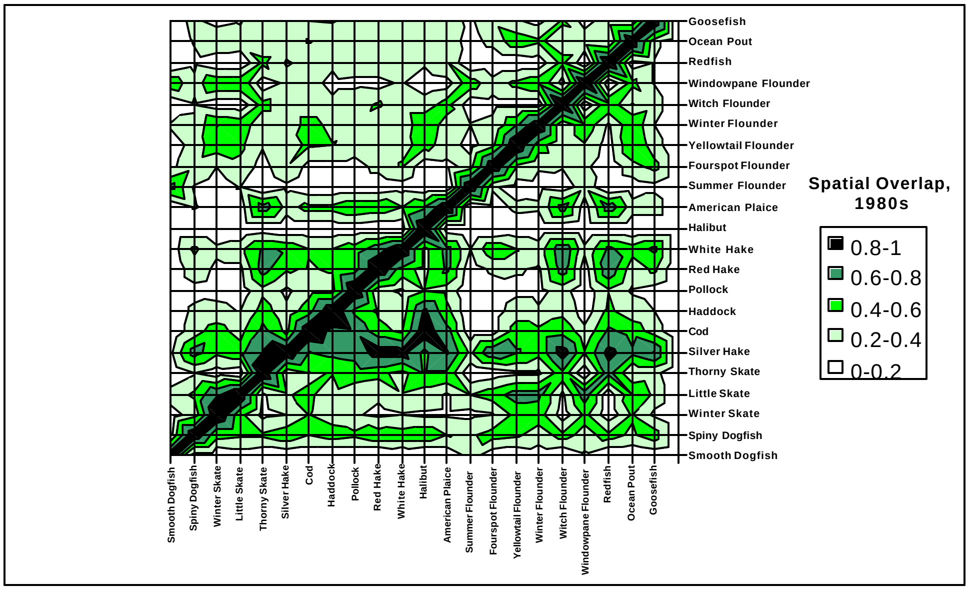

Figure 232 - Spatial overlap of primary finfish species on Georges Bank, 1980s (as modified from Garrison and Link 2000)

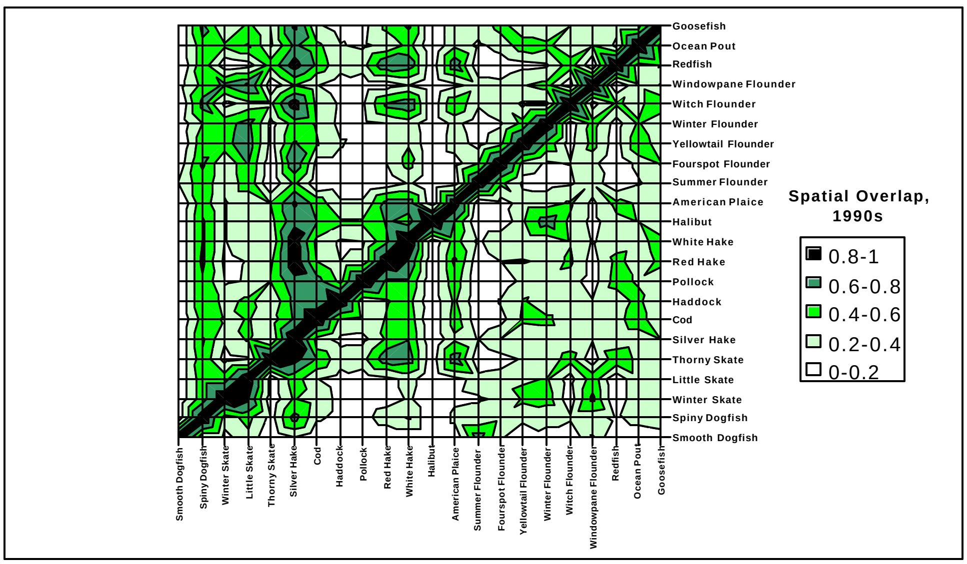

Figure 233 - Spatial overlap of primary finfish species on Georges Bank, 1990s (as modified from Garrison and Link 2000)

Seasonal trends in spatial overlap are also apparent. Spiny dogfish, for example, has a far stronger association and a far broader range of species' associations in the winter than it does in the summer. Similarly, winter skate is a more prevalent co-correspondent in winter than other times of the year. This metric, like the spatial overlap trend over time (above), is sensitive to abundance as evidenced by the lack of spatial overlap between Atlantic halibut and any other species.

9.2.4.1.3 Mid-Atlantic Bight

Three broad faunal zones related to water depth and sediment type were identified for the Mid-Atlantic by Pratt (1973). The "sand fauna" zone was defined for sandy sediments (1% or less silt) which are at least occasionally disturbed by waves, from shore out to 50 m. The "silty sand fauna" zone occurred immediately offshore from the sand fauna zone, in stable sands containing at least a few percent silt and slightly more (2%) organic material. Silts and clays become predominant at the shelf break and line the Hudson Shelf Valley, and support the "silt-clay fauna."

Building on Pratt's work, the Mid-Atlantic shelf was further divided by Boesch (1979) into seven bathymetric/morphologic subdivisions based on faunal assemblages (Table 386, Figure 238). Sediments in the region studied (Hudson Shelf Valley south to Chesapeake Bay) were dominated by sand with little finer material. Ridges and swales are important morphological features in this area. Sediments are coarser on the ridges, and the swales have greater benthic macrofaunal density, species richness and biomass. Faunal species composition differed between these features, and Boesch incorporated this variation in his subdivisions (Table 386). Much overlap of species distributions was found between depth zones, so the faunal assemblages represented more of a continuum than distinct zones.

Habitat Type (after Boesch 1979)	**Description**		
	Depth (m)	**Characterization (Pratt faunal zone)**	**Characteristic Benthic Macrofauna**
Inner shelf	0-30	characterized by coarse sands with finer sands off MD and VA (sand zone)	Polychaetes: *Polygordius, Goniadella, Spiophanes*
Central shelf	30-50	(sand zone)	Polychaetes: *Spiophanes, Goniadella* Amphipod: *Pseudunciola*
Central and inner shelf swales	0-50	occurs in swales between sand ridges (sand zone)	*Polychaetes:* Spiophanes, Lumbrineris, Polygordius
Outer shelf	50-100	(silty sand zone)	Amphipods: *Ampelisca vadorum, Erichthonius* Polychaetes: *Spiophanes*
Outer shelf swales	50-100	occurs in swales between sand ridges (silty sand zone)	Amphipods: *Ampelisca agassizi, Unciola, Erichthonius*
Shelf break	100-200	(silt-clay zone)	not given
Continental slope	>200	(none)	not given

Table 386 - Mid-Atlantic habitat types as described by Pratt (1973) and Boesch (1979) with characteristic macrofauna as identified in Boesch 1979.

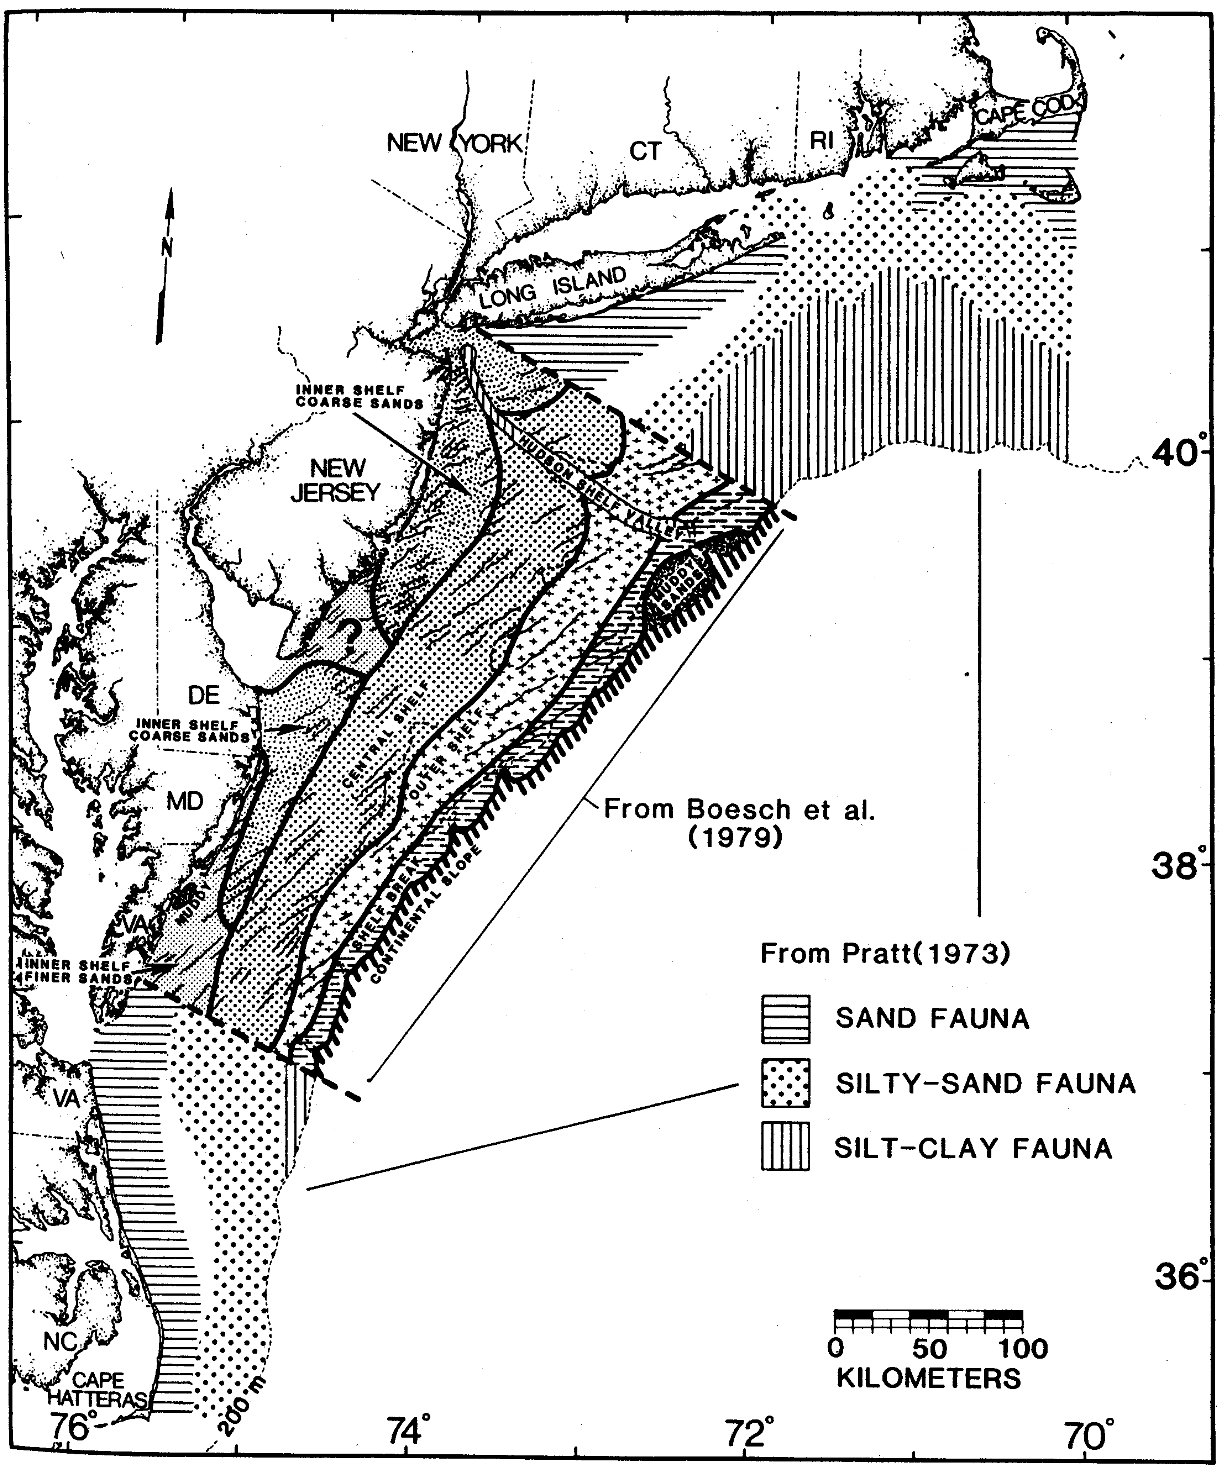

Figure 238 - Schematic representation of major macrofaunal zones on the Mid-Atlantic shelf.
Approximate location of ridge fields indicated. Source: Reid and Steimle (1988).

Wigley and Theroux (1981) found a general trend in declining macrobenthic invertebrate density from coastal areas offshore to the slope, and on the shelf from southern New England south to Virginia/North Carolina. There were no detectable trends in density from north to south on the slope. Number of individuals was greatest in gravel sediments, and declined in sand-gravel, sand-shell, sand, shell, silty sand, silt and finally clay. However, biomass of benthic macrofauna was greatest in shell habitat, followed by silty sand, gravel, sand-gravel, sand, sand-shell, silt and clay.

Demersal fish assemblages were described at a broad geographic scale for the continental shelf and slope from Cape Chidley, Labrador to Cape Hatteras, North Carolina (Mahon *et al.* 1998) and from Nova Scotia to Cape Hatteras (Gabriel 1992). Factors influencing species distribution included latitude and depth.

Results of these studies were similar to an earlier study confined to the Mid-Atlantic Bight continental shelf (Colvocoresses and Musick 1983). In this study, there were clear variations in species abundances, yet they demonstrated consistent patterns of community composition and distribution among demersal fishes of the Mid-Atlantic shelf. This is especially true for five strongly recurring species associations that varied slightly by season (Table 387). The boundaries between fish assemblages generally followed isotherms and isobaths. The assemblages were largely similar between the spring and fall collections, with the most notable change being a northward and shoreward shift in the temperate group in the spring.

Season	Species Assemblage				
	Boreal	Warm temperate	Inner shelf	Outer shelf	Slope
Spring	Atlantic cod little skate sea raven monkfish winter flounder longhorn sculpin ocean pout whiting red hake white hake spiny dogfish	black sea bass summer flounder butterfish scup spotted hake northern searobin	windowpane	fourspot flounder	shortnose greeneye offshore hake blackbelly rosefish white hake
Fall	white hake whiting red hake monkfish longhorn sculpin winter flounder yellowtail flounder witch flounder little skate spiny dogfish	black sea bass summer flounder butterfish scup spotted hake northern searobin smooth dogfish	windowpane	fourspot flounder fawn cusk eel gulf stream flounder	shortnose greeneye offshore hake blackbelly rosefish white hake witch flounder

Table 387 - Major Recurrent Demersal Finfish Assemblages of the Mid-Atlantic Bight During Spring and Fall as Determined by Colvocoresses and Musik (1983).

Steimle and Zetlin (2000) described representative finfish species and epibenthic/epibiotic and motile epibenthic invertebrates associated with mid-Atlantic reef habitats (Table 388). Most of these reefs are human-made structures.

Location (Type)	**Representative Flora & Fauna**		
	Epibenthic/Epibiotic	**Motile Epibenthic Invertebrates**	**Fish**
Estuarine (Oyster reefs, blue mussel beds,other hard surfaces, semi-hard clay and Spartina peat reefs)	Oyster, barnacles, ribbed mussel, blue mussel, algae, sponges, tube worms, anemones, hydroids, bryozoans, slipper shell, jingle shell, northern stone coral, sea whips, tunicates, caprellid amphipods, wood borers	Xanthid crabs, blue crab, rock crabs, spider crab, juvenile American lobsters, sea stars	Gobies, spot, striped bass, black sea bass, white perch, toadfish, scup, drum, croaker, spot, sheepshead porgy, pinfish, juvenile and adult tautog, pinfish, northern puffer, cunner, sculpins, juvenile and adult Atlantic cod, rock gunnel, conger eel, American eel, red hake, ocean pout, white hake, juvenile pollock
Coastal (exposed rock/soft marl, harder rock, wrecks & artificial reefs, kelp, other materials)	Boring mollusks (piddocks), red algae, sponges, anemones, hydroids, northern stone coral, soft coral, sea whips, barnacles, blue mussel, horse mussel, bryozoans, skeleton and tubiculous amphipods, polychaetes, jingle shell, sea stars	American lobster, Jonah crab, rock crabs, spider crab, sea stars, urchins, squid egg clusters	Black sea bass, pinfish, scup, cunner, red hake, gray triggerfish, black brouper, smooth dogfish, sumemr flounder, scad, bluefish amberjack, Atlantic cod, tautog, ocean pout, conger eel, sea raven, rock gunnel, radiated shanny
Shelf (rocks & boulders, wrecks & artificial reefs, other solid substrates)	Boring mollusks (piddocks) red algae, sponges, anemones, hydroids, stone coral, soft coral, sea whips, barnacles, blue mussels, horse mussels, bryozoans, amphipods, polychaetes	American lobster, Jonah crabs, rock crabs, spider crabs, sea stars, urchins, squid egg clusters (with addition of some deepwater taxa at shelf edge)	Black sea bass, scup, tautog, cunner, gag, sheepshead porgy, round herring, sardines, amberjack, spadefish, gray triggerfish, mackerels, small tunas, spottail pinfish, tautog, Atlantic cod, ocean pout, red hake, conger eel, cunner, sea raven, rock gunnel, pollock, white hake
Outer shelf (reefs and clay burrows including “pueblo village community”)			Tilefish, white hake, conger eel

Table 388 - Mid-Atlantic Reef Types, Location, and Representative Flora and Fauna, as Described in Steimle and Zetlin (2000)

9.2.4.1.4 Continental Slope

Polychaetes represent the most important slope faunal group in terms of numbers of individuals and species (Wiebe et al. 1987). Ophiuroids are considered to be among the most abundant slope organisms, but this group is comprised of relatively few species. The taxonomic group with the highest species diversity includes the peracarid crustaceans represented by Amphipoda, Cumacea, Isopoda, and the Tanaidacea. Some species of the slope are widely distributed, while others appear to be restricted to particular ocean basins. The ophiuroids and bivalves appear to have the broadest distributions, while the peracarid crustaceans appear to be highly restricted because they brood their young, and lack a planktonic stage of development. In general, gastropods do not appear to be very abundant, however, past studies are inconclusive since they have not collected enough individuals for large-scale community and population studies.

In general, slope-inhabiting benthic organisms are strongly zoned by depth and/or water temperature, although these patterns are modified by the presence of topography, including canyons, channels, and current zonations (Hecker 1990). Moreover, at depths of less than 800 meters, the fauna is extremely variable and the relationships between faunal distribution and substrate, depth, and geography are less obvious (Wiebe et al. 1987). Fauna occupying hard-surface sediments are not as dense as in comparable shallow-water habitats (Wiebe et al. 1987), but there is an increase in species diversity from the shelf to the intermediate depths of the slope. Diversity then declines again in the deeper waters of the continental rise and plain. Hecker (1990) identified four megafaunal zones on the slope of Georges Bank and southern New England (Table 389).

Zone	Approximate Depth (m)	Gradient	Current	Fauna
Upper Slope	300-700	Low	strong	Dense filter feeders; Scleratinians (*Dasmosmilia lymani, Flabellum alabastrum*), quill worm (*Hyalinoecia*)
Upper Middle Slope	500-1300	High	moderate	Sparse scavengers; red crab (*Geryon quinqueidens*), long-nosed eel (*Synaphobranchus*), common grenadier (*Nezumia*). Alcyonarians (*Acanella arbuscula*, *Eunephthya florida*) in areas of hard substrate
Lower Middle Slope/Transition	1200-1700	High	moderate	Sparse suspension feeders; cerianthids, sea pen (*Distichoptilum gracile*)
Lower Slope	>1600	Low	strong	Dense suspension & deposit feeders; ophiurid (*Ophiomusium lymani*), cerianthid, sea pen

Table 389 - Faunal zones of the continental slope of Georges Bank and southern New England (from Hecker 1990)

One group of organisms of interest because of the additional structure they can provide for habitat and their potential long life span are the Alcyonarian soft corals. Soft corals can be bush or treelike in shape; species found in this form attach to hard substrates such as rock outcrops or gravel. These species can range in size from a few millimeters to several meters, and the trunk diameter of large specimens can exceed 10 cm. Other Alcyonarians found in this region include sea pens and sea pansies (Order Pennatulacea), which are found in a wider range of substrate types. In their survey of northeastern U.S. shelf macrobenthic invertebrates, Theroux and Wigley (1998) found Alcyonarians (including soft corals *Alcyonium sp., Acanella sp., Paragorgia arborea, Primnoa reseda* and sea pens) in limited numbers in waters deeper than 50 m, and mostly at depths from 200-500 m. Alcyonarians were present in each of the geographic areas identified in the study (Nova Scotia, Gulf of Maine, Southern New England Shelf, Georges Slope, Southern New England Slope) except Georges Bank. However, *Paragorgia* and *Primnoa* have been reported in the Northeast Peak region of Georges Bank (Theroux and Grosslein 1987). Alcyonarians were most abundant by weight in the Gulf of Maine, and by number on the Southern New England Slope (Theroux and Wigley 1998). In this study, Alcyonarians other than sea pens were collected only from gravel and rocky outcrops. Theroux and Wigley (1998) also found stony corals (*Astrangia danae* and *Flabellum sp*.) in the northeast region, but they were uncommon. In similar work on the mid-Atlantic shelf, the only Alcyonarians encountered were sea pens (Wigley and Theroux 1981). The stony coral *Astrangia danae*, was also found, but its distribution and abundance was not discussed, and is assumed to be minimal.

As opposed to most slope environments, canyons may develop a lush epifauna. Hecker et al. (1983) found faunal differences between the canyons and slope environments. Hecker and Blechschmidt (1979) suggested that faunal differences were due at least in part to increased environmental heterogeneity in the canyons, including greater substrate variability and nutrient enrichment. Hecker et al. (1983) found highly patchy faunal assemblages in the canyons, and also found additional faunal groups located in the canyons, particularly on hard substrates, that do not appear to occur in other slope environments. Canyons are also thought to serve as nursery areas for a number of species (Hecker 2001; Cooper et al. 1987). The canyon habitats in Table 390 were classified by Cooper et al. (1987).

Most finfish identified as slope inhabitants on a broad spatial scale (Gabriel 1992, Overholtz and Tyler 1985, and Colvocoresses and Musik 1983) (Table 383) are associated with canyon features as well (Cooper et al. 1987). Finfish identified by broad studies that were not included in Cooper et al. (1987) include offshore hake, fawn cusk-eel, longfin hake, witch flounder and armored searobin. Canyon species (Cooper et al. 1987) that were not discussed in the broad scale studies include squirrel hake, conger eel and tilefish. Cusk and ocean pout were identified by Cooper et al. (1987) as canyon species, but classified in other habitats by the broad scale studies.

Habitat Type	Geologic Description	Canyon Locations	Most Commonly Observed Fauna
I	Sand or semi-consolidated silt substrate (claylike consistency) with less than 5% overlay of gravel. Relatively featureless except for conical sediment mounds.	Walls & axis	Cerianthid, pandalid shrimp, white colonial anemone, Jonah crab, starfishes, portunid crab, greeneye, brittle stars, mosaic worm, red hake, four spot flounder, shell-less hermit crab, silver hake, gulf stream flounder
II	Sand or semi-consolidated silt substrate (claylike consistency) with more than 5% overlay of gravel. Relatively featureless.	Walls	Cerianthid, galatheid crab, squirrel hake, white colonial anemone, Jonah crab, silver hake, starfishes, ocean pout, brittle stars, shell-less hermit crab, greeneye
III	Sand or semi-consolidated silt (claylike consistency) overlain by siltstone outcrops and talus up to boulder size. Featured bottom with erosion by animals and scouring.	Walls	White colonial anemone, pandalid shrimp, cleaner shrimp, rock anemone, white hake, starfishes, ocean pout, conger eel, brittle star, Jonah crab, lobster, black-bellied rose fish, galatheid crab, mosaic worm, tilefish
IV	Consolidated silt substrate, heavily burrowed/excavated. Slope generally more than 5º and less than 50º Termed "pueblo village" habitat.	Walls	Starfishes, black-bellied rosefish, Jonah crab, lobster, white hake, cusk, ocean pout, cleaner shrimp, conger eel, tilefish, galatheid crab, shell-less hermit crab
V	Sand dune substrate.	Axis	Starfishes, white hake, Jonah crab, and monkfish

Table 390 - Habitat Types for the Canyons of Georges Bank Described by Geologic Attributes and Characteristic Fauna (from Cooper *et al.* 1987).
Faunal characterization is for depths < 230 m only

9.2.4.2 Assemblages of Northeast Shelf Finfish Species Based on Feeding Habits

A guild is defined by Root (1967) as 'a group of species that exploit the same class of environmental resources in a similar way' and explicitly focuses on classifying species based upon their functional role in a community without regard to taxonomy. The guild is used to simplify the structure and dynamics of complex ecosystems regardless of the mechanism generating resource partitioning. Guild members play similar functional roles within ecosystems (Garrison and Link 2000).

Cluster analysis modified from Garrison and Link (2000) found 14 groups of finfish in the Northeast region with significant dietary similarities. These 14 guilds were broadly categorized into six trophic groups, emphasizing similarities in diet at very broad taxonomic levels. Within these groups, the trophic guilds reflect utilization of specific prey types. For example, Guild 6b (Figure 239) consumed primarily engraulids in contrast to other guilds in the piscivore group.

The dietary guilds in the Northeast US shelf fish community reflect similarity in the utilization of specific prey categories. Within guilds, 10 to 15 prey taxa generally accounted for greater than 70% of predator diets and usually less than five prey accounted for greater than 50% of the diet. A relatively small set of prey taxa distinguishes the observed dietary guild structure (2000).

The general guild structure and levels of dietary overlap in this system are consistent across both temporal and spatial scales. Complimentary analyses to the current study within the Georges Bank region identified similar trophic guilds, similar patterns of size-based shifts in diets, and general stability in the trophic guild structure over the last three decades (Garrison 2000). Despite the notable changes in species composition in the Northeast shelf fish community, the patterns of trophic resource use and guild structure are remarkably consistent (2000).

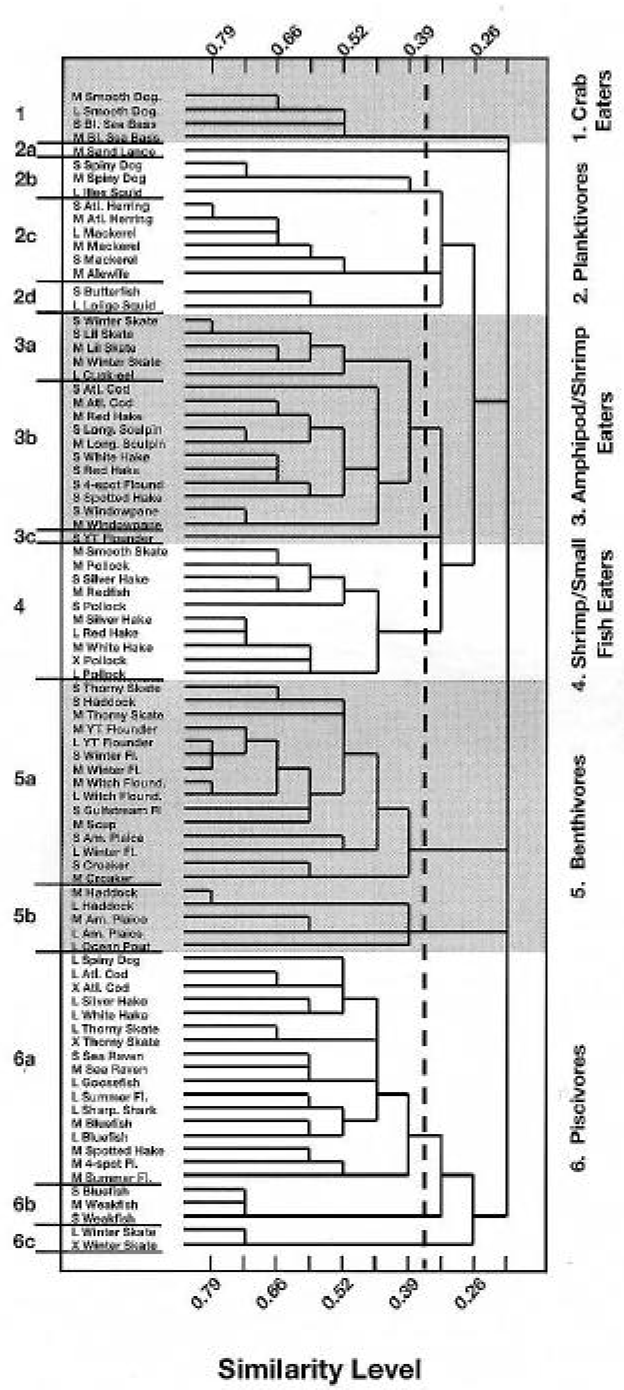

Figure 239 - Dietary guild structure of Northeast finfish species

9.3 Habitat Considerations

9.3.1 Essential Fish Habitat Gear Effect Evaluation and Adverse Impacts Determination

9.3.1.1 Structure of the EFH Adverse Impacts Determination

Section 9.3.1.2 describes commercial fishing gears used in the Northeast region of the U.S. and the geographic distribution and use of the principal bottom-tending gears in three broadly-defined habitat types. It also evaluates the effects of bottom trawls and dredges on benthic marine habitats in the region. Most of this information is derived from the NMFS, NEFMC and MAFMC-sponsored Gear Effects Workshop that evaluated the effects of fishing gears used in the Northeast region on mud, sand, and gravel habitats (NREFHSC 2002) and from an extensive review of relevant gear effects studies (Stevenson et al. 2003). Additional sources of information include work done by the NEFMC Habitat Technical Team and NEFMC and NMFS staff, and a National Research Council report on the Effects of Trawling and Dredging on Seafloor Habitat (NRC 2002). The information in this section serves as the basis for evaluating which gear types, if any, are most likely to have an adverse impact on essential fish habitat for federally-managed species in the NE region.

Section 9.3.1.3 evaluates the vulnerability of all 37 federally-managed species' to gear types found to have potential adverse impacts on EFH. Vulnerability was evaluated according to four broad categories: none (0); low (L); moderate (M); and high (H), based upon a matrix analysis of habitat function, habitat sensitivity and gear use. Results are summarized by species and life stage.

Section 9.3.1.8 summarizes the results and findings of this section, identifying the potential adverse impacts of the three principal mobile, bottom-tending gears on three principal bottom types in the region. These results serve as the basis for analyzing proposed alternatives to minimize the adverse impacts of these gears on EFH.

Sections 9.3.1.9 and 9.3.1.10 addresses non M-S Act fishing activities, and non-fishing related activities, that may adversely affect essential fish habitat.

9.3.1.2 Gear Effects Evaluation

9.3.1.2.1 Overview

Pursuant to the EFH regulations (50 CFR 610.815(a)(2)), FMPs must include an evaluation of the potential adverse effects of fishing on EFH, including effects of each fishing activity regulated under federal FMPs. The evaluation should consider the effects of each fishing activity on each type of habitat found within EFH. FMPs must describe each fishing activity, review and discuss all available and relevant information (such as information regarding the intensity, extent, and frequency of any adverse effect on EFH; the type of habitat within EFH that may be affected adversely; and the habitat functions that may be disturbed), and provide conclusions as to whether and how each fishing activity adversely affects EFH. The evaluation should also consider the cumulative effects of multiple fishing activities on EFH. In completing this evaluation, Councils should use the best scientific information available, as well as other appropriate information sources. Councils should consider different types of information according to their scientific rigor.

Magnuson-Stevens Act / EFH Provisions detailed in the Final Rule mandates that each FMP must: Contain an evaluation of the potential adverse effects of fishing on EFH designated under the FMP, including effects of each fishing activity regulated under the FMP or other Federal FMPs.

Consider the effects of each fishing activity on each type of habitat found within EFH.
Describe each fishing activity, review and discuss all available relevant information, and provide conclusions regarding whether and how each fishing activity adversely affects EFH.

This section, considered the Gear Effects Evaluation for the Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13, satisfies these requirements. The SFA requires the NEFMC to minimize, to the extent practicable, the adverse impacts of fishing on the EFH associated with any federally regulated fishing activities in the Northeast region. To do this, this amendment must evaluate the effects of all fishing gears used in the region on groundfish EFH, following the guidelines indicated above. NEPA requires that each management alternative, either for improving yield or minimizing effects of fishing on groundfish EFH, must be analyzed to evaluate the environmental consequences on other fishery resources and their habitats and benthic communities.

Since the implementation of the Council's Omnibus EFH Amendment of 1998 (NEFMC 1998), NMFS, NEFMC and MAFMC conducted a Gear Effects Workshop that evaluated the effects of fishing gears used in the Northeast region on mud, sand, and gravel habitats (NEREFHSC 2002). Additional sources of information include work done by the NEFMC Habitat Technical Team, and a National Research Council report on the Effects of Trawling and Dredging on Seafloor Habitat (NRC 2002). Additional information is included in this document.

9.3.1.2.2 Gear Descriptions

Updated gear descriptions are included for the following general gear categories: bottom tending mobile gear, bottom tending static gear, pelagic gear, and other gears. The Northeast region falls within the jurisdiction of the NEFMC and MAFMC as well as the individual states from Maine to North Carolina which are represented by the Atlantic States Marine Fisheries Commission (ASMFC). These jurisdictions are responsible for the management of many different fisheries extending from the upper reaches of the rivers and estuaries out to 200 miles offshore at the limit of the Exclusive Economic Zone (EEZ).

Sixty categories of fishing gear were identified as having been associated with landings of federal or state managed species based on a review of the National Marine Fisheries Service commercial fisheries landings data for 1999 and an ASMFC report on gear impacts to submerged aquatic vegetation (Stephan et al. 2000). Fishing gears considered in this report are those used to land any amount of any species managed by either the NEFMC or MAFMC (Table 391) as well as gears that contributed 1% or more of any individual state's total landings for all species (Table 392). Although certain gear types are not managed under the auspices of the MSA, this methodology recognizes that certain gear utilized in state waters may have adverse impacts to EFH that is designated in nearshore, estuarine and riverine areas. Table 393 provides the list of all 60 gears considered and indicates whether the gear is utilized in estuaries, coastal waters (0-3 miles), or offshore waters (3-200 miles). Since the seabed is the location of the habitat types most susceptible to gear disturbances, Table 393 also indicates whether the gear contacts the bottom and if the use of the gear is regulated under a federal FMP. This report considers gear to be regulated under a federal FMP if it is typically utilized to harvest fish under a federal vessel or operators permit. Table 394 indicates gear used in state-managed fisheries that contact the bottom.

9.3.1.2.2.1 Bottom Tending Mobile Gear

9.3.1.2.2.1.1 Otter Trawls

Trawls are classified by their function, bag construction, or method of maintaining the mouth opening. Function may be defined by the part of the water column where the trawl operates (e.g., bottom) or by the species that it targets (Hayes 1983). There is a wide range of otter trawl types used in the Northeast as a result of the diversity of fisheries prosecuted and bottom types encountered in the region (NREFHSC 2002). The specific gear design used is often a result of the target species (whether they are found on or off the bottom) as well as the composition of the bottom (smooth versus rough and soft versus hard). There are two three components of the otter trawl that come in contact with the sea bottom: the doors, the ground cables and bridles which attach the doors to the wings of the net, and the sweep (or foot-rope) which runs along the bottom of the net mouth. Bottom trawls are towed at a variety of speeds, but average about 5.5 km/hr (3 knots or nmi/hr).

9.3.1.2.2.1.1.1 Doors

The traditional otter board is a flat, rectangular wood structure with steel fittings and a steel "shoe" along the bottom that prevents the bottom of the door from damage and wear as it drags over the bottom. Other types include the V-type (steel), polyvalent (steel), oval (wood), and slotted spherical otter board (steel) (Sainsbury 1996). It is the spreading action of the doors resulting from the angle at which they are mounted that creates the hydrodynamic forces needed to push them apart. These forces also push them down towards the sea floor. On fine-grained sediments, the doors also function to create a silt cloud that aids in herding fish into the mouth of the net (Carr and Milliken 1998). In shallow waters, light-weight doors are typically used to ensure that the doors and the net spread fully. In these cases, light foam-filled doors can be used (Sainsbury 1996). Vessels fishing large nets in deeper water require very large spreading forces from the doors. In these cases, a 15 m^2 (49 ft^2) V-door weighing 640 kg (1480 lbs) can provide 9 metric tons of spreading force (Sainsbury 1996).

9.3.1.2.2.1.1.2 Ground Cables and Bridles

Steel cables are used to attach the doors to the wings of the net. The ground cables run along the bottom from each door to two cables (the "bridle") that diverge to attach to the top and bottom of the net wing. The bottom portion of the bridle also contacts the bottom. In New England, fixed rubber discs ("cookies") or rollers are attached to the ground cables and lower bridle. In general, bridles vary in length from 9 m to 73 m (30 - 200 ft) while ground cables can be from 0 to 73 m (200 ft) depending upon bottom conditions and towing speed (Sainsbury 1996). The length of these cables can therefore increase the area swept by the trawl by as much as three fold.

9.3.1.2.2.1.1.3 Sweeps

On smooth bottoms, the sweep may be a steel cable weighted with chain, or may be merely rope wrapped with wire. On rougher bottoms, rubber discs (“cookies”) or rollers are attached to the sweep to assist the trawl's passage over the bottom (Sainsbury 1996). There are two main types of sweep used in smooth bottom in New England (Mirarchi 1998). In the traditional chain sweep, loops of chain are suspended from a steel cable, with only 2-3 links of the chain touching bottom. Contact of the chain with the bottom reduces the buoyancy of the trawl – which would otherwise be negatively buoyant – to the point where it skims along just a few inches above the bottom to catch species like squid and scup that swim slightly above the bottom. The other type of sweep is heavier and is used on smooth bottom to catch flounder. Instead of a cable, rubber cookies stamped from automobile tires are attached to a heavy chain. This type of sweep is always in contact with the bottom. Cookies vary in diameter from 1.5 to 6.5 cm (4 to 16 inches) and do not rotate (Carr and Milliken 1998).

Roller sweeps and rockhoppers are used on irregular bottom (Carr and Milliken 1998). Vertical rubber rollers rotate freely and are as large as 14.5 cm (36 inches) in diameter. In New England, the rollers have been largely replaced with "rockhopper" gear that uses larger fixed rollers and are designed to “hop” over rocks as large as 1 meter in diameter. Small rubber “spacer” discs are placed in between the larger rubber discs in both types of sweep. Rockhopper gear is no longer used exclusively on hard bottom habitats, but is actually quite versatile and used in a variety of habitat types (NREFHSC 2002). “Street-sweepers” were first used in Massachusetts in 1995, replacing heavier rockhopper gear, and consist of circular brushes up to 12.5 cm (31 inches) in diameter. They are lighter than rubber rockhopper gear and can probably fish much rougher bottom than other sweep designs (Carr and Milliken 1998).

Flatfish are primarily targeted with a mid-range mesh flat net that has more ground rigging and is designed to get the fish up off the bottom. A high rise or fly net with larger mesh is used to catch demersal fish that rise higher off the bottom than flatfish (NREFHSC 2002). Crabs, scallops, and lobsters are also harvested in large mesh bottom trawls.

Small mesh bottom trawls are used to capture northern and southern shrimp, whiting, butterfish and squid and usually employ a light chain sweep. Small-mesh trawls are designed, rigged, and used differently than large-mesh fish trawls. Bottom trawls used to catch northern shrimp in the Gulf of Maine, for example, are smaller than most fish trawls and are towed at slower speeds (<2 knots versus 4 knots or so for a fish trawl). Footropes range in length from 12 m to over 30 m (40 - 100 ft), but most are 15 to 27 m (50 - 90 ft). Because shrimp inhabit flatter bottom than many fish do, roller gear tend to be smaller in diameter on shrimp nets because they are not towed over rough bottom (Dan Schick, Maine Dept. of Marine Resources, personal communication). Because shrimp can not be herded in the same manner as fish, footropes on shrimp trawls are bare (no cookies) and are limited to 27 m (90 ft) in length (D. Schick, personal communication). Northern shrimp trawls are also equipped with Nordmore grates in the funnel of the net to reduce the by-catch of groundfish. Southern shrimp trawlers that catch brown and white shrimp typically tow 2-4 small trawls from large booms extended from each side of the vessel (DeAlteris 1998). Northern shrimp trawlers tow a single net astern.

The raised-footrope trawl was designed especially for fishing for whiting, red hake, and dogfish. It was designed to provide vessels with a means of continuing to fish for small mesh species without catching groundfish. In this type of trawl, 1 m (42 inches) long chains connect the sweep to the footrope, which results in the trawl fishing about 0.45 to 0.6 m (1.5-2 ft) above the bottom (Carr and Milliken 1998). The raised footrope and net allows complete flatfish escapement, and theoretically travels over codfish and other roundfish (whiting and red hake tend to swim slightly above the other groundfish). Although the doors of the trawl still ride on the bottom, Carr and Milliken (1998) report that studies have confirmed that the raised footrope sweep has much less contact with the sea floor than does the traditional cookie sweep that it replaces.

An important consideration in understanding the relative effects of different otter trawl configurations is their weight in water relative to their weight in air. Rockhopper gear is not the heaviest type of ground gear used in this region since it loses 80% of its weight in water (i.e., a rockhopper sweep that weighs 1000 pounds on land may only weigh 200 pounds in water) (NREFHSC 2002). Streetsweeper gear is much heavier in the water due to the use of steel cores in the brush components. Plastic-based gear has the smallest weight in water to weight in air ratio (approximately 5%) (NREFHSC 2002). For the same reasons, steel doors are much heavier in water than wooden doors (Mirarchi 1998).

9.3.1.2.2.1.2 Beam Trawls

The beam trawl is much like an otter trawl except the net is spread horizontally by a steel beam that runs the horizontal width of the net rather than with otter boards. The net is spread vertically by heavy steel trawl heads that generally have skid-type devices with a heavy shoe attached (Sainsbury 1996). Beam trawls currently in use in Europe are up to 12 m (40 ft) in width and very heavy, increasing in weight from 3.5 mt (7,700 lbs) in the 1960s to as much as 10 mt (22,000 lbs) in the 1980s (Rogers et al. 1998). Despite the weight of the gear, increased towing power and size of trawlers have allowed towing speeds to reach 14.8 km/hr (8 knots or nmi/hr).

It is believed that beam trawls are not currently used in the Northeast U.S. (NREFHSC 2002). A few beam trawls were used in the 1970s to catch monkfish, but the fishery was unsuccessful. In the mid 1990s, a number of boats off New Bedford, MA used what were referred to as beam trawls, but the gear more closely resembled a scallop dredge rather than the traditional, European beam trawls. There are a few boats that are currently recorded as using beam trawls in the NMFS fishery landings database, but it is believed these were most likely mis-characterized and are actually otter trawls being deployed from the side of the vessels (NREFHSC 2002).

It is unlikely that fishermen would begin using beam trawls in the Northeast U.S. Beam trawls are prevalent in the North Sea where the water is dark and murky and the fisheries target flatfishes, which sit slightly under the sediments. In these fisheries, the beam trawl acts to sieve the fish up off the seafloor. The lack of conventional herding effect and small mouth opening of the beam trawl would not be effective for harvesting U.S. target species. Furthermore, most vessels being used in the Northeastern U.S. do not have the size or power required to handle a beam trawl (NREFHSC 2002). Therefore, beam trawls will not be considered further in this report as a gear type potentially impacting marine habitats off the Northeastern U.S.

9.3.1.2.2.1.3 Hydraulic Clam Dredges

Hydraulic clam dredges have been used in the surfclam (*Spisula solidissima*) fishery for over five decades and in the ocean quahog (*Arctica islandica*) fishery since its inception in the early 1970s. These dredges are highly sophisticated and are designed to: 1) be extremely efficient (80 to 95% capture rate); 2) produce a very low bycatch of other species; and 3) retain very few undersized clams (NREFHSC 2002).

The typical dredge is 3.7 m (12 feet) wide and about 6.7 m (22 feet) long and uses pressurized water jets to wash clams out of the seafloor. Towing speed at the start of the tow is about 4.5 km/hr (2.5 knots or nmi/hr) and declines as the dredge accumulates clams. The dredge is retrieved once the vessel speed drops below about 3 km/hr (1.5 knots), which can be only a few minutes in very dense beds. However, a typical tow lasts about 15 minutes. The water jets penetrate the sediment in front of the dredge to a depth of about 20 - 25 cm (8 - 10 inches), depending on the type of sediment and the water pressure. The water pressure that is required to fluidize the sediment varies from 50 pounds per square inch (psi) in coarse sand to 110 psi in finer sediments. The objective is to use as little water as possible since too much pressure will blow sediment into the clams and reduce product quality. The “knife” (or “cutting bar”) on the leading bottom edge of the dredge opening is 14 cm (5.5 inches) deep for surfclams and 8.9 cm (3.5

inches) for ocean quahogs. The knife "picks up" clams that have been separated from the sediment and guides them into the body of the dredge ("the cage"). If the knife size is not appropriate, clams can be cut and broken, resulting in significant mortality of clams left on the bottom. The downward pressure created by the runners on the dredge is about 1 psi (NREFHSC 2002). The high water pressure associated with the hydraulic dredge can cause damage to the flora and fauna associated with bottom habitats.

Before 1990, two types of hydraulic dredges were common in the fishery, stern rig dredges and side rig dredges. A side rig dredge has a chain bag that drags behind the dredge and smooths out the trench created by the dredge. The chain bag results in significantly more damage to small clams and other bycatch than occurs with the stern rig dredge. Currently, most of the dredges in the fishery are stern rig dredges, which are basically giant sieves. Small clams and bycatch fall through the bottom of the cage into the trench and damage or injury to benthic organisms is minimal. Improvements in gear efficiency have reduced bottom time and helped to confine the harvest of surfclams to a relatively small area in the mid-Atlantic Bight (NREFHSC 2002).

Hydraulic clam dredges can be operated in areas of large grain sand, fine sand, sand and small grain gravel, sand and small amounts of mud, and sand and very small amounts of clay. Most tows are made in large grain sand. Dredges are not fished in clay, mud, pebbles, rocks, coral, large gravel greater than one half inch, or seagrass beds (NREFHSC 2002).

In the soft-clam (*Mya arenaria*) fishery, the dredge manifold and blade are located just forward of an escalator, or conveyor belt, that carries the clams to the deck of the vessel. These vessels are restricted to water depths less than one-half the length of the escalator and are typically operated from 15 m (49ft) vessels in water depths of 2-6 m (6.6 - 20 ft) (DeAlteris, 1998). The escalator dredge is not managed under federal fishery management plans. A variation of this type of dredge, the suction dredge, is used in Europe to harvest several bivalve species. Sediment and clams that are dislodged by water pressure are sucked through a hose to the vessel. These dredges are also restricted to shallow water.

9.3.1.2.2.1.4 Sea Scallop Dredges

The New Bedford scallop dredge is the primary gear used in the Georges Bank and mid-Atlantic sea scallop (*Placopecten magellanicus*) fishery and is very different than dredges utilized in Europe and the Pacific because it is a toothless dredge.

The forward edge of the New Bedford dredge includes the cutting bar, which rides above the surface of the substrate, creating turbulence that stirs up the substrate and kicks objects (including scallops) up from the surface of the substrate into the bag. Shoes on the cutting bar are in contact with and ride along the substrate surface (NREFHSC 2002). A sweep chain is attached to each shoe and attaches to the bottom of the ring bag (Smolowitz 1998). The bag is made up of metal rings with chafing gear on the bottom and twine mesh on the top, and drags on the substrate when fished. Tickler chains run from side to side between the frame and the ring bag and, in hard bottom scalloping, a series of rock chains run from front to back to prevent large rocks from getting into the bag (Smolowitz 1998). New Bedford dredges are typically 4.3 m (14 feet) wide; two of them are towed by a single vessel at speeds of 4 to 5 knots. New Bedford dredges used along the Maine coast are smaller. Towing times are highly variable, depending on how many marketable sized scallops are on the bottom and the location.

In the Northeast region, scallop dredges are used in high and low energy sand environments, and high energy gravel environments. Although gravel exists in low energy environments of deepwater banks and ridges in the Gulf of Maine, the fishery is not prosecuted there (NREFHSC 2002).

The leading edge of scallop dredges used in Europe, Australia, and New Zealand to catch other species of scallop that "dig" into the bottom have teeth which dig into the substrate. This type of dredge is used by smaller vessels that are not able to tow a non-toothed dredge fast enough (4-5 knots) to fish effectively (NREFHSC 2002). Some of the European scallop dredges are spring-loaded so that the cutting bar flexes backward when it contacts a hard object on the bottom, then springs back when the dredge passes over the obstacle. These dredges are approximately 0.75 m (2.5 ft) wide and may be fished in gangs of 3-9 dredges on either side of the vessel (Kaiser et al. 1996a). A typical tooth bar bears 9 teeth, 11 cm (4.3 inches) long, spaced about 8 cm (3 inches) apart. French dredges, 2 m (6.6 ft) wide, are not spring-loaded and generally are fished on cleaner ground. They are fitted with a diving vane to improve penetration of the bottom. Scallop dredges used in Australia and New Zealand are heavy, rigid, wire mesh "boxes" that do not have a chain bag (McLoughlin et al. 1991). A very limited amount of scallop dredging with toothed dredges (e.g., the "Digby" dredge) takes place along the U.S. and Canadian coast of the Gulf of Maine.

9.3.1.2.2.1.5 Other Non-Hydraulic Dredges

9.3.1.2.2.1.5.1 Quahog Dredge

Mahogany quahogs (same species, *Arctica islandica*, as harvested in the mid-Atlantic) are harvested in eastern Maine coastal waters using a dredge that is essentially a large metal cage on skis with 15 cm (6 inch) long teeth projecting at an angle off the leading bottom edge (Pete Thayer, Maine Dept. of Marine Resources, personal communication). Maine state regulations limit the length of the cutter bar to 91 cm (36 inches). The teeth rake the bottom and lift the quahogs into the cage. This fishery takes place in small areas of sand and sandy mud found among bedrock outcroppings in depths of 9 to > 76 m (30 - 250 ft) in state and federal coastal waters north of 43ºE 20'N latitude. These dredges are used on smaller boats, about 9 - 12 m long (30 to 40 ft) and are pulled through the seabed using the boat's engine (NREFHSC 2002). This dredging activity is managed under a federal fishery management plan.

9.3.1.2.2.1.5.2 Oyster or Crab Dredge/Scrape/Mussel Dredge

The oyster dredge is a toothed dredge consisting of a steel frame 0.5-2.0 m (1.6 -6.6 ft.) in width, a tow chain or wire attached to the frame, and a bag to collect the catch. The bag is constructed of rings and chain-links on the bottom to reduce the abrasive effects of the seabed, and twine or webbing on top. The dredge is towed slowly (<1 m/sec) in circles, from vessels 7 to 30 m (23 - 98 ft.) in length (DeAlteris 1998). Crabs are harvested with dredges similar to oyster dredges. Stern-rig dredge boats (approximately 15 m (49') in length) tow two dredges in tandem from a single chain warp. The dredges are equipped with 10 cm (4 inch) long teeth that rake the crabs out of the bottom. (DeAlteris 1998). The toothed dredge is also used for harvesting mussels (Hayes 1983). These dredging activities are not managed under federal fishery management plans.

9.3.1.2.2.1.5.3 Bay Scallop Dredge

Bay scallops usually reside on the bottom. The bay scallop dredge may be 1 to 1.5 m (3.3 - 4.9 ft.) wide and about twice as long. The simplest bay scallop dredge can be just a mesh bag attached to a metal frame that is pulled along the bottom. For bay scallops that are located on sand and pebble bottom, a small set of raking teeth are set on a steel frame, and skids are used to align the teeth and the bag (Sainsbury 1996). This dredging activity is not managed under federal fishery management plans.

9.3.1.2.2.1.5.4 Sea Urchin Dredge

Similar to a simple bay scallop dredge, the sea urchin dredge is designed to avoid damaging the catch. It has an up-turned sled-like shape at the front that includes several leaf springs tied together with a steel bar. A tow bail is welded to one of the springs and a chain mat is rigged behind the mouth box frame. The frame is fitted with skids or wheels. The springs act as runners, enabling the sled to move over rocks without hanging up. The chain mat scrapes up the urchins. The bag is fitted with a codend for ease of emptying. This gear is generally only used in waters up to 100 m (330 ft.) deep (Sainsbury 1996). This dredging activity is not managed under federal fishery management plans.

9.3.1.2.2.1.5.5 Clam "Kicking"

Clam kicking is a mechanical form of hard clam harvest practiced in North Carolina which involves the modification of boat engines so that the propeller is directed downwards instead of backwards (Guthrie and Lewis 1982). In shallow water the propeller wash is powerful enough to suspend bottom sediments and clams into a plume in the water column, which allows them to be collected in a trawl net towed behind the boat (Stephan et al. 2000). This activity is not managed under federal fishery management plans.

9.3.1.2.2.2 Seines

9.3.1.2.2.2.1 Haul Seines

Haul seining is a general term describing operations where a net is set out between the surface and sea bed to encircle fish. It may be undertaken from the shore (beach seining), or away from shore in the shallows of rivers, estuaries or lakes (Sainsbury 1996). Seines typically contact the sea bottom along the lead line. Additionally the net itself may scrape along the bottom as it is dragged to shore or the recovery vessel. This activity is not managed under federal fishery management plans.

9.3.1.2.2.2.1.1 Beach Haul Seines

The beach seine resembles a wall of netting of sufficient depth to fish from the sea surface to the sea bed, with mesh small enough that the fish do not become gilled. A floatline runs along the top to provide floatation and a leadline with a large number of weights attached ensures that the net maintains good contact with the bottom. Tow lines are fitted to both ends. The use of a beach seine generally starts with the net on the beach. One end is pulled away from the beach, usually with a small skiff or dory, and is taken out and around and finally back in to shore. Each end of the net is then pulled in towards the beach, concentrating the fish in the middle of the net. This is eventually brought onshore as well and the fish removed. This gear is generally used in relatively shallow inshore areas. (Sainsbury 1996). This activity is not managed under federal fishery management plans.

9.3.1.2.2.2.1.2 Long Haul Seines

The long haul seine is set and hauled in shallow estuarine and coastal areas from a boat typically 15 m (49 ft.) long. The net is a single wall of small mesh webbing less than 5 cm (2 inches), and is usually greater than 400 m (1440 ft.) in length and about 3 m (9.8 ft.) in depth. The end of the net is attached to a pole driven into the bottom, and the net is set in a circle so as to surround fish feeding on the tidal flat. After closing the circle, the net is hauled into the boat, reducing the size of the circle, and concentrating the fish. Finally, the live fish are brailed or dip-netted out of the net. (DeAlteris 1998). This activity is not managed under federal fishery management plans.

9.3.1.2.2.2.2 Stop Seines

These are seines that are used in coastal embayments to close off the opening to a small cove or bight. This method is used in Maine to harvest schools of juvenile herring (Everhart and Youngs 1981). This activity is not managed under federal fishery management plans.

9.3.1.2.2.2.3 Danish and Scottish Seines

Danish or Long seining (anchor dragging) was developed in the 1850s prior to the advent of otter trawling. The Danish seine is a bag net with long wings, that includes long warps set out on the seabed enclosing a defined area. As the warps are retrieved, the enclosed area (a triangle) reduces in size. The warps dragging along the bottom herd the fish into a smaller area, and eventually into the net mouth. The gear is deployed by setting out one warp, the net, then the other warp. On retrieval of the gear, the vessel is anchored. This technique of fishing is aimed at specific schools of fish located on smooth bottom. In contrast to Danish seining, if the vessel tows ahead while retrieving the gear, then this is referred to as

Scottish seining or fly-dragging. This method of fishing is considered more appropriate for working small areas of smooth bottom, surrounded by rough bottom. Scottish and Danish seines have been used experimentally in U.S. demersal fisheries. Space conflicts with other mobile and fixed gears, have precluded the further development of this gear in the U.S., as compared to Northern Europe (DeAlteris 1998). This activity is managed under federal fishery management plans.

9.3.1.2.2.3 Bottom-Tending Static Gear

9.3.1.2.2.3.1 Pots

Pots are portable, rigid devices that fish and shellfish enter through small openings, with or without enticement by bait (Everhart and Youngs 1981; Hubert 1983). They are used to capture lobsters, crabs, black sea bass, eels and other bottom dwelling species seeking food or shelter (Everhart and Youngs 1981; Hubert 1983). Pot fishing can be divided into two general classifications: 1) inshore potting in estuaries, lagoons, inlets and bays in depths up to about 75 m (250 ft.) and; 2) Offshore potting using larger and heavier vessels and gear in depths up to 730 m (2400 ft.) or more (Sainsbury 1996).

9.3.1.2.2.3.1.1 Lobster Pots

Lobster pots are typically rectangular and are divided into two sections, the chamber and the parlor. The chamber has an entrance on both sides of the pot and is usually baited. Lobsters then move to the parlor via a tunnel (Everhart and Youngs 1981). Escape vents are installed in both areas of the pot to minimize the retention of sub-legal sized lobsters (DeAlteris 1998).

Lobster pots are fished as either 1) a single pot per buoy (although two pots per buoy are used in Cape Cod Bay, and three pots per buoy in Maine waters), or 2) a "trawl" or line with up to 100 pots. According to NREFHSC (2002) there are a number of important features related to lobster pots and their use:

- About 95% of lobster pots are made of plastic-coated wire.
- Floating mainlines may be up to 7.6 m (25 ft.) off bottom.
- Sinklines are sometimes used where marine mammals are a concern.
- Neutrally buoyant lines may soon be required in Cape Cod Bay.
- Soak time depends on season and location - usually 1-3 days in inshore waters in warm weather, to weeks in colder waters.
- Offshore pots are larger (more than 1 m (4 ft) long) and heavier (~ 100 lb or 45 kg), with an average of ~ 40 pots/trawl and 44 trawls/vessel. They have a floating mainline and are usually deployed for a week at a time.
- There has been a three-fold increase in lobster pots fished since the 1960s, with more than four million pots now in use.

Although the offshore component of the fishery is regulated under federal rules, American lobster is not managed under a federal fishery management plan.

9.3.1.2.2.3.1.2 Fish Pots

Black sea bass pots are similar in design to lobster pots. They are usually fished singly or in trawls of up to 25 pots, in shallower waters than the offshore lobster pots or red crab pots. Pots may be set and retrieved 3-4 times per day when fishing for scup (NREFHSC 2002). This activity is managed under a federal fishery management plan. Hagfish pots (55 gallon plastic barrels fitted with a number of one-way entrance funnels) are fished in deep waters on mud bottoms. They are fished in strings of 20-200 traps and set for about six to twelve hours. Cylindrical pots are typically used for capturing eels in Chesapeake Bay, however, half-round and rectangular pots are also used and all are fished in a manner similar to that of lobster pots (Everhart and Youngs 1981). Hagfish and eel activities are not managed under a federal fishery management plan.

9.3.1.2.2.3.1.3 Crab Pots

Crabs are often fished with pots consisting of a wire mesh. A horizontal wire partition divides the pot into an upper and lower chamber. The lower chamber is entered from all four sides through small wire tunnels. The partition bulges upward in a fold about 20 cm (8 inches) high for about one third of its width. In the top of the fold are two small openings that give access to the upper chamber (Everhart and Youngs 1981).

Crab pots are always fished as singles and are hauled by hand from small boats, or with a pot hauler in larger vessels. Crab pots are generally fished after an overnight soak, except early and late in the season (DeAlteris 1998). These pots are also effective for eels (Everhart and Youngs 1981). This activity is not managed under a federal fishery management plan.

Deep sea red crab pots are typically wood and wire traps 1.2 m by 0.75 m (48 by 30 inches) with top entry. Pots are baited and soak for about 22 hours before being hauled. Currently, vessels are using an average of 560 pots in trawls of 75- 180 pots per trawl along the continental slope at depths from 400 to 800 m (1300 - 2600 ft). These vessels are typically 25 - 41 m (90 - 150 ft) in length. Currently there are about 6 vessels engaged in this fishery (NEFMC 2002). This activity is managed under a federal fishery management plan.

9.3.1.2.2.3.2 Traps

A trap is generally a large scale device that uses the seabed and sea surface as boundaries for the vertical dimension. The gear is installed at a fixed location for a season, and is passive, as the animals voluntarily enter the gear. Traps are made of a leader or fence, that interrupts the coast parallel migratory pattern of the target prey, a heart or parlor that leads fish via a funnel into the bay or trap section that serves to hold the catch for harvest by the fishermen. The non-return device is the funnel linking the heart and bay sections (DeAlteris 1998). This activity is not managed under a federal fishery management plan.

9.3.1.2.2.3.2.1 Fish Pound Nets

Pound nets are constructed of netting staked into the sea bed by driven piles (Sainsbury 1996). Pound nets have three sections: the leader, the heart, and the pound. The leader (there may be more than one) may be as long as 400 m (1300 ft) and is used to direct fish into the heart(s). One or more hearts are used to further funnel fish into the pound and prevent escapement. The pound may be 15 m (49 ft) square and holds the fish until the net is emptied. These nets are generally fished in waters less than 50 m (160 ft) deep. Pound nets are also used to catch crabs. This activity is not managed under a federal fishery management plan.

9.3.1.2.2.3.2.2 Fyke and Hoop Nets

Constructed of wood or metal hoops covered with netting, hoop nets are 2.5 to 5 m (8.2 - 16 ft) long, "Y-shaped" nets, with wings at the entrance and one or more internal funnels to direct fish inside, where they become trapped. Occasionally, a long leader is used to direct fish to the entrance. Fish are removed by lifting the rear end out of the water and loosening a rope securing the closed end. These nets are generally fished to about 50 m (160 ft) deep (Sainsbury 1996). A common fyke net is a long bag mounted on one or several hoops which keep the net from collapsing as well as provide an attachment for the base of the net funnels to prevent the fish from escaping. This gear is used in shallow water and extensively in river fisheries. (Everhart and Youngs 1981). This activity is not managed under a federal fishery management plan.

9.3.1.2.2.3.2.3 Weirs

A weir is a simple maze that intercepts species that migrate along the shoreline. Brush weirs are used in the Maine sardine/herring fishery. These are built of wooden stakes and saplings driven into the bottom in shallow waters. The young herring encounter the lead, which they follow to deeper water, finally passing into an enclosure of brush or netting. The concentrated fish are then removed with a small seine (Everhart and Youngs 1981). This activity is not managed under a federal fishery management plan.

9.3.1.2.2.3.2.4 Shallow Floating Traps

In New England, much of the shoreline and shallow subtidal environment is rocky and stakes can not be driven into the bottom. Therefore, the webbing of these traps is supported by floats at the sea surface, and held in place with large anchors. These traps are locally referred to as "floating traps." The catch, design elements and scale of these floating traps is similar to pound nets (DeAlteris 1998).

The floating trap is designed to fish from top to bottom, and is built especially to suit its location. The trap is held in position by a series of anchors and buoys. The net is usually somewhat "T-shaped," with the long portion of the net (the leader net) designed to funnel fish into a box of net at the top of the T. The leader net is often made fast to a ring bolt ashore (Sainsbury 1996). This activity is not managed under a federal fishery management plan.

9.3.1.2.2.4 Sink Gill Nets and Bottom Longlines

9.3.1.2.2.4.1 Sink/Anchor Gill Nets

Individual gill nets are typically 91 m (300 feet) long, and are usually fished as a series of 5-15 nets attached end-to-end. Gill nets have three components: leadline, webline and floatline. Fishermen are now experimenting with two leadlines. Leadlines used in New England are ~65 lb (30 kg.)/net; in the Middle Atlantic leadlines may be heavier. Weblines are monofilament, with the mesh size depending on the target species. Nets are anchored at each end, using materials such as pieces of railroad track, sash weights, or Danforth anchors, depending on currents. Anchors and leadlines have the most contact with the bottom. Some nets may be tended several times/day, (e.g., when fishing for bluefish in the Middle Atlantic). For New England groundfish, frequency of tending ranges from daily to biweekly (NREFHSC 2002). These activities are managed under federal fishery management plans.

9.3.1.2.2.4.2 Stake Gill Nets

Generally a small boat is used inshore so that a gill net is set across a tidal flow and is lifted at slack tide to remove fish. Wooden or metal stakes run from the surface of the water into the sediment and are placed every few meters along the net to hold it in place. When the net is lifted, the stakes remain in place. These nets are generally fished from the surface to about 50 meters deep (Sainsbury 1996). These activities are not managed under federal fishery management plans.

9.3.1.2.2.4.3 Bottom Longlines

Longlining for bottom species on continental shelf areas and offshore banks is undertaken for a wide range of species including cod, haddock, dogfish, skates, and various flatfishes (Sainsbury 1996). A 9.5 m (31 ft) vessel can fish up to 2500 hooks a day with a crew of one and twice that number with 2 crew members. Mechanized longlining systems fishing off larger vessels up to 60 m (195 ft) can fish up to 40,000 hooks per day (Sainsbury 1996).

In the Northeast up to six individual longlines are strung together, for a total length of about 460 m (1500 ft), and are deployed with 20-24 lb (9 - 11 kg) anchors. The mainline is parachute cord or sometimes stainless steel wire. Gangions (lines from mainline to hooks) are 38 cm (15 inches) long and 1-2 m (3-6 ft) apart. The mainline, hooks, and gangions all come in contact with the bottom. Circle hooks are potentially less damaging to habitat features than other hook shapes. These longlines are usually set for only a few hours at a time (NREFHSC 2002). Longlines used for tilefish are deployed in deep water, may be up to 40 km (25 miles) long, are stainless steel or galvanized wire, and are set in a zig-zag fashion (NREFHSC 2002). These activities are managed under federal fishery management plans.

9.3.1.2.2.5 Pelagic Gear

9.3.1.2.2.5.1 Mid-Water Otter Trawl

The mid-water trawl is used to capture pelagic species that school between the surface and the sea bed throughout the water column. The mouth of the net can range from 110 m to 170 m (360 - 560 ft.) and requires the use of large vessels (Sainsbury 1996). Successful mid-water trawling requires the effective use of various electronic aids to find the fish and maneuver the vessel while catching them (Sainsbury 1996). This activity is managed under federal fishery management plans. This gear is not expected to have contact with or impacts upon bottom habitats.

9.3.1.2.2.5.2 Paired Mid-Water Trawl

Pair-trawling is used by smaller vessels which herd small pelagics such as herring and mackerel into the net (Sainsbury 1996). Large pelagic species are also harvested with a huge pelagic pair trawl towed at high speed near the surface. The nets have meshes exceeding 10 m (33 ft.) in length in the jibs and first belly sections, and reduce to cod-end mesh sizes of 20 cm (8 inches) (DeAlteris 1998). This activity is managed under federal fishery management plans. This gear is not expected to have contact with or impacts upon bottom habitats.

9.3.1.2.2.5.3 Purse Seines

Purse seines are very efficient for taking pelagic schooling species. The purse seine is a continuous deep ribbon of web with corks on one side and leads on the other. Rings are fastened at intervals to the lead line and a purse line runs completely around the net through the rings (Everhart and Youngs 1981). One end of the net is fastened to the vessel and the other end to a skiff. The vessel then encircles a school of fish with the net, the net pursed and hauled back to the vessel. Purse seines vary in size according to the vessel size, the size of the mesh, the species sought and the depth to be fished. Tuna seines are nearly one kilometer (0.6 miles) long and fish from 55 - 640 m (180 - 2100 ft.) (Everhart and Youngs 1981). Due to the large depth of the net for tuna purse seines, they have been shown to contact and interact with the sea bottom when fishing in some shallow water locations such as Massachusetts Bay and vicinity (NMFS 2001). However, these interactions are unintended and rare. This activity is managed under federal fishery management plans.

9.3.1.2.2.5.4 Drift Gill Nets

Gillnets operate principally by wedging and gilling fish, and secondarily by entangling (DeAlteris 1998). The nets are a single wall of webbing, with float and lead lines. Drift gillnets are designed so as to float from the sea surface and extend downward into the water column and are used to catch pelagic fish. In this case the buoyancy of the floatline exceeds the weight of the leadline. Drift gillnets may be anchored at one end or set-out to drift, usually with the fishing vessel attached at one end (DeAlteris 1998). This activity is managed under federal fishery management plans. This gear is not expected to have contact with or impacts upon bottom habitats.

9.3.1.2.2.5.5 Pelagic Longline Gear

The pelagic or subsurface longline is a technique directed mostly towards tunas, swordfish, sailfish, dolphin (dorado), and sharks. The gear is typically set at depths from the surface to around 330 m (1100 ft.). The gear can also be set with a main line hanging in arcs below the buoy droplines to fish a band of depths (Sainsbury 1996). The gear is set across an area of known fish concentration or movement, and may be fished by day or night depending upon the species being sought (Sainsbury 1996). The length of the mainline can vary up to108 km (67 miles) depending on the size of the vessel. If the mainline is set level at a fixed depth, then the leader or gangion lengths vary from 2-40 m (6.6 - 130 ft.), so as to ensure the hooks are distributed over a range of depths (DeAlteris 1998). If a line-shooter is used to set the mainline in a catenary shape with regard to depth, then the gangions are usually a single minimal length, but are still distributed by depth (DeAlteris 1998). Each gangion typically contains a baited hook and chemical night stick to attract the fish. Traditional or circle hooks may be used. Swordfish vessels typically fish 20 to 30 hooks per 1.6 km (1 mile) of mainline between 5 and 54 km (3 - 34 miles) in length (Sainsbury 1996). This activity is managed under federal fishery management plans. This gear is not expected to have contact with or impacts upon bottom habitats.

9.3.1.2.2.5.6 Troll Lines

Trolling involves the use of a baited hook or lure maintained at a desired speed and depth in the water (Sainsbury 1996). Usually, two to four or more lines are spread to varying widths by the use of outrigger poles connected to the deck by hinged plates. Line retrieval is often accomplished by means of a mechanized spool. Each line is weighted to reach the desired depth and may have any number of leaders attached, each with a hook and bait or appropriate lure. This gear is generally fished from the surface to about 20 meters (Sainsbury 1996). This activity is managed under federal fishery management plans. This gear is not expected to have contact with or impacts upon bottom habitats.

9.3.1.2.2.6 Other Gear

9.3.1.2.2.6.1 Rakes

A bull rake is manually operated to harvest hard clams and consists of a long shaft with a rake and basket attached. The length of the shaft can be variable but usually does not exceed three times the water depth. The length and spacing of the teeth as well as the openings of the basket are regulated to protect juvenile clams from harvest (DeAlteris 1998). Rakes are typically fished off the side of a small boat. This activity is not managed under federal fishery management plans.

9.3.1.2.2.6.2 Tongs

Tongs are a more efficient device than rakes for harvesting shellfish. Shaft-tongs are a scissor-like device with a rake and basket at the end of each shaft. The fisherman stands on the edge of the boat and progressively opens and closes the baskets on the bottom gathering the shellfish into a mound. The tongs are closed a final time, brought to the surface, and the catch emptied on the culling board for sorting. The length of the shaft must be adjusted for water depth. Oysters are traditionally harvested with shaft tongs in water depths up to 6 m (21 ft.), with shaft tongs 8 m (29 ft.) in length (DeAlteris 1998). Patent tongs are used to harvest clams and oysters and are opened and closed with a drop latch or with a hydraulic ram and require a mechanized vessel with a mast or boom and a winch (DeAlteris 1998). Patent tongs are regulated by weight, length of teeth, and bar spacing in the basket. This activity is not managed under federal fishery management plans

9.3.1.2.2.6.3 Line Fishing

9.3.1.2.2.6.3.1 Hand Lines

The simplest form of hook and line fishing is the hand line. It consists of a line, sinker, leader and at least one hook. The line is usually stored on a small spool and rack and can vary in length. The line varies in material from a natural fiber to synthetic nylon. The sinkers vary from stones to cast lead. The hooks are single to multiple arrangements in umbrella rigs. An attraction device must be incorporated into the hook, usually a natural bait and artificial lure (DeAlteris 1998). Although not typically associated with bottom impacts, this gear can be fished in such as manner so as to hit bottom and bounce or be carried by currents until retrieved. This activity is managed under federal fishery management plans.

9.3.1.2.2.6.3.2 Mechanized Line Fishing

Mechanized line hauling systems have been developed to allow more lines to be worked by smaller crews and use electrical or hydraulic power to work the lines on the spools or jigging machines (Sainsbury 1996). These reels, often termed bandits, are mounted on the vessel bulwarks and have a spool around which the mainline is wound (Sainsbury 1996). Each line may have a number of branches and baited hooks, and the line is taken from the spool over a block at the end of a flexible arm. This gear is used to target several species of groundfish, especially cod and pollock and it has the advantage of being effective in areas where other gears cannot be used. Jigging machine lines are generally fished in waters up to 600 m (2000 ft) deep (Sainsbury 1996). This gear may also have the ability to contact the bottom depending upon the method selected to fish. This activity is managed under federal fishery management plans.

9.3.1.2.2.6.4 Hand Hoes

Intertidal flats are frequently harvested for clams and baitworms using hand-held hoes. These are short handled rake-like devices, which are often modified gardening tools (Creaser et. al. 1983). Baitworm hoes have 5 to 7 tines, 21 to 22 cm (8.3 - 8.7 ft) in length for bloodworms and 34 to 39 cm (13 - 15 inches) for sandworms. Clam hoes in Maine typically have 4 to 5 tines, 15 cm (6 inches) long (Wallace 1997). This activity is not managed under federal fishery management plans.

9.3.1.2.2.6.5 Diving

By either free diving or using SCUBA, divers collect crustaceans, mollusks and some reef fish in shallow water. Most often a support vessel is used to transport the diver(s) to the fishing site and carry the landings to port. In deeper waters, helmet diving systems are used and the diver is tethered to the vessel with air pumped from the surface. This method is most often used by sea urchin divers and some lobster divers. Divers normally use small rakes or hoes to scrape creatures off rocks or dig them out of the seabed. Generally, the catch is placed in bags which are either towed to the surface by the boat or floated to the surface using an air source and a lift bag. Divers rarely work deeper than about 20 m (66 ft) (Sainsbury 1996). This activity is not managed under federal fishery management plans.

9.3.1.2.2.6.6 Spears

Spears came into use when it was found that a pole or shaft with a point on it could be used by a fisherman operating from shore, floating raft, or boat to capture animals previously out-of-reach (DeAlteris 1998). However, the single prong spear required an accurate aim, and fish easily escaped. With the addition of a barb, fish retention was improved; and spears with multi-prong heads increased the likelihood of hitting the target. Spears were initially hand-held, then thrown, then placed in launching devices including cross-bows, spear guns for divers, etc. Spears with long shafts (gigs) are used by fishermen in small boats at night in the Carolina sounds for flounder, through the ice for eels in New England bays, and by divers for fish in coastal waters (DeAlteris 1998). This activity is not managed under federal fishery management plans.

9.3.1.2.3 Distribution of fishing activity by gear type

9.3.1.2.3.1 Introduction

This section of the document includes a series of GIS figures showing the distribution of fishing activity during 1995-2001 by ten minute "squares" of latitude and longitude for six commercial fishing gears that are extensively used in the U.S. Northeast region. Three of them (bottom trawls, scallop dredges, and hydraulic clam dredges) are mobile bottom-tending gears and three (pots, bottom gill nets, and bottom longlines) are fixed bottom-tending gears. Bottom trawls, longlines and gill nets are used to harvest groundfish that are managed by the New England Fishery Management Council. Groundfish are also caught incidentally (as by-catch) in pots, scallop dredges, and clam dredges. All six of these gears have the potential to adversely affect groundfish EFH for in the Northeast region, but the effects of fixed gear are minor compared to the effects of mobile bottom-tending gear (NREFHSC 2002). Also included in this section of the DEIS is an analysis of fishing activity for each gear type among four sub-regions and by surface sediment type within each sub-region and for the region as a whole.

9.3.1.2.3.2 Data Sources and Processing

The data used to perform this analysis were extracted from vessel trip report and clam logbook databases maintained at the U.S. National Marine Fisheries Service (NMFS) Northeast (NE) Regional Office in Gloucester, MA. Data included in the analysis are provided by vessels operating with federal permits that participate in the following fisheries: northeast multispecies; sea scallops; surf clams and ocean quahogs; monkfish; summer flounder; scup; black sea bass; squid, mackerel, and butterfish; spiny dogfish; bluefish; Atlantic herring; and tilefish. Vessels that operate strictly within state waters (generally inside three miles from shore) are not required to have a federal permit and therefore do not submit trip reports. For this reason, fishing trips in some nearshore ten minute squares that include a significant proportion of state waters are under-represented.

Permit holders are required to fill out a VTR form or make a logbook entry for each trip made by the vessel, i.e., each time the vessel leaves and returns to port. In cases where more than one statistical area is fished or the gear is changed during the same trip, a separate report is completed. Fishermen are given the choice of reporting the location of a trip as a point (latitude and longitude or Loran bearings) or just as a statistical area. Only trips that were reported as a point location and therefore could be assigned to a 10 minute square were included in this analysis. Most trips are reported this way. Fishermen report the general location where most of their fishing effort occurred during a trip and the date and time that the vessel left and returned to port. They are also asked to record the number of hauls (tows or sets) made during the trip and the average tow or soak time when the gear was fishing, but this information was judged to be too unreliable and incomplete for use in this analysis. Logbook entries in the clam dredge fishery include time spent fishing and these data were used in this analysis.

VTR and logbook data used in this analysis were compiled for the years 1995-2001. Scallop dredge and otter trawl fishing activity was calculated as the total number of days absent from port during the seven-year period. Days absent for each mobile gear trip were calculated based on the date and time of departure from and return to port in hours and converted to fractions of 24-hr days. Hydraulic clam dredge fishing activity was calculated as days (24 hrs) spent fishing based on the number of hours spent on each trip and excluded trips made by "dry" quahog dredge vessels in Maine. Fishing activity for the three fixed gear types was expressed as the number of trips reported in each ten minute square (TMS).

Days absent calculations for trawl and dredge vessels are clearly preferable to simply summing the number of trips, but over-estimate actual fishing time since they include travel time and any other non-fishing-related activity while vessels are away from port. Thus, the GIS plots and analyses presented here do not represent fishing effort. They were only used to indicate the relative, not the absolute, distribution of fishing activity by geograhical area and sediment type. Toward this end, all GIS input data were compiled and sorted into three categories: low, medium, and high degrees of activity that corresponded to cumulative percentages of 90, 75, and 50% of the total number of days at sea, or days spent fishing for each gear type during the seven-year time period. Data reported from TMS south of Cape Hatteras, North Carolina (35° N) and north of 45° N latitude in the Gulf of Maine were excluded from analysis, as were TMS-binned data from the low end (cumulative percentages >90%) of the frequency distribution. Exclusion of "low end" data (TMS with only a few trips or days) eliminated a large number of spatially misreported trips from analysis.

Also included in this section are GIS plots of fishing activity for scallop dredge vessels operating in the limited access fishery during 1998, 1999, and 2000 which were derived from vessel monitoring systems (VMS) placed aboard each vessel (Rago and McSherry 2001). These plots provide a much more detailed depiction of fishing activity for dredge vessels during these three years than VTR data since they are collected at much higher spatial and temporal resolutions. Data were collected at 20-minute intervals during the time when vessel speed was less than 5 knots in order to differentiate between fishing activity and steaming time and then binned into one nautical mile squares. It is recognized that fishing activity includes other activities besides dredging, e.g., shucking time.

9.3.1.2.3.3 Data Analysis

In each plot, the number of trips or days that accounted for 90% (cumulative) of the total number of trips or days was given as "N" in the title of each figure. Depth contours shown in these figures are for 50 and 100 fathoms. The U.S.-Canada border is shown as a black line and the outer boundary of the U.S. Exclusive Economic Zone (EEZ) is also shown. Ten minute squares that account for 90% of total fishing activity (i.e., all the TMS shown in the low, medium, and high distribution plots) were overlaid as open TMS on sediment types in a second series of GIS plots for each gear type. The surficial sediment layer was modified from a GIS data layer originally made available as a series of hard copy maps by Poppe et al. (1989) and available on a USGS CD-ROM. The original data layer included nine sediment types. For this analysis, silt and clay sediment categories were re-defined as "mud." This resulted in a simplified set of six sediment categories, which were re-named bedrock, gravel, gravelly sand, sand, muddy sand, and mud (Figure 240).

Data were allocated to TMS within the Northeast region (delimited by 35° N latitude) and to four sub-regions, the Gulf of Maine (GOM), Georges Bank (GB), southern New England (SNE), and the Mid-Atlantic (MA). These sub-regions are shown in Figure 241. Each sub-region, and the NE region of which each formed a part, were bounded inshore to exclude state waters and offshore by the 500 fathom depth contour. Boundaries between sub-regions were defined along ten minute parallels of latitude and meridians of longitude so that the only partial TMS were those that intersected with either the inshore or offshore limits of the region. Input files of VTR and logbook data were joined with shape files for each sub-region and the number of trips, days at sea, or days fishing, and the area (in square decimal degrees) encompassed by all the TMS – or portions of TMS – in each fishing activity category (50, 75, and 90%), were calculated.

For the "low" (90%) level of fishing activity, the percentage of the total number of trips or days that occurred in each sub-region during the six or seven-year time period was calculated. Also, the spatial extent to which each sub-region (and the entire NE region) was "fished" by each gear type was calculated as the proportion of the total area within each sub-region that was included within all the designated TMS. For bottom trawls, the amount of closed area on GB and in SNE was deducted from the total area in each sub-region. (All the other gear types had access to these areas for all or a portion of the 1995-2001 time period).

It is important to understand that all calculations involving "area fished" grossly over-estimate the amount of bottom area actually affected by fishing because bottom-tending gear in most cases are not used throughout any given TMS that was assigned to a fishing activity category. This would be particularly true for TMS at the low (90%) end of the distribution, i.e., TMS in which fishing activity is very sparse. Area analyses were only intended to reveal relative differences in the degree of fishing activity between gear types and sub-regions.

Analyses of percent area "fished" were conducted for each gear type and sub-region in terms of the percentage of the total area of each sediment type present in each sub-region was "fished" at the 90% level. These analyses were limited by the very general nature of the available sediment coverage data, and, as mentioned above, by the fact that fishing may take place within a relatively small proportion of the area within a TMS (which covers about 77 square nautical miles), and on a bottom type that either makes up a small proportion of the whole TMS or isn't even represented in the sediment database.

9.3.1.2.3.4 Results

9.3.1.2.3.4.1 Bottom Gill Nets

Bottom gill net trips were made primarily in the GOM (Figure 247 and Figure 248). In none of the other three sub-regions did gill net trips exceed 25% of the total number of gill net trips reported for the entire Northeast region. Gill net trips were reported from a larger area of federal waters in the Northeast region than pot or longline trips (Figure 247). Ten minute squares (TMS) where 90% of the gill net trips were made extended over a larger proportion of the GOM and a smaller proportion of GB, with intermediate values in SNE and the MA sub-regions. Gill net trips were most common in coastal waters in the southwestern portion of the GOM, with some trips reported offshore in the central portion of the gulf (Figure 242). No gill net fishing was reported in coastal waters of central and eastern Maine. Outside the GOM, gill net trips were reported along the western edge of the Great South Channel, in Rhode Island coastal waters, along the south shore of Long Island, and off New Jersey, the Delaware-Maryland-Virginia (DelMarVa) peninsula, and North Carolina. A few trips were also made in three TMS along the 100 f contour at the shelf break in SNE and (apparently) in a single TMS in even deeper water southeast of Hudson Canyon. Gill net trips were more numerous during 1995-2001 than bottom longline trips, but not as numerous as pot trips.

Ten minute squares that accounted for 90% of the gill net fishing trips during 1995-2001 were associated with a higher percentage of sand, gravelly sand, and gravel in the Northeast region than was the case for the other two fixed gear types (Figure 249). All three fixed gear types were used to a much greater extent on mud bottom in the GOM and on sand in the other three sub-regions, reflecting the distribution of sediment types by sub-region (Figure 248). Gill net trips were more strongly associated with coarser sediments in the GOM, SNE, and the MA and with mud and muddy sand in the GB sub-region (Figure 248).

9.3.1.2.3.4.2 Bottom Longlines

Bottom longlining during 1995-2001 was conducted primarily in coastal waters of the southwestern GOM and extended southeast of Cape Cod along the western edge of the Great South Channel Figure 243). A few trips were also reported on the northern edge of GB, in the outer portion of the GOM, in SNE coastal waters, and at scattered locations along the outer continental shelf. Almost all longline trips were reported in the GOM and GB sub-regions, with approximately twice as many in GB (Figure 247). The proportion of each sub-region where 90% of the longline trips were reported diminished from north to south. Of the three fixed gear types, longlines accounted for fewer trips during 1995-2001 than pots or bottom gill nets. Longline trips were also reported from TMS that occupied a smaller percentage of the Northeast shelf area than pot or gill net trips (Figure 242).

Like the other two fixed gear types, bottom longline trips were most commonly reported from TMS in sandy bottom areas, but in relation to the areal extent of each sediment type present in the NE region, longlining was more closely associated with gravelly sand and gravel (Figure 249). Longlining was reported from a very low proportion of mud in the GOM and GB sub-regions, and from a high proportion of sand in the GOM and gravelly sand and gravel areas in the GB sub-region (Figure 248). The low number of trips in SNE were more strongly associated with gravelly sand than with any other sediment type.

9.3.1.2.3.4.3 Pots

Pot fishing trips were distributed primarily throughout GOM coastal waters and in SNE (Figure 247). Trips were also reported from a few TMS along the U.S.-Canada border in the GOM, along the shelf break, and in inshore locations in the New York Bight and southern New Jersey and off the DelMarVa peninsula. Lobster pots accounted for 90% of the total number of trips and dominated pot fishing activity in the GOM and SNE. Hagfish pots (not shown) were used in more offshore waters of the GOM, fish pots (not shown) primarily in coastal SNE waters and in a large area of the mid-Atlantic between southern New Jersey and Cape Henry, and at the tip of the DelMarVa peninsula, and conch and whelk pots (not shown) in Nantucket Sound and off the DelMarVa peninsula. Crab pot trips (not shown) were reported from a number of scattered TMS, but there was a cluster on the southeastern flank of GB and inside the North Carolina barrier islands. The analysis of total pot fishing trips by sub-region – which excludes some data from TMS located inside state waters – revealed, not surprisingly, that most trips were reported in the GOM sub-region (Figure 247). Of the other three sub-regions, SNE accounted for more trips and area than the other two sub-regions, although a notable percentage of the area (but not number of trips) represented by the 90% TMS occurred in the mid-Atlantic sub-region. The extent of pot fishing in the GB sub-region during 1995-2001 was negligible.

Pot fishing trips occurred most often on mud bottom in the GOM and on sand in the other three sub-regions (Figure 248). In proportion to the amount of each sediment type present in each sub-region, pot fishing was more closely associated with sand, gravelly sand, and gravel substrates in the GOM, and with mud, sand, and gravelly sand in SNE. Ten minute squares that accounted for 90% of pot fishing activity in the mid-Atlantic did not represent more than 20% of any sediment type in the region. On GB, where even fewer trips were reported, no more than 12% of any sediment type was associated with 90% TMS.

9.3.1.2.3.4.4 Bottom Trawls

Bottom trawling in federal waters in the Northeast region during 1995-2001 accounted for more than twice as many days absent as scallop dredging and was represented in more than twice as much area (Figure 250). Significant areas were closed to bottom trawlers during the seven-year period (15% of GB and 5% in SNE). These areas account for the large gaps in the distribution of trawling activity on GB and SNE. Bottom trawling, more than any other gear type, was also conducted to a greater extent in deeper water in the GOM, north of GB, and along the shelf break in SNE and the mid-Atlantic. A continuous area of high trawling activity occurred from the central GOM west to the coast, then through the southwestern GOM, down the west side of the Great South Channel and east across the top of Closed Area I on GB. Trawling was also reported west and south of Closed Area II on eastern GB, on the southern portion of GB, throughout most of SNE in inner, mid, and outer shelf waters, along the shelf break in the mid-Atlantic, and in North Carolina coastal waters. There was a large area with no significant amount of trawling in the middle and inner portions of the mid-Atlantic shelf from the New York Bight south to the North Carolina border.

Analysis of VTR data by region showed that trawling activity was fairly evenly distributed among the four regions of the Northeast shelf (Figure 250). The GOM and GB regions, however, ranked somewhat higher than SNE and the mid-Atlantic in most cases. In terms of the area included in TMS that accounted for 90% of the reported number of days absent from port, a larger proportion of the SNE region was trawled than was trawled in any of the other regions and the mid-Atlantic region the least affected. Trawling was distributed over a high proportion of total area in all regions except the mid-Atlantic where it was no more extensive than scallop dredging and only slightly more extensive than hydraulic clam dredging.

Bottom trawling was widely distributed on a variety of substrates in the NE region, but appeared to be more widespread on mud bottom in the GOM and on sand and gravel in the other three regions where coarser substrates are more common (Figure 251). Analysis of VTR data according to sediment type indicated that bottom trawling was less common on sandy substrates in the NE region than dredging and more common on mud and muddy sand than the other two mobile gear types (Figure 252). In terms of the total amount of each sediment type present in the NE region, trawling was distributed over a much higher percentage of mud and muddy sand bottom than dredges and also ranked higher than dredges on sand and gravel and about the same as scallop dredges on gravelly sand. Trawling activity was extensively distributed over all five sediment types in the GOM, GB, and SNE regions (Figure 251). In the mid-Atlantic region, a much smaller proportion of sand and gravelly sand was trawled and no trawling was reported in the very small amount of gravel present in this region.

Otter trawls are used in the mid-Atlantic to harvest scallops. The primary fishing ground (not shown) is located along the shelf break between 37° and 40° N latitude on sandy bottom. They are also used to harvest pandalid shrimp in the Gulf of Maine and penaeid shrimp in North Carolina. Shrimp trawling takes place mostly in coastal and estuarine waters.

9.3.1.2.3.4.5 Scallop Dredges

Scallop dredging in federal waters in the Northeast region during 1995-2001 accounted for less than half as many days absent as bottom trawling, but nearly ten times more time at sea than was spent dredging with hydraulic clam dredges (Figure 250). Portions of the three areas on GB that were closed in 1995 to all bottom-tending gears capable of catching groundfish (including scallop dredges) were opened to scallop dredges in 1999 and 2000. (These areas were therefore included in the spatial calculations of scallop dredging activity for the whole time period). Scallop dredging during 1995-2001 was reported in TMS along the eastern Maine coast, in the extreme southwestern "corner" of the GOM north of Cape Cod, along the western side of the Great South Channel, along the northern edge of GB and on its southeastern flank, and in a very large continuous area reaching from the eastern end of Long Island south across the shelf and in outer shelf waters as far south as the North Carolina border (Figure 245). Large expanses of bottom area in the outer GOM, on the top of GB, in SNE, and in inner shelf waters of the mid-Atlantic did not support any scallop dredging at the 50-90% activity levels. Unlike bottom trawling, scallop dredging was almost completely confined to depths shallower than 50 fathoms. Analysis of VTR data by sub-region showed that about half of the reported scallop dredging days at sea were in the MA region, about 30% in the GB region (the same proportion as for trawls), 10% in SNE, and 5% or less in the GOM (Figure 250). Expressed as a percentage of the total area included within the 90% TMS in each region, the MA region again ranked first, followed by GB, SNE, and the GOM, as before.

Scallop dredging was confined mostly to sandy substrates in the mid-Atlantic region, was common on sand, gravel, and gravelly sand on GB, and (apparently) on mud and sand bottom areas in the GOM (Figure 250 and Figure 251). Large areas of sand in shallower water on GB, and sand, muddy sand, and mud in SNE were not dredged during 1995-2001. Throughout the NE region, scallop dredging was reported for TMS that included a high proportion of sand and very low proportions of any other sediment type (Figure 252). In the two sub-regions where most scallop dredging occurred (GB and mid-Atlantic), fishing was increasingly more common on coarser substrates (Figure 251). The same trend was observed for the entire Northeast region (Figure 250). In the GOM, a very low percentage of mud in the entire region was dredged; sand ranked the highest, with intermediate values for muddy sand, gravelly sand and gravel. In SNE, only sand and gravelly sand supported any significant amount of scallop dredging.

9.3.1.2.3.4.6 Hydraulic Clam Dredges

Fishing activity by hydraulic clam dredge vessels was compiled as time spent fishing and so could not be directly compared with time at sea for scallop dredge and bottom trawl vessels. Nevertheless, clam dredging activity was clearly less intensive during 1995-2001 than for either of the other two major types of mobile gear (Figure 250). The area represented by TMS that accounted for 90% of the total clam dredging activity was about half the area where most scallop dredging was reported and one-fourth the area where most bottom trawling was reported. Hydraulic dredging accounted for a higher percentage of days fished and area in the mid-Atlantic region than in SNE. Hydraulic dredges were used in a larger percentage of SNE than scallop dredges, and a smaller percentage of the mid-Atlantic. Hydraulic clam dredging took place in SNE and the mid-Atlantic, generally in shallower shelf waters than scallop dredging and trawling. A cluster of TMS off the New Jersey coast was heavily fished, as were other TMS further out toward the edge of the shelf, south of Long Island, and in SNE waters (Figure 246). Clam dredges do not operate on GB because ocean quahogs on the bank contain red tide-causing micro-organisms and can not be harvested. Hydraulic clam dredging is restricted to sandy and muddy sand substrates because the gear can be damaged in hard bottom areas (NREFHSC 2002). For this reason, hydraulic dredges are not used in the GOM.

Like the other two mobile gears, hydraulic dredges were used primarily on sandy bottom in the NE region (Figure 252). Relative to the amount of each sediment type available in the NE region, hydraulic dredges were used more on sand and gravelly sand than on gravel and muddy sand. Sand and gravelly sand were more extensively dredged than muddy sand in SNE and gravel and gravelly sand more extensively than sand and muddy sand in the MA region (Figure 251).

GOM = Gulf of Maine, GB = Georges Bank, SNE = southern New England, and MA = Mid-Atlantic.

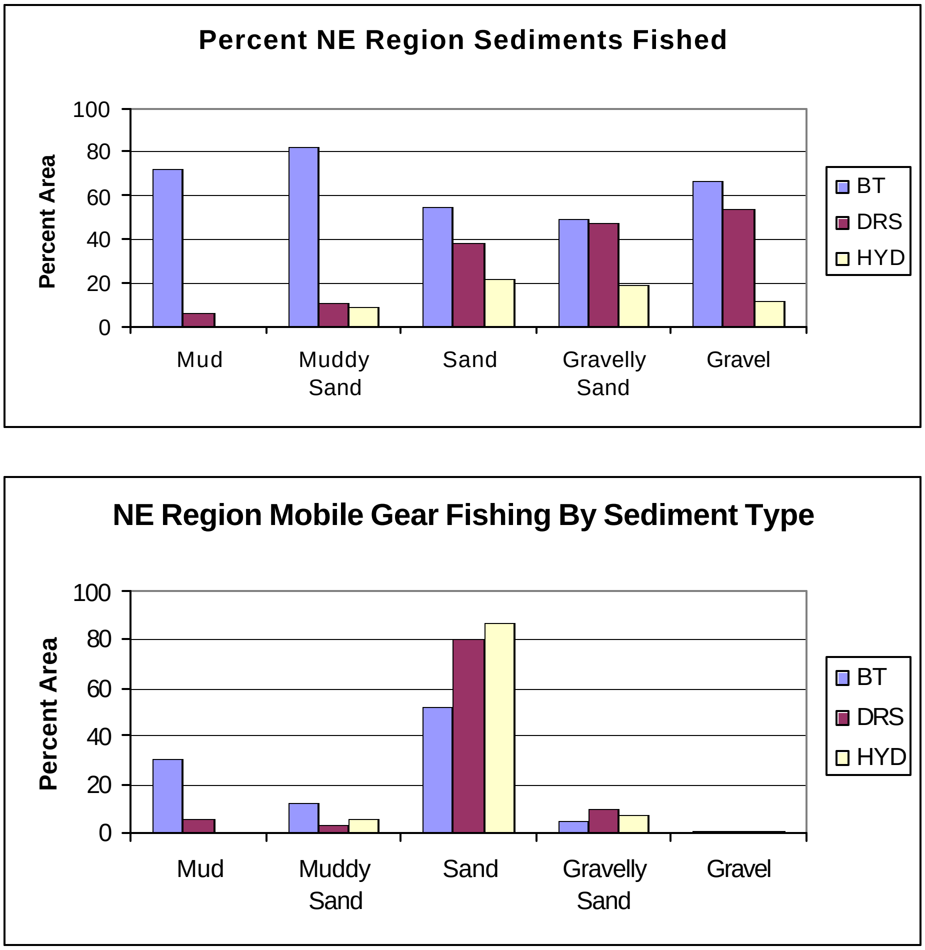

Figure 252 - Percent area by sediment type and percent area of each sediment type present that was included in ten minute squares that accounted for 90% of total fishing activity by bottom trawls, scallop dredges, and hydraulic clam dredges during 1995-2001 in the U.S. Northeast region.

9.3.1.2.4 Types of Gear Effects

9.3.1.2.4.1 Overview of Existing Information

A number of authors have reviewed, to varying extents, existing scientific literature on the effects of fishing on habitat (e.g., Auster et al. 1996, Cappo et al. 1998, Collie 1998, Jennings and Kaiser 1998, Rogers et al. 1998, Auster and Langton 1999, Hall 1999, Collie et al. 2000, Lindeboom and de Groot 2000, Barnette 2001, National Research Council 2002). The following summary of the conclusions reached by these authors is extracted from a recent NOAA report (Johnson 2002).

A number of review papers have focused specifically on the physical effects of bottom trawls. In Europe, an ICES working committee (ICES 1973) concluded that otter trawls, beam trawls and dredges all have similar effects on the seabed, but the magnitude of disturbance increases from shrimp to beam trawls with tickler and stone guards, to Rapido trawls, to mollusc (e.g., scallop) dredges. Kaiser et al. (1996) and Collie et al. (2000) state that, because beam trawls are used almost exclusively in areas that are adapted to frequent wave/tidal action, they are less likely to adversely affect bottom habitats. As mentioned elsewhere in this DEIS, scallop dredges used in Europe and Australia are designed differently than the sweep dredge used in the Northeast region of the U.S. Specifically, they have a row of teeth that penetrate several inches into the bottom and therefore have a greater impact on benthic habitats than the sweep dredge. Beam trawls and Rapido trawls are not used in the U.S. groundfish fishery.

Auster et al. (1996) conducted three studies of mobile fishing gear in the Gulf of Maine and concluded that mobile fishing gear alters the seafloor, and reduces habitat complexity, sedimentary structures, and emergent epifauna. Collie (1998) reviewed studies from New England and concluded that hard bottom benthic habitats (e.g., boulders and gravel pavement) experience significant impacts of mobile bottom-tending fishing gear, while mobile sand habitats are less vulnerable. Jennings and Kaiser (1998) concluded that fishing activities lead to changes in the structure of marine habitats and influence the diversity, composition, biomass, and productivity of the associated biota. They further concluded that these effects vary according to gears used, habitats fished, and the magnitude of natural disturbance, but tend to increase with depth and the stability of the substrate. Auster and Langton (1999) reviewed 22 studies from a wide geographic range and concluded that mobile fishing gear reduces habitat complexity by: (1) directly removing epifauna or damaging epifauna leading to mortality, (2) smoothing sedimentary bedforms and reducing bottom roughness, and (3) removing taxa which produce structure (i.e., taxa which produce burrows and pits). They also concluded that for fixed gear, the area impacted per unit effort is smaller than for mobile gear, but the types of damage to emergent benthos appear to be similar (but not necessarily equivalent per unit effort).

Collie et al. (2000) analyzed 39 published studies to compile and evaluate current findings regarding fishing gear effects on different types of benthic habitat. They found: (1) 89% of the studies were undertaken at depths less than 60 m; (2) otter trawl gear is the most frequently studied; (3) most studies have been done in Northern Europe and Eastern North America. The authors reached several conclusions regarding the effects of fishing: (1) intertidal dredging and scallop dredging have the greatest initial effects on benthic biota, followed by otter trawling and then beam trawling (although beam trawling studies were conducted in dynamic sandy areas, where effects might be less apparent); (2) fauna in stable gravel, mud and biogenic habitats are more adversely affected than those in less consolidated coarse sediments; (3) recovery appears most rapid in less physically stable habitats (inhabited generally by more opportunistic species); (4) we may accurately predict recovery rates for small-bodied taxa, but communities often contain one or two long-lived, vulnerable species; (5) large-bodied organisms are more prevalent before trawling; and (6) the mean initial response to fishing impacts is negative (55% reduction of individual taxa). Based on these findings, the authors suggested that the scientific community abandon short-term small-scale experiments and undertake larger scale experiments that mimic the timing and frequency of disturbance typical of commercial fishing activities.

A working committee of the International Council for the Exploration of the Seas (ICES) issued, in November 2000, a report on the "Effects of Different Types of Fisheries on North Sea and Irish Sea Benthic Ecosystems." This report (ICES 2000) was a summary of findings based on a comprehensive report of the same title edited by Lindeboom and de Groot (1998). The ICES report identified a number of possible effects of beam trawls and bottom otter trawls on benthic habitats and species. Two general conclusions were: 1) low-energy environments are more affected by bottom trawling; and 2) bottom trawling can affect the potential for habitat recovery (i.e., after trawling ceases, benthic communities and habitats may not always return to their original pre-impacted state). Regarding direct habitat effects, the committee concluded that:

<u>Bottom trawls can cause the loss or dispersal of physical features</u> such as peat banks or boulder reefs. These changes are always permanent and lead to an overall change in habitat diversity. This, in turn, can lead to the local loss of species and species assemblages dependant on such features.

<u>Bottom trawling can cause the loss of structure-forming organisms</u> (e.g., colonial bryozoans, Sabellaria, hydroids, seapens, sponges, mussel beds, and oyster beds). These changes may be permanent and can lead to an overall change in habitat diversity. This, in turn, can lead to the local loss of species and species assemblages dependant on such biogenic structures.

<u>Bottom trawling can cause a reduction in complexity</u> by redistributing and mixing surface sediments as well as degrading habitat and biogenic features. This can lead to a decrease in the physical patchiness of the sea floor. These changes are not likely to be permanent.

<u>Bottom trawling can alter the detailed physical structure of the sea floor</u> by reshaping seabed features such as sand ripples and damaging burrows and associated structures. These features provide important habitats for smaller animals and can be used by fish to reduce their energy requirements. These changes are not likely to be permanent.

The committee also identified a number of possible effects of bottom trawling on species.

- Bottom trawling can cause the loss of species from part of their normal range.
- Bottom trawling can cause a decrease in populations which have low rates of turnover.
- The relative abundance of species is altered by bottom trawling.
- Fragile species are more affected by bottom trawling than robust species
- Surface-living species are more affected by bottom trawling than deep-burrowing species.
- Bottom trawling can have sub-lethal effects on individuals.
- Bottom trawling can cause an increase in populations which have high rates of turnover.
- Bottom trawling favors populations of scavenging species.

Direct habitat effects of fishing have also been summarized by Johnson (2002) in four categories: alteration of physical structure, sediment suspension, chemical modifications, and benthic community changes. Most of the effects mentioned below can also be found in the review of the existing gear effects literature that is included in the Gear Effects Evaluation of this SEIS.

Alteration of Physical Structure

Physical effects of fishing gear can include scraping, plowing, burial of mounds, smoothing of sand ripples, removal of stones or dragging and turning of boulders, removal of taxa that produce structure, and removal or shredding of submerged aquatic vegetation (Fonseca et al.1984, Messieh et al. 1991, Black and Parry 1994, Gordon et al. 1998, Kaiser et al. 1998, Lindeboom and de Groot 1998, Schwinghamer et al. 1998, Auster and Langton 1999, Kaiser et al. 1999, Ardizzone et al. 2000). These physical alterations reduce the heterogeneity of the sediment surface, alter the texture of the sediments, and reduce the structure available to biota as habitat. As mobile gear is dragged across the seafloor, parts of some gears can penetrate up to 5-30 cm into the substrate under usual fishing conditions, and likely to greater depths under unusual conditions (Drew and Larsen 1994). This action can leave tracks or even trenches in the seafloor, depending on the sediment type. It is unknown whether or to what extent these human-made features might compensate for the sediment smoothing actions of the gear.

Sediment Suspension

Re-suspension of sediments occurs as fishing gear is dragged along the seafloor. Effects of sediment suspension can include reduction of light available for photosynthetic organisms, burial of benthic biota, smothering of spawning areas, and negative effects on feeding and metabolic rates of organisms. If re-suspension occurs over a large enough area it can actually cause large scale re-distribution of sediments (Messieh et al. 1991, Black and Parry 1994). Re-suspension may also have important implications for nutrient budgets due to burial of fresh organic matter and exposure of deep anaerobic sediment, upward flux of dissolved nutrients in porewater, and change in metabolism of benthic infauna (Mayer et al. 1991, Pilskaln et al. 1998).

Effects of sediment re-suspension are site-specific and depend on sediment grain size and type, water depth, hydrological conditions, faunal influences, and water mass size and configuration (Hayes et al. 1984, LaSalle 1990, Barnes et al. 1991, Coen 1995). Effects are likely more significant in waters that are normally clear compared with areas that are already highly perturbed by physical forces (Kaiser 2000). Schoellhamer (1996) concluded that re-suspension by natural mechanisms in a shallow estuary in west-central Florida was less frequent and of smaller magnitude than anthropogenic mechanisms (e.g., fishing) and that sediments disturbed by fishing were more susceptible to re-suspension by tidal currents. Modeling by Churchill (1989) revealed that re-suspension by trawling is the primary source of suspended sediment over the outer continental shelf of the eastern U.S., where storm-related stresses are weak. In the Kattegat Sea (Sweden), sandy sediments above the halocline were more affected by wind-induced impacts than by fishing, but mud sediments below the halocline experienced an increase in frequency of 90% in the spring and summer and of 75-85% in the autumn and winter due to fishing (Floderus and Pihl 1990). Thus, even when recovery times are fast, persistent disturbance by fishing could lead to cumulative impacts. In contrast, Dyekjaer et al. (1995) found that in Denmark, although local effects of short duration might occur, annual release of suspended particles by mobile fishing gear is relatively unimportant compared with that resulting from wind and land runoff.

Chronic suspension of sediments and resulting turbidity can also affect aquatic organisms through behavioral, sublethal and lethal effects, depending on exposure. Species reaction to turbidity depends on life history characteristics of the species. Mobile organisms can move out of the affected area and quickly return once the disturbance dissipates (Simenstad 1990, Coen 1995). Even if species experience high mortality within the affected area, species with short life history stages and high levels of recruitment or high mobility can repopulate the affected area quickly. However, if effects are protracted and occur over a large area, recovery through recruitment or immigration will be hampered. Furthermore, chronic re-suspension of sediments may lead to shifts in species composition by favoring those species that are better suited to recover or those that can take advantage of the pulsed nutrient supply as nutrients are released from the seafloor to the euphotic zone (Churchill 1989).

Changes in Chemistry
Fishing can produce changes to the chemical makeup of both the sediments and overlying water mass through mixing of subsurface sediments and porewater. In shallow water this mixing might be insignificant in relation to that produced by tidal and storm surge and wave action, but in deeper, more stable waters, this mixing can have significant effects (Rumohr 1998). In a shallow, eutrophic sound in the North Sea, fishing caused an increase in average ammonia content (although horizontal variations prevented interpretations of these increases) and a decrease in oxygen due to the mixing of reduced particles from within the sediments (Riemann and Hoffman 1991). Also in the North Sea, fishing enhances the phosphate released from sediment by 70-380 metric tons per year for otter trawls and by 10,000-70,000 metric tons per year for beam trawlers (ICES 1992). These pulses are partially compensated by lower fluxes after the trawl passes. It is important to remember that these releases recycle existing nutrients, rather than adding new nutrients, such as nutrients derived from rivers and land runoff (ICES 1992). During seasons when nutrients are low, mixing of the sediments could cause increased primary production and/or eutrophication.

Changes to Benthic Communities
Benthic communities are affected by fishing gear through damage to the benthos in the path of the gear and disturbance of the seafloor to a depth of up to 30 cm. Many kinds of epibenthic animals are crushed or buried, while infauna is excavated and exposed on the seabed. This is in addition to smothering addressed above.

Specific impacts from fishing depend on the life history, ecology and physical characteristics of the biota present (Bergman and Van Santbrink 2000). Mobile species that exhibit high fecundities and rapid generation times will recover more quickly than non-mobile, slow-growing organisms. In Mission Bay, California, polychaetes with reduced larval phases and postlarval movements had small-scale dispersal abilities that permitted rapid re-colonization of disturbed patches that maintained high infaunal densities (Levin 1984). Those with long-lived larvae were only available for successful re-colonization if the timing of disturbance coincided with periods of peak larval abundance; however, these species were able to colonize over much larger distances. Rijnsdorp and Van Leeuwen (1996) found that increased growth in the smallest size classes of plaice in the North Sea correlated to eutrophication and seabed disturbance caused by beam trawls. The authors hypothesized that trawling caused a shift in the benthic community from low-productive, long-lived species to high-productive, short-lived species that benefited from increased nutrient availability. This potentially could have led to increased prey availability, and thus, higher growth rates for the juvenile plaice.

The physical structure of biota also affects their ability to sustain and recover from physical impacts with fishing gear. Thin shelled bivalves and starfish show higher damage than solid-shelled bivalves in fished areas (Rumohr and Krost 1991). Animals that are able to retract below the surface of the seafloor or live below the penetration depth of the fishing gear will sustain much less damage than epibenthic organisms that inhabit the sediment surface. Animals that are more elastic and can bend upon contact with fishing gear will suffer much less damage than those that are hard and inflexible (Eno et al. 2001). Kaiser et al. (2000) found that chronic fishing around the Isle of Man, in the Irish Sea, has removed large-bodied fauna such that benthic communities are now dominated by smaller-bodied organisms that are less susceptible to physical disturbance. Off the northwest shelf of Australia, a switch of dominant fish species from lethrinids and lutjanids (which are almost exclusively associated with habitats supporting large epibenthos) to saurids and nemipterids (which were found on open sand) occurred after removal of epibenthic fauna by trawling (Sainsbury et al. 1993, 1994) has been documented.

Increased fishing pressure can also lead to changes in distribution of species, either through movement of animals away from or towards the fished area (Kaiser and Spencer 1993, 1996, Ramsay et al. 1996, Kaiser and Ramsay 1997, Ramsay et al. 1998, Bradshaw et al. 2000, Demestre et al. 2000). Frid and Hall

(1999) found higher prevalence of fish remains and scavengers and a lower abundance of sedentary polychaetes in stomach contents of dabs in the North Sea in areas of higher fishing effort. Kaiser and Spencer (1994) document that gurnards and whiting aggregate over beam trawl tracks and have higher numbers of prey items in their stomachs shortly after trawling. Based on these studies, researchers have speculated that mobile fishing may lead to increased populations of species that exhibit opportunistic feeding behavior. Fonds and Groenewold (2000) modeled results for the southern North Sea indicating that the annual amount of food supplied by beam trawling is approximately 7% of the food demand of common benthic predators. This level could help maintain populations but is insufficient to support further population growth.

The most recent and comprehensive summary of gear effects on benthic marine habitats was prepared by the National Research Council. This report, entitled "Effects of Trawling and Dredging on Seafloor Habitat" (NRC 2002) reiterated four general conclusions regarding the types of habitat modifications caused by trawls and dredges.

- Trawling and dredging reduce habitat complexity.
- Repeated trawling and dredging result in discernable changes in benthic communities.
- Bottom trawling reduces the productivity of benthic habitats.
- Fauna that live in low natural disturbance regimes are generally more vulnerable to fishing gear disturbance.

The NRC report also summarized the indirect effects of mobile gear fishing on marine ecosystems. It did not consider the effects of all gear types, only the two (trawls and dredges) that are considered to most affect benthic habitats. It also provided detailed information from only a few individual studies.
An additional source of information used in this DEIS is the report of a gear effects workshop sponsored by the New England and Mid-Atlantic Fishery Management Councils in October 2001 (NREFHSC 2002). This report includes conclusions reached by a panel of experts on the effect of different gears on benthic habitat types in the Northeast U.S. and is appended to this document (Appendix IV). Refer to the following tables in that report for conclusions on these gear types: Clam Dredges, Scallop Dredges, Otter Trawls, Pots and Traps, and Sink Gill Nets and Bottom Longlines. The results of the workshop have been considered in the next section, which includes a review of the relevant fishing gear effects literature.

9.3.1.2.4.2 Review of Fishing Gear Effects Literature Relevant to the U.S. Northeast Region

Forty-four publications were reviewed for this document. They included all known studies (written in English) that examined the effects of the three principal mobile, bottom-tending fishing gears used in the Northeast U.S. on benthic marine habitats. Only publications that evaluated the direct habitat effects of fishing by these gears were reviewed (i.e., modifications to the physical structure of the seafloor or effects on benthic organisms that live in or on the seafloor). Effects of fishing on resource populations were not included, nor were studies that evaluated the indirect effects of fishing on marine ecosystems caused by the selective removal of species targeted by the gear or which are caught incidentally (as by-catch) during fishing.

Both peer-reviewed and non-peer-reviewed publications were included, but most were peer-reviewed. To be included, accounts of research projects had to be complete and describe methods and results. Abstracts and poster presentations were not included. The summaries in this document are, in all cases, based on primary source documents. Two bottom-tending mobile gear types that are widely used in other parts of the world, but not in the Northeast U.S. – beam trawls and toothed scallop dredges – were not included even though considerable research has been conducted on their habitat effects. Also excluded were studies done on the effects of other gear types used strictly in inshore state waters in habitats where sea scallops are not found (e.g., escalator dredges in submerged aquatic vegetation) and any research relating to fixed and pelagic gear effects. Fixed bottom gears used in the Northeast region (e.g., lobster pots, bottom longlines and gill nets) have minimal impacts on benthic habitats (Eno et al. 2001, NREFHSC 2002).

The review is organized by gear and substrate type. The four substrate types were mud, sand, gravel/rock, and mixed substrate for studies that were conducted in more than a single sediment type. Nine of the 44 studies that were reviewed included information for more than one gear type or for one gear type in more than one substrate or study area and were therefore summarized in more than a single gear/substrate category. Thirty of the 53 individual research accounts were for bottom otter trawls, six were for scallop dredges, and seven for hydraulic dredges. In addition, ten addressed the combined effects of more than one gear type and are referred to as “multiple gears.” Twenty-four of the studies were done in sandy substrate, 11 in mud, 5 in gravel and rocky bottom, and 13 in mixed substrate. Geographically, 18 were conducted in the Northeast U.S. (North Carolina to Maine), 13 elsewhere in North America (U.S. and Canada), 16 in Europe and Scandinavia, and 6 in Australia and New Zealand.

Each gear/substrate category includes a table summarizing the main points of each study. These include the location, depth, sediment, results, recovery information, and methodological approach of each study. Results summarized in the tables include positive and negative results, e.g., increases and decreases in abundance of non-resource benthic organisms caused by fishing, as well as instances when there were no detectable effects of fishing. Blank cells in the recovery column indicate that the study was not designed to provide information on recovery times. Information in the last column includes the nature of the research (experimental or observational), whether or not the study area was being commercially fished at the time of the study, and how the experimental fishing was conducted (single or multiple tows, discrete or repeated disturbance events, and – if known – the average number of tows to which any given area of bottom was exposed).

Results are summarized for all the studies in each gear-substrate category. Each summary begins with an introductory paragraph that includes general information, such as:

- The number of studies that examined physical and biological effects;
- How many studies were done in different geographic areas and depth ranges;
- How many examined recovery of affected habitat features;
- The number of studies performed in areas that were closed to commercial fishing vs. areas that were commercially fished at the time of the study;
- How many involved single vs. multiple tows; and
- How many were conducted either during a single, discrete time period or during a more prolonged period of time that was intended to simulate actual commercial fishing activity.

Physical and biological effects for each gear-substrate category are then summarized in separate paragraphs. When necessary, biological effects are presented separately for single disturbance and repeated disturbance experimental studies, and for observational studies.

9.3.1.2.4.2.1 OTTER TRAWLS

9.3.1.2.4.2.1.1 Otter Trawls – Mud

Results of 11 studies are summarized (Table 395). All of them were conducted during the last 11 years, five in North America, four in Europe, and one in Australia. One was performed in an inter-tidal habitat, one in very deep water (250 m), and the rest in a depth range of 14-90 meters. Seven of them were experimental studies, three were observational, and one was both. Two examined physical effects, six of them assessed biological effects, and three studies examined physical and biological effects. One study evaluated geochemical sediment effects. In this habitat type, biological evaluations focused on infauna: all nine biological assessments examined infaunal organisms and four of them also included epifauna. Habitat recovery was monitored on five occasions. Two studies evaluated the long-term effects of commercial trawling, one by comparing benthic samples from a fishing ground with samples collected near a shipwreck, while another evaluated changes in macrofaunal abundance during periods of low, moderate, and high fishing effort during a 27-year time period. Four of the experimental studies were done in closed or previously un-trawled areas and three in commercially fished areas. One study examined the effects of a single tow and six involved multiple tows, five restricted trawling to a single event (e.g., one day) and two examined the cumulative effects of continuous disturbance.

Physical Effects

Note that citations are numbered and refer to the references listed in Table 395.

Trawl doors produce furrows up to 10 cm deep and berms 10-20 cm high on mud bottom. Evidence from four studies (2,3,7,9) indicates that there is a large variation in the duration of these features (2-18 months). There is also evidence that repeated tows increase bottom roughness (11), fine surface sediments are re-suspended and dispersed (7), and rollers compress sediment (2). A single pass of a trawl did not cause sediments to be turned over (7), but single and multiple tows smoothed surface features (4,7).

Biological Effects

Single disturbance experimental studies

Two single-event studies (2,9) were conducted in commercially trawled areas. Experimental trawling in intertidal mud habitat in the Bay of Fundy (Canada) disrupted diatom mats and reduced the abundance of nematodes in trawl door furrows, but recovery was complete after 1-3 months (2). There were no effects on infaunal polychaetes. In a sub-tidal mud habitat (30-40 m deep), benthic infauna were not affected (9). In two assessments performed in areas that had not been affected by mobile bottom gear for many years (4,10), effects were more severe. In both cases, total infaunal abundance and the abundance of individual polychaete and bivalve species declined immediately after trawling (4,10). In one of these studies (10), there were also immediate and significant reductions in the number of species and species diversity. Positive effects included reduced porosity, increased food value, and increased chlorophyll production in surface sediments. Most of these effects lasted less than 3.5 months. In the other (4), two tows removed 28% of the epifauna on mud and sand substrate and epifauna in all trawled quadrats showed signs of damage. These results were not reported separately for mud bottom.

Repeated disturbance experimental studies

Two studies of the effects of repeated trawling were conducted in areas that had been closed to fishing for six years and >25 years. In one (6), multiple tows were made weekly for a year and, in the other (11), monthly for 16 months. In one case, 61% of the benthic species sampled tended to be negatively affected, but significant reductions were only noted for brittlestars (6). In the other, repeated trawling had no significant effect on the numbers of infaunal individuals or biomass (11). In this study, the number of infaunal species increased by the end of the disturbance period. Some species (e.g., polychaetes) increased in abundance, while others (e.g., bivalves) decreased. Community structure was altered after five months of trawling and did not fully recover until 18 months after trawling ended.

Observational studies

An analysis of benthic sample data collected from a fishing ground over a 27-year period of high, medium, and low levels of fishing effort showed an increased abundance of organisms belonging to taxa that were expected to increase at higher disturbance levels, whereas those that were expected to decrease did not change in abundance (5). Results of another study indicated that a trawling ground had fewer benthic organisms and fewer species than an un-exploited site near a shipwreck (1). Trawling in deep water apparently dislodged infaunal polychaetes, causing them to be suspended in near-bottom water (8).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Ball et al. 2000	Irish Sea	75 m	Sandy silt	Reduced infaunal and epifaunal richness, diversity, number of species and individuals in fishing ground compared to wreck site.		Experimental trawling in heavily fished prawn fishing ground, unfished area near a shipwreck used as control.
2	Brylinsky et al. 1994	Bay of Fundy, , Nova Scotia, Canada	Inter-tidal	Silt and coarse sand overlain with silty layer	Door tracks in sediment, rollers compressed sediment; S decrease in nematodes and benthic diatoms in door tracks, no effects on larger infaunal organisms (mostly polychaetes).	Furrows visible 2-7 months; nematodes recovered in 1-1.5 mos, diatoms in about 1-3 mos.	Four trawling experiments (repeated tows during a single day) at two locations in a trawled area, effects evaluated for 1.5-4 mos.
3	DeAlteris et al. 1999	Narragansett Bay, Rhode Island, USA	14 m	Mud	Doors produced tracks 5-10 cm deep and adjacent berm 10-20 cm high.	No changes in hand dug trenches for > 60 days.	Diver observations
4	Drabsch et al. 2001	Gulf of St. Vincent, South Australia	20 m	Fine silt	Trawl door tracks, smoothing of topographic features, S decrease in total infaunal abundance and one group of polychaetes, damaged epifauna.		Experimental trawling (2 tows per unit area in 1 day) in area with no trawling for 15 years (1 site), effects evaluated after 1 week.

Table 395 - Effects of Otter Trawls on Mud Substrate Habitat: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
5	Frid et al. 1999	NE England (North Sea)	80 m	Silt/clay	S increase in total number of individuals in taxa predicted to increase at high fishing effort and number of errant polychaetes, no effect of increasing effort on total number of individuals expected to decrease, but S decline in sea urchins.		Related changes in benthic fauna in a heavily trawled location to low, high, and moderate fishing activity and changes in phytoplankton production over 27 yrs.
6	Hansson et al. 2000	Fjord on the west coast of Sweden	75-90 m	Clay	61% infaunal species negatively affected and S reductions in brittlestars during last 6 mos of disturbance period, S reductions in total biomass and number of individuals in trawled and control sites, abundance of polychaetes, amphipods and molluscs not affected.		Experimental trawling for 1 year (2 tows per wk, 24 tows per unit area) in area closed to fishing for 6 yrs (3 treatment and 3 control sites), effects evaluated during last 5 mos of experiment.
7	Mayer et al. 1991	Maine coast, USA	20 m	Mud	Dispersal of fine surface sediment, doors made furrows several cm deep, some planing of surface features, but no plowing of bottom or burial of surface sediments.		Experimental trawling (single tow), examined immediate effects on sediment composition and food value to sediment depth of 18 cm.

Table 395 - Effects of Otter Trawls on Mud Substrate Habitat: Summary of Published Studies(cont.)

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
8	Pilskaln et al. 1998	Gulf of Maine (USA)	250 m	Mud	Greater abundance of suspended infaunal polychaetes in more heavily-trawled area.		Deployed sediment traps in fishing grounds 25-35 m above substrate.
9	Sanchez et al. 2000	Coast of Spain, Mediterranean Sea	30-40 m	Mud	Door tracks in sediment, no change in number of infaunal individuals or taxa or abundance of individual taxa, no changes in community structure.	Door tracks still clearly visible after 150 hrs.	Experimental trawling in trawled area at 2 sites swept once and twice in a single day, effects evaluated after 24, 72, 102, and 150 hrs.
10	Sparks-McConkey & Watling 2001	Penobscot Bay, Maine (USA)	60 m	Mud	S decline in porosity, increased food value, and increased chlorophyll production of surface sediments, S reductions in number of infaunal individuals and species, species diversity, and abundances of 6 polychaete and bivalve species, S increase in nemerteans.	All geochemical sediment properties and all but one polychaete/bivalve species recovered within 3.5 mos, nemerteans still more abundant after 5 mos.	Experimental trawling (4 tows in 1 day) in untrawled area, pre-trawl sampling of sediments and infauna for a year, recovery monitored for 5 mos.

Table 395 - Effects of Otter Trawls on Mud Substrate Habitat: Summary of Published Studies(cont.)

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
11	Tuck et al. 1998	West coast of Scotland	30-35 m	Fine silt	Tracks in sediment, increased bottom roughness, no effect on sediment characteristics; S increase in number of infaunal species after 16 mos and during 18 mo recovery period, no change in biomass or number of individuals; S increase in polychaetes, decrease in bivalves; S alteration in community structure after 5 mos, S reduction in diversity during first 22 mos.	Door tracks still evident after 18 months, bottom roughness recovered after 6 mos; nearly complete recovery of infaunal community within 12 mos, complete after 18 mos	Experimental trawling for 1 day/mo (1.5 tows per unit area) for 16 mos in area closed to fishing for >25 years, recovery monitored after 6, 12, and 18 mos

Table 395 - Effects of Otter Trawls on Mud Substrate Habitat: Summary of Published Studies(cont.)

9.3.1.2.4.2.1.2 Otter Trawls – Sand

Results of 14 studies are summarized (Table 396). One of them was described in a 1980 publication, all the rest have been published since 1998. Six studies were conducted in North America (three in a single long-term experiment on the Grand Banks), four in Australia, and four in Europe. Ten are experimental studies. Eight of them were done in depths less than 60 m, one at 80 m, and four in depths greater than 100 m. Three studies examined the physical effects of trawling, ten were limited to biological effects, and one examined both. Five of the biological studies were restricted to epifauna, one only examined infauna, and five included epifauna and infauna. The only experiment that was designed to monitor recovery was the one on the Grand Banks, although surveys conducted in Australia documented changes in the abundance of benthic organisms five years after closed areas were established. Two studies compared benthic communities in trawled areas of sandy substrate with undisturbed areas near a shipwreck. Six studies were performed in commercially exploited areas, five in closed areas, two compared closed and open areas, and one was done in a test tank. All the experimental studies examined the effects of multiple tows (up to 6 per unit area of bottom) and observational studies in Australia assessed the effects of 1-4 tows on emergent epifauna. Trawling in four studies was limited to a single event (1 day to 1 week), whereas the Grand Banks experiment was designed to evaluate the immediate and cumulative effects of annual 5-day trawling events in a closed area over a three-year period.

Physical effects

A test tank experiment showed that trawl doors produce furrows in sandy bottom that are 2 cm deep, with a berm 5.5 cm high (7). In sandy substrate, trawls smoothed seafloor topographic features (4,14), re-suspended and dispersed finer surface sediment (7), but had no lasting effects on sediment composition (14). Trawl door tracks lasted up to one year in deep water (14), but only for a few days in shallow water (3). Seafloor topography recovered within a year (14).

Biological effects

Single disturbance experimental studies

Two single-event studies (2,6) were conducted in commercially trawled areas. In one of these studies (2), otter trawling caused high mortalities of large sedentary and/or immobile epifaunal species. In the other (6), there were no effects on benthic community diversity. Neither of these studies investigated effects on total abundance or biomass. Two studies were performed in un-exploited areas. One study documented effects on attached epifauna. In one (11), single tows reduced the density of attached macrobenthos (>20 cm) by 15% and four tows by 50%. In the other (4), two tows removed 28% of the epifauna on mud and sand substrate and epifauna in all trawled quadrats showed signs of damage. These results were not reported separately for sand bottom. Total infaunal abundance was not affected, but the abundance of one family of polychaetes was reduced.

Repeated disturbance experimental studies

Intensive experimental trawling on the Grand Banks reduced the total abundance and biomass of epibenthic organisms and the biomass and average size of a number of epibenthic species (12). Significant reductions in total infaunal abundance and the abundance of 15 taxa (mostly polychaetes) were detected during only one of three years, and there were no effects on biomass or taxonomic diversity (9).

Observational studies

Changes in macrofaunal abundance in a lightly trawled location in the North Sea were not correlated with historical changes in fishing effort (5), but there were fewer benthic organisms and species in a trawling ground in the Irish Sea than in an un-exploited site near a shipwreck (1). In the other "shipwreck study," however, changes in infaunal community structure at increasing distances from the wreck were related to changes in sediment grain size and organic carbon content (8). The Alaska study (10) showed that epifauna attached to sand were less abundant inside a closed area, significantly so for sponges and anemones. A single tow in a closed area in Australia removed 89% of the large sponges in the trawl path (13).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Ball et al. 2000	Irish Sea	35 m	Muddy sand	Lower number of infaunal and epifaunal species and individuals, species diversity and richness compared to wreck site.		Experimental trawling in heavily fished prawn fishing ground, unfished area near a shipwreck used as control.
2	Bergman and Santbrink 2000	Southern North Sea (Dutch coast)	<30-50 m	Silty sand and sand	High (20-50%) mortalities for 6 sedentary and/or immobile megafaunal (>1 cm) species, <20% for 10 others, from a single pass of the trawl, S effects on 11 of 54 occasions.		Experimental trawling (1.5 tows per unit area) in commercially trawled area, effects assessed after 24-48 hrs.
3	DeAlteris et al. 1999	Narragansett Bay, Rhode Island (USA)	7 m	Sand	No tracks.	Hand dug trenches not visible after 1-4 days.	Diver observations.
4	Drabsch et al. 2001	Gulf of St. Vincent, South Australia	20 m	Coarse sand with shells.	Trawl door tracks, smoothing of topographic features, removal of and damage to epifauna, no S effects on total infaunal abundance, S reduction in density for one family of polychaetes after 1 week.		Experimental trawling (2 tows per unit area) in area with no trawling for 15 years, effects assessed after 1 week (site 1) and 3 mos (site 2).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
5	Frid et al. 1999	NE England (North Sea)	55 m	Sand	Total abundance of benthic macrofauna increased as phytoplankton abundance increased, no correlation with fishing effort.		Related changes in benthic fauna in a lightly trawled location to low, high, and moderate fishing activity and changes in phytoplankton production over 27 yrs.
6	Gibbs et al. 1980	Botany Bay, New South Wales, Australia	Shallow estuary	Sand with 0-30% silt/clay	Sediment plume, no consistent effects on benthic community diversity, very little disturbance of seafloor.		Sampling before, immediately after, and 6 mos after 1 week of experimental trawling in fished location, control area located 200 km away.
7	Gilkinson et al. 1998	Test tank to simulate Grand Banks of Newfoundland		Sand	Trawl door created 5.5 cm berm adjacent to 2 cm furrow, bivalves displaced.		Observed effects of commercial otter door model in test tank.
8	Hall et al. 1993	North Sea	80 m	Coarse sand	Abundance of infauna related to changes in sediment type and organic content, not distance from shipwreck.		Sampled infauna at increasing distance from a shipwreck (proxy for increasing fishing effort).

Table 396 - Effects of Otter Trawls on Sand Substrate Habitat: Summary of Published Studies(cont.)

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
9	Kenchington et al. 2001	Grand Banks, Newfoundland	120-146 m	Fine to medium grain sand	S short-term reductions in total abundance and abundance of 15 infaunal taxa (mostly polychaetes) in only 1 of 3 years , no short-term effects on biomass or taxonomic diversity, no long-term effects.	Infaunal organisms that were reduced in abundance in 1994 had recovered a year later.	Experimental trawling (3-6 tows per unit area) in closed area 1, 2 and 3 years after closure, lightly exploited for >10 yrs, effects evaluated within several hrs or days after trawling and after one year.
10	McConnaughey et al. 2000	Eastern Bering Sea, Alaska	44-52 m	Sand with ripples	Reduced abundance (S for sponges and anemones), more patchy distribution, and S decrease in species diversity of sedentary epifauna, mixed responses of motile taxa and bivalves.		Compared abundance of epifauna caught in small-mesh trawl inside and outside an area closed to trawling for almost 40 years.
11	Moran & Stephenson 2000	Northwest Australia	50-55 m	Not given, presumed to be sand	Single tow reduced density of macrobenthos (>20 cm) by 15%, 4 tows by 50%.		Video surveys before and after 4 experimental trawling events (1 tow per unit area) at 2-day intervals in unexploited area.

Table 396 - Effects of Otter Trawls on Sand Substrate Habitat: Summary of Published Studies(cont.)

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
12	Prena et al. 1999	Grand Banks, Newfoundland	120-146 m	Fine to medium grain sand	24% average decrease in epibenthic biomass, S reductions in total and mean individual epifaunal biomass and biomass of 5 of 9 dominant species, damage to echinoderms.		Experimental trawling (3-6 tows per unit area) in closed area 1, 2 and 3 years after closure, lightly exploited for >10 yrs.
13	Sainsbury 1997	Northwest Australia	< 200 m	Calcareous sands	Decreased abundance of benthic organisms and fish associated with large epifauna, removal of attached epifauna (single tow removed 89% of sponges >15 cm).	Increased catch rates of fish associated with large epifauna and small (<25 cm) benthos within 5 yrs, recovery of large epifauna takes >5 yrs.	Compared historical survey data (before and after fishing started) to data collected in area that remained open to commercial trawlers and area closed for 5 years.
14	Schwinghamer et al. 1998	Grand Banks, Newfoundland	120-146 m	Fine and medium grain sand	Tracks in sediment, increased bottom roughness, sediment re-suspension and dispersal, smoothing of seafloor and removal of flocculated organic material, organisms and shells organized into linear features.	Tracks last up to 1 year, recovery of seafloor topography within 1 year.	Experimental trawling (3-6 tows per unit area) in closed area 1, 2 and 3 years after closure, lightly exploited for >10 yrs.

9.3.1.2.4.2.1.3 Otter Trawls – Gravel/Rocky Substrate

Three studies of otter trawl effects on gravel and rocky substrates are summarized in this report (Table 397). All three were conducted in North America. Two were done in glacially-affected areas in depths of about 100 to 300 meters using submersibles and the third was done in a shallow coastal area in the southeast U.S. One involved observations made in a gravel/boulder habitat in two different years before and after trawling affected the bottom. The other two were experimental studies of the effects of single trawl tows. One of these was done in a relatively un-exploited gravel habitat and the other on a smooth rock substrate in an area not affected by trawling. Two studies examined effects to the seafloor and on attached epifauna and one only examined effects on epifauna. There were no assessments of effects on infauna. Recovery was evaluated in one case for a year.

Physical effects

Trawling displaced boulders and removed mud covering boulders and rocks (1) and rubber tire ground gear left furrows 1-8 cm deep in less compact gravel sediment (2).

Biological effects

Trawling in gravel and rocky substrate reduced the abundance of attached benthic organisms (e.g., sponges, anemones, and soft corals) and their associated epifauna (1,2,3) and damaged sponges, soft corals, and brittle stars (2,3). Sponges were more severely damaged by a single pass of a trawl than soft corals, but 12 months after trawling all affected species – including one species of stony coral – had fully recovered to their original abundance and there were no signs of damage (3).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Auster et al. 1996	Gulf of Maine (Jeffreys Bank)	94 m	Gravel/boulder with thin mud veneer.	Gravel base exposed, boulders moved, reduced abundance of erect sponges and associated epifaunal species.		Submersible and video observations in same location in 1987 and 1993, changes attributed to trawling.
2	Freese et al. 1999	Gulf of Alaska	206-274 m	93% pebble, 5% cobble, 2% boulder.	Boulders displaced, groundgear left furrows 1-8 cm deep in less compact sediment, layer of silt removed, S reductions in abundance of sponges, anemones, and sea whips, damage to sponges, sea whips and brittle stars.		Video observations from a submersible 2-5 hr after single trawl tows in area exposed to little or no commercial trawling for about 20 years.

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
3	Van Dolah et al. 1987	Georgia, SE U.S. coast	20 m	Smooth rock with thin layer of sand and attached epifauna.	Reduced abundance of and damage to large sponges and soft corals, esp barrel sponges and stick corals; no S effects on abundance of vase/finger sponges, or stony corals.	Full recovery of damaged organisms and abundance within 12 mos.	Experimental study using diver counts of large sponges and corals before, immediately after, and 12 mos after a single trawl tow in an un-exploited area.

Table 397 - Effects of Otter Trawls on Gravel/Rock Substrate Habitat: Summary of Published Studies

9.3.1.2.4.2.1.4 Otter Trawls – Mixed Substrates

Three studies of the effects of otter trawls on mixed substrates are summarized (Table 398). All three were conducted in North America and relied on sonar and observations made by divers or from a submersible. One of them (2) combined submersible observations and benthic sampling to compare the physical and biological effects of trawling in a lightly fished and heavily fished location in California with the same depth and variety of sediment types. One was a survey of seafloor features produced by trawls in a variety of bottom types (1) and the other primarily examined the physical effects of single trawl tows on sand and mud bottom (3).

Physical effects

Trawl doors left tracks in sediments that ranged from less than 5 cm deep in sand to 15 cm deep in mud (1,3). In mud, fainter marks were also made between the door tracks, presumably by the footgear (1). A heavily trawled area had fewer rocks, shell fragments, and biogenic mounds than a lightly trawled area (2).

Biological effects

The heavily trawled area in California had lower densities of large epifaunal species (e.g., sea slugs, sea pens, starfish, and anemones) and higher densities of brittle stars and infaunal nematodes, oligochaetes, and one species of polychaete (2). There were no differences in the abundance of molluscs, crustaceans, or nemerteans between the two areas. However, since this was not a controlled experiment, these differences could not be attributed to trawling. Single trawl tows in Long Island Sound attracted predators and suspended epibenthic organisms into the water column (3).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Canadian DFO 1993	Bras d'Or Lakes, Nova Scotia (Canada)	10-500 m	Mud, sand, gravel, and boulders	Trawl doors left parallel marks (furrows and berms), fainter marks from footgear, primarily in mud.		Side scan sonar survey after area was closed to mobile gear for 1 yr.
2	Engel and Kvitek 1998	California (USA)	180 m	Gravel, sand, silt, and clay	S fewer rocks, shell fragments, rocks and mounds in HT area; lower densities of large epibenthic taxa in HT area (S for seapens, seastars, anemones, and sea slugs), higher densities of nematodes, oligochaetes, brittlestars and one species of polychaete in HT area, no differences between areas for crustaceans, molluscs, or nemerteans.		Used a submersible and grab samples (3 yrs) to compare lightly trawled (LT) and heavily trawled (HT) commercial fishing sites with same sediments and depth.
3	Smith et al. 1985	Long Island Sound, New York (USA)	Not given	Sand and mud	Tracks in sediment (<5 cm in sand, 5-15 cm in mud), attraction of predators, suspension of epibenthic organisms.	Tracks "naturalized" by tidal currents.	Video and diver observations.

9.3.1.2.4.2.2 NEW BEDFORD SCALLOP DREDGES

9.3.1.2.4.2.2.1 New Bedford Scallop Dredges – Sand

Three studies of the effects of New Bedford scallop dredges on sand substrate are summarized, all performed since 1990 (Table 399). One was conducted in an estuary on the Maine coast (3) and two on offshore banks in the Gulf of Maine (1,2). Two of them were observational in nature, but did not include any direct observations of dredge effects. The other one was a controlled experiment conducted in an unexploited area in which a single dredge was towed repeatedly over the same area of bottom during a single day. One study examined physical effects and two examined physical and biological effects. One of them included an analysis of geochemical effects to disturbed silty-sand sediments.

Physical effects

Dredging disturbed physical and biogenic benthic features (sand ripples and waves, shell deposits [1], and amphipod tube mats [2]), caused the loss of fine surficial sediment (3), and reduced the food quality of the remaining sediment (3). Sediment composition was still altered six months after dredging, but the food quality of the sediment had recovered by then.

Biological effects

There were significant reductions in the total number of infaunal individuals in the estuarine location immediately after dredging and reduced abundances of some species (particularly one family of polychaetes and photid amphipods), but no change in the number of taxa (3). Total abundance was still reduced four months later, but not after six months. The densities of two megafaunal species (a tube-dwelling polychaete and a burrowing anemone) on an offshore bank were significantly reduced after commercial scallop vessels had worked the area (2).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Auster et al. 1996	Stellwagen Bank, Gulf of Maine (USA)	20-55 m	Coarse sand	Disturbance of storm sand ripples and low sand waves, dispersal of shell deposits in wave troughs.		Examined gear tracks in side-scan sonar images.
2	Langton & Robinson 1990	Fippennies Ledge, Gulf of Maine (USA)	80-100 m	Gravelly sand with some gravel, shell hash, and small rocks	Coarser substrate, disruption of amphipod tube mats, piles of small rocks and scallop shells dropped from surface, S reductions in densities of tube dwelling polychaete and burrowing anemone.		Submersible observations made two years apart, before and after commercial dredging of area.
3	Watling et al. 2001	Damariscotta River, Maine (USA)	15 m	Silty sand	Loss of fine surficial sediments, lowered food quality of sediment, reduced abundance of some taxa, no changes in number of taxa, S reductions in total number of individuals 4 mos after dredging.	No recovery of fine sediments, full recovery of benthic fauna and food value within 6 mos.	Experimental study (23 tows in one day), effects on macrofauna (mostly infauna) evaluated 1 day and 4 and 6 mos after dredging.

Table 399 - Effects of New Bedford Scallop Dredges on Sand Habitat: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

9.3.1.2.4.2.2.2 New Bedford Scallop Dredges - Mixed Substrates

Three studies have been conducted on mixed glacially-derived substrates, two of them over 20 years ago and one 10 years ago (Table 400). All were done in the northwest Atlantic (one in the U.S. and two in Canada) at depths of 8 to 50 m. Two observational studies examined physical effects and one experimental study examined effects on sediment composition to a sediment depth of 9 cm. The experimental study evaluated the immediate effects of a single dredge tow. None of these studies evaluated habitat recovery or biological effects, although one (3) examined geochemical effects.

Physical effects

Direct observations in dredge tracks in the Gulf of St. Lawrence documented a number of physical effects to the seafloor, including bottom features produced by dredge skids, rings in the chain bag, and the tow bar (1,2). Gravel fragments were moved and overturned and shells and rocks were dislodged or plowed along the bottom (2). Sampling one day after a single dredge tow revealed that surficial sediments were re-suspended and lost and that the dredge tilled the bottom, burying surface sediments and organic matter to a depth of 9 cm, increasing the grain size of sediments above 5 cm, and disrupting a surface diatom mat (3). Microbial biomass at the sediment surface increased as a result of dredging.

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Caddy 1968	Northumberland Strait, Gulf of St. Lawrence, Canada	20 m	Mud and sand	Drag tracks (3 cm deep) produced by skids, smooth ridges between them produced by rings in drag belly, dislodged shells in dredge tracks.		Diver observations of physical effects of two tows.
2	Caddy 1973	Chaleur Bay, Gulf of St. Lawrence, Canada	40-50 m	Gravel over sand, with occasional boulders	Suspended sediment, flat track, marks left by skids, rings and tow bar, gravel fragments less frequent (many overturned), rocks dislodged or plowed along bottom.		Submersible observations of tow tracks made less than 1 hr after single dredge tows.
3	Mayer et al. 1991	Coastal Gulf of Maine (USA)	8 m	Mud, sand and shell hash	Lowered sediment surface by 2 cm,injection of organic matter and finer sediment into lower 5-9 cm, increased mean grain size in upper 5 cm, disruption of surface diatom mat, increased microbial biomass at sediment surface.		Experimental study, compared dragged and undragged sites before and 1day after a single dredge tow.

Table 400 - Effects of New Bedford Scallop Dredges on Mixed Substrate Habitat: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

9.3.1.2.4.2.3 Hydraulic Clam Dredges

9.3.1.2.4.2.3.1 Hydraulic Clam Dredges – Sand

Results of six hydraulic dredge studies in sandy substrates are summarized (Table 401). Five of them (2-6) examined the effects of "cage" dredges of the type used in the Northeast region of the U.S. and one (1) examined the effects of escalator dredges, which affect sandy bottom habitats similarly to "cage" dredges. Three of them were published prior to 1990, and three since then. Three were performed in North America (two in the U.S. and one in Canada), one in the Adriatic Sea and two in Scotland. There have been no published studies in North America since 1982. One of the North American studies was conducted on the U.S. continental shelf at a depth of 37 m and two in near shore waters and depths of 7 – 12 m. The two European studies were done in even shallower water (1.5 – 7 m). The North American studies were all observational in nature and the European studies were controlled experiments. One study compared effects in commercially dredged and un-dredged areas and four were conducted in un-dredged areas. The sixth study compared infaunal communities in an actively dredged, a recently dredged, and an un-dredged location off the New Jersey coast. All six studies examined physical and biological effects of dredging. Recovery was evaluated in four cases for periods ranging from just a few minutes (sediment plumes) to 11 weeks.

Physical effects

Hydraulic clam dredges created steep-sided trenches 8-30 cm deep that started deteriorating immediately after they were formed (1, 3-6). Trenches in a shallow, inshore location with strong bottom currents filled in within 24 hours (4). Trenches in shallow, protected, coastal lagoons were still visible two months after they were formed (5). Hydraulic dredges also fluidized sediments in the bottom and sides of trenches (6), created mounds of sediment along the edges of the trench (6), re-suspended and dispersed fine sediment (4), and caused a re-sorting of sediments that settled back into trenches (2). In one study (6), sediment in the bottom of trenches was initially fluidized to a depth of 30 cm and in the sides of the trench to 15 cm. After 11 weeks, sand in the bottom of the trench was still fluidized to a depth of 20 cm. Silt clouds only last for a few minutes or hours (3,4). Complete recovery of seafloor topography, sediment grain size, and sediment water content was noted after 40 days in a shallow, sandy environment that was exposed to winter storms (1).

Biological effects

Some of the larger infaunal organisms (e.g., polychaetes, crustaceans) retained on the wire mesh of the conveyor belt used in an escalator dredge, or that drop off the end of the belt, presumably die (1). Benthic organisms that are dislodged from the sediment, or damaged by the dredge, temporarily provided food for foraging fish and invertebrates (1,4). Hydraulic dredging caused an immediate and significant reduction in the total number of infaunal organisms in two studies (1,6) and in the number of macrofaunal organisms in a third study (5). There were also significant reductions in the number of infaunal species in one case (6) and in the number of macrofaunal species and biomass in another (5). In this study (5), polychaetes were most affected. One study failed to detect any reduction in the abundance of individual taxa (1). Evidence from the study conducted off the New Jersey coast indicated that the number of infaunal organisms and species, and species composition, were the same in actively dredged and un-dredged locations (2).

Recovery times for infaunal communities were estimated in three studies. All of them (1,5,6) were conducted in very shallow (1.5-7 m) water . Total infaunal abundance and species diversity had fully recovered only five days after dredging in one location where tidal currents reach maximum speeds of three knots (6). Some species had recovered after 11 weeks. Total abundance recovered 40 days after dredging in another location exposed to winter storms, when the site was re-visited for the first time (1). Total infaunal abundance (but not biomass) recovered within two months at a protected, commercially exploited site (5), where recovery was monitored at three-week intervals for two months, but not at a nearby, unexploited site. The actual recovery time at the exposed sub-tidal site (1) was probably much quicker than 40 days, the only point in time when the post-experimental observations were made.

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Hall et al. (1990)	Scotland	7 m	Fine sand	Shallow trenches (25 cm deep) and large holes, sediment "almost fluidized," S increase in median grain size in trenches, S reductions in numbers of infaunal organisms, no effect on abundance of individual species, some mortality (not assessed) of large polychaetes and crustacea retained on conveyor belt or returned to sea surface.	Complete recovery of physical features and benthic community after 40 days, filling of trenches and holes accelerated by winter storms.	Experimental study in unexploited area to evaluate effects of commercial escalator dredging activity, recovery evaluated after 40 days.
2	MacKenzie, 1982	Southern New Jersey (USA)	37 m	Very fine to medium sand	Re-sorting of sediments, no effect on number of infaunal individuals or species, or on species composition.		Comparison of actively fished, recently fished and never fished areas on the continental shelf.
3	Medcof & Caddy 1971	Southern Nova Scotia (Canada)	7-12 m	Sand and sand-mud	Smooth tracks with steep walls, 20 cm deep; sediment cloud.	Sediment plume lasted 1 minute; dredge tracks still clearly visible after 2-3 days.	SCUBA & submersible observations of the effects of individual tows.
4	Meyer et al. 1981	Long Island, New York (USA)	11 m	Very fine to medium sand	>20 cm deep trench, mounds on either side of trench, silt cloud, attraction of predators.	Trench nearly indistinct, predator abundance normal after 24 hours; silt settled in 4 minutes.	SCUBA observations following a single tow in a closed area, effects evaluated after 24 hrs.

Table 401 - Effects of Hydraulic Clam Dredges on Sand Substrate Habitat: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

5	Pranovi & Giovanardi 1994	Adriatic Sea (Italy)	1.5-2 m	Sand	8-10 cm deep trench; S decrease in total abundance, biomass, and diversity of benthic macrofauna in fishing ground; no S effects outside fishing ground.	After 2 mos, dredge tracks still visible, densities (especially of small species and epibenthic species) in fishing ground recovered, biomass did not.	Experimental dredging (single tow) in previously dredged and undredged areas in coastal lagoon, recovery monitored every 3 weeks for 2 mos.
6	Tuck et al. 2000	Outer Hebrides, Scotland	2-5 m	Medium to fine sand	Steep-sided trenches (30 cm deep), sediments fluidized up to 30 cm, S decrease in total abundance and number of infaunal species, polychaetes most affected.	Trenches no longer visible but sand still fluidized after 11 weeks, species diversity and total abundance recovered within 5 days, abundance of some species recovered after 11 weeks.	Experimental dredging (individual tows at 6 sites) in area closed to commercial dredging, recovery evaluated after 11 weeks.

Table 401 - Effects of Hydraulic Clam Dredges on Sand Substrate Habitat: Summary of Published Studies(cont.)

9.3.1.2.4.2.3.2 Hydraulic Clam Dredges - Mixed Substrates

An in situ evaluation of hydraulic dredge effects in sand, mud, and coarse gravel in the mid-Atlantic Bight indicated that trenches fill in quickly, within several days in fine sediment and more rapidly than that in coarse gravel (Table 402). Dredging dislodged benthic organisms from the sediment, attracting predators.

Reference	Location	Depth	Sediment	Effects	Recovery	Approach
Murawski & Serchuk 1989	Mid-Atlantic Bight, USA	Not given	Sand, mud and coarse gravel	Trench cut, temporary increase in turbidity, disruption of benthic organisms in dredge path, attraction of predators.	Trenches filled quickly in coarse gravel, but took several days in fine sediments.	Submersible observations following hydraulic cage dredge tows.

Table 402 - Effects of Hydraulic Clam Dredges on Mixed Substrate Habitat: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

9.3.1.2.4.2.4 Multiple Gear Types

9.3.1.2.4.2.4.1 Multiple Gear Types – Sand

The results of a single observational study of multiple gear types on sand habitats (at depths that varied from 15 to 70 m) are summarized in this report (Table 403). This study (2) compared sandy shallow and deep water sites on the south coast of England that were exposed to low, medium, and high levels of fishing effort by mobile and fixed gear. Low effort areas that were closed to trawls and dredges had more emergent epifauna (soft corals and hydroids) and were dominated by relatively high-biomass epifauna and infauna, whereas high effort areas fully exposed to fixed and mobile gear had higher abundances of small-bodied organisms. Deep (53-70 m) coarse-medium sand offshore sites were more affected by fishing than deep, medium sand or shallow (15-17 m), inshore, fine sand sites.

Reference	Location	Depth	Sediment	Effects	Recovery	Approach
Kaiser et al. 2000b	England (South Devon Coast)	15-70 m	Fine, medium, and coarse sand	No S effect of high fishing effort on numbers of infaunal or epifaunal species or individuals; reduced abundance of larger, less mobile, and emergent epifauna, higher abundance of more mobile species, fewer high-biomass organisms and more smaller-bodied species in high effort areas, infauna in deeper coarse-medium sand habitat most affected by fishing.		Compared benthic communities in areas of high, medium and low fishing intensity by fixed and mobile gears.

Table 403 - Effects of Multiple Gears on Sand Substrate Habitat: Summary of Published Studies

9.3.1.2.4.2.4.2 Multiple Gear Types – Gravel/Rock

Two recent observational studies of mobile gear effects on sediments and epifauna in gravel bottom on the northern edge of eastern Georges Bank (42-90 m) are summarized (Table 404). Study sites were distinguished by depth and the presence or absence of fishing disturbance. Sediments in undisturbed sites were slightly coarser with more sand and cobble. There were significantly more organisms, higher biomass, and greater species diversity at the undisturbed sites in both depths, but there were also significantly higher values in disturbed and undisturbed deep sites than in disturbed and undisturbed shallow sites. Percent cover of an encrusting colonial polychaete was also significantly higher at these sites, but emergent hydroids and bryozoans were significantly more abundant in deep, undisturbed sites and at shallow, disturbed sites. Overall, emergent epifauna was more abundant in deep water, but there was no significant disturbance effect.

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1,2	Collie et al. 1997, 2000	Eastern Georges Bank (U.S. and Canada)	42-90 m	Pebble/cobble "pavement" with some overlying sand	S higher total densities, biomass, and species diversity in undisturbed sites, but also in deeper water (i.e. effects of fishing could not be distinguished from depth effects), 6 species abundant at U sites, rare or absent at D sites; sediments in U sites slightly coarser with more sand and cobble; percent cover of tube-dwelling polychaetes, hydroids, and bryozoans S higher in deep water, but no disturbance effect.		Benthic sampling, video and still photos in two shallow (42-47 m) and four deep (80-90 m) sites disturbed (D) and undisturbed (U) by trawls and scallop dredges.

Table 404 - Effects of Multiple Gear Types on Gravel/Rocky Substrate: Summary of Published Studies

S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

9.3.1.2.4.2.4.3 Multiple Gear Types - Mixed Substrates

Six observational studies of the effects of multiple gear types on mixed substrates are summarized (Table 405). Surveys were conducted in the Gulf of Maine inside and outside an inshore area closed to mobile fishing gear and in an offshore area that was disturbed by mobile fishing gear (1). A series of three publications examined long-term (100+ years) changes in benthic habitats and communities in the Wadden Sea, some of which were attributed to fishing (2-4). A study in New Zealand (5) tested ten predictions of how increasing fishing activity affects benthic communities by comparing benthic samples and underwater video footage from areas exposed to varying degrees of commercial fishing effort. A sixth study (6) examined areas on eastern Georges Bank that were affected by mobile bottom gear.

Significant increases were observed in the abundance of sea cucumbers and emergent epifauna, and in the number of bottom depressions created by organisms such as lobsters, scallops, and crabs, on sand-cobble-shell substrate inside the Gulf of Maine closed area (1). Side scan sonar and ROV surveys of Stellwagen Bank revealed evidence that otter trawls and New Bedford scallop dredges disturb sand waves and ripples, disperse shell deposits, remove emergent epifauna, and disturb microalgal cover (1). Disturbed sand and gravel areas of Georges Bank were characterized by trawl and dredge tracks, sparse epifauna, mounds of gravel presumably produced by fishing gear, and smoother bottom (6). In the New Zealand study (5), there were four significant effects of increased fishing activity by bottom trawls, Danish seines, and toothed scallop dredges in mud and sand substrates that were consistent across all sampling methodologies. These were reduced density of large epifauna, echinoderms, and long-lived surface dwelling organisms, and an increased density of small, opportunistic species. The loss of biogenic reefs and changes in benthic community composition (fewer mollusk and amphipod species and more polychaete species) in the Wadden Sea were in part attributed to fishing activity (2-4).

No.	Reference	Location	Depth	Sediment	Effects	Recovery	Approach
1	Auster et al. 1996	Coastal Gulf of Maine (USA)	30-40 m	Sand-shell	S more sea cucumbers and bottom depressions inside closed area.		ROV and video observations inside and outside an area closed to mobile gear for 10 years.
1	Auster et al. 1996	Coastal Gulf of Maine (USA)	30-40 m	Cobble-shell	S more emergent epifauna inside closed area.		ROV and video observations inside and outside an area closed to mobile gear for 10 years.
1	Auster et al. 1996	Stellwagen Bank (Gulf of Maine, USA)	20-55 m	Sand with gravel and shell	Disturbed sand ripples and sand waves, dispersed shell deposits, absence of epifauna and reduced microalgal cover in trawl and dredge tracks.		Side-scan sonar survey and ROV observations.
2,3,4	Reise and Schubert, 1987; Riesen and Reise 1982; Reise 1982	Wadden Sea (Netherlands)	<23 m	Mud, coarse sand and some pebbles	Loss of oyster and Sabelleria reefs, decrease in abundance of 28 species (molluscs and amphipods), 23 “new” species (mostly polychaetes).		Compared benthic surveys conducted during time period when oysters were over-exploited and trawl fishery developed on Sabellaria reefs (1869-1986)..

Table 405 - Effects of Multiple Gears on Mixed Substrate Habitat: Summary of Published Studies
S = statistically significant; U = undisturbed; D = disturbed; HT = heavily trawled; LT = lightly trawled

5	Thrush et al. 1998	Hauraki Gulf, New Zealand	17-35 m	Mud and sand	S reductions in density of large epifauna, echinoderms, and long-lived surface dwellers; S increases in density of small, opportunistic species; 15-20% variability in macrofaunal community composition attributed to fishing pressure.		Tested ten predictions of the effects of increasing fishing intensity on benthic community structure by comparing samples and video images from 18 stations exposed to varying degrees of commercial fishing pressure by bottom trawls, Danish seines, and scallop dredges.
6	Valentine and Lough 1991	Eastern Georges Bank		Sand and gravel	Trawl and dredge tracks in sediments, sparse epifauna, gravel mounds and smoother bottom in disturbed areas.		Side scan sonar and submersible observations of area presumed to be disturbed by trawls and scallop dredges.

Table 405 - Effects of Multiple Gears on Mixed Substrate Habitat: Summary of Published Studies(cont.)

9.3.1.3 Vulnerability of Essential Fish Habitat to Bottom-tending Fishing Gears

The purpose of this section is to evaluate potential adverse effects of bottom-tending fishing gears regulated by the Magnuson-Stevens Act (MSA) on benthic EFH in the Northeast region of the U.S. as required by the EFH final rule, 50 CFR 600.815(a)(2)(I). The EFH final rule recommends that the evaluation consider the effects of each fishing activity on each type of habitat found within the EFH for any affected species and life stage. The EFH rule further recommends that the following information be reviewed in making an evaluation: intensity, extent, and frequency of any adverse effects on EFH; the types of habitat within EFH that may be adversely affected; habitat functions that may be disturbed; and conclusions regarding whether and how each fishing activity adversely affects EFH.

9.3.1.4 Vulnerability Requirements

The EFH final rule requires that EFH designations be based upon the best available information. This information may fall into four categories that range from the least specific (Level 1) to the most specific (Level 4). These categories are defined as follows:

Level 1: Presence/absence data are available to describe the distribution of a species (or life history stage) in relation to potential habitats for portions of its range.
Level 2: Quantitative data (i.e., density or relative abundance) are available for the habitats occupied by a species or life history stage.
Level 3: Data are available on habitat-related growth, reproduction, and/or survival by life history stage.
Level 4: Data are available that directly relate the production rates of a species or life history stage to habitat type, quantity, and location.

Existing EFH designations in the Northeast region are based primarily on Level 2 information. This level of information is inadequate for making definitive determinations of the consequences of fishing-related habitat alterations on EFH for any species or life stage in the Northeast region because the habitat alterations caused by fishing can not be linked to any known effect on species productivity. Therefore, this section of the report qualitatively evaluates the vulnerability of benthic EFH for each species and life history stage (eggs, larvae, juveniles, adults, and spawning adults) in the Northeast region to the effects of five bottom-tending fishing gear types (Tables 6.1 – 6.42). Vulnerability is defined as the likelihood that the functional value of EFH would be adversely affected as a result of fishing. Given the limited nature of the information available for this evaluation, emphasis was placed on the identification of potential adverse impacts of fishing on benthic EFH.

Information used to perform these evaluations included: 1) the EFH designations adopted by the Mid-Atlantic, New England, and South Atlantic Fishery Management Councils; 2) the results of a Fishing Gear Effects Workshop convened in October 2001 (NREFHSC 2002); 3) the information provided in this report, including the results of existing scientific studies, and the geographic distribution of fishing gear use in the Northeast region; and 4) the habitats utilized by each species and life stage as indicated in their EFH designations and supplemented by other references.

9.3.1.5 Species-specific Vulnerability Tables

The following five fishing gear classifications were evaluated: otter trawls (OT); New Bedford style scallop dredges (SD); hydraulic clam dredges (CD); pots and traps (PT); and sink gill nets and bottom long lines (NL). Vulnerability was evaluated according to four broad categories: none (0); low (L); moderate (M); and high (H), based upon a matrix analysis of habitat function, habitat sensitivity and gear use. The matrix analysis consistently applied these criteria to all benthic life stages and species. Adult and spawning adult life stages were combined due to the difficulty in distinguishing between the two. In some cases (e.g., pelagic life stages that are not vulnerable to bottom-tending fishing gear effects) a vulnerability ranking was not applicable (NA).

A number of criteria were considered in the evaluation of the vulnerability of EFH for each species and life stage. The rationale for each determination is outlined by species in Tables 6.1 through 6.42. First, the habitat's value to each species and life stage was characterized to the extent possible, based on its function in providing shelter, food and/or the right conditions for reproduction. For example, if the habitat provided shelter from predators for juvenile or other life stages, gear impacts that could reduce shelter were of greater concern. In cases where a food source was closely associated with the benthos (e.g. infauna), the ability of a species to use alternative food sources was evaluated. Additionally, since benthic prey populations may also be adversely affected by fishing, gear impacts that could affect the availability of prey for bottom-feeding species or life stages were of greater concern than if the species or life stages were piscivorous. In most cases habitat usage was determined from the information provided in the EFH Source Documents (NOAA Technical Memorandum NMFS-NE issues 123-153) with additional information from Colette and Klein-MacPhee (2002).

Another criterion was the sensitivity of the habitat to disturbance and its ability to recover from any effects of fishing given the range of natural disturbances experienced in the environment. These considerations took into account available information on the energy level of the natural environment, including the degree of disturbance from tidal and storm-related currents. High-energy sand habitats were considered to be less vulnerable to fishing gear effects than low energy deep-water habitats or structurally complex habitats. This concept is adopted from the models developed by Auster and Langton (1999) and the Northeast Fishing Gear Effects Workshop (NREFHSC 2002).

The extent to which each of the five bottom-tending gear types is used in areas that are designated as EFH for any given species and life stage was evaluated by examining the spatial distribution of fishing activity for individual gears for the period 1995-2001. Maps of fishing activity within ten-minute squares of latitude and longitude were derived from NMFS vessel trip report and clam logbook databases. Squares were ranked according to the number of trips for fixed gear, and either the number of hours absent from port or the number of hours fishing for mobile gears. This evaluation included the predominant substrates and depth ranges in which each gear is used. Habitats or areas that are not normally fished with a particular gear were considered to be less vulnerable to that gear.

The pot/trap and net/line gear types were considered to have the least impact of the five gear types evaluated. Based on the limited information available (Eno *et al.* 2001, NREFHSC 2002), the vulnerability of all EFH to pot and trap usage was considered to be low and is not discussed in the species accounts. Similarly, there is little scientific information that evaluates the effects of gill nets and long-lines on benthic marine habitats, and none evaluates these effects in the Northeast region. The panel of experts that met in October 2001 ranked their concern over impacts from fixed gear well below concern about mobile bottom-tending gears (NREFHSC 2002). Like pots and traps, the vulnerability of EFH for all benthic species and life stages to nets and lines was rated as low (L) and is not discussed in the species accounts.

The greatest concern is for the vulnerability of benthic EFH to mobile bottom-tending gears, which is addressed by species in Table 406- Table 447. In the Northeast U.S., these gear types include various types of bottom otter trawls, New Bedford scallop dredges, and hydraulic clam dredges. Otter trawls are responsible for most of the fisheries landings throughout the Northeast region. They are used in a variety of substrates, depths, and areas. Scallop dredges are used in sand and gravel substrates, and hydraulic dredges are used only in sand, shell, and small gravel within well-defined areas.

The information in the species EFH vulnerability tables is arranged in columns that summarize the geographical extent of EFH for each life stage, its depth range, seasonal occurrence, and a brief EFH description that includes – for benthic life stages – substrate characteristics. The information in columns 2-5 was derived from EFH designations that have been adopted by the three Atlantic coast Fishery Management Councils. Additional information is provided at the bottom of each table to explain the rationale that was used in making the gear-specific EFH vulnerability rankings. This information was extracted from the EFH source documents and other sources and sometimes differs somewhat from the information included in the EFH designation.

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Eggs	GOME, GB and estuaries from Passamaquoddy Bay to Saco Bay, ME and from Mass. Bay to Cape Cod Bay, MA	30 - 90	All year in GOME Dec - June on GB Peaks April & May both	Surface waters	NA	NA	NA	NA	NA
Larvae	GOME, GB, Southern NE and estuaries from Passamaquoddy Bay to Saco Bay, ME and from Mass Bay to Cape Cod Bay, MA	30-130	Between January and August, with peaks in April and May	Surface waters	NA	NA	NA	NA	NA
Juveniles	GOME and estuaries from Passamaquoddy Bay to Saco Bay, ME and from Mass Bay to Cape Cod Bay, MA	45-150		Bottom habitats with fine-grained sediments or substrate of sand or gravel	M	M	0	L	L
Adults	GOME, GB and estuaries from Passamaquoddy Bay to Saco Bay, ME and from Mass Bay to Cape Cod Bay, MA	45-175		Bottom habitats with fine-grained sediments or a substrate of sand or gravel	H	H	0	L	L
Spawning Adults	GOME, GB and estuaries from Passamaquoddy Bay to Saco Bay, ME and from Mass Bay to Cape Cod Bay, MA	<90	March through June	Bottom habitats of all substrate types	H	H	0	L	L

Rationale: American plaice (Hippoglossoides platessoides) juveniles, adults, and spawning adults are concentrated in the Gulf of Maine, where they occupy a variety of habitat types with substrates of gravel or fine grained sediments including sand. Plaice avoid rocky and hard bottom areas and prefer fine, sticky but gritty sand mixtures and mud, as well as oozy mud in deep basins (Klein-MacPhee 2002a). Plaice have been caught a considerable distance off the bottom and move off the bottom at night (Klein-MacPhee 2002a). They feed primarily on epibenthic invertebrates (mostly echinoderms and amphipods), so there is a potential that prey resources may be affected adversely by otter trawls and scallop dredges, particularly in areas of lower energy and expected slower habitat recovery. EFH vulnerability to these gears was rated as high for adults and moderate for juveniles primarily because spawning occurs on the bottom. Since hydraulic clam dredges do not typically operate in the Gulf of Maine, vulnerability for this gear was rated as none.

Table 407 - Atlantic Cod EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Rationale: Atlantic cod (Gadus morhua) are distributed regionally from Greenland to Cape Hatteras, NC, from nearshore to depths greater than 400 m. In U.S. waters, they are concentrated on Georges Bank and in the Gulf of Maine, on rough bottom from 10 - 150 m (Klein-MacPhee 2002b; Fahay et al. 1999). Eggs and larvae are pelagic so EFH vulnerability is not applicable.

Juvenile cod are found mostly in nearshore shoal waters or on offshore banks. Cobble is preferred over finer grained sediments, and this life stage appears to use benthic structure and cryptic coloration to escape from predation (Fahay et al. 1999). Juvenile cod may benefit, perhaps strongly, from physical and biological complexity (Lindholm et al. 2001) (see discussion in 9.3.1.2.4). Otter trawls and scallop dredges have been shown to reduce habitat complexity (see Section 9.3.1.2.4) therefore EFH Vulnerability to these gear types is rated as high since the gear may affect the functional value of EFH for this life stage. Vulnerability to clam dredges was rated as none since this gear is not operated in juvenile cod EFH (see 9.3.1.2.3).

Adults and spawning adults occupy a variety of hard bottom habitat types including rock, pebbles, and gravel, and tend to avoid finer sediments. Cod are euryphagous, eating a wide variety of prey including fish, decapods, amphipods, and polychaetes (Fahay et al. 1999). Although adult cod are primarily found on rough bottom, the scientific literature does not indicate that this habitat type serves the same function as it does for juvenile cod, which is ranked as high. Based on the variable diet and lack of evidence for direct functional value of benthic habitat. EFH vulnerability to otter trawls and scallop dredges is rated as moderate. Adult cod may use areas where clam dredges operate, such as the nearshore waters of New Jersey, on a seasonal basis. Clam dredges operate only in sand (NREFHSC 2002), and the recovery of benthic communities from the effects of clam dredging in nearshore, sandy habitats is fairly rapid. Clam beds are not chronically disturbed by dredging since the population of clams, which are benthic infauna, must recover before fishing is again profitable (NREFHSC 2002). Based on this information and the rationale described for otter trawls and scallop dredges, habitat vulnerability for hydraulic clam dredges was rated as low. EFH vulnerability for adults applies to spawning adults as well.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 – No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 407 - Atlantic Cod EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear(cont.)

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Eggs	GOME, GB		Between late fall and early spring, peak Nov. and Dec.	Pelagic waters to the sea floor	0	0	0	0	0
Larvae	GOME, GB			Surface waters	NA	NA	NA	NA	NA
Juveniles	GOME, GB	20 - 60		Bottom habitats with a substrate of sand, gravel, or clay	M	M	0	L	L
Adults	GOME, GB	100-700		Bottom habitats with a substrate of sand, gravel, or clay	M	M	0	L	L
Spawning Adults	GOME, GB	<700	Between late fall and early spring, peaks in Nov. and Dec.	Bottom habitats with a substrate of soft mud, clay, sand, or gravel; rough or rocky bottom locations along slopes of the outer banks	M	M	0	L	L

Rationale: Atlantic halibut (Hippoglossus hippoglossus) are found in the boreal and subarctic Atlantic, south to New Jersey, and were once fairly common from Nantucket Shoals to Labrador (Klein-MacPhee 2002a). They have been found at depths from 25 m to 1000 m, but 700 - 900 m is probably the deepest they are found in any numbers.

Atlantic halibut eggs are bathy-pelagic and are fertilized on the bottom (Klein-MacPhee 2002a, Cargnelli et al. 1999g). Since eggs occur close to, but not on the bottom, scallop dredges, otter trawls, and hydraulic clam dredges are not expected to affect the functional value of the habitat for this life stage and EFH vulnerability was rated as none.

Juvenile, adult and spawning adult halibut occupy a variety of habitat types north of Nantucket Shoals. Adults are not found on soft mud or on rock bottom (Cargnelli et al. 1999g), however, spawning is occasionally associated with complex habitats. Juvenile halibut feed mostly on annelid worms and crustaceans, then transition to a diet of mostly fish as adults (Klein-MacPhee 2002a). EFH vulnerability to scallop dredges and otter trawls was rated as moderate for juveniles and adults. EFH vulnerability for clam dredges was rated as none since this gear type does not operate in halibut EFH (see 9.3.1.2.3).

Table 409 - Atlantic Herring EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Spawning Adults	GOME, GB, southern NE and middle Atlantic south to Delaware Bay and Englishman/ Machias Bay Estuary	20 - 80	July through November	Bottom habitats with a substrate of gravel, sand, cobble and shell fragments, also on aquatic macrophytes	L	L	0	L	L

Rationale: Atlantic herring (Clupea harengus**)** is a coastal pelagic species ranging from Labrador to Cape Hatteras in the western Atlantic (Reid et al. 1999,
Munroe 2002). For most pelagic life stages (larvae, juveniles, adults) EFH vulnerability to bottom-tending fishing gear is not applicable. Atlantic herring eggs are laid in high energy, benthic habitats on rocky, pebbly, gravelly or shell substrates or macrophytes (Reid et al. 1999, Munroe 2002). These habitats are less susceptible to fishing gear impacts since they have evolved under a high energy disturbance regime (strong bottom currents). Vulnerability of herring egg EFH to scallop dredges and otter trawls is considered to be low. Although these gears may directly effect the eggs, only the effect of the gear on the functional value of the habitat was considered for this evaluation. EFH vulnerability from clam dredges were considered to be none since this gear does not operate in areas of herring egg EFH.

Spawning adults are c losely associated with the bottom. Effects on the functional value of habitat from mobile gears are unknown and were rated as low since spawning occurs on the bottom. EFH vulnerability from clam dredges was rated as none for the reasons described above. Spawning could be disrupted by noise associated with these gears, but this issue was not addressed as a habitat related issue.

Rationale: Atlantic salmon (Salmo salar**)** eggs and larvae are found in riverine areas where the fishing gears under consideration are not used, so EFH vulnerability is not applicable. It is important to note that these life stages are particularly vulnerable to non-fishing related impacts such as point source discharges and polluted runoff. Juveniles and adults are pelagic in nature, and vulnerability of EFH to bottom-tending fishing gear is not applicable for these life stages.

Life Stage	Geographic Area of EFH	Depth [1] (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability

[1] Depth range given in EFH description.

Juvenile and adult sea scallops (***Placopecten magellanicus***) are found on the continental shelf of the northwest Atlantic, from the Gulf of St. Lawrence south to Cape Hatteras typically between 18 and 110 m, but also as shallow as 2 m in estuaries and embayments along the Maine coast and as deep as 384 m (Packer et al. 1999a). In the Gulf of Maine, populations have been reported at depths of 170-180 m. Scallops are rarely found at depths <55 m in "southern areas."

Rationale: Scallop eggs are slightly heavier than seawater and are thought to remain on the bottom during development, but bottom habitats have no known functio nal value for eggs and therefore their vulnerability to fishing was rated as low for all gear types. There are four pelagic larval stages and EFH vulnerability to fishing gear impacts for these larval stages is not applicable. However, the last larval stage is benthic; at this stage larvae settle to the bottom (as "spat") and attach to hard surfaces (Packer et al. 1999a). Settlement occurs in areas of gravelly sand with shell fragments. Spat are very delicate and do not surviv e on shifting sand bottoms. The availability of suitable surfaces on which to settle appears to be a primary requirement for successful reproduction (Packer et al. 1999a). There is a close association between the bryozoan, *Eucratea loricata*, and spat. *Eucratea* attach to adult scallops, and have been found to contain large numbers of spat. EFH for benthic phase larvae was given a low rating for vulnerability to all three mobile gear types because any disturbance of the bottom they would cause would most likely re-distribute bottom sediments suitable for settlement (gravel, pebbles, shell fragments), but not reduce their availability. Juveniles are found mainly on gravel, small rocks, shells, and silt. During their second growing season (5-12 mm) they become mobile and leave the original substrate on which they settled and re-attach to shells and bottom debris. Otter trawls, scallop dredges and hydraulic clam dredges are used in bottom habitats occupied by juvenile scallops, but the disturbance of the seafloor caused by these gears does not adversely affect the functional value of the habitat and therefore the vulnerability of juvenile scallop EFH to mobile benthic gears was rated as low. The same conclusion was reached for fixed gear which cause negligible disturbance to the seafloor. Juveniles and adults are found in benthic habitats with at least some water movement, which is critical for feeding, oxygen and removal of waste; optimal growth for adults occurs at 10 cm/sec (Packer et al. 1999a). Adult scallops inhabit coarse substrates, usually gravel, shell, and rock. Because fine clay particles interfere with feeding activity, scallops are not usually found on muddy bottom. No scientific information exists that indicates mobile fishing gears have a negative im pact on the functional value of adult scallop EFH. The vulnerability of adult scallop EFH to mobile benthic gears was therefore rated as low.

Table 412 - Haddock EFH - Vulnerability to Effect of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Spawning Adults	GB, Nantucket Shoals, Great South Channel, throughout GOME	40-150	January to June	Bottom habitats with a substrate of pebble gravel or gravelly sand	H	H	L	L	L

Rationale: Haddock (Melanogrammus aeglefinus**)** are found from Greenland to Cape Hatteras and are common throughout the Gulf of Maine, Georges Bank, and southern New England (Cargnelli et al. 1999f, Klein-MacPhee 2002b). Juveniles older than 3 months and adults are demersal and generally found in waters from 10 to 150 m in depth. Juveniles are usually found in waters shallower than 100 m. Haddock spawn over pebble gravel substrate, and avoid ledges, rocks, kelp and soft mud (Cargnelli et al. 1999f). Haddock eggs and larvae are pelagic, and EFH vulnerability to fishing gear is not applicable.

Juvenile haddock, like juvenile cod, may benefit, perhaps strongly, from physical and biological complexity. In general, haddock have a stronger benthic affinity than cod (Klein-MacPhee 2002b). Juvenile haddock are chiefly found over pebble gravel substrates (Cargnelli et al. 1999f). Once demersal, they feed on benthic fauna, and their primary prey items are crustaceans and polychaetes. The habitat complexity that appears to be important to juvenile haddock can be reduced by otter trawls and scallop dredges, and benthic prey may be affected. Juvenile haddock EFH is considered to be highly vulnerable to these two gear types. Vulnerability to clam dredges was rated as low since there is some use of this gear in juvenile EFH.

Adult haddock are found on broken ground, gravel, pebbles, clay, smooth sand, and sticky sand of gritty consistency, with a preference for smooth areas around rock patches (Klein-MacPhee 2002b). They feed indiscriminately on benthic invertebrates, and occasionally on fish. Adults (including spawning adults) occupy a variety of habitat types which may be affected by otter trawls and scallop dredges. Adults may be less closely linked to complex habitats then juveniles, but there is still some association. Haddock are expected to be more strongly linked to benthic habitats than cod since haddock primarily feed on benthic invertebrates while cod are primarily piscivorous. Benthic prey resources for haddock may be adversely affected by scallop dredges or otter trawls in areas of lower energy and expected slower habitat recovery. Overall, adult EFH vulnerability to these gear types is rated as high. Clam dredges operate only in sand and the associated recovery period is short (Table 5.15). Moreover, clam dredging is not expected to create a chronic disturbance in these areas since the population of clams, which are benthic infauna, must recover before fishing is again profitable therefore, habitat vulnerability for clam dredges is rated as low.

Table 413 - Monkfish EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Spawning Adults	Outer continental shelf in the middle Atlantic, mid-shelf off southern NE, outer perimeter of GB, all areas of GOME	25-200	February to August	Bottom habitats with substrates of a sand-shell mix, algae covered rocks, hard sand, pebbly gravel, or mud	L	L	L	L	L
Rationale: Monkfish (Lophius americanus), are demersal anglerfish found from Newfoundland south to Florida, but are common only north of Cape Hatteras (Steimle et al. 1999c). Juveniles are primarily found at depths between 40-75 m while adults are concentrated between 50-100 m. In the Gulf of Maine, adults occur primarily between the depths of 130 - 260 m. Occasionally, adults are seen at the surface. Both juveniles and adults (including spawning adults) occur on substrates ranging from mud to gravelly sand, algae and rocks. A monkfish has been observed digging depressions in the bottom substrate with its pectoral fins until its back was almost flush with the surrounding bottom (Caruso 2002). The monkfish is a sight predator which uses its highly modified first dorsal fin as an angling apparatus to lure small fishes towards its mouth (Caruso 2002). Monkfish eat a wide array of prey items, but mainly fish and cephalopods. Monkfish have been reported to ingest a variety of seabirds. There are no indications in the literature that any monkfish life stage is habitat limited or that the functional value of its habitat could be adversely affected by fishing. Vulnerability of adult and juvenile EFH to mobile fishing gear was rated as low. Monkfish eggs and larvae are pelagic, and vulnerability to bottom-tending fishing gear is not applicable.

Table 414 - Ocean Pout EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Spawning Adults	GOME, GB, southern NE, middle Atlantic south to Delaware Bay and the following estuaries: Passamaquoddy Bay to Saco Bay; Mass Bay, and Cape Cod Bay	<50	Late summer to early winter, peaks in Sept. and October	Bottom habitats with a hard bottom substrate, including artificial reefs and shipwrecks	H	H	H	L	L

Rationale: Ocean pout (Zoarces americanus**)** is a demersal species found in the western Atlantic from Labrador south to Cape Hatteras (Steimle et al. 1999e). It can occur in deeper waters south of Cape Hatteras, and has been found as deep as 363 m (Klein-MacPhee and Collette 2002a). It is found in most estuaries and embayments in the Gulf of Maine, and is caught in greatest abundance by the NEFSC trawl survey off southern New England (Steimle et al. 1999e).

Ocean pout eggs are laid in nests in crevices, on hard bottom or in holes and protected by the female parent for 2.5 to 3 months until they hatch (Klein-MacPhee and Collette 2002a). Potential impacts to habitat from otter trawls, scallop dredges and clam dredges include knocking down boulder piles, removing biogenic structure and filling in bottom depressions, which may disturb nests and/or leave these areas less suitable for nests. In addition, fishing may frighten parents from nests leaving eggs susceptible to predation. Egg EFH is therefore considered to have a high vulnerability to all bottom-tending mobile gear.

Ocean pout have a relatively short larval stage, and in fact some authors (Klein-MacPhee and Collette 2002a) suggest that there is no larval stage (Steimle et al. 1999e). Since the NEFMC designated EFH for this life stage, it is considered here. Larvae (hatchlings) remain near the nest site; however, there is little information on their use of habitats. Larvae do not appear to be as closely associated with the bottom as eggs or juveniles; however, it is anticipated that loss of structure may impact larvae to some degree. Larval EFH was determined to have high vulnerability to mobile bottom-tending gears.

Juvenile pout are found under rocks, shells and algae, in coastal waters and are closely associated with the bottom (Steimle et al. 1999e). They feed on benthic invertebrates such as gammarid amphipods and polychaetes. It is expected that loss of structure may be a fairly significant impact to juvenile EFH. Vulnerability of juvenile EFH to all mobile gear was considered to be high.

Adult pout are found in sand and gravel in winter and spring, and in rocky/hard substrate areas for spawning and nesting (Klein-MacPhee and Collette 2002a). They create burrows in soft sediments, and their diet consists mainly of benthic invertebrates including mollusks, crustaceans and echinoderms. Because of the strong benthic affinity of ocean pout, it is anticipated that vulnerability of adult EFH to all mobile gear is high.

Spawning Adults	Outer continental shelf of GB and southern NE south to the Middle Atlantic Bight	330 - 550	Spawn throughout the year	Bottom habitats	L	L	0	L	L

Rationale: Offshore hake (Merluccius albidus**),** are distributed over the continental shelf and slope of the northwest Atlantic, ranging from the Grand Banks south to the Caribbean and Gulf of Mexico (Chang et al. 1999a, Klein-MacPhee 2002c). Juveniles and adults are found in deeper waters, and are most abundant at depths between 150 - 380 m. They are an important component in the slope community off Florida, and are reportedly caught near the outer edge of the Scotian shelf, and on the slopes of deep basins in the Gulf of Maine and the continental slope from the southeastern edge of Georges Bank south. Because of their depth preference, very little is known about the offshore component of the stock. Moreover, offshore hake are similar in appearance to silver hake, and may have been misidentified in earlier studies. They are taken commercially as by-catch in the silver hake fishery. No information is available on substrate preferences for juveniles and adults. Eggs and larvae are pelagic, and EFH vulnerability to fishing gears is not applicable.

Juvenile and adult offshore hake appear to feed at or near the bottom, and are primarily piscivorous (feeding particularly on clupeids, anchovies, and lanternfishes) but they also eat crustaceans and squid (Klein-MacPhee 2002c). There is evidence of adult diel vertical migration. Only limited information exists about this species, and none of it indicates that offshore hake have a very strong bottom affinity, or that impacts from fishing gear would affect the functional value of their habitat. Although spawning occurs near the bottom, the actual use of benthic habitat during spawning is unknown. The vulnerability of adult and juvenile EFH to otter trawls and scallop dredges is expected to be low. Vulnerability to clam dredges is rated as none since the gear does not operate in the EFH of this species.

Rationale: Pollock (Pollachius virens**)** range from the Hudson straits to North Carolina (Klein-MacPhee 2002b), and are most common on the Scotian Shelf, Georges Bank, the Great South Channel and Gulf of Maine (Cargnelli et al. 1999d). They segregate into schools by size, and avoid water warmer than about 15?C (Klein-MacPhee 2002b). They are active fish that live at any depth between the bottom and the surface, depending upon food supply. They are associated with coastal areas and offshore shoals, and are found from shore out to depths of about 325 m, but are most common from 75-175 m (Cargnelli et al. 1999d). Juveniles frequently occupy the rocky intertidal zone, which may serve as a nursery area (Klein-MacPhee 2002c). Neither adults nor juveniles are selective in substrate type.

Pollock are opportunistic, and the diet of both juveniles and adults consists mainly of euphausiid crustaceans, but fish, other crustaceans and squid are also eaten (Cargnelli et al. 1999d, Klein-MacPhee 2002c). Adults spawn over broken bottom and the slopes of offshore banks, and eggs are pelagic. Based on food habits, and the distribution and behavior of pollock, vulnerability of juvenile EFH to benthic mobile gear is characterized as low. Since pollock spawn on the bottom, the vulnerability of adult EFH to otter trawls and scallop dredges has been rated as moderate. EFH vulnerability from clam dredges has been rated as low for juveniles and adults since there is limited use of this gear in pollock EFH. Pollock eggs and larvae are pelagic, so EFH vulnerability to fishing gear is not applicable.

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Spawning Adults	GOME, southern edge of GB, continental shelf off southern NE, and middle Atlantic south to Cape Hatteras and following estuaries: Sheepscott R., Mass Bay, Cape Cod Bay, Buzzards Bay, & Narragansett Bay	<100	May to November, peaks in June and July	Bottom habitats in depressions with a substrate of sand and mud	M	M	L	L	L

Rationale: Red hake (Urophycis chuss) is a demersal species that ranges from southern Newfoundland to North Carolina, and is most abundant between Georges Bank and New Jersey (Steimle et al. 1999d). They occur at depths between 35 - 980 m, and are most common between 72 - 124 m (Klein-MacPhee 2002b). Larvae, juveniles, and adults have been found in estuaries from Maine south to Chesapeake Bay (NEFMC 1998). Eggs and larvae are pelagic, and EFH vulnerability to bottom-tending fishing gear is not applicable.

Juvenile red hake are found in live Atlantic sea scallops or empty scallop shells, and are also associated with other objects such as other shells, sponges, and rocks (Klein-MacPhee 2002b). Shelter appears to be a critical habitat requirement for this life stage (Able and Fahay 1998), and physical complexity, including biogenic structure other than scallop shells, may be important (Auster et al. 1991, 1995). Their diet consists mainly of amphipods and other infauna and epifauna. Juvenile hake EFH is considered to be highly vulnerable to all three mobile gear groups.

Adult red hake feed mainly on euphausiids, and also consume other invertebrates and fish (Klein-MacPhee 2002b). They are found mainly on soft bottoms (sand and mud) where they create depressions or use existing depressions. They are also found on shell beds, but not on open, sandy bottom. Otter trawls and scallop dredges operate in these soft bottom and shell bed areas and have been shown to affect the structural components of these habitats. Offshore in Maryland and northern Virginia, adult red hake are found on temperate reefs and hard bottom areas. There is a potential that otter trawls could operate in hard bottom areas and adversely affect the functional value of these reef habitats. Vulnerability of red hake EFH to otter trawls and scallop dredges is assessed as moderate. Clam dredges would not typically operate in these hard bottom areas, nor in the softer sediments with which red hake are usually associated in the northern extent of their range, but there is some overlap between adult EFH and clam dredge use in sandy habitats. EFH vulnerability to clam dredges is characterized as low.

Rationale: Redfish (Sebastes spp.) include both the Acadian redfish (Sebastes fasciatus) and the deepwater redfish (Sebastes mentella). These two species are difficult to discriminate at all life stages, hence they are usually combined (Pikanowski et al. 1999). Acadian redfish range from Iceland to New Jersey, and deepwater redfish occur from the Gulf of Maine north. Where the species overlap, the deepwater redfish occurs in deeper water. They range in depth from 25 - 592 m (Klein-MacPhee and Collette 2002b), with adults most common from 125 - 200 m and juveniles between 75 and 175 m (Pikanowski et al. 1999). In general, information about redfish is very limited. Females bear live young and larvae are pelagic, so habitat vulnerability is not applicable to eggs or larvae.

Redfish are found chiefly on silt, mud or hard bottom and rarely over sand (Pikanowski et al. 1999). On the Scotian shelf they are strongly associated with fine-grained clay/silt bottom (Klein-MacPhee and Collette 2002b), as well as deposits of gravel and boulders (Pikanowski et al. 1999). It is hypothesized that redfish do not prefer a particular bottom type, but may be more exposed to predation over a featureless bottom due to their sedentary nature. There is limited evidence that juveniles use anemones and boulders for cover (Pikanowski et al. 1999). Early demersal phase Acadian redfish have been observed to occur primarily in piled boulder habitats while late-juvenile redfish occur in both piled boulder, gravel and dense cerianthid anemone habitats (Auster et al., in prep.). Habitat vulnerability from otter trawls and scallop dredges in boulder habitats is high as gear can overturn boulders and reduce the number of crevices as well as dislodge cerianthid anemones from the bottom.

Redfish are benthic during the day, and become more active at night when they rise off the bottom, following the vertical migration of their primary euphausiid prey (Pikanowski et al. 1999). They also eat some benthic fish. Adult EFH was determined to be moderately vulnerable to impacts from otter trawls and scallop dredges. Clam dredges do not operate in areas of redfish EFH so vulnerability was rated as none.

Larvae	GOME, southern edge of GB, southern NE to middle Atlantic and the following estuaries: Mass Bay, to Cape Cod Bay		May in mid-Atlantic area, Aug. & Sept. in GOME, GB area	Pelagic waters	NA	NA	NA	NA	NA
Juveniles	GOME, southern edge of GB, southern NE to middle Atlantic and the following estuaries: Passamaquoddy Bay to Great Bay; Mass Bay to Cape Cod Bay	5 - 225	May-September	Pelagic stage - pelagic waters; Demersal stage - Bottom habitat with seagrass beds or substrate of mud or fine-grained sand	M	M	0	L	L
Adults	GOME, southern edge of GB, southern NE to middle Atlantic and the following estuaries: Passamaquoddy Bay to Great Bay; Mass Bay to Cape Cod Bay	5 - 325		Bottom habitats with substrate of mud or fine-grained sand	L	L	0	L	L

Table 419 - White Hake EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Spawning Adults	GOME, southern edge of GB, southern NE to middle Atlantic	5 - 325	April to May - southern part of range; August - Sept.- northern part of range	Bottom habitats with substrate of mud or fine-grained sand in deep water	L	L	0	L	L

Rationale: White hake (Urophycis tenuis**)** adults co-occur geographically with red hake, and their habits are similar, but white hake are distributed in a wider range of depths and temperatures (Chang et al. 1999c, Klein-MacPhee 2002b). They are found from Labrador south to North Carolina, and occasionally stray as far as Florida and Iceland. They inhabit coastal estuaries and occur across the continental shelf to the submarine canyons along the upper continental shelf, and in the basins of the Gulf of Maine. Adult distribution in the region is focused in the Gulf of Maine and along the southern slope of Georges Bank. All life stages are found in estuaries in the vicinity of the Gulf of Maine (NEFMC 1998).

Most pelagic juveniles cross the shelf and enter estuaries from Canada south to the Mid-Atlantic, although some may also settle to the bottom in as yet unknown shelf habitats (Klein-MacPhee 2002b). Demersal juveniles are found in nearshore waters out to a depth of about 225 m (Chang *et al*. 1999c). Eelgrass is an important habitat for juveniles, but its functional importance is unknown; this life stage is not necessarily dependent upon structure (Able and Fahay 1998). Young-of-the-year white hake feed mainly on shrimp, mysids and amphipods. Since otter trawls and scallop dredges can negatively impact eelgrass (Stephan *et al.* 2000) in estuaries, vulnerability of juvenile white hake EFH to these gears is characterized as moderate. Hydraulic clam dredges are not utilized in estuaries of the Gulf of Maine so vulnerability to this gear is rated as none.

Adults prefer benthic deposits of fine grained sediments (Chang et al. 1999c). They feed primarily on fish, cephalopods, and crustaceans. Since they are not benthivores and have not been documented to use benthic habitats for cover, EFH vulnerability to otter trawls and scallop dredges is characterized as low. Clam dredges are not operated in areas of adult EFH and vulnerability to this gear is rated as none.

Adult	GOME, GB, continental shelf off southern NE, middle Atlantic south to Cape Hatteras and the following estuaries: Passamaquoddy Bay to Casco Bay, Mass Bay to Cape Cod Bay	30-325		Bottom habitats of all substrate types	L	L	L	L	L
Spawning Adults	GOME, GB, continental shelf off southern NE, middle Atlantic south to Cape Hatteras and the following estuaries: Mass Bay and Cape Cod Bay	30-325		Bottom habitats of all substrate types	L	L	L	L	L

Rationale: Whiting or silver hake (Merluccius bilinearis**)** range from Newfoundland south to Cape Fear, NC, and are most common from Nova Scotia to New Jersey (Morse et al. 1999). They are distributed broadly, and are found from nearshore shallows out to a depth of 400 m (Klein-MacPhee 2002c). All life stages have been found in estuaries from Maine to Cape Cod Bay (Morse et al. 1999). The vertical movement of offshore hake is governed chiefly by their pursuit of prey; both juveniles and adults show a vertical migration off the bottom at night when feeding activity is greatest.

In the Mid-Atlantic Bight, juvenile whiting have been found in greater densities in areas with greater amphipod tube cover (Auster et al. 1997). Further, silver hake size distributions in sand wave habitats are positively correlated with sand wave period (i.e., the spacing between sand waves), suggesting energetic or prey capture benefits in particular sand wave environments (Auster et al in press). Juveniles are primarily found on silt or sand substrate and feed mainly on crustaceans, including copepods, amphipods, euphausiids, and decapods (Morse et al. 1999). The vulnerability of juvenile EFH to mobile gear was rated as moderate because of the potential connection between structure and habitat suitability for this life stage.

Adult whiting rest on the bottom in depressions by day, primarily over sand and pebble bottoms, and rarely in rockier areas. In the Mid-Atlantic, adults were found on flat sand, sand wave crests, shell, and biogenic depressions, but were most often found on flat sand. At night, adults feed on anchovies, herring, lanternfish, and other fishes (Klein-MacPhee 2002c). Piscivory increases with size for this species. Vulnerability of adult whiting EFH to the three mobile gear types was rated as low because of whiting=s piscivorous food habits and preference for higher energy sand environments which recover quickly from fishing gear impacts (see Section 5). Eggs and larvae of this species are pelagic, so habitat vulnerability to fishing gear is not applicable.

Rationale: Windowpane flounder (Scophthalmus aquosus**)** is distributed in coastal waters from the Gulf of St. Lawrence to Florida, and are most abundant on Georges Bank and in the New York Bight (Klein-MacPhee 2002d). Windowpane are abundant in estuaries from Maine through the Chesapeake Bay (NEFMC 1998). They are a shoal-water fish, with a depth range of up to 200 m, but are most abundant in waters less than 50 m deep. Both juveniles and adults are found on muddy sediments in the Gulf of Maine, and fine, sandy sediments on Georges Bank and in New England and the Mid-Atlantic Bight.
Mysids are the main prey item of juveniles (Klein-MacPhee 2002d). Adults have been shown to feed exclusively on nekton and show little need for bottom structure (Chang et al. 1999b). EFH vulnerability to the three types of mobile gear was rated as low for both these life stages. Windowpane eggs and larvae are pelagic, so EFH vulnerability to fishing gear is not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Spawning Adults	GB, inshore areas of GOME, southern NE, middle Atlantic south to Delaware Bay and the following estuaries: Passamaquoddy Bay to Delaware Inland Bays	<6	February to June	Bottom habitats including estuaries with substrate of mud, sand, gravel	M	M	M	L	L

Rationale: Winter flounder (Pseudopleuronectes americanus**)** range from Labrador to Georgia, and are most abundant from the Gulf of St. Lawrence to Chesapeake Bay (Klein-MacPhee 2002a). All lifestages are common in estuaries from Maine through Chesapeake Bay. Juveniles and adults are found in waters less than 100 m deep, and most are found from shore to 30 m. They range far upstream in estuaries, and have been found in freshwater.

Winter flounder lay demersal adhesive eggs in shallow water less than 5 m in depth, with the exception of spawning areas on Georges Bank and Nantucket shoals (Pereira et al. 1999). Substrates include sand, muddy sand, mud and gravel, with sand the most common. Although otter trawls, scallop dredges and clam dredges may affect the eggs directly, this was not considered a habitat impact. Since there is no indication that the eggs rely on any structure, egg EFH vulnerability to these three gears was rated as low. Since early stage larvae are associated with the bottom and are at times demersal (Able and Fahay 1998) larval EFH vulnerability to all gears were also rated as low instead of none.

Juvenile and adult winter flounder are found on mud and sand substrates, and adults are also seen on cobble, rocks and boulders (Pereira et al. 1999). Both life stages can be opportunistic feeders, however their main prey items are infaunal invertebrates. Because of their reliance on infauna and their ability to use alternative food supplies, EFH vulnerability to the three mobile gear types for these the adults stages was ranked as moderate.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Juveniles	GOME, outer continental shelf from GB south to Cape Hatteras	50-450 to 1500		Bottom habitats with fine-grained substrate	M	L	0	L	L
Adults	GOME, outer continental shelf from GB south to Chesapeake Bay	25-300		Bottom habitats with fine-grained substrate	M	L	L	L	L
Spawning Adults	GOME, outer continental shelf from GB south to Chesapeake Bay	25-360	March to November, peaks in May-August	Bottom habitats with fine-grained substrate	M	L	L	L	L

Rationale: Witch flounder (Glyptocephalus cynoglossus) range from Newfoundland south to Cape Hatteras. In U.S. waters, this species is common throughout the Gulf of Maine, and is found in deeper areas of and adjacent to Georges Bank and along the continental shelf edge and upper slope (Cargnelli et al 1999e, Klein-MacPhee 2002a).

Juvenile and adult witch flounder are found mainly over fine muddy sand, or mud. Though their diet is comprised mainly of polychaetes, they feed on other invertebrates as well (Cargnelli et al. 1999e). Since these life stages occur in areas of lower natural disturbance and rely on infauna, EFH vulnerability to impacts from otter trawls were rated as moderate. Impacts from scallop dredging may be less severe, since scallop dredges are not usually used in muddy habitat; however, vessel trip reports indicated scallop dredging in areas of witch flounder EFH, therefore, vulnerability to scallop dredges was rates as low. Juvenile EFH vulnerability to clam dredges was rated as none since clam dredges are not used in mud or in water depths where juvenile witch flounder are primarily found. However, EFH vulnerability to clam dredges for adults was rated as low since clam dredges do operate in adult EFH. Eggs and larvae of witch flounder are pelagic, so vulnerability of EFH to fishing gear impacts is not applicable.

Adults	GB, GOME, southern NE continental shelf south to Delaware Bay and the following estuaries: Sheepscot R., Casco Bay, Mass Bay to Cape Cod Bay	20 - 50		Bottom habitats with substrate of sand or sand and mud	M	M	M	L	L
Spawning Adults	GB, GOME, southern NE continental shelf south to Delaware Bay and the following estuaries: Mass Bay to Cape Cod Bay	10-125		Bottom habitats with substrate of sand or sand and mud	M	M	M	L	L

Rationale: Yellowtail flounder (Limanda ferruginea) are found from the Gulf of St. Lawrence south to the Chesapeake Bay (Klein-MacPhee 2002a, Johnson et al. 1999). They are most abundant on the western half of Georges Bank, western Gulf of Maine, east of Cape Cod, and off southern New England (Johnson et al. 1999). Their usual depth range is from 10 - 100 m (Klein MacPhee 2002a). Juveniles and adults are found in some New England estuaries while eggs and larvae are found more frequently in these habitats (NEFMC 1998). Yellowtail eggs and larvae are pelagic, so EFH vulnerability is not applicable.

Yellowtail flounder feed mainly on benthic macrofauna, primarily amphipods and polychaetes (Johnson et al. 1999). Adults eat mostly crustaceans while juveniles focus on polychaetes. Both life stages are found on substrates of sand or sand and mud. Vulnerability of juvenile and adult EFH to the three types of mobile gear was rated as moderate because of the potential affect of these gears on infaunal yellowtail prey.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT- Pots and Traps; NL - Gill Nets and Longlines. Adults	Southern flank of GB and south the Cape Hatteras, NC	200-1300		Bottom habitats of continental slope with a substrate of silts, clays, and all silt-clay-sand composites	L	0	0	L	L
Spawning Adults	Southern flank of GB and south the Cape Hatteras, NC	200-1300		Bottom habitats of continental slope with a substrate of silts, clays, and all silt-clay-sand composites	L	0	0	L	L

Rationale: Red crab **(**Chaeceon (Geryon) quinquedens**)** are found on the outer continental shelf and slope of the western Atlantic from Nova Scotia into the Gulf of Mexico (Steimle et al. 2001). They are found on the bottom, chiefly between water depths of 200 and 1800. EFH depth range for juveniles is from 700 to 1800 m, and for adults EFH ranges from 200-1300 m. They are found on substrates ranging from silt and clay to hard substrates.

Red crab are opportunistic benthic feeders/scavengers, with a diet of epifauna and other opportunistically available items (Steimle et al. 2001). Post-larval juveniles feed on a wide variety of infaunal and epifaunal benthic invertebrates. Small crabs eat sponges, hydroids, gastropods and other organisms. Larger crabs eat similar small benthic fauna and larger prey including demersal and mid-water fishes.

The only fishery using mobile bottom gear which operates in red crab EFH is the monkfish trawl fishery (NEFMC 2002). The vulnerability of adult and juvenile red crab EFH to otter trawls was characterized as low because of their opportunistic feeding habits. Vulnerability to scallop dredges and clam dredges was rated as none since those gears do not operate in red crab EFH. Larval red crabs are pelagic and EFH vulnerability is not applicable. The "habitat" for eggs is the female carapace, therefore EFH vulnerability for this life stage is also not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT- Pots and Traps; NL - Gill Nets and Longlines. Table 427 - Black Sea Bass EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Adults	Demersal waters over continental shelf from GOME to Cape Hatteras, NC, also includes estuaries: Buzzards Bay, Narragansett Bay, Gardiners Bay, Great South Bay, Barnegat Bay to Chesapeake Bay; Tangier/ Pocomoke Sound and James River	20- 50	Wintering adults (Nov. to April) offshore, south of NY to NC; inshore, estuaries from May to October	Structured habitats (natural & man-made) sand and shell substrates preferred	H	H	H	L	L

Rationale: Black sea bass (Centropristis striata) are found in coastal waters of the northwest Atlantic, from Cape Cod south to Cape Canaveral (Klein-MacPhee 2002e). Occasionally they stray as far north as the Bay of Fundy (Gulf of Maine). Juveniles are common in high salinity estuaries. Adults and juveniles are found in estuaries from Massachusetts south to the James River, VA (Stone et al. 1994).

Black sea bass larvae are pelagic, but then become demersal and occupy structured inshore habitat such as sponge beds, eelgrass beds, shellfish beds, shell patches, and other rough bottoms (Steimle et al. 1999a) and offshore shell patches including clam beds (Able and Fahay 1998). The availability of structure limits successful postlarval and/or juvenile recruitment (Steimle et al. 1999a). Juveniles are diurnal visual predators that feed on benthic invertebrates and small fish. Adults are also structure oriented, and thought to use structure as shelter during day- time, but may stray off it to hunt at night.

Each of these life stages is associated with structure that may be vulnerable to fishing gear impacts, so vulnerability was rated as high for all mobile gear. It is important to note that structured habitats comprised of wrecks or other artificial reefs prone to damage by mobile gear may be avoided by fishermen. This is true of high relief natural areas as well. Black sea bass eggs are pelagic, so vulnerability to EFH is not applicable. Although larvae are pelagic, they do become demersal as they transition into juveniles. Therefore, larvae were rated the same as juveniles.

Rationale: Loligo or longfin squid (Loligo pealeii**)** is a pelagic schooling species. It is distributed in continental shelf and slope waters from Newfoundland to the Gulf of Venezuela (Cargnelli et al. 1999a). Most life stages of loligo squid are pelagic; however, encapsulated eggs are laid in masses, called Amops@ which are attached to structures such as rocks and algae on substrates of sand, mud, or hard bottom (Cargnelli et al. 1999a). ***As of this writing, EFH is not designated for Loligo eggs, however it will be designated in the near future. Once Loligo egg EFH is designated its EFH will be rated as highly vulnerable to otter trawls and scallop dredges, particularly since biogenic structures are used as attachment sites.									
Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 431 - Loligo Squid EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Eastern edge of GB and GOME throughout the Atlantic EEZ	8-245		Throughout substrate to a depth of 3ft within federal waters, occurs progressively further offshore between Cape Cod and Cape Hatteras	L	L	L	L	L
Adults	Eastern edge of GB and GOME throughout the Atlantic EEZ	8 - 245	Spawn May-Dec. with several peaks	Throughout substrate to a depth of 3ft within federal waters, occurs progressively further offshore between Cape Cod and Cape Hatteras	L	L	L	L	L

Rationale: Ocean quahog (Arctica islandica) juveniles are found in offshore sandy substrate, and may survive in muddy intertidal areas (Cargnelli et al. 1999b). Adults are found in similar offshore habitats, just below the surface of the sediment, usually in medium to fine-grained sand. Although clam dredges remove clams from the sediment, the habitat's functional value is probably not affected. Juvenile and adult EFH vulnerability was therefore rated as low for all mobile gears. Ocean quahog eggs and larvae are pelagic, therefore EFH vulnerability is not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0- No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 432 - Ocean Quahog EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Eastern edge of GB and the GOME throughout Atlantic EEZ	0 -60, low density beyond 38		Throughout substrate to a depth of 3 ft within federal waters, burrow in medium to coarse sand and gravel substrates, also found in silty to fine sand, but not in mud	L	L	L	L	L
Adults	Eastern edge of GB and the GOME throughout Atlantic EEZ	0 -60, low density beyond 38	Spawn-summer to fall	Throughout substrate to a depth of 3 ft within federal waters	L	L	L	L	L

Rationale: Atlantic surfclams (Spisula solidissima**)** are found in sandy continental shelf habitats from the southern Gulf of St. Lawrence to Cape Hatteras, North Carolina (Cargnelli et al. 1999c). They burrow into substrates from fine to coarse sandy gravel and are not found in mud. Although clam dredges remove clams from the sediment, the habitat's functional value is probably not affected. Juvenile and adult EFH vulnerability was therefore rated as low for all mobile gears. Surfclam eggs and larvae are pelagic, therefore EFH vulnerability is not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 - No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Adults	Continental shelf from GOME to Cape Hatteras, NC includes the following estuaries: Cape Cod Bay to Long Island Sound; Gardiners Bay to Hudson R./ Raritan Bay; Delaware Bay & Inland Bays; & Chesapeake Bay	(2 - 185)	Wintering adults (November - April) are usually offshore, south of NY to NC	demersal waters north of Cape Hatteras and Inshore estuaries (various substrate types)	L	L	L	L	L

Rationale: Scup (Stenotomus chrysops**)** is a temperate species that occurs primarily from Massachusetts to South Carolina, although it has been reported as far north as the Bay of Fundy and Sable Island Bank, Canada (Steimle et al. 1999f). Scup are primarily benthic feeders that use a variety of habitat types. Juveniles forage on epibenthic amphipods, other small crustaceans, polychaetes, mollusks, fish eggs, and larvae. They occur over a variety of substrates, and are most abundant in areas without structure. Limited observations of scup have shown periodic use of seafloor depressions for cover (Auster et al. 1991, 1995).
Adults are found on soft bottoms or near structures. During the summer they are closer inshore and found on a wider range of habitats. In the winter they congregate offshore in areas that are expected to serve as a thermal refuge (Klein-McPhee 2002f), particularly deeper waters of the outer continental shelf and around canyon heads. Smaller adults feed on echinoderms, annelids, and small crustaceans. Larger scup consume more squids and fishes. Since juvenile scup are primarily benthic feeders, their EFH was rated as moderately vulnerable to impacts from mobile bottom gear. EFH for adults was rated as low since there is less of a reliance on benthic prey items.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT- Pots and Traps; NL - Gill Nets and Longlines. Adults	GOME through Cape Hatteras, NC across the Continental shelf; Continental shelf waters South of Cape Hatteras, NC through Florida; also includes estuaries from Passamaquaddy Bay to Saco Bay; Mass Bay & Cape Cod Bay	10-450		Continental shelf waters and estuaries	L	L	L	L	L

Rationale: Spiny dogfish (Squalus acanthias**)** is a coastal shark with a circumboreal distribution and is one of the most abundant sharks in the western North Atlantic (McMillan and Morse 1999). Female dogfish are viviparous, so EFH designations were limited to juveniles and adults. Smaller dogfish have been reported to feed primarily on crustaceans, with an increase in piscivory in larger individuals (Burgess 2002). Fish, mainly schooling pelagic species, constitute 50% of their diet. Their voracious and opportunistic feeding behavior was emphasized by McMillan and Morse (1999). Since neither of these life stages appears to be closely tied to benthic organisms, the vulnerability of their EFH to mobile gears was rated as low.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Juveniles	Over continental shelf from GOME to Cape Hatteras, NC; South of Cape Hatteras to Florida; also includes estuaries from Waquoit Bay to James R.; Albemarle Sound to Indian R.	0.5-5 in estuary		Demersal waters, on muddy substrate but prefer mostly sand; found in the lower estuaries in flats, channels, salt marsh creeks, and eelgrass beds	M* * L	L	L	0	0

Table 436 - Summer Flounder EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
Adults	Over continental shelf from GOME to Cape Hatteras, NC; South of Cape Hatteras to Florida; also includes estuaries from Buzzards Bay, Narragansett Bay, Conn. R. to James R.; Albemarle Sound to Broad R.; St. Johns R., & Indian R.	0 - 25	Shallow coastal and estuarine waters during warmer months, move offshore on outer continental shelf at depths of 150m in colder months	Demersal waters and estuaries	M** L	L	L	0	0

Rationale: Summer flounder (Paralichthys dentatus**)** occur in the shallow estuarine waters and outer continental shelf from Nova Scotia to Florida with the center of their range located in the Middle Atlantic Bight (Packer et al. 1999b). Juvenile summer flounder are opportunistic feeders, and their diet includes mysids, fish, and some crustaceans (Packer et al. 1999b). There are gradual changes in the diet of summer flounder, with fish becoming more important as a food source as individuals get older and larger. Adults are also opportunistic feeders, with fish and crustaceans making up a significant portion of their diet.

Eelgrass and macroalgae has been designated as a habitat area of particular concern (HAPC) for adult and juvenile summer flounder. Stephan et al. (2000) determined that otter trawls could result in below-ground impacts to submerged aquatic vegetation (SAV), which, of all the impacts to SAV possible from fishing gear, was ranked as the impact of greatest concern. This determination was qualified by an acknowledgment that factors relevant to trawl use and the type of SAV species present, must be considered for a more precise evaluation of the effects of this gear type in SAV habitat. * *Based on potential impacts to SAV, the vulnerability of the summer flounder HAPC to otter trawls is rated as moderate. Vulnerability to scallop or clam dredges was considered low since these gears are not typically used in estuaries where SAV is found.

Since adults and juveniles are both opportunistic feeders, their EFH vulnerability (aside from the HAPC) was rated as low for all bottom tending gear. Summer flounder eggs and larvae are pelagic so EFH vulnerability is not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 - No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 436 - Summer Flounder EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear(cont.)

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Eggs	US-Canadian Boundary to VA/NC boundary (shelf break; GB to Cape Hatteras)	76-365	Serial spawning March - November; peaks April – October	Water column	NA	NA	NA	NA	NA
Larvae	US-Canadian Boundary to VA/NC boundary (outer continental shelf - GB to Cape Hatteras)	76-365	Feb. - Oct; peaks July – October	Water column	NA	NA	NA	NA	NA
Juveniles	US-Canadian Boundary to VA/NC boundary (shelf break, submarine canyon walls and flanks - GB to Cape Hatteras)	76-365	All year - may leave GB in winter	Rough bottom, small burrows, and sheltered areas – Substrate rocky, stiff clay, human debris	H	L	0	L	L
Adults	US-Canadian Boundary to VA/NC boundary (shelf break, submarine canyon walls and flanks - GB to Cape Hatteras)	76-365	All year - may leave GB in winter	Rough bottom, small burrows, and sheltered areas – Substrate rocky, stiff clay, human debris	H	L	0	L	L

Rationale: Tilefish (Lopholatilus chamaeleontieps**)** are restricted to the continental shelf break south of the Gulf of Maine (Steimle et al. 1999b). They occupy a number of habitats, including scour basins around rocks or other rough bottom areas that form burrow-like cavities, and pueblo habitats in clay substrate. The dominant habitat type is a vertical burrow in a substrate of semi-hard silt/clay, 2 - 3 m deep and 4 - 5 m in diameter with a funnel shape. These burrows are excavated by tilefish, and then secondary burrows are created by other organisms, including lobsters, conger eels, and galatheid crabs. Tilefish are visual daytime feeders on galatheid crabs, mollusks, shrimps, polychaetes and occasionally fish. Mollusks and echinoderms are more important to smaller tilefish. Little is known about juveniles of the species.

A report to the Mid-Atlantic Fishery Management Council (Able and Muzeni 2002) from a video survey in areas of tilefish habitat identified trawl tracks through these areas, and concluded that trawling caused a re-suspension of bottom sediments. The report noted that re-suspended sediments fill burrows in and/or cause physiological stress to tilefish that are present. No obvious structural impacts to the habitat were identified. However, due to the tilefish's reliance on structured shelter and the need for further study, the vulnerability of tilefish EFH to otter trawls was ranked as high. Clam dredges operate in shallow, sandy waters typically uninhabited by tilefish, so EFH vulnerability was rated as none for this gear. Scallop vessel monitoring data (Section 4) indicate that scallop dredges operate to a small extent in areas overlapping tilefish EFH, therefore EFH vulnerability to scallop dredges was ranked as low. Tilefish eggs and larvae are pelagic, therefore EFH vulnerability is not applicable.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Larvae	Along the Atlantic coast from Virginia through the Florida Keys	<50		Estuarine wetlands especially important (flooded saltmarshes, brackish marsh, tidal creeks, mangrove fringe, seagrasses)	NA	NA	NA	NA	NA
Juveniles	Along the Atlantic coast from Virginia through the Florida Keys	<50	Found throughout Chesapeake Bay from Sept. - Nov.	Utilize shallow backwaters of estuaries as nursery areas and remain until they move to deeper water portions of the estuary associated with river mouths, oyster bars and front beaches	L	0	0	L	L

Table 438 - Red Drum EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Adults	Along the Atlantic coast from Virginia through the Florida Keys	<50	Found in Chesapeake in spring and fall and also along eastern shore of VA	Concentrate around inlets, shoals, and capes along the Atlantic coast – shallow bay bottoms or oyster reef substrate preferred, also nearshore artificial reefs	L	L	L	L	L
Rationale: Red drum (Sciaenops ocellatus**)** are distributed in estuarine and coastal waters depending upon their stage of maturity (McGurrin 1994). Juvenile red drum are found in shallow estuarine backwaters and as they grow they move to deeper areas. Submerged aquatic vegetation is particularly important habitat for juvenile drum. Sub-adult and adult red drum are found on estuarine bay bottoms or oyster reefs, and in nearshore coastal waters including the beach zone out to several miles from shore. Juvenile and adult red drum have a varied diet. Smaller juveniles eat copepods and mysids, while larger individuals eat decapods (crabs & shrimp), fish and plant material (McGurrin 1994). Although SAV is an important habitat for juvenile red drum, EFH vulnerability to otter trawls was rated as low since its use in SAV is limited. Scallop dredges and hydraulic clam dredges usually are not used in juvenile red drum EFH, therefore, EFH vulnerability for these gears was rated as none. Since red drum feed on a variety of organisms, and adults are found in many habitat types, vulnerability of adult EFH to mobile bottom gear was rated as low. Red drum eggs and larvae are pelagic therefore, EFH vulnerability is not applicable.									
Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 439 - Spanish Mackerel, Cobia, and King Mackerel EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear(cont.)

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
All Life Stages	Chesapeake Bay to the south through the Florida Straight (and into the Gulf of Mexico)	290-570		Continental slope in flat areas of foraminifera ooze, on distinct mounds of dead coral, ripple habitat, dunes, black pebble habitat, low outcrop, and soft bioturbated habitat	L	0	0	L	L

Rationale: Golden crab (Chaceon fenneri) inhabit the continental slope of Bermuda and the southeastern United States from Chesapeake Bay south through the Florida Straight and into the Gulf of Mexico (SAFMC 1998). Although similar to red crab, less is known about this species. They are categorized as opportunistic scavengers, and are found in depths from 290 - 570 m on substrates of foraminiferon ooze, dead coral mounds, and deep ripple habitat, dunes, and black pebble habitat. Scallop dredges and clam dredges do not operate in golden crab EFH due to depth so EFH vulnerability was rated as none. Most otter trawling operates in depths less than 200 m so EFH vulnerability was rated as low for this gear type.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 - No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 440 - Golden Crab EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Eastern GOME, GB, SNE, MAB to Hudson Canyon	0-750 mostly <150		Bottom habitats with mud, gravel, and sand substrates	M	M	L	L	L
Adults	Eastern GOME, GB, SNE, MAB to Hudson Canyon	0-750 mostly <150		Bottom habitats with mud, gravel, and sand substrates	M	M	L	L	L

Rationale: Barndoor skate (Dipturus laevis**)** occur from Newfoundland south to Cape Hatteras, but are most abundant on Georges Bank and in the Gulf of Maine. They are found on soft mud, sand and gravel. (Packer et al. in press (a)). Barndoor skate feed on invertebrates usually associated with the bottom - including polychaetes, gastropods, and bivalves - squid and fish. Smaller individuals feed primarily on polychaetes, copepods and amphipods while larger individuals capture larger and more active prey (McEachran 2002, Packer et al. in press (a)). A single fertilized egg is encapsulated in a leathery capsule known as a Amermaids purse.@ The young hatch in late spring or early summer and are thought to be about 180-190 mm in length, although very little information is available on this life stage (Packer et al. in press(a)).

Juvenile EFH was considered to be moderately vulnerable to otter trawls and scallop dredges because of the closer association of juveniles to a benthic invertebrate diet. Adult EFH vulnerability to otter trawls and scallop dredges was rated as moderate due primarily to their reproductive habits. EFH vulnerability to clam dredges was rated as low for juveniles and adults because this gear is not extensively used in EFH.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 441 - Barndoor Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	GOME, along shelf to Cape Hatteras, NC; includes the estuaries from Hudson River/Raritan Bay south to the Chesapeake Bay mainstem	0 - 500 mostly <111		Bottom habitats with substrate of soft bottom along continental shelf and rocky or gravelly bottom	M	M	M	L	L
Adults	GOME, along shelf to Cape Hatteras, NC; includes the estuaries from Hudson River/Raritan Bay south to the Chesapeake Bay mainstem	0 - 500 mostly <111		Bottom habitats with substrate of soft bottom along continental shelf and rocky or gravelly bottom	M	M	M	L	L

Rationale: Clearnose skate (Raja eglanteria**)** occur in the Gulf of Maine, but are most abundant from Cape Hatteras north to Delaware Bay. They are found over soft bottoms of mud and sand, and also occur on rocky or gravelly bottoms. They have been captured from shore out to depths of 330 m, but are most abundant at depths less than 111 m. (Packer et al. in press (b)). Adults and juveniles feed on polychaetes, amphipods, decapod crustaceans, mollusks, and fish. Like barndoor skates, crabs and benthic invertebrates are more important for smaller, younger individuals, and the importance of fish in the diet increases with age (McEachran 2002; Packer et al. in press(b)). A single fertilized egg is encapsulated in a leathery case. Eggs are deposited in the spring or summer and hatch 3 months later.

Juvenile EFH was considered to be moderately vulnerable to otter trawls, scallop dredges and clam dredges because of the closer association of juveniles to a benthic invertebrate diet. Adult EFH vulnerability to otter trawls, scallop dredges and clam dredges was rated as moderate due primarily to their reproductive habits.

Table 442 - Clearnose Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Eggs	GB through MAB to Cape Hatteras, NC; includes the estuaries from Buzzards Bay south to the Chesapeake Bay mainstem	<27		Bottom habitats with sandy substrate	L	L	L	L	L
Juveniles	GB through MAB to Cape Hatteras, NC; includes the estuaries from Buzzards Bay south to the Chesapeake Bay mainstem	0-137 mostly 73-91		Bottom habitats with sandy or gravelly substrate or mud	M	M	M	L	L
Adults	GB through MAB to Cape Hatteras, NC; includes the estuaries from Buzzards Bay south to the Chesapeake Bay mainstem	0-137 mostly 73-91		Bottom habitats with sandy or gravelly substrate or mud	M	M	M	L	L

Rationale: Little skate (Leucoraja erinacea**)** range from Nova Scotia to Cape Hatteras, and are most abundant on Georges Bank and in coastal waters south to the mouth of Chesapeake Bay. They have been found at depths up to 500 m, but are most common at depths less than 111 m. In southern New England, juveniles and adults have been associated with microhabitat features including biogenic depressions and flat sand during the day (Auster et al. 1991, 1995). They are generally found on sandy or gravelly bottoms, but also occur on mud. They co-occur with winter skate, and are more active at night, although they appear to feed throughout the day and night. The most important prey are amphipods and decapod crustaceans, followed by polychaetes. Prey items of minor importance include bivalves, isopods, and fish. Similar to barndoor and clearnose skates, the use of fish as a food source increases with increasing size. Smaller skates eat more amphipods, and larger skate consume more decapod crustaceans (Packer et al. in press (c)).

A single fertilized egg is encapsulated in a leathery case which is deposited on sandy substrate. The cases have sticky filaments that adhere to bottom substrates. In one study, eggs deposited in the late spring and early summer required five to six months to hatch. Other studies have shown incubation to exceed one year. When the young hatch, they are considered juveniles and are fully developed, measuring from 93-102 mm in total length (Packer et al. in press (c)).

Vulnerability of juvenile EFH to mobile bottom gear was characterized as moderate because of the species dependence on benthic organisms in its diet. Vulnerability of adult EFH to mobile bottom gear was characterized as moderate due to its reproductive habits. Little skate is the only skate species in which EFH has been designated for eggs. Although bottom tending mobile gear may have adverse effects upon the eggs themselves, this was not considered to be a habitat impact. Since the bottom substrate appears to provide an attachment point for the eggs the EFH vulnerability to mobile gear was rated as low instead of none.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 - No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 443 - Little Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Nantucket shoals and southern edge of GB to Cape Hatteras, NC	33-530 mostly 74-274		Bottom habitats with soft substrate, including sand/mud bottoms, mud with echinoid and ophiuroid fragments, and shell and pteropod ooze	M	M	M	L	L
Adults	Nantucket shoals and southern edge of GB to Cape Hatteras, NC	33-530 mostly 74-274		Bottom habitats with soft substrate, including sand/mud bottoms, mud with echinoid and ophiuroid fragments, and shell and pteropod ooze	M	M	M	L	L

Rationale: Rosette skate (Leucoraja garmani virginica) is a deeper water species that occurs along the outer shelf and continental slope from Nantucket Shoals to the Dry Tortugas, Florida. North of Cape Hatteras, it is most abundant in the southern section of the Chesapeake Bight. It occurs on soft bottoms, including sand and mud, at depths from 33-530 m, and is most common between 74 and 274 m. Juveniles tend to be found between 100 - 140 m. Major prey items include polychaetes, copepods, cumaceans, amphipods, Crangon, crabs, squid, octopods, and small fishes. A single fertilized egg is encapsulated in a leathery case. Egg cases are found in mature females most frequently in the summer (Packer et al. in press (d)).

Information on rosette skate is very limited. Because of the limited information available, the apparent dependence of the juveniles of this species on benthic organisms in its diet, and the reproductive habits of the adults, EFH vulnerability to mobile bottom gear was characterized as moderate.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. NA - not applicable; 0 - No vulnerability; L - Low vulnerability; M - moderate vulnerability; H - high vulnerability; EFH - essential fish habitat; * derived from matrix analysis – see appendix. **Note that the information presented in columns 2-5 is derived from the EFH descriptions and may not completely agree with information provided in the rationale.**

Table 444 - Rosette Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Offshore banks of GOME	31-874 mostly 110-457		Bottom habitats with a substrate of soft mud (silt and clay), sand, broken shells, gravel and pebbles	M	M	0	L	L
Adults	Offshore banks of GOME	31-874 mostly 110-457		Bottom habitats with a substrate of soft mud (silt and clay), sand, broken shells, gravel and pebbles	H	H	0	L	L

Rationale: Smooth skate (Malacoraja senta) center of abundance is the Gulf of Maine. It occurs along the Atlantic coast from the Gulf of St. Lawrence south to South Carolina, at depths between 31-874 m. It is most abundant between 110-457 m. Analysis of NEFSC trawl survey data found juvenile skate most abundant between depths of 100-300 m during the time period from 1963-69. Smooth skate are found mostly over soft mud and clay of the Gulf of Maine=s deepwater basins, but also over the Gulf=s off shore banks with substrates of sand, shell, and/or gravel (Packer et al. in press (e)).

The diet of smooth skate is generally limited to epifaunal crustaceans, with decapod shrimp and euphausids as the most common prey, followed by amphipods and mysids. The diet shifts from amphipods and mysids to decapods as smooth skate grow (Packer et al. in press (e)). The diet of smooth skate is more restricted than other skate species (McEachran 2002).

The vulnerability of juvenile smooth skate EFH to otter trawls and scallop dredges was characterized as moderate because of the dietary habits of this species. The vulnerability of adult EFH was rated as high for otter trawls and scallop dredges because of the benthic diet as well as the reproductive habits of the species. Vulnerability to clam dredges was considered to be none for juveniles and adults since this gear is not used in the Gulf of Maine.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 445 - Smooth Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	GOME and GB	18-2000 mostly 111-366		Bottom habitats with a substrate of sand gravel, broken shell, pebbles, and soft mud	M	M	0	L	L
Adults	GOME and GB	18-2000 mostly 111-366		Bottom habitats with a substrate of sand gravel, broken shell, pebbles, and soft mud	M	M	0	L	L

Rationale: Thorny skate (Amblyraja radiata) range from Greenland south to South Carolina. In the Northeast region, it is most commonly seen in the Gulf of Maine and on the Northeast Peak and northern Great South Channel of Georges Bank. It is one of the most common skates in the Gulf of Maine, and occurs over a wide variety of bottom substrates, from sand, gravel, and broken shell to mud. It is found at depths ranging from 18 - 1200 m, and is reported to be most common between 50-350 m. A single fertilized egg is encapsulated in an egg case. Females with fully formed egg cases have been captured year round, though the percentage of mature females with egg cases is higher in the summer (Packer et al. in press (f)).

The primary prey of thorny skates are polychaetes and decapods, followed by amphipods and euphausiids. Fish and mysids are also consumed in lesser quantities. According to a survey from Nova Scotia to Cape Hatteras, thorny skate prey varies with skate size. Skates less than 40 cm total length feed mostly on amphipods, skates greater than 40 cm fed on polychaetes and decapods, and fishes were a major dietary component for skates larger than 70 cm. In general, with increasing size, mysids decreased in the diet while fishes increased (Packer et al. in press (f)).

Since juvenile thorny skate appear to be more reliant on benthic invertebrates, vulnerability of EFH to otter trawls and scallop dredges for this life stage was characterized as moderate. For adults, EFH vulnerability to otter trawls and scallop dredges was characterized as moderate because of their reproductive habits. EFH vulnerability to clam dredges was rated as none for juveniles and adults since there is no overlap between thorny skate EFH and areas in which clam dredges are used.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 446 - Thorny Skate Pending EFH - Vulnerability to Effects of Bottom-Tending Fishing Gear

Life Stage	Geographic Area of EFH	Depth (m)	Seasonal Occurrence	EFH Description	EFH Vulnerability*				
					OT	SD	CD	PT	NL
Juveniles	Cape Cod Bay, GB, SNE shelf through MAB to North Carolina; includes the estuaries from Buzzards Bay south to the Chesapeake Bay mainstem	0-371 mostly <111		Bottom habitats with substrate of sand and gravel or mud	M	M	M	L	L
Adults	Cape Cod Bay, GB, SNE shelf through MAB to North Carolina; includes the estuaries from Buzzards Bay south to the Chesapeake Bay mainstem	0-371 mostly <111		Bottom habitats with substrate of sand and gravel or mud	M	M	M	L	L

Rationale: Winter skate (Leucoraja ocellata) are found from Newfoundland south to Cape Hatteras. They are most abundant on Georges Bank and in coastal waters south to the mouth of the Hudson River. They are found over substrates of sand, gravel, and mud, in depths from shore out to 371 m, and are most common in less than 111 m of water. A single fertilized egg is encapsulated in a leather case and deposited on the bottom during summer in the northern portion of the range. Deposition has been reported to extend through January off southern New England. Young are fully developed at hatching (Packer et al. 1999g).

Polychaetes and amphipods are the most important prey items, followed by decapods, isopods, bivalves, and fish. In general, crustaceans make up over 50% of the diet for skate smaller than 61 cm, and fish and bivalves are a major component of the diet for skates larger than 79 cm. Crustaceans declined in importance with increasing skate size while polychaetes increased, until skates reached 81 cm.

Since juvenile winter skate appear to be more reliant on benthic invertebrates, vulnerability of EFH to mobile gear for this life stage was characterized as moderate. For adults, EFH vulnerability to mobile gear was characterized as moderate because of their reproductive habits.

Definitions: GOME - Gulf of Maine; GB - Georges Bank; NE - New England; HAPC - Habitat Area of Particular Concern; YOY - Young-of-Year: OT - Otter Trawls; SD - New Bedford Scallop Dredge; CD - Hydraulic Clam Dredge; PT - Pots and Traps; NL - Gill Nets and Longlines. Table 449) was developed for each benthic life stage for each species to determine the vulnerability of its EFH to effects from bottom tending mobile gear. Six criteria were qualitatively evaluated for each life stage based upon existing information. Each evaluation consisted of a score based upon a predefined threshold. The first three criteria were related to habitat function and included shelter, food and reproduction. Scores for these criteria were determined as follows:

Shelter: (Scored from 0-2) If the lifestage has no dependence upon bottom habitat to provide shelter then a 0 was selected. Almost every lifestage evaluated has some dependence upon the bottom for shelter so 0 was seldom used with the exception of a few egg lifestages. If the lifestage has some dependence upon unstructured or non-complex habitat for shelter it was scored a 1. For example, flatfishes that rely primarily on cryptic coloration for predator avoidance or small scale sand waves for refuge were scored a 1. If the lifestage has a strong reliance on complex habitats for shelter it was scored a 2. For example, species such as juvenile cod and haddock that are heavily reliant on structure or complex habitat for predator avoidance were scored a 2.

Food: (Scored from 0-2) If the lifestage has no dependence on benthic prey it was scored a 0. For example, eggs were always scored a 0 as were lifestages that fed exclusively in the plankton. If the lifestage utilizes benthic prey for part of its diet but not exclusively a benthic feeder it was scored a 1. For example, species feeding opportunistically on crabs as well as squid or fish were scored a 1. If the lifestage feeds exclusively on benthic organisms and cannot change its mode of feeding it was scored a 2.

Reproduction: (Scored from 0-1) If the species has no dependence upon bottom habitats for spawning or its lifestage was not a reproductive stage it was scored a 0. For example, species that spawn in the water column were scored a 0 as well as juveniles of all species. If the species has some dependence upon bottom habitats for spawning it was scored a 1. For example, species that spawn on or over the bottom were scored a 1. This criteria was the most difficult to assess since there is limited knowledge on spawning behaviors for many species.

Habitat Sensitivity: (Scored from 0-2) This criterion no longer evaluates the function of the habitat for the species but looks at its overall sensitivity to disturbances in a relative fashion. The habitat needed by the species was based primarily upon its EFH designation. If a habitat was not considered sensitive to disturbance it was scored a 0. However, a score of 0 was not used for any benthic habitat type. If the habitat was considered to have a low sensitivity it was scored a 1. For example, habitats that are typically characterized as high energy environments without structural complexity or have rapid recovery rates they were scored a 1 (e.g. high energy sand environments). If the habitat type was considered highly sensitive it was scored a 2. For example, habitats that are characterized as structurally complex (such as habitats supporting epibenthic communities, boulder pile fields, etc.) or have very slow recovery rates (such as low energy deepwater environments) were scored a 2. These scores were based upon the existing conceptual models that show a direct relationship between structural complexity of the habitat and recovery time with increasing vulnerability.

Habitat Rank: The habitat rank was determined quantitatively as the sum of the previous scores (shelter + food + reproduction + habitat sensitivity). Another way to characterize the habitat rank is the relative vulnerability of the habitat to non-natural physical disturbance. The rank could range from 0-7, with 7 being the most vulnerable.

Gear Distribution: (Scored from 0-2) This criterion factors in the use of a particular gear type (otter trawl, scallop dredge, hydraulic clam dredge) in EFH for a particular lifestage. If the gear is not used in the described EFH it was scored a 0. If the gear operates in only a small portion of the described EFH it was scored a 1. If the gear operates in more than a small amount of the described EFH it was scored a 2. Distribution was determined as the qualitative overlap of EFH on the Vessel Trip Report location data which has been described in previous sections of this report.

Gear Rank: The gear rank provides the vulnerability of EFH to a particular gear type and was calculated as the product of the Habitat Rank x Gear Distribution. Based upon natural breaks in the rankings frequency distribution the following interpretations of the ranking have be made: **0 = no vulnerability** to the gear. This could only be attained if the gear was not used in the habitat (gear distribution = 0). **1 - 6 = low vulnerability** to the gear. This generally occurred where the gear has minimal overlap with EFH (gear distribution = 1) and Habitat Rank was less than 7. Additionally, low vulnerability could be in habitats with high gear overlap (gear distribution = 2) but where Habitat Rank was low (3 or less). **7 - 9 = moderate vulnerability** to the gear. This typically occurred where gear overlap with EFH was high (gear distribution = 2) and habitat rank was 4 or, overlap with EFH was low (gear distribution = 1) and Habitat Rank was 7. **10 - 14 = high vulnerability** to the gear. This occurred only if the gear overlap with EFH was high (gear distribution = 2) and the habitat rank was 5 or more.

GEAR RANK (Vulnerability of EFH to particular gear) = (Habitat Rank) x (Gear Distribution)

CRITERIA	RANK	KEY
Shelter	0-2	0 = no dependence 1 = lower dependence, not reliant on complex structure 2 = strong dependence, reliant on complex structure
Food	0-2	0 = no dependence on benthic prey 1 = includes benthic prey 2 = relies exclusively on benthic prey
Reproduction	0-1	0 = no dependence (e.g. spawns in water column or life stage not reproductive) 1 = dependence (e.g. spawns on or over bottom)
Habitat Sensitivity	0-2	0 = not sensitive 1 = low sensitivity (i.e. no habitat structure/complexity issues, rapid recovery rates, e.g. high energy sand habitats 2 = highly sensitive (e.g. habitat structural/complexity issues, slow recovery rates, i.e. deep water/low energy habitats)
Habitat Rank	**= Shelter + Food +Reproduction + Habitat Sensitivity**	
Gear Distribution	0-2	0 = gear not utilized in this habitat 1 = gear operates in a small portion of this habitat 2 = gear operates in much of this habitat
Gear Rank	**= Habitat Rank X Gear Distribution**	

Table 448 - Summary of the criteria used to identify the EFH vulnerability determinations.

Summary: GEAR RANK is the vulnerability of the EFH to the gear type. In terms of the EFH Vulnerability Section, Gear Rank is the following: 0 = none, 1-6 = Low vulnerability, 7-9 = Moderate vulnerability, 10-14 = High vulnerability.

9.3.1.7 Statement of Council Concurrence

The Council concurs with the conclusions reached by the Gear Effects Workshop and reviewed by in this document concerning the description of effects on benthic habitat and determinations of adverse effects of fishing on EFH by gears used in the multispecies fishery in the Northeastern U.S.

9.3.1.8 Summary of Adverse Impacts

The EFH Final Rule (50 CFR Part 600) provides guidance to the Regional Fishery Management Councils for identifying fishing activities that adversely impact essential fish habitat (EFH). In addition to the EFH Final Rule, guidance provided by the Habitat Conservation Division (HCD) headquarters office in the form of a memo dated October 2002 was followed in the preparation of this section of Amendment 13. This evaluation should primarily include the impacts of activities associated with the fishery that is the subject of the management action, as well as other federally-managed and state-managed fishing activities. Based on the guidance provided by the EFH Final Rule and the HCD office, this determination focuses on the effects of fishing activities in the New England multi-species fishery on groundfish EFH. It also includes information on the effects of other federally-managed fishing activities on groundfish EFH, and identifies gears used in state-managed fisheries that could affect groundfish EFH. Most of the information needed to complete this determination is provided in more detail in previous sub-sections of 9.3.1.2 and 9.3.1.3.

The EFH Final Rule also stipulates that "each FMP must minimize to the extent practicable the adverse effects of fishing on EFH that is designated under other federal FMPs". Federally-managed species that could be affected by the New England groundfish fishery are listed in Table 449. These species and life stages were ranked according to the vulnerability of their EFH to the effects of mobile, bottom-tending gear (see Section 9.3.1.3). EFH for those ranked as moderately or highly vulnerable were included in this adverse impacts evaluation.

For this determination, fishing activities are interpreted to mean fishing gears, since there is not enough information available to support a more detailed determination based on different fishing practices used with each gear type. Adverse impacts associated with each gear type are assessed for specific habitat types that make up groundfish EFH. Only benthic habitats are considered, since the gears used to catch groundfish are bottom-tending gears. Habitat type is based on type of substrate, and, to some extent, depth and degree of exposure to natural disturbance. These simplifications were made in order to allow maximum use of the information available and to provide an evaluation that encompasses as broad a range of the relevant fisheries and affected habitats as possible.

EFH for those ranked as moderately or highly vulnerable were included in this adverse impacts evaluation. For the purposes of this action, EFH vulnerability that is ranked as low is considered to have a potential adverse effect to EFH that is minimal and temporary in nature. Therefore, the Council will eliminate from further consideration any EFH that has a low vulnerability to scallop dredges, otter trawls and clam dredges. Refer to Table 449 for a detailed look at the vulnerability rankings based on shelter, food, reproduction, habitat sensitivity, habitat rank, gear distribution and gear rank. Background on how vulnerability was determined in this exercise is useful for understanding how EFH could be adversely affected as a result of fishing with different gear types. Vulnerability was divided into four broad categories, including: none (0); low (L); moderate (M); and high (H), based upon a matrix analysis of habitat function, habitat sensitivity and gear use. Several criteria were qualitatively evaluated for each life stage based upon existing information. Each evaluation consisted of a score based upon a predefined threshold. The criteria used and the key describing what each ranking stands for is described in Table 448. Depth range and substrates that are included in the EFH designations for those species that have been determined to be adversely impacted indicate that, as a group, they occupy a wide range of depths and bottom types (Table 450).

Species	Lifestage	Vuln. to Otter Trawling	Vuln. to Scallop Dredging	Vuln. To Clam Dredges	Depth (m) (EFH Designation)	Substrate (EFH Designation)

9.3.1.8.1 EFH Designations

Fifteen species are included in the NEFMC Multispecies Fishery Management Plan. Depth ranges and substrates that are included in the EFH designations for the benthic life stages of these species (Table 451) indicate that, as a group, they occupy a wide range of depths and bottom types.

Species	Life Stage	Depth	Substrate
American Plaice	A	45-150	Fine-grained sediments or substrate of sand or gravel
American Plaice	J	45-175	Fine-grained sediments or substrate of sand or gravel
Atlantic Cod	A	10-150	Rocks, pebbles, or gravel
Atlantic Cod	J	25-75	Cobble or gravel
Atlantic Halibut	A	20-60	Sand, gravel, or clay
Atlantic Halibut	J	100-700	Sand, gravel, or clay
Haddock	A	35-100	Pebble gravel
Haddock	J	40-150	*Broken ground, pebbles, smooth hard sand, smooth*
Ocean Pout	A	<110	Dig depressions in soft sediments
Ocean Pout	J	<80	*Smooth bottom near rocks or algae*
Ocean Pout	L	<50	*Close to nesting areas*
Ocean Pout	E	<50	*Sheltered nests in holes or crevices on hard bottom*
Offshore Hake	A	150-380	*Bottom habitats*
Offshore Hake	J	170-350	*Bottom habitats*
Pollock	A	15-365	Hard bottom including artificial reefs
Pollock	J	0-250	Aquatic vegetation or a substrate of sand, mud, or
Red Hake	A	10-130	Depressions with a substrate of sand and mud
Red Hake	J	<100	Shell fragments and live scallops
Redfish	A	50-350	Silt, mud, or hard bottom
Redfish	J	25-400	Silt, mud, or hard bottom
White Hake	A	5-325	Mud or fine-grained sand
White Hake	J	5-225	Seagrass beds or substrate of mud or fine-grained
Whiting	A	30-325	All substrate types
Whiting	J	20-270	All substrate types
Windowpane	A	1-75	Mud or fine-grained sand
Windowpane	J	1-100	Mud or fine-grained sand
Winter Flounder	A	1-100	Mud, sand, or gravel
Winter Flounder	J	1-50	Mud or fine-grained sand
Witch Flounder	A	25-300	Fine-grained substrate
Witch Flounder	J	50-450	Fine-grained substrate
Yellowtail Flounder	A	20-50	Sand or sand and mud
Yellowtail Flounder	J	20-50	Sand or sand and mud

Table 451 - Depths and Substrates Associated With Essential Fish Habitats for Benthic Life Stages of 15 Species Included in the New England Multi-Species Fishery Management Plan

A similar description of the depth and substrate features of EFH for the remaining 18 federally-managed species with benthic life stages is not included because EFH for the 15 species that are managed under the Multi-Species FMP already covers a broad range of habitat types. The areal extent of EFH for the juvenile and adult stages of all 33 species includes virtually the entire Northeast shelf.

9.3.1.8.2 Gear Descriptions

Commercial fishing gear types that contact the bottom and are defined for data-reporting purposes are listed in Table 393. Some of them are federally-regulated and others that are only used in state waters are not.

Federally-regulated gears that contact the bottom can be divided into two types, mobile and stationary (or fixed) gears. Mobile, bottom-tending gears fall into two major groups, trawls and dredges. Types of trawls used in the Northeast region include otter trawls for fish, scallops, and shrimp, and Scottish and Danish seines. Federally-managed dredges include scallop and clam dredges. Bottom-tending fixed gears include sink and stake gill nets, long lines, pots and traps used to catch lobsters, crabs, and fish, and floating traps. Descriptions of these gears, and other gears used in the Northeast Region, are provided in 9.3.1.2.2 of this document. The descriptions for trawls and dredges include some information on individual components that contact the bottom and some details about fishing practices (types of bottom fished, towing speeds, etc.). Bottom otter trawls are described as a single category, with some information on differences in gear design and configuration for trawls used to target particular resources (fish, scallops, or shrimp) or habitat types (smooth vs. rocky bottom). Of all the bottom-tending gears that have the potential to adversely affect benthic EFH in the NE region, bottom otter trawls are the most diverse group.

9.3.1.8.3 Distribution of Fishing Activity

The three primary gears used to harvest groundfish in New England are bottom otter trawls, bottom gill nets, and bottom longlines. Two other bottom-tending gears used in other federally-managed fisheries are hydraulic clam dredges and scallop dredges. Information on the spatial distribution of fishing activity for these five gear types during 1995-2001 is provided in 9.3.1.2.3. The geographic distributions of the ten minute squares (TMS) of latitude and longitude that accounted for most of the trips or days absent from port reported in the NMFS vessel trip database for these five gears are as follows:

Bottom gill net trips during 1995-2001 were made primarily in the Gulf of Maine (GOM). Gill net trips were most common in coastal waters in the southwestern portion of the GOM, with some trips reported offshore in the central portion of the Gulf (Figure 242). No gill net fishing was reported in coastal waters of central and eastern Maine. Outside the GOM, gill net trips were reported along the western side of the Great South Channel, in Rhode Island coastal waters, along the south shore of Long Island, and off New Jersey, the Delaware-Maryland-Virginia (DelMarVa) Peninsula, and North Carolina. A few trips were also made in three ten minute squares along the 100 fathom contour at the shelf break in southern New England and (apparently) in a single TMS in even deeper water southeast of Hudson Canyon. Gill net trips made in federal waters were about five times more numerous during 1995-2001 than bottom longline trips.

Bottom longlining during 1995-2001 was conducted primarily in coastal waters of the southwestern GOM and extended southeast of Cape Cod along the western edge of the Great South Channel (Figure 243.) A few trips were also reported on the northern edge of Georges Bank (GB), in the outer portion of the GOM, in southern New England (SNE) coastal waters, and in several TMS along the outer continental shelf – particularly south of Nantucket Island and in the vicinity of Hudson Canyon.

Bottom trawling in federal waters in the Northeast region during 1995-2001 accounted for 150% more days absent from port as scallop dredging and 23 times more days absent than days spent fishing with clam dredges. Significant areas were closed to bottom trawlers on GB and in SNE (Figure 241). Bottom trawling, more than any other fishing activity, was conducted to a greater extent in deeper water in the GOM, north of GB, and along the shelf break in SNE and the Mid-Atlantic (MA) region. A continuous area of high trawling activity occurred from the central GOM west to the coast, then through the southwestern GOM, down the west side of the Great South Channel and east across the top of Closed Area I on GB. Trawling was also reported west and south of Closed Area II on eastern GB, on the southern portion of GB, throughout most of SNE in inner, mid, and outer shelf waters, along the shelf break in the MA, and in North Carolina coastal waters. There was a large open access area with no, or minimal, trawling in the middle and inner portions of the MA shelf from the New York Bight south to the North Carolina border. Trawling activity was fairly evenly distributed among the four sub-regions of the Northeast shelf (see map of sub-regions, Figure 241).

Scallop dredging in federal waters in the Northeast region during 1995-2001 accounted for less than half as many days absent as bottom trawling, but nearly ten times more time at sea than was spent dredging with hydraulic clam dredges. Scallop dredging during 1995-2001 was reported in TMS along the eastern Maine coast, in the extreme southwestern "corner" of the GOM north of Cape Cod, along the western side of the Great South Channel, along the northern edge of GB and on its southeastern flank, and in a very large continuous area reaching from the eastern end of Long Island south across the shelf that included outer shelf waters as far south as the North Carolina border (Figure 245). Large expanses of bottom area in the outer GOM, in the central part of GB, in SNE, and in inner shelf waters of the MA did not support any notable amount of scallop dredging. Unlike bottom trawling, scallop dredging was almost completely confined to depths shallower than 50 fathoms. Analysis of VTR data by sub-region showed that about half of the reported scallop dredging days at sea were in the MA sub-region, about 30% in the GB sub-region (the same proportion as for trawls), 10% in SNE, and 5% or less in the GOM.

Hydraulic clam dredging activity was much less intensive during 1995-2001 than for either of the other two major types of mobile gear. Hydraulic clam dredging took place in SNE and the MA, generally in shallower shelf waters than scallop dredging and trawling (Figure 246). A cluster of TMS off the New Jersey coast was heavily fished, as were other TMS further out toward the edge of the shelf, south of Long Island, and in SNE waters. Clam dredges do not operate on GB because ocean quahogs on the bank contain red tide-causing micro-organisms and cannot be harvested. Hydraulic clam dredging is restricted to sandy and muddy sand substrates because the gear can be damaged in hard bottom areas. For this reason, hydraulic dredges are not used in the GOM.

9.3.1.8.4 Potential Adverse Impacts of Fishing Activities

9.3.1.8.4.1 Gears That Could Adversely Impact Groundfish EFH

Of the five gear types that are either used to harvest the 15 species of groundfish that are managed under the NEFMC Multi-Species FMP, or which are capable of catching groundfish (i.e., as by-catch), or which are used in other federally-managed fisheries, there are three that could adversely affect benthic EFH for the 15 groundfish species listed in Table 451. These are bottom otter trawls, scallop dredges, and hydraulic clam dredges. This conclusion is based on two recent reports. The first of these (NREFHSC 2002) is the report of a workshop held in October 2001 that examined the habitat effects of gears used in the Northeast region on three substrate types (gravel, sand, and mud). A panel of experts concluded that otter trawls and scallop dredges were the two highest priority gears in terms of impacts, with minimal impacts for clam dredges, nets and lines, and pots and traps. Clam dredges were ranked lower than otter trawls and scallop dredges because they are used primarily in sandy, high-energy environments that are exposed to extreme natural disturbances and because the fishery operates in a much smaller area than the scallop and groundfish fisheries.

The second report (Morgan and Chuenpagdee 2003) evaluated the effects of ten different commercial fishing gears on marine ecosystems in U.S. waters. It differentiated between habitat impacts and by-catch issues and listed the effects of each gear type in more detail than the first report. (It also relied on input from a larger group of experts and used more scientifically-based methods for collecting and analyzing the information). The report concluded that bottom trawls and dredges have very high habitat impacts, bottom gillnets and pots and traps have low to medium impacts, and bottom longlines have low impacts. Individual types of trawls and dredges were not evaluated. The impacts of bottom gill nets, traps, and longlines were limited to warm or shallow-water environments with rooted aquatic vegetation or "live bottom" environments (e.g., coral reefs).

9.3.1.8.4.2 Potential Adverse Impacts of Bottom Trawls and Dredges

Section 9.3.1.2.4 of this document describes the general effects of trawls and dredges on benthic marine habitats, as reported in three recent reports (ICES 2000, Johnson (2002), and NRC (2002). (The report by Morgan and Chuenpagdee was not available when this summary was written: it generally confirms the findings of the other three reports). All four of these reports are international or national in scope and include information on the effects of types of trawls and dredges not used in the Northeast region of the U.S. (e.g., beam trawls and toothed scallop dredges) and affected habitats not found in the NE region (e.g, coral reefs and maerl beds). The conclusions reached are, nevertheless, pertinent to an evaluation of potential adverse impacts of the types of trawls and dredges used in this region. To re-iterate, the four major types of habitat modification caused by bottom trawls that are identified in the ICES (2001) report are the following:

Loss or dispersal of physical features such as peak banks or boulder reefs (changes are always permanent and lead to an overall change in habitat diversity, which can in turn lead to the local loss of species and species assemblages dependant on such features);

Loss of structure-forming organisms such as bryozoans, tube-dwelling polychaetes, hydroids, seapens, sponges, mussel beds, and oyster beds (changes may be permanent and can lead to an overall change in habitat diversity which can in turn lead to the local loss of species and species assemblages dependant on such biogenic features);

Reduction in complexity caused by redistributing and mixing of surface sediments and the degradation of habitat and biogenic features, leading to a decease in the physical patchiness of the sea floor (changes are not likely to be permanent);

Alteration of the detailed physical features of the sea floor by reshaping seabed features such as sand ripples and damaging burrows and associated structures which provide important habitats for smaller animals and can be used by fish to reduce their energy requirements (changes are not likely to be permanent).

The NRC (2002) report also identified three major effects of trawling and dredging, the first two of which are also mentioned in the ICES (2001) report:

- Reduced habitat complexity;
- Discernible changes in benthic communities (caused by repeated trawling and dredging);
- Reduced productivity of benthic habitats.

The four effects of trawling identified in the ICES (2001) report are listed in order of decreasing permanence. Given the MSA definition of “adverse” as “more than minimal and not temporary,” the first effect is clearly adverse. The second effect may be permanent and the other two are not likely to be permanent. However, they are still considered as potential adverse impacts since they are effects that could persist in certain habitats that are exposed to more or less continual, or frequently repeated, trawling activity. Furthermore, given the similarity in the habitat effects of dredges and trawls noted in the NRC (2002) and Morgan and Chuenpagdee (2003) reports, all of these potential adverse effects are considered to apply equally well to both gear types.

Looking at the effects of bottom trawls, scallop dredges, and hydraulic clam dredges in the NE region, there is more specific information to evaluate. According to the October 2001 workshop report (NREFHSC 2002), otter trawls had greater overall impacts than scallop dredges, but affected physical and biological structure equally. Effects on biological structure scored higher than effects on physical structure for both gears. In addition, trawls were judged to have some effects on major physical features.

Additional information is provided in this report on the recovery times for each type of impact for all three gears in mud, sand, and gravel habitats ("gravel" includes other hard-bottom habitats). This information makes it possible to rank these three substrates in terms of their vulnerability to the effects of bottom trawling and dredging, bearing in mind that other factors such as frequency of disturbance from fishing and from natural events are also important. Otter trawls and scallop dredges were assigned higher impact scores in gravel, mud ranked second for trawls (and sand third), and sand ranked second for scallop dredges (this gear is not used in mud habitats). Clam dredges had low impacts compared to scallop dredges and trawls and are only used in sand.

Effects of trawls on major physical features in mud (deep-water clay-bottom habitats) and gravel bottom were described as permanent, and impacts to biological and physical structure were given recovery times of months to years in mud and gravel. Impacts of trawling on physical structure in sand were of shorter duration (days to months) given the exposure of most continental shelf sand habitats to strong bottom currents and/or frequent storms.

For scallop dredges in gravel, recovery from impacts to biological structure was estimated to take several years and, for impacts to physical structure, months to years. In sand, biological structure was estimated to recover within months to years and physical structure within days to months. Clam dredges are only used in sandy habitats where impacts to biological structure were estimated to last for months to years (depending on species composition) and impacts to physical structure, days to months.

Results of a comprehensive review of available gear effect publications that were relevant to the NE region of the U.S. are summarized in 9.3.1.2.4.2. Positive and negative effects of otter trawls, scallop dredges, and hydraulic clam dredges from 32 of these publications are listed by substrate type in Table 452 - Table 456 along with recovery times (when known). Without more information on recovery times, it is difficult to be certain which of the negative effects listed in these tables last for, say, more than a month or two. In fact, it is difficult to conclude in some cases (e.g., furrows produced by trawl doors) whether the habitat effect is positive, negative, or just neutral. Despite these shortcomings in the information, the scientific literature for the NE region does provide some detailed results that confirm the previous determinations of potential adverse impacts of trawls and dredges that were based on the ICES (2001), NRC (2002), and Morgan and Chuenpagdee (2003) reports.

Physical Effects	**Recovery**
Doors produce furrows/berms	2-18 months
Repeated tows increase bottom roughness	
Re-suspension/dispersal of fine sediments	
Rollers compress sediments	
Smoothing of surface features	
Biological Effects	
Reduced infaunal abundance	Within 3 ½ months (1 of 2 studies)
Reduced number of infaunal species	Within 3 ½ months
Reduced abundance of polychaete/bivalve species	Within 3 ½ months (1 of 2 studies)
Increased food value of sediments	
Increased chlorophyll production of surface sediments	
Removal/damage of epifauna	
Reduced abundance of brittlestars	
Increased number of infaunal species	
Increased abundance of polychaetes	
Decreased abundance of bivalves	
Altered community structure	18 months

Table 452 – Effects and Recovery Times of Bottom Otter Trawls on Mud Substrate in the Northeast Region as Noted By Authors of Eight Gear Effect Studies.

Physical Effects	Recovery
Doors produce furrows/berms	Few days – a year
Smoothing of surface features	Within a year
Re-suspension/dispersal of fine sediments	No lasting effects
Biological Effects	
Mortality of large sedentary and/or immobile epifaunal species	
Reduced density of attached macrobenthos	
Removal/damage of epifauna	
Reduced abundance of polychaetes	
Reduced abundance/biomass of epibenthic organisms	
Reduced biomass/average size of many epibenthic species	
Epifauna (sponges/anemones) less abundant in closed areas	

Table 453 - Effects and Recovery Times of Bottom Otter Trawls on Sand Substrate in the Northeast Region as Noted By Authors of Twelve Gear Effect Studies.

Physical Effects	Recovery
Displaced boulders	
Removal of mud covering boulders and rocks	
Groundgear leave furrows	
Biological Effects	
Reduced abundance of attached organisms (sponges, anemones, soft corals)	
Damaged sponges, soft corals, brittle stars	12 months

Table 454 – Effects and Recovery Times of Bottom Otter Trawls on Gravel and Rock Substrate in the Northeast Region as Noted By Authors of Three Gear Effect Studies.

Physical Effects	Recovery
Disturbed physical/biogenic structures	
Loss of fine surficial sediments	More than 6 months
Reduced food quality of sediments	Within 6 months
Biological Effects	
Reduction in total number of infaunal individuals	Within 6 months
Reduced abundance of some species (polychaetes/amphipods)	
Decreased densities of two megafaunal species	

Table 455 – Effects and Recovery Times of Chain Sweep Scallop Dredges on Sand Substrate in the Northeast Region as Noted By Authors of Three Gear Effect Studies.

Physical Effects	Recovery
Trenches/mounds along sides	1 day – 2 months or more
Fluidized sediments in trenches	More than 11 weeks
Re-suspension/dispersal of fine sediments	
Re-sorting of sediments in trench (coarse sediments at bottom)	Within 40 days
Increased turbidity	Minutes - hours
Biological Effects	
Reduction in total number of infaunal organisms	
Reduction in macrofaunal organisms	
Reduction in number of infaunal species	
Reduction in macrofaunal species/biomass (especially polychaetes)	

Table 456 – Effects and Recovery Times of Hydraulic Clam Dredges on Sand Substrate in the Northeast Region as Noted By Authors of Six Gear Effect Studies.

Given the evidence that there are potential adverse impacts of trawls on hard-bottom, sand, and mud habitats, of scallop dredges on hard-bottom and sand habitats, and of clam dredges on sand habitats in the NE region, the next step is to relate the intensity of fishing activity with each of these gear types to the distribution of these three substrates in the region. This comparison is over-simplified because it does not take into account other factors such as depth and the degree of natural disturbance, the quality of the sediment distribution is limited, and fishing activity is quantified by ten minute squares (TMS) of latitude and longitude. However, it generally indicates where within the region the adverse impacts of these three gears are concentrated.

The analysis in Section 9.3.1.2.3 indicates that the ten-minute-squares (TMS) that account for most of the bottom trawling in the region overlay a high percentage (>40%) of five different sediment types (Figure 252), even though most of the TMS are associated with sand since sand is the primary sediment type in the region. The results show that dredging is more closely related to sand (and less to the other sediment types) than trawling, but scallop dredges are used over a larger area than clam dredges and in a higher percentage of sand, gravelly sand, and gravel bottom areas. Bottom trawling during 1995-2001 was almost equally divided between the Gulf of Maine, Georges Bank, southern New England, and the Mid-Atlantic sub-regions, whereas scallop and clam dredging was more concentrated in the Mid-Atlantic (Figure 250). A significant amount of scallop dredging also took place on Georges Bank, likewise for clam dredging in southern New England. The frequency of scallop dredge activity increased relative to the amount of each sediment type present, with sediment grain size on Georges Bank and in the Mid-Atlantic (Figure 251). The same was true for clam dredges in the Mid-Atlantic and in southern New England.

The following conclusions can therefore be reached:

- Adverse and potentially adverse habitat impacts from bottom trawling occur throughout most of the NE region on a variety of substrates;
- Adverse and potentially adverse habitat impacts from scallop dredging occur primarily in the Mid-Atlantic and secondarily on Georges Bank on sand, gravelly sand, and gravel substrates;
- Adverse and potentially adverse habitat impacts from hydraulic clam dredging occur primarily in the Mid-Atlantic and secondarily in southern New England on sand substrates.

Based on these conclusions, bottom trawls are determined to have the largest adverse impact to benthic habitats in the NE region because they are used on more days at sea than dredges, and therefore affect a larger area of bottom, and because they affect a variety of substrates over a large area. It must be noted, however, that there is a large variety of bottom otter trawls that are designed to be used in specific bottom conditions to catch certain species, and that some of them affect benthic habitats more so than others. This conclusion therefore refers to bottom otter trawls in a generic sense. Scallop dredges (specifically, New Bedford style chain sweep dredges) rank second and have a larger impact than hydraulic clam dredges because they are affect a larger bottom area (larger fishing grounds and more bottom time), and their adverse effects are limited to sand and gravel substrates (not mud). Clam dredges only impact sandy substrates and are used in a much smaller area than scallop dredges or trawls.

9.3.1.8.4.3 Cumulative Impacts of All Three Gears

Because the potential adverse impacts of trawls and dredges are so similar (see Section 9.3.1.8.4.2) bottom otter trawls, scallop dredges, and clam dredges can be considered as a group and their cumulative effects as a function of the fishing activity of all three gears added together. In state waters, which are designated as EFH for one or more species in the multi-species assemblage, the cumulative effects of mobile, bottom-tending gear would also include adverse impacts from other types of dredges listed in Table 393. The combined effect of otter trawls, scallop dredges, and clam dredges was ranked considerably higher in gravel (and other hard-bottom habitats) than in sand (ranked second) and mud (ranked third)). Impacts on biological structure were considered to be more severe than impacts on physical structure, with removal of major physical features ranking third). A fourth effect, changes in benthic prey, was not adequately evaluated because there was not enough information available. Combined impacts to gravel and sand habitat were primarily to biological structure, with gravel ranking higher than sand. Impacts on physical structure were judged to be the same in gravel and sand. Impacts in mud ranked low, with removal of major physical structures scoring higher than impacts to physical and biological structure.

9.3.1.8.4.4 Species/Life Stages With Vulnerable EFH

A final step in the process of assessing the potential adverse impacts that was taken for this amendment is the determination of which of the 39 federally-managed species in the Northeast region have EFH which is vulnerable to the adverse impacts of otter trawls, scallop dredges, and clam dredges (Table 449). This evaluation was conducted by examining known life history information for each benthic life stage of these species that describes how habitat features such as three-dimensional structure and prey populations are affected by fishing activities for each gear type. Twenty-four species were determined to have EFH for at least one life stage that was moderately or highly vulnerable to the adverse effects of mobile, bottom-tending gear. Thirteen of the 15 species that are included in the multi-species assemblage were included in the list. Species and life stages that are not listed are adult and juvenile offshore hake, juvenile pollock, adult silver hake and white hake, juvenile winter flounder, and adult and juvenile windowpane. Assessments of habitat management measures that are intended to minimize the adverse impacts of fishing in this amendment/EIS should focus on the species and life stages.

The Council concurs with the EFH vulnerability determinations and has determined the following:

Notes: E = eggs lifestage, L = larvae lifestage, J = juvenile lifestage, and A = adult lifestage

Otter Trawls

The use of Otter Trawls may have an adverse effect on the following species (and life stages) EFH as designated in Amendment 11 to the Northeast Multispecies FMP (1998):

American plaice (Juvenile (J), Adult (A)), Atlantic cod (J, A), Atlantic halibut (J, A), haddock (J, A), ocean pout (E, L, J, A), red hake (J, A), redfish (J, A), white hake (J), silver hake (J), winter flounder (A), witch flounder (J, A), yellowtail flounder (J, A), red crab (J, A), black sea bass (J, A), scup (J), tilefish (J, A), barndoor skate (J, A), clearnose skate (J, A), little skate (J, A), rosette skate (J, A), smooth skate (J, A), thorny skate (J, A), and winter skate (J, A).

Scallop Dredge (New Bedford style)

The use of New Bedford style Scallop Dredges may have an adverse effect on the following species (and life stages) EFH as designated in Amendment 11 to the Northeast Multispecies FMP (1998):

American plaice (J, A), Atlantic cod (J, A), Atlantic halibut (J, A), haddock (J, A), ocean pout (E, L, J, A), red hake (J, A), redfish (J, A), white hake (J), silver hake (J), winter flounder (J, A), yellowtail flounder (J, A), black sea bass , (J, A), scup (J), barndoor skate (J, A), clearnose skate (J, A), little skate (J, A), rosette skate (J, A), smooth skate (J, A), thorny skate (J, A), and winter skate (J, A).

Hydraulic Clam Dredges

The use of Hydraulic Clam Dredges may have an adverse effect on the following species (and life stages) EFH as designatged in Amendment 11 to the Northeast Multispecies FMP (1998):

Atlantic cod (A), black sea bass (J, A), clearnose skate (J, A), little skate (J, A), ocean pout (E, L, J, A), red hake (J), rosette skate (J, A), scup (J), silver hake (J), winter flounder (A), winter skate (J, A), and yellowtail flounder (J, A).

Gear types other than otter trawls, scallop dredges and hydraulic clam dredges (in the context of the Northeast Multispecies fishery) were not found to have adverse effects the Essential Fish Habitat as currently designated in this region.

9.3.1.9 Non-Magnuson-Stevens Act Fishing Activities that may Adversely Affect EFH

There are a number of fishing activities that may adversely affect EFH that are not necessarily managed under the Magnuson-Stevens Act. For example, state fisheries, some recreational fisheries, subsistence fishing, and even research projects. When these activities are added together, they may have the potential to cumulatively impact habitat. It is difficult to keep track of every non-Magnuson fishing activity and measure all of these activities occurring along the coast, but the EFH Regional Steering Committee has gathered information about the various fishing gears used in the Northeastern United States and their potential effects on EFH. Table 457 describes the fishing gears used in estuaries and bays, coastal waters, and offshore waters of the EEZ from Maine to North Carolina. Notice the variety of gears used in state waters for non-Magnuson related fishing activities, and whether these gears come in contact with the bottom or not.

9.3.1.10 Non-fishing Related Activities that may Adversely Affect EFH

The Omnibus Habitat Amendment (1998), Amendment 11 to the Northeast Multispecies FMP, identified numerous potential non-fishing threats to essential fish habitat. The chemical, biological, and physical threats to riverine, inshore, and offshore habitats are extensively discussed in Section 5.2 of the Omnibus document. Overall, the major threats to marine and aquatic habitats are a result of increasing human population and coastal development, which is contributing to an increase of human generated pollutants. These pollutants are being discharged directly into riverine and inshore habitats by way of both *point* and *non-point* sources of pollution. Point sources of pollution include industrial discharge, power plants, sewage treatment plants, disposal of dredged materials, energy and mineral exploration, marine transportation, coastal and port development, and erosion. Non-point sources include run-off, wildlife feces, industrial shipping, recreational boating, septic systems, and contaminated groundwater and sediments. Table 458 summarizes the Non-Fishing Related Threats to EFH. Refer to Amendment 11 to the Northeast Multispecies FMP (1998) for a more complete discussion of these potential threats.

Table 458 - Non-Fishing Related Threats to EFH and Activities and Sources Contributing the Threats

Source: Habitat Omnibus Amendment (1998)

9.3.2 Conservation and Enhancement

The Magnuson-Stevens Fishery Conservation and Management Act requires all fishery management plans (FMPs) to identify actions to promote the conservation and management of fishery resources. Prior to the concept of essential fish habitat (EFH), conservation primarily involved management measures to reduce overfishing and rebuild overfished stocks. The Habitat Omnibus Amendment (1998) strengthened the role of the New England Fishery Management Council to further conserve and enhance EFH and related fishery resources. Section 6.0 of the EFH Amendment describes options to avoid, minimize, or compensate for the adverse effects of activities identifies as non-fishing threats to essential fish habitat.

The conservation and enhancement options promoted by the Council include, as directed in the Interim Final Rule: the enhancement of rivers, streams, and coastal areas; improving water quality and quantity; watershed analysis and planning; and habitat creation. The Habitat Omnibus Amendment detailed recommendations to address fishing threats including chemical, biological, and physical threats. Furthermore, the state, non-profit, and other federal agencies that are working with the Council to develop programs to monitor and research habitat are highlighted in that document as well.

9.3.3 Prey Species

Appendix A of the Habitat Omnibus Amendment (1998) describes the life history and habitat characteristics of all Council-managed species. The abundance of major prey items in the diet of these managed species are listed within the Appendix, which are based on the NEFSC bottom trawl survey data. This information is important to consider when analyzing prey species and essential fish habitat, however existing law does not require the Council to define prey species as EFH. Technical guidance from NOAA general counsel encouraged the Councils to identify the prey species for the species managed under the FMP and describe the habitat of those significant prey species to aid in the determination of adverse effects to their habitat. This information should be included in the “adverse effects” section of the EFH FMP, rather than the description and identification section. Therefore, the Habitat Omnibus Amendment is sufficient to date, and the EFH Source Documents should be referred to when evaluating adverse effects of EFH (Appendix A of EFH Amendment).

9.3.4 Research and Information Needs

The regulatory text of the EFH Final Rule directs the Council to include in the EFH amendment recommendations, preferably in priority order, for research efforts that the Council and NMFS view as necessary for carrying out their EFH management mandate. The need for additional research is to make available sufficient information to support a higher level of description and identification of EFH. Additional research may also be necessary to identify and evaluate actual and potential adverse effects on EFH including, but not limited to, direct physical alteration, impaired habitat quality/functions, cumulative impacts from fishing, or indirect adverse effects such as sea level rise, global warming and climate shifts, and non-equipment related fishery impacts. The need for additional research on the effects of fishing equipment on EFH is also included. The research needed to quantify and mitigate adverse effects on EFH is identified in this amendment as well.

The Council hopes to coordinate with NMFS in identifying research priorities for EFH; therefore, the Council supports the recent work compiled by the Northeast Region EFH Steering Committee (2000). 9.3.4 is the result of what the EFH Steering Committee discussed related to habitat research needs. Five major research categories were identified: habitat characterization needs, gear impacts, specific habitat studies, data collection needs, and anthropogenic impacts. Research priority is given when appropriate, and potential funding sources are identified as well. The Habitat Technical Team recognizes that all research priorities are important, but the cost and length of a project are critical factors in determining its overall priority. The length of recovery for a specific habitat type may be a realistic goal for short-term research, but until a determination is made on how fish are linked to these habitats, management will not benefit from these projects. The Council's EFH Technical Team identified high-resolution mapping of the ocean floor as the research need with the highest benefit to EFH research, but is also the most expensive. It is important for the Council to assist the research community to identify what habitat research is currently taking place, so future research can be directed to complete these projects into one integrated EFH dataset for the Northwest Atlantic.

Research Category	Research Need	Priority	Potential Funding Source	Council/ ASMFC Interest
Habitat Characterization Needs	Provide high resolution benthic/sediment mapping of mid-Atlantic and New England areas # Identify and describe biogenic structure and biological communities associated with different physical habitat types # Develop mechanism for fishing industry-supported, high resolution sediment mapping in the Gulf of Maine and Georges Bank. Use Canadian sea scallop industry mapping effort as an example to establish process for similar mapping efforts in U.S. waters	HIGH HIGH HIGH	Examples - NOAA (Habitat Characterization Initiative?), NMFS, Sea Grant, Councils NE Cooperative Research Funds	All All NEFMC

9.3.5 Identification of HAPCs

This review will take place during the next Habitat Omnibus Amendment scheduled to be completed in 2004. The process for considering new HAPC proposals is outlined in the Council's Habitat Annual Review and Report of 2000. This process will be followed during the next Omnibus Amendment.

9.3.6 Review and Revision of EFH Components of FMPs

The Council conducts a review of EFH designations at least once every five years, and this will take place during the upcoming Habitat Omnibus Amendment 2.

9.4 Human Environment

9.4.1 Overview of Affected Human Environment Section

The Affected Human Environment section describes the New England multispecies fishery from 1994 to the present, examining how management actions and changes in fishing activity have shaped the fishing industry and fishing communities over time. Social, economic and fishery information presented in this section are useful in describing the response of the fishery to past management actions and predicting how the present action may affect the multispecies fishery. Additionally, this section of the document establishes a descriptive baseline for the fishery with which to compare actual and predicted future changes that result from management actions. For a complete discussion of prior management actions leading up to Amendment 13, refer to section 0, "Brief History of Prior Management Actions."

This information helps to meet the legal requirements of the Council under the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA), the National Environmental Policy Act (NEPA), and other applicable laws. Specifically, it addresses National Standard 8, established in a 1996 amendment to the Magnuson-Stevens Act. National Standard 8 of the MSFCMA states that: *Conservation and management measures shall, consistent with the conservation requirements of this act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (a) provide for sustained participation of such communities, and (b) to the extent practicable, minimize adverse economic impacts on such communities.*

National Standard 8 requires the Council to consider the importance of fishery resources to affected communities and provide those communities with continuing access to fishery resources, but it does not allow the Council to compromise the conservation objectives of the management measures. "Sustained participation" is interpreted as continued access to the fishery within the constraints of the condition of the resource.

NEPA requires federal agencies to consider the interactions of natural and human environments and the impacts on both systems of any changes due to governmental activities or policies. This analysis should be done by means of "a systematic, interdisciplinary approach which will ensure the integrated use of the natural and social sciences ... in planning and decision-making" [NEPA section 102(2)(a)]. Environmental values must be considered and weighed on par with technical and economic considerations. Environmental values include angler satisfaction, job satisfaction, an independent life-style for commercial fishermen, and the opportunity to see species in the wild for the non-consumptive user of marine fishery resources.

NEPA specifies that the term *human environment* shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment [40 CFR 1508.14]. When analyses predict that a fishery management action or policy will have a *significant* effect on the human environment, a detailed Environmental Impact Statement (EIS) with analysis of these impacts must be prepared. Amendment 13 addresses this requirement with a complete, detailed EIS.

A full range of impact assessments – ecological, economic, and social – are necessary not only to meet MSFCMA and NEPA requirements, but also to improve the Council's decision-making process. The following discussion provides a useful tool for assessing the environmental impacts of Amendment 13 and the cumulative effects of past, present and future management actions.

The Affected Human Environment section is organized in the following format:

Section 9.4.2 - Commercial Harvesting Sector
This section describes the composition of the fleet in terms of permit category, gear type, vessel size, and home port state. Discussion of the multispecies fishery focuses primarily on the years 1996 through 2001, inclusive. Because of their significant effects on the multispecies fishery, Amendments 5 (1994) and 7 (1996) to the multispecies plan are used as historical markers to frame the discussion of the commercial harvesting sector.

Section 9.4.3 - Recreational Harvesting Sector
The recreational harvesting sector, which comprises both individual anglers and charter/party boats, is described independent of the commercial sector. While the recreational sector is increasing in magnitude within the multispecies fishery, it cannot be analyzed in conjunction with the commercial sector because of differences in the way landings data are reported and managed. The recreational catch is composed primarily of cod, haddock and winter flounder. Pollock, other flounder and hake contribute to a less substantial portion of the recreational catch.

Section 9.4.4 - Wholesale Trade and Processing Sector
This section describes the processing sector, distinguishing between the fresh fish processing and frozen fish processing industries. In addition, it includes information on wholesale firms, which do not process fish but buy from processors and sell to retail outlets, institutions, and other consumers.

Section 9.4.5 - Fishing Communities
In this amendment, coastal communities throughout the northeast region are organized into primary and secondary *port groups* based on participation in the groundfish fishery since the 1994 fishing year. This section includes landings and revenues information by community group as well as social and demographic statistics compiled by the Census Bureau for counties.

9.4.2 Commercial Harvesting Sector

9.4.2.1 Characterizing the Commercial Fishery as a Whole

The multispecies fishery in the Northeastern United States is made up of a commercial sector and a recreational sector, which target the twelve species that constitute the large-mesh multispecies management unit and the three small-mesh species managed as a separate multispecies unit. Fishery information in this section reflects ten of the twelve large-mesh species, excluding ocean pout and Atlantic halibut.

Total and groundfish (large-mesh regulated multispecies) landings have generally demonstrated a positive trend from 1994 to 2001 (Table 460). Total landings by multispecies vessels increased an average of approximately 4.3% each year from 1994 to 2001, while groundfish landings increased, on average, 5.3% annually during that period. Groundfish landings fluctuated between 1994 and 2001, decreasing about 10% from 1994 to 1995, increasing slightly from 1996 to 1997, decreasing to a small extent in the following two years, and increasing again approximately 45% from 1999 to 2001.

	1994	1995	1996	1997	1998	1999	2000	2001
Total Landings, **all species**	418,071	438,497	453,540	528,788	522,683	467,931	486,302	550,562
Total Landings, **groundfish only**	75,334	67,779	72,384	72,734	71,649	71,517	90,775	104,325
Total Revenues, **all species**	$361,479	$348,628	$339,489	$327,839	$318,870	$382,718	$405,996	$389,118
Total Revenues, **groundfish only**	$94,025	$85,503	$82,444	$82,244	$87,614	$87,615	$95,306	$99,740

Table 460 - Landings (thousands of pounds) and revenues (thousands of 1999 dollars) of multispecies vessels, 1994-2001

Data are for multispecies permit holders only. Data reported by fishing year – May 1 to April 30. Revenues expressed in 1999 dollars. Data Source: NMFS Dealer database.

Total revenues trends did not closely mimic total landings trends across all years (Figure 253). From 1994 to 1997 and 2000 to 2001, total landings increased while revenues decreased because low-value small non-multispecies comprised an increasing proportion of the total landings while the proportion of high-value species decreased across both time periods. Where the opposite occurred from 1998 to 1999, the proportion of high-value species increased while that of low-value small non-multispecies decreased. Total revenues were somewhat variable throughout the time period, decreasing from 1994 to 1998, increasing an average of 13% per year from 1998 to 2001, and decreasing about 4% from 2000 to 2001. Trends in groundfish revenues generally reflect groundfish landings trends. Groundfish revenues decreased between 1994 and 1996 then generally trended upwards between 1996 and 2001, although they did not demonstrate increases greater than about 8% between any two consecutive years.

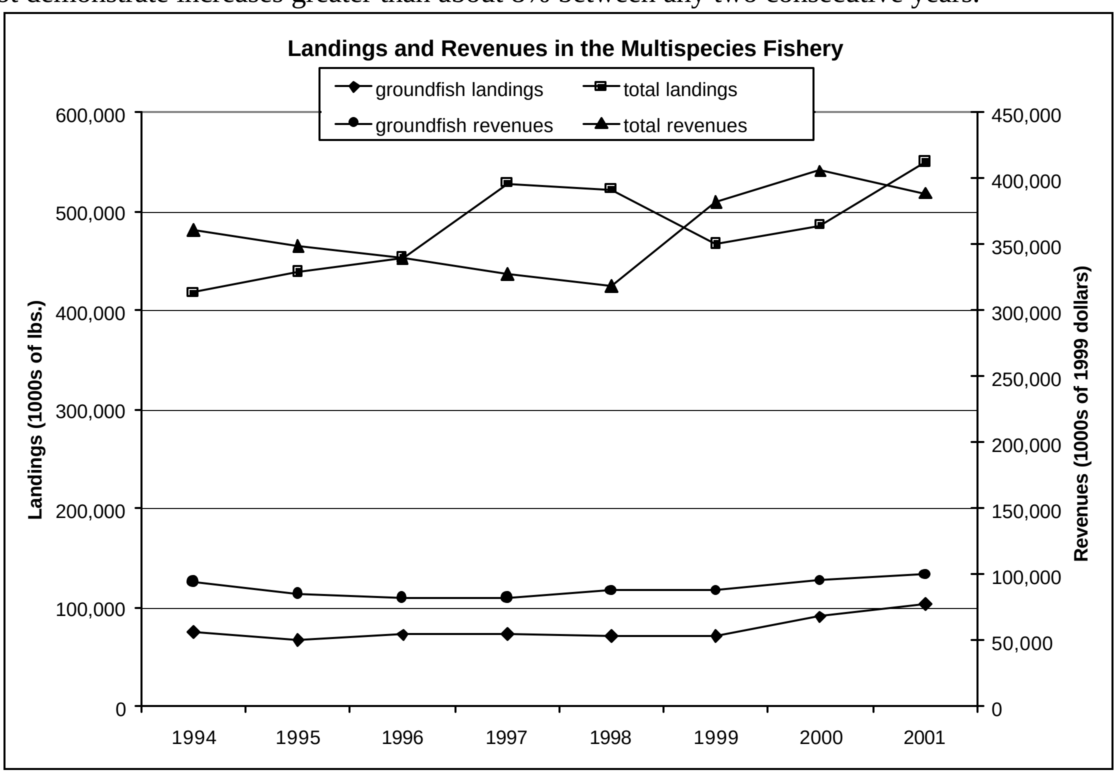

Figure 253 – Landings and Revenues in the Multispecies Fishery, 1994-2001

Fleet Composition
The total number of multispecies permits declined from 1996 to 1998 but increased in later years, returning to nearly its 1996 level by 2001. Since 1996, open access permits have made up the greatest proportion of total multispecies permits. From 1996 to 2001, the highest total landings were brought in by Fleet DAS and Open Access vessels. Across all years, Individual DAS vessels were more financially dependent on groundfish than vessels in other permit categories. This is also reflected in day-at-sea use by Individual DAS vessels, which used the greatest percentage of their allocated category DAS in each year from 1996 to 2001. In general, while numbers of individual, fleet and small vessel exemption permits declined from 1996 to 2001, numbers of hook gear, large mesh fleet and open access permits increased. Combination vessel and large mesh individual permits remained relatively constant across the time period.

The multispecies fleet is composed primarily of small to medium-sized vessels. Vessels from 30 to 50 feet have consistently made up the greatest proportion of multispecies vessels from 1994 to 2001. In general, the number of smallest vessels has diminished most substantially, demonstrating the greatest percent declines from 1994 to 2001, particularly in the periods directly following Amendments 5 and 7. The smallest vessels, while contributing the least groundfish landings in all years from 1994 to 2001, demonstrated the greatest average annual percent increases from year to year during this time period, particularly after 1999. In general, larger vessels have home ports in southern states and at the southern range of mid-Atlantic states (North Carolina, Virginia, Florida) while smaller vessels reside in the northern Atlantic states (Massachusetts, New Hampshire, Maine).

The number of multispecies vessels active in the groundfish fishery as a percentage of total active multispecies vessels indicates that a substantial amount of latent effort exists in the fishery. In 2001, there were nearly three times more multispecies permits than vessels which actually reported landings of groundfish. The number of active groundfish vessels has generally remained steady from 1996 to 2001. Many changes in distribution of landings among permit categories represent shifts in participation across categories rather than extensive movement in and out of the fishery entirely.

An investigation of the non-multispecies permits held by multispecies permit holders demonstrates that squid/mackerel/butterfish, lobster and scallop fisheries have been important fisheries to multispecies vessels which have sought diversification as a means of supplementing their income obtained from groundfish since 1994.

Bottom trawls were the top gear indicated as primary gear type from 1995 to 2001, followed by hook and line vessels and sink gillnets, the majority of these day boats. Between 1994 and 2001, bottom trawls accounted for a large majority of total and groundfish landings in each year. Total bottom trawl landings decreased overall from 1994 to 2001 primarily as a result of restrictions in other fisheries, evident in the fact that groundfish landings by bottom trawls increased over this time period. Following bottom trawls, the next four top contributors to total landings were "other" gears, sink gillnets, scallop dredges, and midwater trawls. Bottom longlines, which ranked third in contribution to groundfish landings, exhibited the greatest percent decline in landings of any of the gears. Hook and line groundfish landings exhibited a dramatic increase from 1996 to 2001. DAS use increased from 1996 to 2001 for each of the four primary gear types. Bottom trawls used the greatest percentage of allocated DAS from 1996 to 2001, while hook and line vessels utilized the smallest percentage of days allocated.

Fleet composition by state has remained relatively consistent for both active multispecies vessels in all fisheries and active multispecies vessels in the groundfish fishery from 1996 to 2001. The multispecies fleet is dominated by vessels with home ports in Massachusetts and Maine. Massachusetts vessels dominated all limited access permit categories throughout the period. From 1996 to 2001, the percent of Category A (Individual DAS) vessels from Massachusetts decreased slightly while increasing slightly in

Maine. New Hampshire also increased participation in this permit category. The number of Massachusetts vessels in the largest permit category, Category B (Fleet DAS), remained fairly constant from 1996 to 2001. Maine, Rhode Island and New York vessels together with those from Massachusetts made up the majority of this category over the time period. Vessels in combined open access categories were distributed more evenly among states than vessels in limited access categories.

Total and groundfish landings were highest for Massachusetts vessels in all years from 1996 to 2001. Total landings in Massachusetts, Rhode Island and New Jersey, the three highest contributing states to total landings, declined in the late '90s. Groundfish landings were highest in Massachusetts and Maine from 1996 to 2001, generally decreasing from the mid- to late-1990s. Groundfish landings in both states increased in the later years of the time period. Permitted multispecies vessels with home ports in some southern New England and mid-Atlantic states, though contributing a high percentage of landings to the total, are less active than Maine and New Hampshire vessels in the groundfish fishery. Those states may be more dependent on non-groundfish fisheries such as scup, squid, mackerel and butterfish. Maine and Massachusetts are clearly the largest stakeholders in the New England groundfish fishery with highest groundfish landings and revenues from 1996 to 2001. In examining groundfish revenues as a percentage of total revenues, however, New Hampshire fisheries are most heavily dependent on groundfish, followed by those in Maine.

All of the New England states increased their use of allocated DAS after Amendment 7 (1996). Active vessels in Maine and New Hampshire have used a higher percentage of allocated DAS than vessels in other states since 1997. Active vessels in New York and New Jersey have used a lower percentage of allocated DAS than vessels in other states since 1997.

9.4.2.2 Predictability of Landings and Revenues

An analysis was conducted in Amendment 7 (1996) that predicted landings and revenues of the large mesh species (groundfish) and the combined cod-haddock-yellowtail group from 1996 to 2005. The observed landings fell within the 95% confidence interval for predicted landings in every year from 1996 to 2000 (Table 461).

	1996	1997	1998	1999	2000
5% level	63,700	49,500	60,200	70,800	83,900
Observed	72,514	72,935	71,793	71,100	90,036
95% level	92,400	73,600	97,500	121,700	142,800

Table 461 - Total landings (in thousands of pounds) of regulated large mesh species from Amendment 7 analyses. Predicted values (at the 5th and 95th percentile) vs. observed, 1996-2000

Data are for multispecies permit holders only. Data reported by fishing year – May 1 to April 30. Data Source: NMFS Dealer Database and Amendment 7 to the Northeast Multispecies Fishery Management Plan.

Combined cod-haddock-yellowtail landings fell within the 95% confidence interval for predicted landings in every year since implementation of Amendment 7 except for 1997, when the observed landings exceeded the 95% level by almost 10 million pounds (Table 464). Mortality objectives may not have been met in 1997.

	1996	1997	1998	1999	2000
5% level	24,700	13,600	19,000	24,400	30,900
Observed	33,565	33,232	33,616	36,366	47,754
95% level	37,800	23,400	35,300	46,300	57,700

Table 462 - Total landings (in thousands of pounds) of combined cod-haddock-yellowtail from Amendment 7 analyses. Predicted values (at the 5th and 95th percentile) vs. observed, 1996-2000

Data are for multispecies permit holders only. Data reported by fishing year – May 1 to April 30. Data Source: NMFS Dealer Database and Amendment 7 to the Northeast Multispecies Fishery Management Plan.

Total revenues observed for the years 1996 and 1998 through 2000 fell within the 95% confidence interval for revenues predicted in Amendment 7 (Table 463). The observed revenue for 1997 exceeded the 95% confidence level by nearly 10 million dollars.

	1996	1997	1998	1999	2000
5% level	$64,239	$53,401	$61,981	$70,900	$70,300
Observed	$82,020	$82,628	$87,594	$86,719	$93,428
95% level	$84,560	$72,819	$92,124	$107,366	$107,000

Table 463 - Total gross revenue (in thousands of dollars) of regulated large mesh species from Amendment 7 analyses. Predicted values (at 5th and 95th percentile) vs. observed, 1996-2000

Data are for multispecies permit holders only. Revenues expressed in 1999 dollars. Data reported by fishing year – May 1 to April 30. Data Source: NMFS Dealer Database and Amendment 7 to the Northeast Multispecies Fishery Management Plan.

Combined cod, haddock and yellowtail revenues exceeded the predicted range in 1997, 1998 and 2000 (Table 464). These divergences may have resulted from price assumptions used in the model which were based on landings lower than those predicted in 1997. Prices were calculated *ex post facto* for this analysis from the observed landings and revenues in 1996 through 2000 (Table 465). The price reached a period high of $1.32 in 1998.

	1996	1997	1998	1999	2000
5% level	$28,224	$18,289	$23,596	$29,240	$30,700
Observed	$36,966	$38,738	$44,416	$47,064	$53,657
95% level	$40,643	$28,902	$39,966	$49,110	$51,900

Table 464 - Total revenues (in thousands of dollars) of combined cod-haddock-yellowtail from Amendment 7 analyses. Predicted values (at 5th and 95th percentile) vs. observed, 1996-2000

Data are for multispecies permit holders only. Revenues expressed in 1999 dollars. Data reported by fishing year – May 1 to April 30. Data Source: NMFS Dealer Database and Amendment 7 to the Northeast Multispecies Fishery Management Plan.

	1996	1997	1998	1999	2000
Average Price	$1.10	$1.17	$1.32	$1.29	$1.12

Table 465 - Average price per pound of combined cod-haddock-yellowtail based on total group revenue and landings from Dealer database, 1996-2000

Data are for multispecies permit holders only. Revenues expressed in 1999 dollars. Data reported by fishing year – May 1 to April 30. Data Source: NMFS Dealer Database

The analytical model used to generate these data was generally successful at predicting groundfish landings with 95% confidence but predicted revenues less accurately. For both total groundfish and combined cod, haddock and yellowtail revenues, the observed values in some years exceeded the predicted range. This may have resulted from certain assumptions used in the model.

9.4.2.3 AHE Data Caveats

Data Sources
NMFS Dealer Database
NMFS Permit Database
NMFS Enforcement Database

Reported Numbers of Vessels
When evaluating the number of vessels reported in any given table in the following sections it is necessary to understand exactly which vessels those numbers represent. Depending on the way in which the data were queried, a different number of vessels will emerge. In each of the following sections, there are two tables describing the number of vessels active in the multispecies fishery. The first is associated with total landings by permitted multispecies vessels. In this table, the number given for each fishing year is the quantity of vessels which possess multispecies permits and were active in *any* fishery, which may or may not include the regulated multispecies fishery, in that given fishing year. The second table is associated with groundfish landings only. In this table, the number given for each fishing year is the quantity of vessels which possess multispecies permits and were active in the *groundfish* fishery, having landed at least one pound of regulated groundfish, in that given fishing year. The total number of active vessels with multispecies permits that land *any* species is not equal to the total number of vessels with multispecies permits, because some of these permitted vessels may not be active in any fishery in a given fishing year. This value, the total number of active and inactive vessels with multispecies permits, is discussed in Section 9.4.2.4.1, Fishing Activity by Permit Category. In all sections, the fishing activity discussed is associated only with vessels that hold a multispecies permit--one large-mesh limited access multispecies permit *OR* one or more open access multispecies permits.

Permit Categories
The permit categories referred to in Section 9.4.2.4.1 are those established in Amendment 7 (1996). Revenue is reported as gross revenue and does not take into account the changes in fixed and operating costs over time (net revenue). Landings and revenue data for charter/party vessels are not discussed in conjunction with other commercial sector permit categories since charter/party landings are reported in number of fish, rather than weight.

9.4.2.4 Fishing Activity in the Commercial Harvesting Sector

Since the implementation of Amendment 5 in 1994, some major additions to the existing management plan have included a days-at-sea program to control effort, large year-round and seasonal closed areas, trip limits, and inshore rolling closures. The following four sections examine changes in fishing activity within the commercial harvesting sector resulting from these management actions over time. The commercial harvesting sector may be described as a function of its multiple components, including gear types, vessels, and communities. In this section, activity in the commercial sector is characterized in terms of **permit category**, **vessel length class**, **gear type** and **home port state**. Because of the way in which the data is queried for each of these descriptive approaches, total numbers of vessels, landings and revenues may differ slightly among the four sections. Where such anomalies occur, we have attempted to provide a clear explanation. The *Data Caveats* section at the beginning of each discussion also provides important information regarding these data.

9.4.2.4.1 Fishing Activity by Permit Category

Under Amendment 7 the following permit categories were created:

A Individual DAS
B Fleet DAS
C Small vessel exemption
D Hook gear
E Combination vessel
F Large mesh individual DAS
G Large mesh fleet DAS

H Handgear
I Charter/Party
J Scallop multispecies possession limit
K Non-regulated species

A-G are limited access multispecies permit categories, described in CFR 648.82. H-K are open access multispecies permit categories, described in CFR 648.88.

The limited access permit categories are briefly described below. For a complete discussion of how DAS were allocated to vessels in each category, refer to Amendment 7.

Limited Access Permit Categories

(A) Individual DAS:

Individual DAS vessels are subject to DAS restrictions. Any vessel issued a valid Individual DAS permit as of July 1, 1996 (except those that were issued a gillnet permit) was assigned to the Individual DAS category in Amendment 7.

(B) Fleet DAS:

Fleet DAS vessels are subject to DAS restrictions. Any vessel issued one of the following permits as of July 1, 1996 was assigned to the Fleet DAS category in Amendment 7: Fleet DAS permit, Gillnet permit, limited access Hook-Gear permit, "Less than or equal to 45 ft (13.7 m)" permit to a vessel larger than 20 ft (6.1 m) in length as determined by its most recent permit application.

(C) Small Vessel Exemption:

Small vessel category vessels may retain up to 300 lb (136.1 kg) of cod, haddock, and yellowtail flounder, combined, and one Atlantic halibut per trip without being subject to DAS restrictions. These vessels are not subject to possession limits for other NE multispecies. Any vessel that has a valid limited access multispecies permit, was fishing with a small vessel category permit (less than or equal to 45 ft (13.7 m)) as of July 1, 1996, and is 20 ft (6.1 m) or less in length as determined by the vessel's last application for a permit, was assigned to the small vessel category in Amendment 7.

(D) Hook-gear:

Hook gear vessels are subject to DAS restrictions. Each hook-gear vessel is limited to 4,500 rigged hooks and is prohibited from possessing gear other than hook gear on board.

(E) Combination vessel:

Combination vessels are subject to DAS restrictions. A vessel issued a valid limited access multispecies permit and qualified to fish as a combination vessel as of July 1, 1996 was assigned to the Combination vessel category in Amendment 7.

(F) Large Mesh Individual DAS:
Large mesh individual DAS vessels are subject to DAS restrictions. Large Mesh Individual vessels are required to fish for the entire year with either gillnet gear with a minimum size of 7-inch (17.78 cm) diamond mesh or with trawl gear with a minimum size of 8-inch (20.32 cm) diamond mesh in order to remain in this category.

(G) Large Mesh Fleet DAS:
Large mesh fleet DAS vessels are subject to DAS restrictions. Large Mesh Fleet vessels were required to fish with either gillnet gear with a minimum size of 7-inch (17.78-cm) diamond mesh or trawl gear with a minimum mesh size of 8-inch (20.32-cm) diamond mesh.

Open Access Permit Categories
(H) Handgear permit:
A vessel with a valid open access multispecies handgear permit is allowed to possess and land up to 300 lb (136.1 kg) of cod, haddock, and yellowtail flounder, combined, one Atlantic halibut per trip, and an unlimited quantity of the other NE multispecies, provided that the vessel did not use or possess on board gear other than rod and reel or handlines while in possession of, fishing for, or landing NE multispecies, and provided it has at least one standard tote on board. A Handgear permit vessel may not fish for, possess, or land regulated species from March 1 through March 20 of each year.

(I) Charter/party permit:
Any charter/party permit category vessel is subject to restrictions on gear, recreational minimum fish sizes, possession limits, and specified prohibitions on sale.

(J) Scallop multispecies possession limit permit:
A vessel that has been issued a valid open access scallop multispecies possession limit permit may possess and land up to 300 lb (136.1 kg) of regulated species when fishing under a scallop DAS, provided the vessel does not fish for, possess, or land haddock from January 1 through June 30 and provided the vessel has at least one standard tote on board.

(K) Non-regulated multispecies permit:
A vessel issued a valid open access, non-regulated multispecies permit may possess and land one Atlantic halibut and an unlimited quantity of the other non-regulated multispecies. The vessel is subject to restrictions on gear, area, and time and other restrictions.

Amendment 7 permit categories *replaced* those established in Amendment 5 (1994), listed below:

Limited Access Permit Categories
1. Individual DAS
2. Fleet DAS
3.Vessels 45 feet or less in length
4. Hook gear only
5. Combination vessel
6. Gillnet vessel

Open Access Permit Categories
7. Hook gear only

8. Possession limit

Data Caveats

Number of vessels, landings and revenues are reported by permit category for the years 1996 to 2001. General landings trends are discussed for the years 1994 and 1995. Data for these years by permit category will be included in the Final EIS for Amendment 13.

Since an individual may possess more than one open access permit, the open access categories (except charter/party) were combined with permit records that were not associated with actual landings eliminated to produce a mutually exclusive list of vessels associated with open access permits. The Charter/Party permit category is discussed in the Recreational Harvesting Sector section of the document. Multispecies permit holders may either possess only one limited access multispecies permit and *no* open access multispecies permits **OR** one or more open access multispecies permits.

Number of Vessels by Permit Category

The total number of permits is separated into the seven limited access permit categories below (Table 466). Open access categories were combined and are reported as a single value for each year. "Unknown" is listed for vessels which did not report a permit category. The total number of permits with unknown permit category was highest in 1996 (26.8% of total multispecies permits) most likely because it was the first year in which vessels were transitioning into the new Amendment 7 permit categories. These vessels with unknown permit category will be discussed minimally. From 1997 to 2001, "unknown" permits made up an average of 7.3% of the total.

The total number of multispecies permits decreased from 4,298 permits in 1996 to 3,541 permits in 1998, a decline of 17.6%. After 1998, this number increased an average of 4.7% per year, from 3,541 permits in 1998 to 4,066 in 2001. For all years after 1996 open access vessels make up the greatest percentage of total vessels, increasing from 32.1% in 1996 to 52.6% in 2001 with an average of 45.8% across the time period. *The open access category is expanding, having increased an average of nearly 10% each year from 1996 to 2001.*

Fleet vessels make up the greatest proportion of limited access vessels, averaging 75.5% of the total (not including open access boats). This proportion of all limited access vessels has decreased from 78.8% in 1996 to 73.2% in 2001. Vessels with hook gear permits make up the second greatest number of limited access vessels in all years after 1996, with a mean of 10.8% of the total number of limited access multispecies permits over the time period. The number of hook gear permits increased until 1998 and subsequently decreased. Individual permits composed the second greatest number of limited access permits in 1996 and the third greatest number of limited access permits in following years, averaging 8.6% of the total from 1996 to 2001. Individual permits dropped from 9.4% of the number of limited access multispecies permits in 1997 to 8.6% of this number in 2001.

In general, while numbers of individual, fleet DAS, and small vessel exemption permits declined from 1996 to 2001, numbers of hook gear, large mesh fleet DAS and open access permits increased. Combination vessel and large mesh individual DAS permits remained relatively constant across the time period.

Permit Category	1996	1997	1998	1999	2000	2001
Individual DAS	160	167	135	136	134	140
Fleet DAS	1,390	1,339	1,244	1,258	1,245	1,194
Small Vessel Exemption	16	16	12	15	14	10
Hook Gear	141	195	197	198	186	176
Combination Vessel	48	46	44	43	47	47
Large Mesh, Individual DAS	0	2	1	1	2	2
Large Mesh, Fleet DAS	10	16	18	19	27	62
Open Access Combined	1,381	1,740	1,628	1,777	1,971	2,140
Unknown Category	1,152	281	262	267	275	295

Table 466 - Total number of multispecies vessels by permit category, 1996-2001
Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

The numbers discussed above represent only the number of total multispecies permits in the fishery, and do not differentiate between active and inactive (latent) permits. Table 467 shows the permitted multispecies vessels that are active in <u>any</u> fishery, with landings not limited to groundfish. These vessels are associated with total landings (Table 470) and total revenues (Table 471). Vessels active in the groundfish fishery, or those which landed at least one pound of groundfish in each of the given fishing years, are reported in Table 468. These vessels are associated with groundfish landings (Table 472) and groundfish revenues (Table 473). The problem with latent effort in the multispecies fishery is evident when the numbers of active vessels are compared to the numbers of permits alone. In the years 1996 through 2001, multispecies vessels active in any fishery, as a percent of total permitted vessels, ranged from 49.5% to 54.6%. The number of total active vessels (those which landed at least one pound of any species) generally trended downward from 1996 to 2000 and increased nearly 5% from 2000 to 2001.

Table 467 - Number of multispecies vessels active in any fishery by permit category, 1996-2001
Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Permitted multispecies vessels that were active in the groundfish fishery itself represent an even smaller fraction of the total permits (Table 468). As a percentage of the number of vessels which were active in *any* fishery, those active in the *groundfish* fishery ranged from 61.6% to 67.1% in 1996 through 2001. In 2001, there were nearly three times more permitted multispecies vessels than vessels which actually reported landings of groundfish. This number of active groundfish vessels (those which landed at least one pound of groundfish) decreased slightly from 1996 to 1999 and increased slightly in the following years, yet generally remained steady across the time period.

Among both the active total and the active groundfish vessels, the greatest percent decreases were exhibited in the Fleet DAS and Individual permit categories, with an average annual percent decline of about 7% in each category. For active groundfish vessels only, the greatest increases were in numbers of large mesh fleet (avg. annual increase of 47.8%) and open access vessels (avg. annual increase of 8.2%). It is important to note that vessels are allowed to change permit categories from year to year, and a decline in one category may result from movement of vessels into another category and not due to loss of active vessels from the groundfish fishery. This is particularly evident in the years 1999 through 2001, when the total number of multispecies vessels active in the groundfish fishery was increasing while the number of vessels in some permit categories decreased during this period. For example, it is likely that the Fleet DAS category, which diminished from 1996 to 2001, experienced a movement of Fleet vessels into the Large Mesh Fleet category, which expanded during that same time period.

Permit Category	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**

<u>Permits in Other Fisheries</u>

As is evident in the discrepancies between number of vessels active in any fishery and those active in the groundfish fishery, multispecies permit holders are engaged in other regulated, non-groundfish fisheries. To determine which other fisheries multispecies permit holders participate in, the composition of total permits held by multispecies permit holders was determined. Only the years following implementation of Amendment 7 permit categories are included in these analyses (1996-2001). Some of the other species permits multispecies permit holders now possess were not in existence in some years prior to the present. For example, monkfish and dogfish permits were not required until fishing year 1999. Most of the other permits held by multispecies permit holders were in existence by 1999, with the exception of tilefish.

Because of the addition of new permit requirements for various regulated species, the average number of permits held by an individual multispecies permit holder has increased from 3.25 permits in 1994 to 7.32 permits in 2001. In 1994, 25.9% of multispecies permit holders had a single multispecies permit and no additional permits. This percentage dropped to 23.2% in 1996 and again to 9.7% in 2001. One to five additional permits (other regulated species permits or additional open access multispecies permits) were held by 67% of multispecies permit holders in 1994 and 70.4% in 1996, decreasing to 34.4% in 2001. Six to ten additional permits were held by 7% of multispecies permit holders in 1994 and 6.4% in 1996, rising in subsequent years to 39.4% in 2001. Eleven to fifteen additional permits were held by no multispecies permit holders in 1994 and 1996, and rose to 14.5% in 2001.

These data show that multispecies permit holders are likely to hold between one and ten additional permits, depending on permit requirements from year to year. Few multispecies permit holders will depend on a single multispecies permit, especially with the increasing need to obtain permits in order to stay active in other fisheries. However, even with the increasing availability of new species permits in fishing years following 1998, few multispecies permit holders will choose to *maximize* their number of permits, that is, obtain the most additional permits possible. This is evident in the very small percentage of permit holders obtaining more than ten additional permits and is possibly explained by the broad geographic range of the species for which there are permits available.

Out of the total number of permits they possessed, multispecies Category A (Individual DAS) vessels had the greatest proportion of non-multispecies permits of any of the permit categories. In 1996, 81% of the permits held by multispecies category A vessels were non-multispecies permits, increasing to 91% in 2001. Multispecies Category D (Hook gear) vessels tended to have the lowest proportion of non-multispecies permits of their total permits held. 59% of the permits held by multispecies category D vessels were non-multispecies permits in 1996, increasing to 82% in 2001. (Table 469)

Calculating the average number of permits per multispecies permit holder including *only* those permits which have been required since 1994 has, of course, different results. This number has ranged from 2.9 to 3.5 permits from 1994 to 2001, remaining very consistent across the time period. The specific types of permits owned by multispecies permit holders may have changed since Amendment 5, and permits have been redistributed among different fishery participants. However, despite effort reduction programs and stricter regulations in the groundfish and related fisheries, permit holders have not, on average, lost numbers of permits.

The variety of available permits has increased since 1996 and has had an effect on the composition of the permits held by multispecies permit holders. From 1996 to 1998, most of the non-multispecies permits possessed by groundfish vessels were squid/mackerel/butterfish permits, followed by scallop, lobster, fluke and surf clam permits. From 1999 to 2001, squid/mackerel/butterfish permits comprised the highest percentage of non-multispecies permits, followed by lobster, dogfish, monkfish and scallop permits. With the new requirements for dogfish and monkfish permits, scallop permits made up a smaller percentage of the total “other” permits held by multispecies vessels. Clearly, however, squid/mackerel/butterfish, lobster, and scallop fisheries have remained important fisheries for multispecies vessels which have sought diversification as a means of supplementing their income obtained from groundfish.

Table 469 – Summary of Permit Distribution Among Multispecies Permit Holders

Landings and Revenues by Permit Category

From 1996 to 2001, the highest total landings were brought in by Fleet DAS and Open Access vessels (Table 470). Fleet DAS and Individual DAS vessels also landed a substantially greater percentage of groundfish landings than vessels in other categories, averaging 95% of the total in each year from 1996 to 2001 (Table 472). However, this proportion of groundfish landings attributed to vessels in Fleet DAS and Individual DAS categories decreased from 96.8% in 1996 to 92.3% in 2001. Other categories increased their contribution to groundfish landings during these years, including Large mesh Fleet DAS vessels which expanded their groundfish landings from 37,000 pounds in 1996 to 2,272,000 pounds in 2001. Open Access, Combination, and Hook Gear vessels also substantially increased their groundfish landings over the six years. As discussed previously, these changes primarily represent shifts in participation among different permit categories rather than extensive movement in and out of the fishery entirely. Vessels in the Small Vessel Exemption category contributed least to groundfish landings in all years. To maintain confidentiality, landings associated with the small number of Large Mesh Individual DAS vessels were not reported. The landings in Table 472 are associated with the number of vessels in Table 468.

Total revenue trends were similar to those for total landings across permit categories (Table 471). Across all years, Individual DAS vessels were more financially dependent on groundfish than vessels in other permit categories (Table 473). Groundfish revenues accounted for, on average, 69% of total revenues in this permit category. Fleet DAS and Hook Gear vessels ranked second in dependence on groundfish—for each, groundfish revenues averaged 30% of total revenues.

DAS Use by Permit Category

According to the NMFS Enforcement call-in database, the percent of total DAS allocated to all permit holders that was used by vessels that reported activity via the call-in system, increased annually from 22% in 1996 to 42% in 2001. Permitted vessels that called in used between 37% (1996) and 59% (2001) of their allocated DAS, an average annual increase of 4.4%. The Individual DAS permit category used the greatest percentage of their allocated category DAS in each year from 1996 to 2001. In the last three fishing years (1999-2001), this permit category used more than 90% of their allocated DAS. Although the Fleet DAS permit category accounted for the greatest use of total allocated DAS to vessels that used the call-in system (55% to 65% of total allocated DAS from 1996 to 2001), they used only 28% to 53% of their allocated category DAS. Hook gear permit holders used the smallest percentage of their allocated category DAS, increasing from 7% in 1996 to 26% in 2001 but maintaining the lowest fraction of allocated DAS used by any permit category each year. Table 474 provides additional information about the distribution of DAS activity by permit category.

Table 474 - Days-at-Sea usage by limited access permit category, 1996-2002

This table includes data from multispecies/monkfish DAS trips (in which the multispecies and monkfish clocks run concurrently). DAS totals include any adjusted gillnet DAS totals. Cells with shading are not comparable to previous years. Data Source: NMFS Enforcement DAS Call-In Database

Summary

The total number of multispecies permits declined from 1996 to 1998 but increased in later years, returning to nearly its 1996 level by 2001. Since 1996, open access permits have made up the greatest proportion of total multispecies permits. The open access permit category is expanding, having increased an average of nearly 10% each year from 1996 to 2001. Fleet DAS vessels make up the greatest proportion of limited access vessels, followed by Hook Gear vessels and Individual DAS vessels. In general, while numbers of individual, fleet and small vessel exemption permits declined from 1996 to 2001, numbers of hook gear, large mesh fleet and open access permits increased. Combination vessel and large mesh individual permits remained relatively constant across the time period.

The number of multispecies vessels active in the groundfish fishery as a percentage of total active multispecies vessels indicates that a substantial amount of latent effort exists in the fishery. In 2001, there were nearly three times more multispecies permits than vessels which actually reported landings of groundfish. The number of active groundfish vessels has generally remained steady from 1996 to 2001. There have also been changes in distribution among permit categories, probably the most movement occurring between fleet DAS and large mesh fleet DAS vessels.

An investigation of the non-multispecies permits held by multispecies permit holders demonstrates that squid/mackerel/butterfish, lobster and scallop fisheries have been important fisheries to multispecies vessels which have sought diversification as a means of supplementing their income obtained from groundfish since 1994.

From 1996 to 2001, the highest total landings were brought in by Fleet DAS and Open Access vessels. Fleet DAS and Individual DAS vessels also landed a substantially greater percentage of groundfish landings than vessels in other categories in this time period. Vessels in the Small Vessel Exemption category contributed least to groundfish landings in all years. Many changes in distribution of landings among permit categories represent shifts in participation across categories rather than extensive movement in and out of the fishery entirely.

Total revenues trends did not closely mimic total landings trends across all years due to changes in species composition of total landings and the differing market values of those species. Groundfish revenues decreased between 1994 and 1996 then generally trended upwards between 1996 and 2001. Across all years, Individual DAS vessels were more financially dependent on groundfish than vessels in other permit categories. This is also reflected in day-at-sea use by Individual DAS vessels, which used the greatest percentage of their allocated category DAS in each year from 1996 to 2001.

9.4.2.4.2 Fishing Activity by Vessel Length Class

Data on fishing activity were compiled by length classes. Based on the recommendations of the NEFMC Groundfish Oversight Committee, four distinct ranges were identified as separate vessel length classes.

Length Class 1: Vessels less than 30 feet in length
Length Class 2: Vessels 30 feet to less than 50 feet in length
Length Class 3: Vessels 50 feet to less than 75 feet in length
Length Class 4: Vessels greater than or equal to 75 feet in length

Data Caveats

The vessel length data were gathered from the vessels' permit applications for each fishing year and compiled on a trip-by-trip basis.

The total number of vessels by length class was generated from the NMFS permit database and includes all active and inactive permitted multispecies vessels with reported lengths. Data are reported since 1994.

Number of Vessels by Length Class

Vessels from 30 to 50 feet have consistently made up the greatest proportion of multispecies vessels from 1994 to 2001. Vessels less than 30 feet make up the second largest length class, with just under half the number of 30 to 50 foot vessels. The largest vessels make up the smallest percentage of the total. (Table 475)

In general, the number of smallest vessels has diminished most substantially, demonstrating the greatest percent declines of all length classes from 1994 to 2001, particularly in the periods directly following Amendments 5 and 7. From 1994 to 1996, vessels less than 30 feet in length showed the greatest percent decline in numbers (23.7% decrease from 1994 to 1996), followed by vessels 50 to less than 75 feet (3.9% decrease) and vessels 30 to less than 50 feet (7% decrease), with very little change in vessels 75 feet or greater.

Across all length classes the greatest declines occurred from 1996 to 1998. Again, in this 2-year period the smallest vessels (less than 30 feet) experienced the greatest losses, the number dropping 20.8%. The number of vessels in the 30 to less than 75 foot range decreased about 17% in these years. The number of large vessels (75 feet and greater) decreased 14.4%. Since 1998, the number of vessels in each length class has increased or remained relatively constant, with the greatest annual increase among vessels under 30 feet, averaging about 10% per year.

Vessel Length Class	1994	1995	1996	1997	1998	1999	2000	2001
Less than 30 feet	1162	1074	887	788	702	745	810	933
30 feet to less than 50 feet	2289	2381	2200	1891	1823	1934	2046	2081
50 feet to less than 75 feet	825	823	767	708	636	651	646	646
75 feet or greater	446	456	444	415	380	384	399	406
Total	**4,722**	**4,734**	**4,298**	**3,802**	**3,541**	**3,714**	**3,901**	**4,066**

Table 475 - Total number of multispecies vessels by length class, 1994-2001

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Landings and Revenues by Vessel Length Class

Vessels less than 30 feet in length demonstrated the greatest annual percent increases in total landings in each year from 1994 to 1996 (Table 476). However, revenues for these vessels declined during that same time period, from $2,279,000 dollars in 1994 to $1,498,000 dollars in 2001 (Table 477). From 1996 to 1997, the largest vessels (75 feet and greater) demonstrated a greater percent increase in total landings than smaller vessels (under 75 feet). Revenues for vessels greater than 30 feet in length generally trended upwards across the time period, with some variability. The largest vessels experienced a constant slight decline in total revenues from 1994 to 1998, with a 23.5% increase from 1998 to 1999 and a 11.2% increase from 1999 to 2000. All length classes experienced declines in revenues through 1998, with the smallest vessels (under 30 feet) demonstrating the greatest percent loss per year.

Groundfish landings generally increased across all length classes between 1994 and 2001 (Table 478). Vessels 75 feet and greater were responsible for the highest total landings in every year from 1994 to 2001, followed by vessels 50-75 feet, 30-50 feet and under 30 feet. However, vessels 50 to less than 75 feet contributed to the highest groundfish landings, with vessels 75 feet and greater following closely.

Landings of vessels 50 to less than 75 feet were 28,892,000 pounds in 1994, fluctuated slightly between 1994 and 1997, and steadily increased after 1997, reaching 43,645,000 pounds in 2001. Vessels 75 feet and greater landed 26,249,000 pounds in 1994 with landings dropping about 3 million pounds in 1995 and increasing to 35,194,000 pounds in 2001. Groundfish landings by vessels 30 to less than 50 feet fluctuated between 17,800,000 pounds and 19,483,000 pounds from 1994 to 1998. Landings in this length class decreased about 8.5% from 1998 to 1999 and increased 48.7% from 1999 to 2001. The smallest vessels, while contributing the least groundfish landings in all years from 1994 to 2001, demonstrated the greatest average annual percent increases from year to year during this time period, particularly after 1999. The groundfish landings by vessels less than 30 feet in length increased 27.2% from 491,000 pounds in 1999 to 625,000 pounds in 2000, and from that point increased an additional 33.9% to 836,000 pounds in 2001.

Groundfish revenues decreased between 2% and 9% in all length classes from 1994 to 1996. Groundfish revenue trends were generally positive across all length classes from 1996 to 2001(Table 479). Although revenues generated by vessels less than 30 feet comprised only 1% of total groundfish revenues per year from 1994 to 2001, revenues in this length class demonstrated the greatest percent increases over the time period.

Vessel Length Class	1994	1995	1996	1997	1998	1999	2000	2001
Less than 30 feet	1,215	1,545	2,008	1,632	1,307	1,273	1,899	1,574

DAS Use by Length Class

The total number of vessels using DAS increased just 3% from 1998 to 2000 (Table 480). Since 2000, the total number of permitted limited access vessels has declined. The number of DAS used by all length classes has increased since 1997. Generally, larger vessels use a higher percentage of their allocated DAS. Since 1996, active limited access vessels in all length classes have been using a greater percentage of their allocated DAS. Vessels less than 50 feet in length used 49% of their allocated DAS, while vessels 50 feet and greater used 71% of their allocated DAS. Vessels up to 29 feet experienced the largest recent increase in DAS use (37%) between fishing years 2000 and 2001, although vessels in the 30-49 foot length class used the greatest raw number of DAS in 2001.

Permit Categories		Total Number of Permitted Vessels with Allocated DAS (1)	Total Days-at-Sea Allocated (2)	Number of Permitted Vessels that Called In (3)	DAS Allocated to Vessels that Called In (4)	Total DAS Used by Vessels that Called In (5)	% of total allocated DAS Used by Vessels that called in ((5)/(2)*100)	% of allocated DAS (to vessels that called in) Used by Vessels that Called In ((5)/(4)*100)

Cells with shading are not comparable to previous years. Data Source: NMFS Enforcement DAS Call-In Database, NMFS Permit Database

Summary

The multispecies fleet is composed primarily of small to medium-sized vessels. Vessels from 30 to 50 feet have consistently made up the greatest proportion of multispecies vessels from 1994 to 2001. In general, the number of smallest vessels has diminished most substantially, demonstrating the greatest percent declines of all length classes from 1994 to 2001, particularly in the periods directly following Amendments 5 and 7. Across all length classes the greatest declines occurred from 1996 to 1998, with vessels under 30 feet experiencing the greatest losses. Since 1998, the number of vessels in each length class has increased or remained relatively constant, with the greatest annual increase among vessels under 30 feet.

The smallest vessels demonstrated the greatest annual percent increases in total landings in each year from 1994 to 1996. However, revenues for these vessels declined during that same time period. From 1996 to 1997, the largest vessels demonstrated a greater percent increase in total landings than smaller vessels. All length classes experienced declines in total revenues through 1998, with the smallest vessels (under 30 feet) demonstrating the greatest percent loss per year.

Groundfish landings generally increased across all length classes between 1994 and 2001. The largest vessels, while making up the smallest percentage of total vessels, were responsible for the highest total landings in every year from 1994 to 2001. However, vessels 50 to less than 75 feet contributed to the highest *groundfish* landings, with vessels 75 feet and greater following closely. Groundfish landings by mid-sized vessels fluctuated between 1994 and 1998. The smallest vessels, while contributing the least groundfish landings in all years from 1994 to 2001, demonstrated the greatest average annual percent increases from year to year during this time period, particularly after 1999. Groundfish revenues decreased slightly in all length classes from 1994 to 1996. Groundfish revenue trends were generally positive across all length classes from 1996 to 2001.

9.4.2.4.3 Fishing Activity by Gear Type

Many different gear types are used to harvest the resource in the multispecies fishery. These gears are described in detail under "Gear Descriptions" (Section 9.3.1.2.2 of the Amendment 13 EFH DEIS). The four primary gear types in the multispecies fishery, as determined from the monetary value of landings associated with that type of gear, are the **bottom trawl**, **bottom longline**, **hook and line** and **sink gillnet**.

Vessel owners are required to report their primary gear type on their multispecies permit application. On each Vessel Trip Report, the permit holder is instructed to list the actual gear used to harvest the landed catch on that trip. The gear actually used to catch the fish landed may or may not coincide with the primary gear designation on the vessel's permit application.

Data Caveats

Primary Gear Types and Landings by Gear

For fishing activity reported by permit category, vessel length class, and home port state, reported number of vessels are associated with reported landings and revenues. This is not true for fishing activity by gear type. All NMFS permit records of vessels associated with a primary gear type as indicated on their permit application were merged with NMFS dealer records on a trip-by-trip basis to eliminate records of vessels without multispecies permits and those records of gears not associated with a particular trip (i.e., total landings greater than zero). It is important to note that the total number of vessels by primary gear type in Table 481 is not directly associated with the landings reported in Table 482 and Table 484. In other words, 85,422,000 pounds of groundfish were caught and landed by vessels using bottom trawls, but those vessels did not necessarily indicate bottom trawls as the primary gear type on their permit. **Total**

and groundfish landings in this section are reported by the gear type physically used to harvest the fish landed. In some cases, the gear used to harvest the catch on a specific trip was not equivalent to the gear reported by the vessel owner as the primary gear type. **The total number of *vessels* was determined based on the primary gear type indicated on each permit** in order to avoid double-counting of vessels for which more than one gear type is associated with real landings of fish in any given fishing year.

Day and trip gillnet totals were queried from the NMFS Enforcement database. Because some vessels may not have reported whether they were day or trip gillnetters, the sink gillnet total is, in all cases, higher than the sum of day and trip gillnets. Additionally, the day and trip gillnet categories were not introduced until 1997 and therefore, cannot be distinguished in 1995 and 1996. For all gear types, records from 1994 were excluded from Table 481 because of concerns about the accuracy of the data.

"All other" gears represent permits that did not report a primary gear type or permits indicating actual gear types that do not fall into any of the specific categories listed. For landings and revenues, the values associated with the "other" gear category may also represent aggregate records reported by dealers that include multiple trips of one or more vessels.

Number of Vessels by Primary Gear Type

Bottom trawls were the top gear indicated as primary gear type from 1995 to 2001, making up 33-36% of the total number of vessels in those years. From 1996 to 1997, the number of vessels with bottom trawls as primary gear types decreased about 7% and remained fairly steady after 1997. Hook and line vessels represented 15-20% of the total in each year from 1995 to 2001 and sink gillnets 11-17% of the total in this same period. From 1997 to 2001, the number of vessels using primarily day gillnets was 2.5 to 3 times that using trip gillnets. Midwater trawls were indicated in very small numbers. (Landings reflect that while the use of midwater trawls contributed significantly to total landings, groundfish landings associated with this gear are negligible.) The relative proportions of each gear type remained fairly consistent during the period, with the exception of shrimp trawls which decreased substantially as a percentage of the total, falling an average of 14.5% per year. (Table 481)

Gear Type	**1995**	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Landings and Revenues by Gear Used

Between 1994 and 2001, bottom trawls accounted for an average of 45.5% of the total landings in each year (Table 482). Following bottom trawls, the next four top contributors to total landings were "other" gears (which, as discussed above, likely include aggregate records), sink gillnets, scallop dredges, and midwater trawls. The relative ranks of these gears differed slightly from year to year. From 1994 to 2001, midwater trawl landings increased, on average, 43% from each year to the next, while landings by scallop dredges increased an average of 16.7% annually. The rise in midwater trawl landings may have resulted from the initiation of a herring permit in 1997 which required herring vessels to report landings, many of which did not do so prior to the permit requirement. Shrimp trawl landings declined, with an average drop of 16.6% each year. Total bottom trawl landings decreased from 1994 to 1996, increased from 1996 to 1998, and decreased at a relatively constant low rate from 1998 to 2001. Total sink gillnet landings fluctuated during the time period, decreasing overall from 1994 to 2001. This decline is primarily the result of restrictions in the dogfish and monkfish fisheries. Hook and line landings generally trended upward, doubling from 1994 to 2001. Bottom longline landings decreased slightly over the period. Total revenues trends mirrored changes in total landings (Table 483). Total revenues increased substantially for midwater trawls, although these revenues are only attributed to a *minute* quantity of groundfish landings. Although some multispecies permit holders indicated midwater trawls as their primary gear type, this gear is primarily used to harvest non-groundfish species, including herring.

Gear Type	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**

Groundfish landings by gear type exhibited slightly different trends (Table 484). Bottom trawls again accounted for the overwhelming bulk of landings in each year from 1994 to 2001. The proportion of bottom trawl groundfish landings increased every year from 72% in 1994 to 82% in 2001. Bottom trawl groundfish landings increased an average of 7.4% from year to year. Sink gillnets landed the second highest percentage of groundfish during these years, its percent contribution decreasing from 20.1% in 1994 to 13.2% in 2001. Gillnet landings declined throughout the late '90s, and increased 8.8% from 12,653,000 pounds in 2000 to 13,769,000 pounds in 2001, a level comparable to that in 1995. While day gillnet landings have remained higher than trip gillnet landings from 1995 to 2001, trip gillnets have increased their percent contribution to total gillnet landings. In 1997, day gillnet landings were almost twice that of trip gillnets and in 2001, day landings were only 1.3 times greater than trip landings. Bottom longlines, which ranked third in contribution to total groundfish landings, exhibited the greatest percent decline in landings of any of the gears, decreasing an average of 5.6% annually. Bottom longline groundfish landings dropped from 5,337,000 pounds in 1994 to 2,870,000 pounds in 1996 and fluctuated throughout the late '90s, falling again to 2,767,000 pounds in 2001. Hook and line vessels demonstrated the most dramatic increase in landings, with groundfish landings fourteen times higher in 2001 than in 1994. Midwater trawl landings fell below 1,000 pounds in all years except 1999, making a negligible contribution to total groundfish landings. Revenue trends generally mimicked landings trends from 1994 to 2001 (Table 485). Sink gillnet revenues exhibited the greatest percent declines, their revenue in 2001 28.6% lower than that in 1994. Revenues for this gear type experienced the steepest drop from 1994 to 1995 (14%). Despite a 8.8% increase in groundfish landings by sink gillnets from 2000 to 2001, revenues only increased 0.2% in that period.

DAS Use by Gear Type
For this discussion, refer to Table 486.

Bottom Trawl:
In 1996 there were 480 active vessels in the bottom trawl sector, 85% of the total number of permitted bottom trawl vessels. The percentage of active vessels increased over the next five years, reaching 95% in 2001. DAS use by bottom trawl vessels increased steadily from 1996 to 2001. 51% of the DAS allocated to active permitted bottom trawl vessels were used by these vessels in 1996 and 72% of allocated DAS were used by active bottom trawl vessels in 2001.

Bottom Longline:
In 1996 there were 41 active vessels in the bottom longline sector, 89% of the total number of permitted bottom longline vessels. The percentage of active vessels increased over the next five years, reaching 93% in 2001. DAS use by bottom longline vessels generally increased from 1996 to 2001. 30% of the DAS allocated to active permitted bottom longline vessels were used by these vessels in 1996 and 65% of allocated DAS were used by active bottom longline vessels in 2001.

Hook and Line:
In 1996 there were 94 active vessels in the hook and line sector, 53% of the total number of permitted hook and line vessels. The percentage of active vessels increased over the next five years, reaching 64% in 2001. DAS use by hook and line vessels generally increased from 1996 to 2001. 9% of the DAS allocated to active permitted hook and line vessels were used by these vessels in 1996 and 31% of allocated DAS were used by active hook and line vessels in 2001.

Sink Gillnet:
In 1996 there were 140 active vessels in the sink gillnet sector, 89% of the total number of permitted sink gillnet vessels. The percentage of active vessels increased over the next five years, reaching 99% in 2001. DAS use by sink gillnet vessels increased from 1996 to 1997, decreased slightly through 1999 and increased again, reaching its highest level in 2001. 34% of the DAS allocated to active permitted sink gillnet vessels were used by these vessels in 1996 and 69% of allocated DAS were used by active sink gillnet vessels in 2001.

Table 486 - Days-at-Sea Usage by Gear Type, 1995-2002

Summary

Bottom trawls were the top gear indicated as primary gear type from 1995 to 2001, followed by hook and line vessels and sink gillnets, the majority of these day boats. Midwater trawls were indicated in very small numbers. The relative proportions of each gear type remained fairly consistent during the period, with the exception of shrimp trawls which decreased substantially as a percentage of the total.

Between 1994 and 2001, bottom trawls accounted for a large majority of total and groundfish landings in each year. Total bottom trawl landings decreased overall from 1994 to 2001 primarily as a result of restrictions in other fisheries, evident in the fact that groundfish landings by bottom trawls increased over this time period. Following bottom trawls, the next four top contributors to total landings were “other” gears, sink gillnets, scallop dredges, and midwater trawls. Sink gillnets landed the second highest percentage of groundfish but both total and groundfish landings by gillnets decreased from 1994 to 2001. Bottom longlines, which ranked third in contribution to groundfish landings, exhibited the greatest percent decline in landings of any of the gears. From 1994 to 2001, midwater trawl and scallop dredge total landings increased, while shrimp trawl total landings declined. Midwater trawl groundfish landings are extremely low in all years. Hook and line total landings generally trended upward from 1994 to 2001, with groundfish landings exhibiting a dramatic increase. Bottom longline landings decreased slightly over the period. Revenue trends generally mimicked landings trends from 1994 to 2001.

DAS use increased from 1996 to 2001 for each of the four primary gear types. Bottom trawls used the greatest percentage of allocated DAS from 1996 to 2001, while hook and line vessels utilized the smallest percentage of days allocated.

9.4.2.4.4 Fishing Activity by Home Port State

Data Caveats

Home Port vs. Principal Port

In order to examine dependence on the groundfish fishery by state, the number of vessels and their associated landings and revenues are reported primarily by home port state. Home port state is indicated on the permit and represents the state in which the associated vessel resides. Principal port is also indicated on the permit and represents the state in which the associated vessel reports the majority of its landings. This is declared by the permit holder. Principal port and home port may be one and the same or may differ. For example, a vessel which obtained its permit in Stonington, Connecticut may land its catch in Point Judith, Rhode Island. In this case, the home port state is Connecticut while the principal port state is Rhode Island. Principal port may also differ from principal port of *landing*, which is determined based on the actual port in which the vessel landed the majority of its catch over the year, as determined solely from dealer records. For example, a vessel may declare a principal port of Portsmouth, New Hampshire with the intention of landing the majority of its annual catch there but actually land a greater percentage of its catch in Gloucester, Massachusetts within a given fishing year. Principal port and principal port of landing are not discussed in the Affected Human Environment of Amendment 13. However, where home port was not reported or documented incorrectly, principal port state replaced home port state. The majority of the permits were associated with a true home port.

“Other” States

States in which the number of vessels made up less than 1% of the total number in each fishing year from 1996 to 2001 were combined into an “Other” category. The landings associated with these states are very low.

Number of Vessels by Home Port State

Fleet composition by state has remained relatively consistent for both active multispecies vessels in all fisheries and active multispecies vessels in the groundfish fishery from 1996 to 2001. The multispecies fleet is dominated by vessels with home ports in Massachusetts and Maine. The following tables provide a breakdown of percent of total number of vessels for each state averaged over the period from 1996 to 2001 (Table 487 and Table 488).

Home Port State	Average Percent of Total Vessels, 1996-2001
MA	42.1%
ME	13.8%
NY	10.3%
NJ	9.8%
RI	9.7%
NH	4.9%
VA	3.8%
NC	3.2%
CT	0.9%
All Others	each less than 1%

Table 487 - Composition of fleet (permitted multispecies vessels active in *any* fishery) by home port state, 1996-2001

Calculated using Table 489 and Table 490.

Home Port State	Average Percent of Total Vessels, 1996-2001
MA	51.1%
ME	12.6%
RI	10.6%
NY	9.7%
NJ	6.2%
NH	5.9%
VA	1.5%
NC	1.4%
CT	0.6%
All Others	each less than 1%

Table 488 - Composition of fleet (permitted multispecies vessels active in *groundfish* fishery) by home port state, 1996-2001

Calculated using Table 489 and Table 490.

New York, New Jersey and Rhode Island each contribute approximately 10% of the total number of permitted multispecies vessels active in any fishery (landings of any species). Massachusetts vessels make up over 50% of the permitted multispecies vessels active in the groundfish fishery, with Maine following at 12.6%. Rhode Island and New York again contribute about 10% of the total active groundfish vessels each, while New Jersey makes a lower contribution at 6.2%. New Hampshire contributes a greater percentage of vessels to the total number of multispecies vessels active in the groundfish fishery (almost 6%) than to the number of vessels active in any fishery (almost 5%). Connecticut vessels account for less than 1% of the multispecies fleet.

Average Length and Horsepower of Multispecies Vessels by Home Port State

Table 491 shows the average length and horsepower of multispecies vessels by homeport state. From 1994 to 2000, the average length of Massachusetts vessels has varied little, ranging from 40 feet to 42 feet. Average horsepower of Massachusetts vessels has remained stable, ranging from 340 to 350 between 1994 and 2000. In New Hampshire the average length steadily increased from 33 feet in 1994 to 39 feet in 2000. New Hampshire vessels also experienced a gradual increase in average horsepower from 298 to 367. Of the New England states, Connecticut and Rhode Island vessels have the greatest average length (between 40 and 50 feet). Overall, North Carolina and Virginia are home to the largest vessels, averaging approximately 70 feet. Vessels from Virginia have declined in average length from 1994 to 2000. In general, vessels homeported in states outside of New England had higher average horsepower than those in the New England states. This is particularly evident when comparing the average horsepower of

Massachusetts, Maine and New Hampshire vessels, which ranged from approximately 300 to 350, with that of New Jersey and Delaware vessels, which ranged from approximately 450 to 700. Additionally, larger vessels have home ports in southern states and at the southern range of mid-Atlantic states (North Carolina, Virginia, Florida) while smaller vessels reside in the northern Atlantic states (Massachusetts, New Hampshire, Maine).

Table 491 - Average vessel length and horsepower by home port state, 1994-2000

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Note: This data was not updated for 2001. Current averages may be slightly different across all years due to updated and corrected data in the source databases.

Number of Vessels by Home Port State and Permit Category

The following tables provide insight into the way participants in different permit categories are distributed among states. These numbers represent permitted multispecies vessels active in any and all fisheries (not just active in the groundfish fishery). The values correspond to the totals in Table 489.

Vessels with home ports in Massachusetts and Maine together make up the overwhelming majority of category A vessels. On average, Massachusetts vessels compose 64% of the vessels in this category, this percentage decreasing slightly from 1996 to 2001. Maine contributed an average of 23.6% of the vessels from 1996-2001, this percentage increasing slightly over the time period. Between 1996 and 2001, Massachusetts and Maine vessels together made up 87.6% of the individual DAS vessels. During this time period, the percent of Massachusetts vessels of the total number decreased slightly, while increasing slightly in Maine. New Hampshire also increased participation in this permit category, increasing from 3 vessels in 1996 to 7 in 2001 (Table 492).

State	1996	1997	1998	1999	2000	2001
MA	95	99	87	82	80	79

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Category B (Fleet DAS) is the largest permit category. Again, it is dominated by Massachusetts vessels, averaging 41.2% of the total from 1996 to 2001. The proportion of Massachusetts vessels remained very consistent over this time period, while Maine's contribution decreased slightly and Connecticut's increased. Massachusetts, Maine, Rhode Island and New York vessels together compose 81.5% of the fleet on average over the time period (Table 493).

State	1996	1997	1998	1999	2000	2001

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Category C (small vessel exemption) is a very small permit category, with a maximum of four participating vessels in any state for a given fishing year. This category is made up of vessels almost entirely homeported in Massachusetts and Rhode Island. From 1996 to 2001, Massachusetts averaged 2.8 vessels per year while Rhode Island averaged 2.5 (Table 494).

State	1996	1997	1998	1999	2000	2001

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Vessels from Massachusetts make up between 72% and 81.3% of the category D (Hook gear) vessels from 1996 to 2001. This proportion has generally trended upward across the time period. New York vessels contribute the second highest participation level, followed by New Hampshire. The number of hook gear vessels in New Hampshire decreased from 5 in 1996 to 2 in 2001. In Rhode Island, the number increased from 1996 to 1997 but decreased from 1999 to 2000 after a period of relative consistency (Table 495).

State	1996	1997	1998	1999	2000	2001

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

In category E (combination vessels), Massachusetts vessels made up the greatest percentage of the total, this number remaining very consistent from 1996 to 2001 (between 24 and 25 boats). In 1996, both Virginia and New Jersey had six category E vessels. By 2000, this number had decreased to 3 vessels in New Jersey while remaining at 6 in Viriginia. Both states demonstrated further declines from 2000 to 2001. The number of category E vessels in North Carolina increased slightly from 1996 to 2001. With the exception of Massachusetts, New England vessels are poorly represented in this permit category (Table 496).

Table 496 - Number of permit category E (Combination vessel) multispecies vessels active in any fishery by home port state, 1996-2001

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

In 1996, 44.4% of category G (Large mesh, fleet DAS) vessels were from Massachusetts, this percentage increasing to 66.7% in 2000. The number of vessels in Rhode Island declined substantially across this time period, decreasing from 33% of the total number in 1996 to 3% of the total in 2001. New Hampshire increased its number of category G vessels five-fold between 2000 and 2001. In previous years, however, New Hampshire and New Jersey each contributed between 1 and 2 vessels in each year to the total (Table 497).

Data Source: NMFS Permit Database. Data are for multispecies permit holders only. Data reported by fishing year--May 1 to April 30.

Vessels in combined open access categories were distributed more evenly among states than vessels in any other permit category. Massachusetts vessels made up between 30 and 35% of the total number in each year from 1996 to 2001, followed by Maine and New Jersey. The number of open access vessels in Massachusetts increased over the time period from 186 in 1996 to 270 in 2001. New Jersey demonstrated the greatest percent increase in number of open access vessels, the number in 2001 75.8% greater than that in 1996. The number of open access vessels in Maine, however, decreased over the six years, with a period low of 48 vessels in 2000. The number of Maine vessels was variable between 1998 and 2001, fluctuating in those years but demonstrating a net decrease in numbers. Virginia and New York had comparable numbers of vessels, increasing between 1996 and 2001. The number of open access vessels in Rhode Island more than doubled from 1996 to 2001 (Table 498).

Landings and Revenues by Home Port State

Total and groundfish landings were highest for Massachusetts vessels in all years from 1996 to 2001. Massachusetts landings changed little between 1996 and 1997 but declined from 1997 to 2000. Total Massachusetts landings increased 32% from 2000 to 2001. Rhode Island and New Jersey contributed the second highest total landings during this period. For vessels with home ports in Rhode Island, landings increased 15.4% from 1996 to 1998, then decreased steadily from 115,016,000 pounds in 1998 to 86,590,000 pounds in 2001 (a decline of 24.7%). Total landings by New Jersey vessels increased 34.2% from 1996 to 1998, dropped from 107,158,000 pounds in 1998 to 81,878,000 pounds in 1999 and increased once again (16%) from 1999 to 2001. In Maine, landings fluctuated from 1996 to 2001 with a general increasing trend over the time period. The average annual percent change for vessels with home ports in Maine was 20.5%. (Table 499)

Table 499 - Total landings by multispecies vessels by home port state, 1996-2001

Data Source: NMFS Permit and Dealer Databases. Data are for multispecies permit holders only. Data reported by fishing year—May 1 to April 30. ***Revenues expressed in thousands of 1999 dollars; Landings in thousands of pounds.***

Massachusetts groundfish landings increased slightly from 1996 to 1997, decreased about 10% from 1997 to 1998, and rose from 42,312,000 pounds in 1998 to 61,687,000 pounds in 2001, an increase of 45.8%. Groundfish landings in Maine decreased an average of 4.8% annually from 1996 to 1999, a net 13.8% drop in landings during this time period, and increased an average of 21% annually from 1999 to 2001, with a net increase of 60% in these years. New Hampshire landings made up the third highest percentage of the total groundfish landings in 1996, nearly equaled landings in Rhode Island in 1995, and fell behind Rhode Island in the following years. While New Hampshire landings remained relatively constant from 1996 to 2001, Rhode Island landings increased or remained steady in every year, the landings in 2001 almost three times higher than those in 1996. New York landings also increased, from 1,323,000 pounds in 1996 to 4,096,000 pounds in 2000, dropping about 25% from 2000 to 2001. New Jersey landings varied in the early years of the time series, rising steadily after 1998 and falling again in 2001. Connecticut exhibited the most variable trend in landings over the time period, though generally increasing from 1998 through 2001. (Table 500)

Table 500 - Groundfish landings by multispecies vessels by home port state, 1996-2001

Data Source: NMFS Permit and Dealer Databases. Data are for multispecies permit holders only. Data reported by fishing year—May 1 to April 30. ***Revenues expressed in thousands of 1999 dollars; Landings in thousands of pounds.***

For the most part, changes in revenues reflect landings trends and have generally increased in all states *except* in Rhode Island and Massachusetts for total landings and Delaware and Florida for groundfish landings (Table 501 and Table 502). Massachusetts, Rhode Island, New Jersey and Maine generated the greatest *total* revenues from 1996 to 2001 while Massachusetts, Maine, New Hampshire and Rhode Island generated greatest *groundfish* revenues in those years. About 60% of total groundfish landings were brought in by Massachusetts vessels and 20% by Maine vessels across the time period. Permitted multispecies vessels with home ports in some southern New England and mid-Atlantic states, though contributing a high percentage of landings to the total, are less active than Maine and New Hampshire vessels in the groundfish fishery. Those states may be more dependent on non-groundfish fisheries such as scup, squid, mackerel and butterfish. Maine and Massachusetts, however, clearly are the largest stakeholders in the New England groundfish fishery with highest groundfish landings and revenues in 1996 through 2001.

In examining groundfish revenues as a percentage of total revenues, however, New Hampshire fisheries are most heavily dependent on groundfish, groundfish revenues increasing from 49% of total fishery revenues in 1996 to 60% in 1998, and decreasing to 48% in 2001 (Table 503). The dependence of multispecies vessels from Maine on groundfish as a percent of total fishery revenues was second to that of New Hampshire vessels, ranging from 42% to 55% and generally increasing over the time period. Delaware vessels ranked third in terms of dependence, followed by Massachusetts and Connecticut. Vessels with home ports in New York, Rhode Island and Florida all demonstrated similar levels of dependence on northeast multispecies. It is important to note that although the home ports of these vessels are associated with certain states, these are not necessarily the states in which the vessels are landing their catches. Instead, examining fishing activity by home port state is a means of predicting where the revenue streams are moving geographically.

Table 503 - Home port state groundfish dependence by multispecies vessels (groundfish revenues over total revenues)

Calculated from Table 501 and Table 502.

DAS Use by Home Port State

Table 504 describes DAS-use by state. These data illustrate the relative changes in the distribution of fishing activity on a regional basis. Because not all vessels were in the DAS program prior to the 1997 fishing year, 1995 and 1996 data may not reflect the entire groundfish fleet operating during those years. All of the New England states increased their use of allocated DAS after Amendment 7 (1996). Active vessels in Maine and New Hampshire have used a higher percentage of allocated DAS than vessels in other states since 1997. Both Maine and New Hampshire used 70% or more of their allocated DAS in 2001. Active vessels in New York and New Jersey have used a lower percentage of allocated DAS than vessels in other states since 1997. In 2001, active vessels in New York and New Jersey used 36% and 29% of their allocated DAS, respectively.

Table 504 - Days-at-Sea Usage by Home Port State, 1995-2002 (cont.)

Summary

Fleet composition by state has remained relatively consistent for both active multispecies vessels in all fisheries and active multispecies vessels in the groundfish fishery from 1996 to 2001. The multispecies fleet is dominated by vessels with home ports in Massachusetts and Maine. In general, larger vessels have home ports in southern states and at the southern range of mid-Atlantic states (North Carolina, Virginia, Florida) while smaller vessels reside in the northern Atlantic states (Massachusetts, New Hampshire, Maine).

Massachusetts vessels dominated all limited access permit categories throughout the period. From 1996 to 2001, the percent of Category A (Individual DAS) vessels from Massachusetts decreased slightly while increasing slightly in Maine. New Hampshire also increased participation in this permit category. The number of Massachusetts vessels in the largest permit category, Category B (Fleet DAS), remained fairly constant from 1996 to 2001. Maine, Rhode Island and New York vessels together with those from Massachusetts made up the majority of this category over the time period. Category C (small vessel exemption) is a very small permit category, with most vessels from Massachusetts and Rhode Island across all years. After Massachusetts, New York and New Hampshire made up the majority of Category D (Hook gear) vessels. In category E (combination vessels), the number of Massachusetts vessels remained very consistent from 1996 to 2001. With the exception of Massachusetts, New England vessels are poorly represented in this permit category. The number of category G (Large mesh, Fleet DAS) vessels in Rhode Island, the second most represented state, declined substantially across this time period while the number of New Hampshire vessels increased sharply from 2000 to 2001. Vessels in combined open access categories were distributed more evenly among states than vessels in limited access categories. New Jersey demonstrated the greatest percent increase in number of open access vessels, while these vessels generally diminished in Maine. The number of open access vessels in Rhode Island more than doubled from 1996 to 2001.

Total and groundfish landings were highest for Massachusetts vessels in all years from 1996 to 2001. Landings in Massachusetts, Rhode Island and New Jersey, the three highest contributing states to total landings, declined from around 1997 or 1998 to 1999 or 2000. In Maine, total landings fluctuated from 1996 to 2001 with a general increasing trend over the time period. Groundfish landings were highest in Massachusetts and Maine from 1996 to 2001, generally decreasing from 1996 or 1997 to 1998 or 1999. Groundfish landings in both states demonstrated increases in the later years of the time period. While New Hampshire landings remained relatively constant from 1996 to 2001, Rhode Island landings increased or remained steady in every year, the landings in 2001 almost three times higher than those in 1996. New York landings also generally increased while New Jersey landings varied in the early years of the time series, rose steadily after 1998 and fell again in 2001. Connecticut exhibited the most variable trend in landings over the time period, though generally increasing from 1998 through 2001.

For the most part, changes in revenues reflect landings trends and have generally increased in all states *except* in Rhode Island and Massachusetts for total landings and Delaware and Florida for groundfish landings. Massachusetts, Rhode Island, New Jersey and Maine generated the greatest *total* revenues from 1996 to 2001 while Massachusetts, Maine, New Hampshire and Rhode Island generated greatest *groundfish* revenues in those years. Permitted multispecies vessels with home ports in some southern New England and mid-Atlantic states, though contributing a high percentage of landings to the total, are less active than Maine and New Hampshire vessels in the groundfish fishery. Those states may be more dependent on non-groundfish fisheries such as scup, squid, mackerel and butterfish. Maine and Massachusetts, however, clearly are the largest stakeholders in the New England groundfish fishery with highest groundfish landings and revenues in 1996 through 2001. In examining groundfish revenues as a percentage of total revenues, however, New Hampshire fisheries are most heavily dependent on groundfish, followed by those in Maine.

All of the New England states increased their use of allocated DAS after Amendment 7 (1996). Active vessels in Maine and New Hampshire have used a higher percentage of allocated DAS than vessels in other states since 1997. Active vessels in New York and New Jersey have used a lower percentage of allocated DAS than vessels in other states since 1997.

9.4.2.4.5 Description of the GOM Cod Fishery 1996-2001

Since adoption of Amendment 7, six framework adjustments were adopted to reduce fishing mortality on GOM cod (frameworks 20, 25, 26, 27, 31, and 33). The distributional impacts of these management actions are often debated and bear on the design of the proposed alternatives, as some argue that Amendment 13 should redress inequities caused by earlier management actions. Appendices of the annual MSMC report included tables showing activity in the GOM and GB cod fisheries. Numbers of vessels by size and gear, as well as the annual landings of cod for various sectors, are summarized in these tables. The data from earlier reports were combined into summary tables to illustrate trends in the GOM cod fishery over time. Although these data summarize landings of GOM cod, they do not reflect all the impacts of recent management measures on fishermen. For example, these results do not show changes in the landing of other species that resulted from the regulations.

Table 505 shows the number of unique vessels that reported landing at least one pound of GOM cod for fishing years 1996 (implementation of Amendment 7) through 2001. The number of vessels participating in this fishery declined from 754 in FY 1996 to 487 in FY 1999, but rose to 537 by FY 2001. Much of the decline can be attributed to vessels that landed less than 1,000 pounds of GOM cod annually: in FY 1996, 281 vessels participated at this low level, but only 78 in FY 2001, a decline of 203 vessels. Also, vessels landing more than 80,000 pounds of GOM cod declined. In FY 1996, 42 vessels landed more than 80,000 lbs., but the number of vessels in this category declined rapidly to only 14 vessels in FY 97 and 2 vessels in FY 2000 before increasing slightly to 4 vessels in FY 2001. Forty three percent of GOM cod landings in FY 1996 were on vessels that landed over 80,000 pounds annually, while only 4 percent of the GOM cod in FY 2000 came from these vessels.

A description of the amount of GOM cod landed by gear and vessel size is summarized in the MSMC reports. Table 506 shows that trawl vessel landings of GOM cod have declined 35 percent since FY 1996, while gillnet landings declined 36 percent over the same period. GOM cod landings by Hook Gear vessels declined 67%. Within the gear sectors, distinct differences occur among vessel size classes. Small trawl vessels are the only category that had higher GOM cod landings in FY 2001 than in FY 1996, showing an 84 per cent increase. Prior to FY 2000, GOM cod landings from small trawl vessels steadily decreased, but a large increase in the last two years resulted in the highest landings over the period. Inspection of tables in earlier reports reveals that this increase occurred largely due to increased landings in New Hampshire and Massachusetts ports (primarily Gloucester). Larger trawl vessels have had significant reductions in GOM cod landings – 64 percent for vessels of 51 – 150 GRT, and 91 percent for vessels over 150 GRT. All gillnet vessel sizes have reduced GOM cod landings, ranging from a 36 percent reduction for vessels 50 GRT and under to 30 percent for gillnet vessels between 51 and 150 GRT. Almost all hook gear landings are from vessels 50 GRT or less. The hook gear sector has reduced GOM cod landings by 65 percent since FY 1996, but hook gear accounted for only 6% of total GOM cod landings in 1996-1997.

The distribution of GOM cod landings across vessel size/gear categories has changed since FY 1996 (Table 507). Trawl vessels over 150 GRT landed over 12% of the GOM cod in FY 1996, but now land only 2%. In FY 1996, trawlers of 51-150 GRT (31 percent) and gillnet vessels of 50 GRT or less (33 percent) accounted for the bulk of GOM cod landings. In FY 2001, 84 percent of GOM cod was landed by vessels of 50 GRT and under, 39 percent by small trawl vessels (who have nearly tripled their percentage of GOM cod since FY 1996) and 33 percent by small gillnet vessels. Hook gear vessels landed 6 percent of the GOM cod in FY 1997 but landed only 2 percent in FY 2001.

Table 508 summarizes landings by gear (trawl, gillnet, and hook gear only) and state of landing. The greatest percentage decline from FY 1996 to FY 2001 occurred for landings of GOM cod in Maine (46%) followed closely by Massachusetts (38%). GOM cod landings in New Hampshire declined 19%. As a result of these differences, the share of GOM landings by state has changed. Landings in Massachusetts now account for 55% of GOM cod landings, Maine accounts for 25%, and New Hampshire accounts for 20%. Within gear sectors and states, all sectors have rebounded somewhat from the low landings in FY 1999, but for the three major states, only trawl vessels landing in New Hampshire have seen a real increase (69%) in GOM cod landings since FY 1996.

To summarize:

- The number of vessels reporting landing GOM cod has declined by 29 percent since FY 1996. There has been a 10 percent increase in the number of vessels participating in this fishery since FY 1999.
- Within the GOM cod fishery, there are fewer vessels landing very large or very small amounts of cod than in FY 1996.
- With respect to the impact of the framework adjustments on the cod catch of different gears, the adjustments have been remarkably even-handed for two of three major gear types. The change in GOM cod catch of trawl (-35%) and gillnet (-36%) vessels between FY 1996 and FY 2001 is nearly identical. Hook gear vessels, however, suffered reduced landings the most (68%) and now account for only 2 percent of GOM cod landings compared to 6% of total landings in 1997.
- The change in cod catch by vessel size has not been even- handed, with smaller vessel sizes generally benfiting from lower reductions in their GOM cod catch. Vessels over 150 GRT reduced their GOM cod catch by 91 percent, and vessels of 51-15- gross tons reduced catch by 61 percent. These changes are probably due to a combination of regulatory restrictions and increased opportunities for larger vessels as GB haddock and yellowtail flounder stocks rebuilt. Small vessels have only reduced their cod catch by 7 percent, in large measure because small trawl vessels (50 GRT and under) have significantly increased landings of GOM cod since FY 1996. By contrast, gillnet vessels less than 150 gross tons have had GOM cod landings reduced by approximately one-third.

9.4.2.4.6 Effects of *Conservation Law Foundation et al. v. Donald Evans et al.* on Fishing Activity

On December 28, 2001, a judge granted the plaintiff's motion for summary judgment in the case of *CLF et al. v. Evans*. The court determined the defendants had not complied with the Sustainable Fisheries Act in Framework Adjustment 33 to the FMP. Specifically, the court determined that the framework violates the overfishing, rebuilding, and bycatch provisions of the SFA, while Amendment 9 violates the bycatch provisions of the SFA. After several months of discussion with parties to the lawsuit, the court issued an order establishing interim management measures and giving NMFS until August, 2003 to adopt measures that are in full compliance with all provisions of the M-S Act. This deadline was later extended to May 1, 2004 after NMFS discovered possible problems with the trawl survey.

The interim measures approved by the court included an additional year round closed area on Cashes Ledge, modifications to the seasonal closed areas, several changes to gear requirements, revised possession limits, and a limitation on the use of DAS to the maximum DAS used by a permit during the 1996 through 2000 fishing years reduced by 20 percent. The expected impacts of these interim measures were analyzed in NMFS 2002. A preliminary review of the actual impact of the measures is summarized below.

When evaluating changes from FY 2001 to FY 2002, the buyout of 222 active limited access permits at the end of FY 2001 must be considered. The number of vessels removed by the buyout are shown below for gear, length, and homeport state.

Home Port State	Number of Permits

30 to Less than 50	150
50 to less than 75	24
75+	7

Figure 254 – Number of limited access groundfish permits removed by the 2002 vessel buyout program

DAS Allocations

The DAS allocations that resulted from the court order are shown in section 9.4.2.4. Table 509 compares the number of permits and DAS allocated in fishing year 2002 to fishing year 2001. Forty-six percent of the DAS allocated in fishing year 2001 have been allocated in fishing year 2002. The differences in DAS allocated to various permit categories are similar to the DAS use patterns over the past five years with the exception of the individual and combination DAS permit categories. As a group, individual vessels have used over 85 percent of their allocated DAS since fishing year1997, but under the court order received only 78 percent of the DAS allocated in fishing year 2001. Combination vessels show the opposite trend. They have generally used about half their allocations since 1997, but under the court order received 71 percent of their 2001 allocation. Individual and large mesh permit categories were allocated less DAS than were used in fishing year 2001, while the other categories received more DAS than used in 2001.

With respect to the distribution of allocated DAS by permit category, a larger percentage of allocated DAS are held by individual permit holders in FY 2002 compared to 2001. All other permit categories have a smaller number of DAS. This change follows the patterns of DAS used in recent years: individual vessels, as a group, have used a larger percentage of their allocated DAS. Allocations to each permit holder may not follow the same patterns as those for permit categories as a group. When evaluating these changes, the results of the permit buyback by permit category should be considered.

Categories	Number of Permitted Vessels in 2002/Permitted Vesels in 2001	2002 Allocated DAS as a percentage of 2001 Allocated DAS	DAS Used FY 2001	DAS Allocated FY 2002	DAS Used FY 2002	Percent of Total DAS Allocated in FY 2001	Percent of Total DAS Allocated in FY 2002
Individual	101%	78%	16,276	13,884	12,329	11%	19%

Large Mesh	98%	57%	4,493	4,113	2,849	5%	6%
Total	88%	46%	65,275	71,218	41,410	100%	100%

Table 509 – 2002 DAS allocations as a percentage of 2001. (Source: NMFS NERO)

Allocations of DAS by vessel homeport state (as listed on the vessel's permit) can also be examined to see if the court order may affect the distribution of fishing activity (Table 510). New Hampshire vessels received the highest percentage of their 2001 allocation (56 percent), followed by Connecticut (54 percent). Maine, Massachusetts, and Rhode Island received similar percentages (45-48 percent). New York (34 percent) and New Jersey (34 percent) are the states receiving the lowest percentage of their FY 2001 allocations. These allocations are very similar to the percent of allocated DAS used in fishing year 2001 for all states. Massachusetts vessels increased their share of the total by 3 percent, while the court order reduced New York's share of the total by 3 percent. New Hampshire and Rhode Island gained slightly, and Maine and New Jersey lost slightly. Overall, the court order does not appear to have significantly changed the distribution of DAS allocations by homeport state. Only New Hampshire vessels were allocated fewer DAS in FY 2002 than were used in FY 2001.

State (Homeport)	Number of Permitted Vessels in 2002/Permitted Vessels in 2001	2002 Allocated DAS as a percentage of 2001 Allocated DAS	DAS Used FY 2001	DAS Allocated FY 2002	DAS Used FY 2002	Percent of Total DAS Allocated to each state FY 2001	Percent of Total DAS Allocated to each state FY 2002
Maine	84%	45%	9,397	9,598	5,943	14%	13%
New Hampshire	96%	56%	4,582	4,293	2,576	5%	6%

Table 510 – Comparison of 2002 DAS allocations to 2001 DAS allocations, based on homeport state. (Source: NMFS NERO)

Table 511 shows DAS changes based on vessel length. All vessel length classes received more DAS in FY 2002 than used in FY 2001. There does, however, appear to be a shift in the allocation from smaller to larger vessels. The two smaller size classes have a smaller share of the DAS allocation as a result of the court order, while the two larger classes have a larger share. Vessels in the 50 to 74 foot size class "gained" the largest share of DAS. This shift follows the fact that in recent years larger vessels have used a higher percentage of their DAS.

Categories	Number of Permitted Vessels in 2002/Permitted Vessels in 2001	2002 Allocated DAS as a percentage of 2001 Allocated DAS	DAS Used FY 2001	DAS Allocated FY 2002	DAS Used FY 2002	Percent of Total DAS Allocated FY 2001	Percent of Total DAS Allocated FY 2002

Table 511 - Comparison of 2002 DAS allocations to 2001 DAS allocations based on vessel length class. (Source: NMFS NERO)

In summary, the court order changed the distribution of allocated DAS by permit category and vessel length class. It had only minor effects on the distribution of DAS by homeport state, with New York and New Jersey the states most affected by the allocation. In almost every category, more DAS were allocated in 2002 than were used in 2001. The sole exception is the individual DAS permit category, which received fewer DAS than were used in FY 2001. Impacts on individual vessels within a category may differ from these broad patterns.

DAS Use

DAS use for the period May 2002 through April 2003 is shown in Table 474 (permit category), Table 480 (length), Table 486 (primary gear), and Table 504 (homeport state). There is a 37 percent decline in DAS used in the groundfish fishery in FY 2002, with 41,169 DAS used by all permit categories. This compares to 65,276 DAS used during the same period the previous year. This decline in effort is the result of less fishing activity, changes in DAS counting (prohibition on front-loading the clock, limitations on DAS use May – July, etc.), and the re-distribution of DAS. All permit categories, states, and vessel length classes were allocated more DAS in FY 2002 than they used.

There were only minor changes in the precentage of the total DAS used by each permit category, and the distribution of DAS use is similar to what took place between FY 1996 and FY 2001. For example, individual permit category vessels used between 25 and 42 percent of the total DAS used – in FY 2002, this category used 30 percent. Similarly, fleet vessels used between 55 and 66 percent of the total DAS from FY 1996 through FY 2001, and used 60 percent of the total in FY 2002. Examining DAS use by length, homeport state, and gear also shows that FY 2002 DAS use did not differ appreciably from the patterns of use from FY 1996 through FY 2001. In conclusion, while the DAS allocations in FY 2003 were distributed differently than in previous years, the distribution of DAS use was unchanged.

Landings

Preliminary landings information by stock area is only available for the months of May through December. Table 512 compares this period in FY 2001 to FY 2002 for selected stocks. The measures implemented by the court order clearly reduced landings for most stocks, but there is considerable variation from stock to stock. Witch flounder and white hake landings declined by about 10 percent Landings for both cod stocks are about one-third lower in 2002 than in 2001. GOM haddock, GB yellowtail flounder, and SNE/MA winter flounder landings have declined over 40 percent. In contrast to the general trend of reduced landings, GB haddock landings increased nearly 50 percent and GB winter flounder landings increased by nearly 30 percent.

Tthis preliminary analysis does not explain the differences in reductions between between stocks. On the surface, DAS restrictions imposed by the court order might have been expected to reduce landings of offshore GB sotcks more than inshore stocks, but that trend is not well-defined as GB cod has the same reduction as GOM cod, and GB winter flounder and haddock landings increased. Some of these differences might be explained by increased catch rates as a result of stock increases, as both GB haddock and GB winter flounder are increasing in size. Liberalization of the GB haddock trip limit may also have counter-acted some of the court ordered restrictions.

Revenues

Revenue information for 2002 was compared to revenue information for 2001. Revenues received and pounds landed for eleven groundfish species are shown by state in Table 513 and Table 514. Only the period May – December was examined. This is the period of 2002 affected by the FW 33 court order for which data is available due to lags in the reporting system. Some data for 2002 may not yet be entered, so these revenues should be considered preliminary. All revenues are shown in constant 2001 dollars.

Landings for these eleven groundfish species for the May – December period declined from about 70 million pounds in 2001 to 55 million pounds in 2002. Revenues, however, only declined by 3 percent, indicating a substantial adjustment in prices received for groundfish. Groundfish revenues in Rhode Island increased by 48 percent, Massachusetts revenues showed no change, while all other states showed a decline. Maine (-12 percent) and New Hampshire (-8 percent) showed similar reductions, as did New York (-48 percent) and New Jersey (-53 percent). Connecticut data is incomplete. Closer inspection of the table shows that in general revenues from cod and white hake declined, revenues from haddock increased, and revenues for other species were similar in each year. Those states that increased revenue from haddock generally faired better than the others.

Groundfish revenues for the top ten groundfish landing ports are shown in Table 515. While there was some shuffling in the ranking of the ports, the same ports for this period were in the top ten each year. Point Judith (31 percent), Boston (5 percent), Gloucester (3 percent) and New Bedford (1 percent) increased goundfish revenues in the May – December 2002 period compared to the same period in 2001. Chatham (-6 percent), Hampton NH (-9 percent), Scituate and Provincetown (-12 percent), Portland (-14 percent) and Portsmouth (-20 percent) saw declines in revenues. Once again, those ports that were able to increase haddock revenues fared better than those ports that did not.

Table 516 shows 2001 and 2002 groundfish revenues for the May – December period for principal gear types in constant dollars. Trawl gear revenues were unchanged, with declines in cod, yellowtail flounder, plaice and pollock offset by gains from haddock, white hake, and grey sole. Gillnet revenues declined by 2 percent. Longline and handline revenues declines by 47 percent and 43 percent respectively. Cod revenues for these gears were nearly reduced in half.

9.4.2.5 Capacity Reduction

Fishing capacity is the level of output a fishing fleet is able to produce given specified conditions and constraints. Maximum fishing capacity results when all fishing capital is applied over the maximum amount of available (or permitted) fishing time, assuming that all variable inputs are utilized efficiently. Excess capacity in the Northeast multispecies fishery has been addressed in several ways. The expanded Northeast Fishing Capacity Reduction Program (FCRP) was initiated in September 1996 after a brief pilot program which resulted in the removal of 11 vessels from the fishery. Congress later made $10 million available for implementing a multispecies permit buyout program that would target removal of some latent effort by 2002. Latent effort, often measured in unused DAS, has been of particular concern because of its potential to significantly increase capacity in the fishery. DAS may not be used by vessels for a number of reasons, including the choice not to fish or fishing in another fishery while retaining a multispecies permit.

The Report to Congress on Northeast Multispecies Harvest Capacity and Impact of Northeast Fishing Capacity Reduction, prepared by NMFS in December 2001, discusses the effects of the FCRP from 1996 to 2000. Vessel activity was analyzed in the Report to Congress by means of two indices: (a) the Capital Inventory Index (CII), which provides an estimate of the total amount of capital, weighted by vessel characteristics, that exists in the Northeast multispecies fishery at any given time; and (b) Estimated Fishing Capacity (EFC), which is defined in terms of expected catch in 100,000-pound units.

In general, while there were some measurable benefits of the FCRP, most positive effects were difficult to separate from those of Amendment 7, implemented in 1996. The FCRP did, however, remove 79 vessels in 1996 and 1997 that were more active than most of the remaining vessels. In 1997, 10% of the physical capital, as measured by the CII, was removed in comparison to the 1996 limited access baseline. 5% of fishing capacity, as measured by the EFC, was removed in comparison to this same baseline. Based on 1997 DAS allocations, the FCRP removed 5% of 1997 allocated DAS. These efforts probably resulted in a short-term reduction in fishing mortality, although the long-term effects are less certain. Substantial latent capacity remains and may be in the process of re-entry into the fishery, indicated by the fact that the EFC utilization rate in 2000 (36%) was the highest of all years from 1996 to 2000.

The New England Fishery Management Council created an ad hoc capacity committee in 1999 to further examine ways to eliminate excess capacity from the multispecies fishery. Their recommendations were incorporated into the development of management alternatives in Amendment 13 that focus on reducing capacity.

9.4.2.6 Spatial and Seasonal Distribution of Fishing Effort on Gulf of Maine and Georges Bank Cod

Changes in the spatial and temporal distribution of fishing effort on cod in the Gulf of Maine and Georges Bank from 1996 to 2000 were observed by examining the landings and days absent associated with a sample of 30 minute squares within the region. The NMFS Logbook (VTR) database was queried to create a dataset which linked landings and days absent with area fished in Georges Bank (GB) and the Gulf of Maine (GOM) on a trip by trip basis for the years 1996 through 2000. For each logbook entry, area fished was translated into a particular 30 minute square (1,190.25 square miles) in the Gulf of Maine or Georges Bank. The numbered grid of 30 minute squares used to evaluate spatial fishing effort is shown in Figure 255.

Figure 255 - Map of 30' squares in the Gulf of Maine and Georges Bank

Year-round and seasonal closed areas, DAS reductions, and trip limit changes may have all contributed to changes in cod landings and fishing effort. Beginning with Framework 25, a series of "rolling closures" or closures of blocks for short periods of time (1-2 months) were instituted in the Gulf of Maine. A complete description of these and other closures is available in section 1.2 (Summary of Current Measures) of the Multispecies Monitoring Committee's 2001 Report to the New England Fishery Management Council. These and other closures resulted in fishing effort shifts across the region as fishermen moved out of newly closed areas into open fishing grounds.

Logbooks may not always provide complete and accurate information about the multispecies fishery. Logbook data can be rife with inaccuracies due to human recording errors both at sea and in the transferring of information from paper to an electronic format. For this reason, it is important that definitive conclusions about fishing effort in the multispecies fishery are not drawn on the basis of information recorded in logbooks.

Landings

For the Gulf of Maine and Georges Bank, the 30' squares that were most important to the groundfish fishery were identified as those which were among the top ten most heavily fished squares in at least one year from 1996 to 2000. The percentages of total Gulf of Maine and Georges Bank cod landings attributed to fishing effort in the most important 30' squares are presented graphically to illustrate fishing effort shifts (Figure 256 and Figure 257).

In 1996, fishing in block 132 in the Gulf of Maine accounted for the highest percentage of cod landings, followed by blocks 129 and 124 (Figure 256). From 1997 to 2000, the percentage of cod landings in block 129 decreased. Effort also decreased slightly in block 132 which remained the second greatest contributor to landings from 1997 to 2000, after block 124. By 1998, fishing effort in block 124 had expanded to account for nearly 30% of the total cod landings in the Gulf of Maine. While effort in block

132 remained relatively stable from 1997 to 2000, it fluctuated slightly in block 124. The percentage of total cod landings more than doubled in block 124 from 1996 to 1998, decreased slightly in 1999 and rose again nearly to its 1998 level in the year 2000. Effort in block 139 decreased from 1996 to 2000 and most other blocks exhibited only minor effort shifts over the time period described. These data suggest that a moderate shift in effort to areas further inshore occurred from 1996 to 2000.

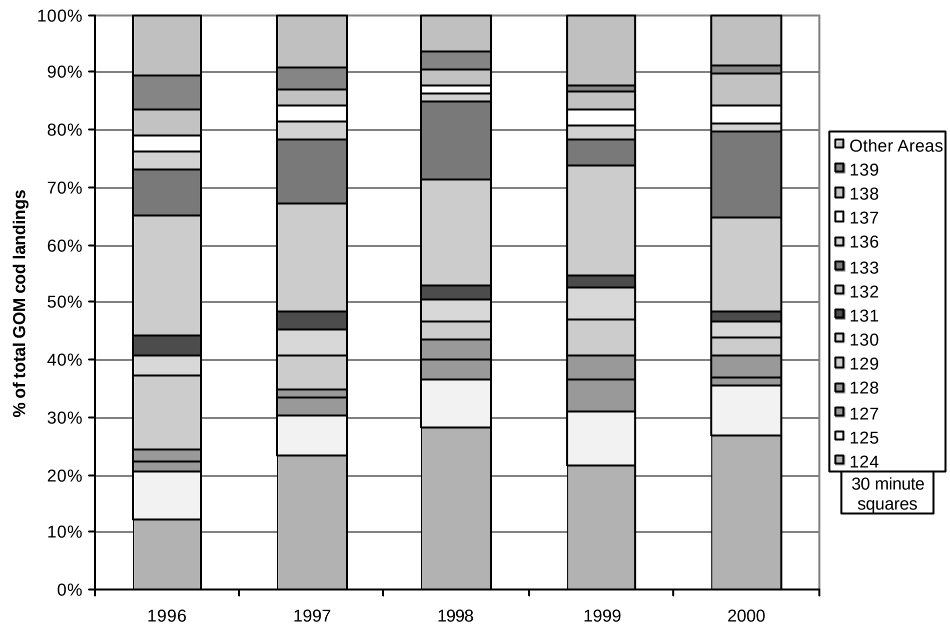

Figure 256 - Percentage of total cod landings attributed to fishing effort in the Gulf of Maine (by 30' squares), 1996-2000
Source Data: NMFS VTR database. Years denote calendar years.

On Georges Bank, fishing in block 98 accounted for the highest percentage of total cod landings from 1996 to 2000 (Figure 257). Effort in this block was highest during the five year period in 1999, contributing to 30% of total cod landings, but decreased to about 20% in 2000. Effort in blocks 110 and 111 decreased between 1996 and 2000, while generally increasing in blocks 80, 81 and 118. The pattern of expanding and contracting effort in block 113 mirrored that in block 111 from 1996 to 1998. However, in 1999 and 2000 the percentage of cod landings contributed by effort in block 111 decreased while increasing in block 113. This change suggests that some fishing effort may be moving further inshore. As in the Gulf of Maine, effort in most other blocks remained relatively stable. In Georges Bank, most of the fishing effort is concentrated at the western edge of Closed Area I and the northern and eastern edges of Nantucket Lightship Closed Area. Fishing effort on Georges Bank appears to be more broadly distributed than in the Gulf of Maine, with many blocks associated with similar proportions of cod landings.

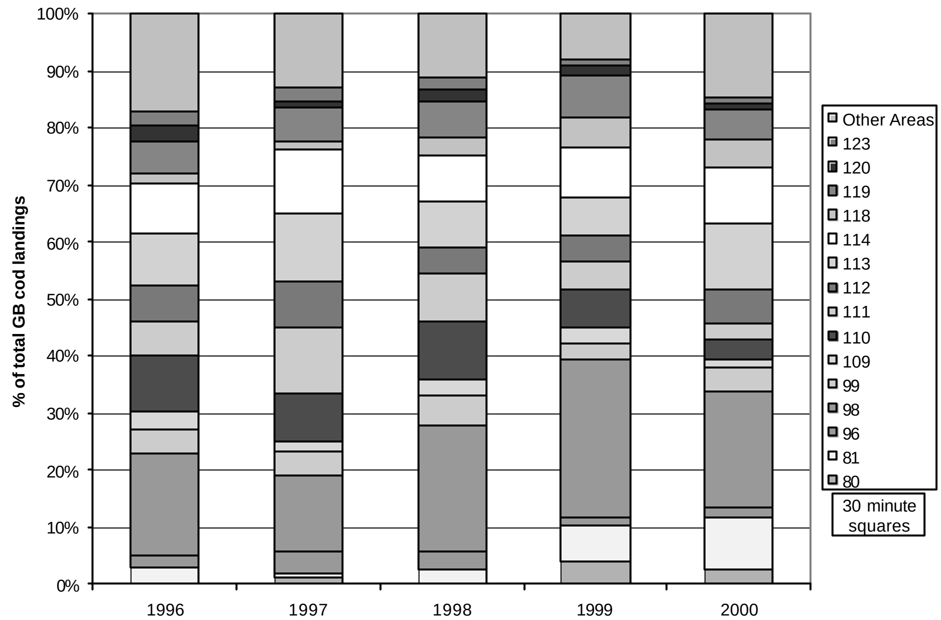

Figure 257 - Percentage of total cod landings attributed to fishing effort on Georges Bank (by 30' squares), 1996-2000
Source Data: NMFS VTR database. Years denote calendar years.

Days Absent
The method of analysis described above was also used to examine the distribution of days absent by vessels fishing for cod in the Gulf of Maine and Georges Bank. Days absent are the days recorded in vessel trip reports (logbooks) as days fished. Days absent are not necessarily equivalent to days-at-sea (DAS) because the way they are recorded in logbooks differs among individuals. Some fishermen record days absent as they do DAS, indicating the times called in and out as recorded on the DAS clock, while others record days absent by calendar day. The only way to link days fished with area fished is through examination of logbook data. DAS as documented by NMFS are not considered in these analyses.

As expected, the spatial distribution of fishing effort measured in days absent in the Gulf of Maine mirrored the pattern of landings in the 30' squares (Figure 258). Days absent that were fished in blocks 124 and 132 exceeded days fished in other blocks. Percent of days absent by vessels fishing for cod increased slightly from 1996 to 2000 in blocks 128 and 138. In general, the distribution of percentage of days absent among the most heavily fished blocks in the Gulf of Maine was more even than the distribution of percentage of cod landings.

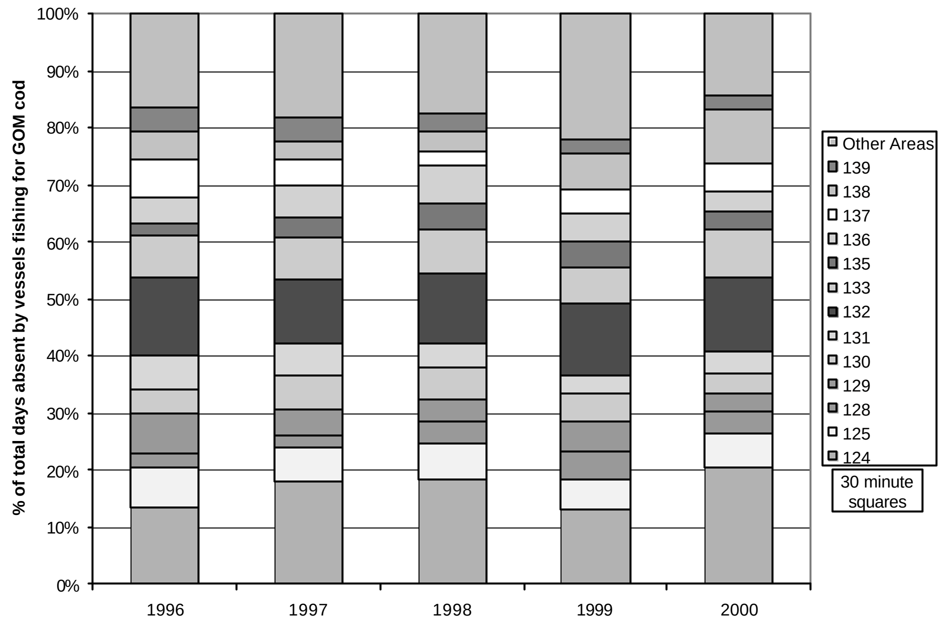

Figure 258 - Percentage of total days absent in the Gulf of Maine (by 30' squares), 1996-2000
Source Data: NMFS VTR database. Years denote calendar years.

As for the Gulf of Maine, fishing effort measured in percentage of days absent on Georges Bank mirrored effort measured in percentage of landings (Figure 259). The highest percentage of days absent occurred in block 98. A particularly striking feature of the data for Georges Bank is that percentages of days absent by vessels fishing for Georges Bank cod were very consistent from year to year, suggesting that fishing effort shifted very little on an annual basis in the years 1996 to 2000.

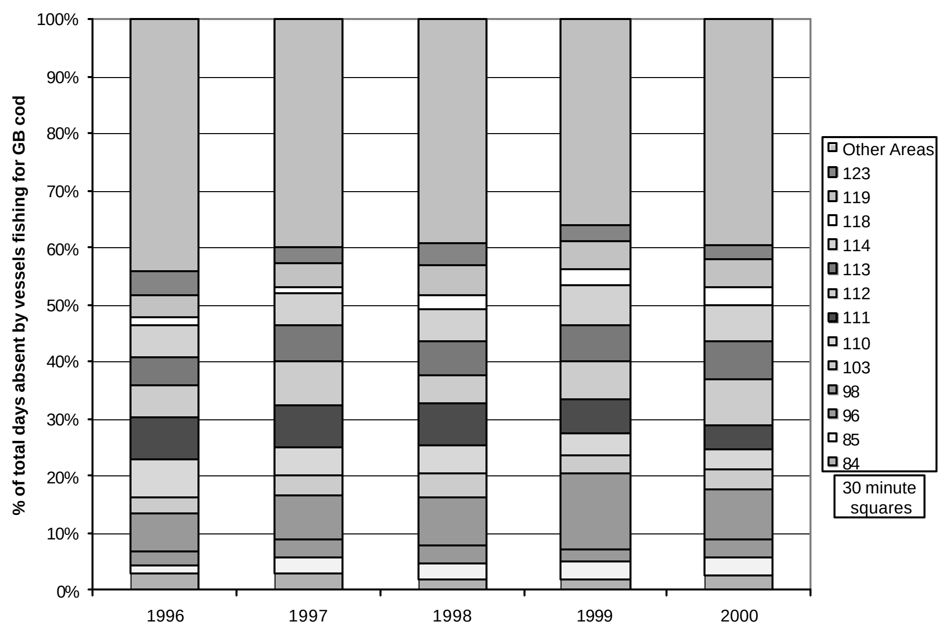

Figure 259 - Percentage of total days absent on Georges Bank (by 30' squares), 1996-2000
Source Data: NMFS VTR database. Years denote calendar years.

Seasonality
Temporal shifts in fishing effort were also examined. The percent of total days absent by vessels fishing for Georges Bank and Gulf of Maine cod is shown for each month from 1996 to 2000. The highest percentage of total cod landings in both the Gulf of Maine (5-20%) and Georges Bank (9-20%) occurred from April to June (Figure 260 and Figure 261). For both regions the peak month was May. It is likely that the beginning of the fishing year on May 1 initiates increased fishing effort as days-at-sea are renewed to the fleet. The percentage of total cod landings on Georges Bank declines more gradually between June and November than in the Gulf of Maine, where a sharp decrease in percentage of landings occurs from June to July. While the sharp decrease in percent of total Georges Bank cod landings in May 2000 may represent the effects of a new Georges Bank area closure in that year, it is likely a result of anomalous data. The highest percentage of days absent by vessels fishing for Georges Bank and Gulf of Maine cod also occurred from about April to June. Although a distinctly higher concentration of landings occurs during the late spring and early summer months, the percentage of days absent by both Georges Bank and Gulf of Maine vessels are distributed more evenly throughout the year.

9.4.2.7 Groundfish Vessel Safety

The United States Coast Guard's First Coast Guard District Office maintains an extensive database of fishing vessel safety incidents that occurred in the northwest Atlantic since January 1, 1993. Most of the information is for reportable casualties, defined as:

- A grounding;
- Loss of propulsion, primary steering or any associated control system that reduces the maneuverability of the vessel;
- An occurrence materially and adversely affecting the vessel's seaworthiness including but not limited to: fire, collision, sinking and flooding;
- A loss of life;
- An injury that requires professional medical treatment and that renders the individual unfit to perform his or her routine duties;
- An occurrence causing property damage in excess of $25,000.

In addition, the database includes information on Emergency Position Indicating Radio Beacon (EPIRB) alerts and trip terminations because of safety violations. The data for 1993 through 1999 are available to the public via a website (www.uscg.mil/d1/staff/m/fvs/statistics.html).

While the data are not organized by fishery, in many instances the type of vessel (scalloper, longline, gillnet, trawler, etc.) is recorded. Trawls, gillnets, and longlines are three of the primary gear types used to catch groundfish. While these gears are used in a variety of fisheries, examining the number of accidents on vessels using these gear types may give an indication of the number of accidents that occurred in the groundfish fishery.

Figure 264 shows the number of accidents for all fisheries since 1996, reported by groundfish fishing year. The number of equipment problems has declined annually since 1997 and sinking, taking on water, termination and EPIRB activation also generally decreased from 1997 to 2001. Fires increased from 1996 to 2000 and all other accidents varied without trend during these years. Figure 265 illustrates information on the same type of casualties, but only for incidents identified as being on trawl, gillnet, or longline vessels. The trends are similar to those for accidents in all fisheries. A proportionately greater increase in deaths occurred on trawl, gillnet or longline vessels than on all types of vessels between 1999 and 2000.

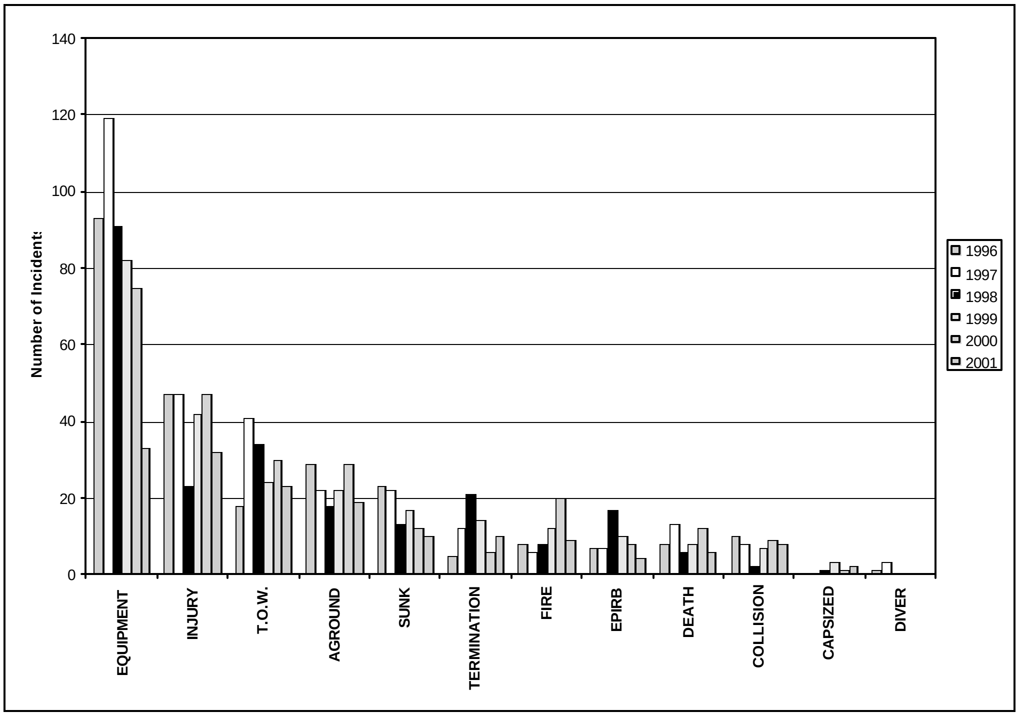

Figure 264 - Vessel safety incidents in all fisheries
*Source Data: USCG, unpublished data. *2001 data are current through 10/31/01*
All years denote fishing years – May 1 – April 30.

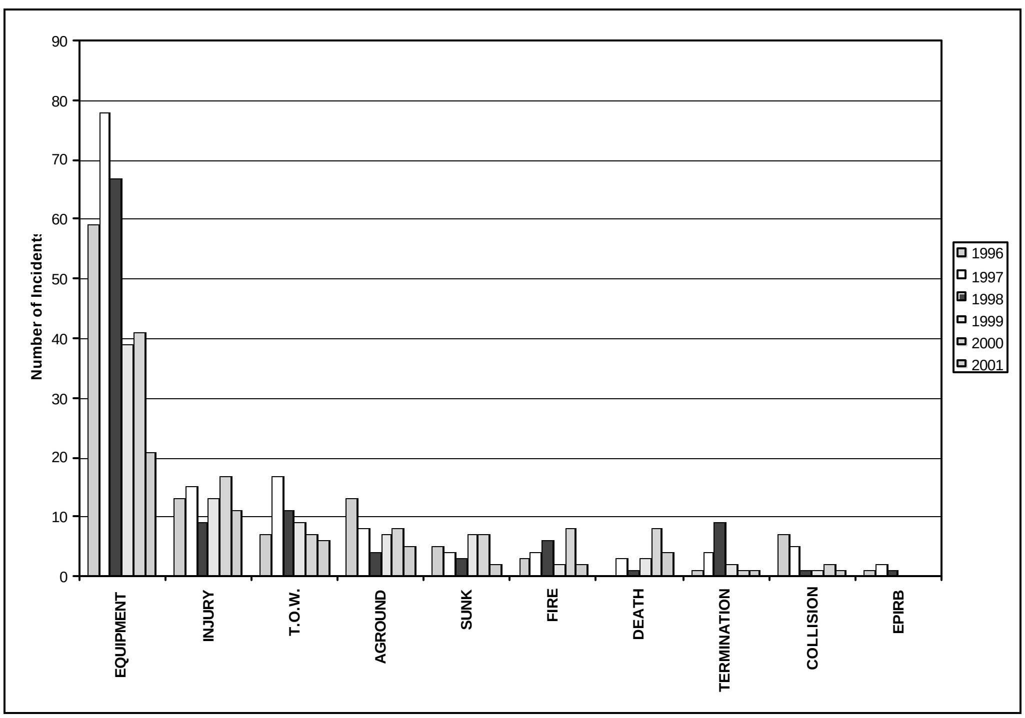

Figure 265 - Vessel safety incidents on trawl, gillnet, and longline vessels
*Source Data: USCG, unpublished data. *2001 data are current through 10/31/01*
All years denote fishing years – May 1 – April 30.

Figure 266 summarizes reported deaths or injuries for all fisheries. The number of injuries in all fisheries declined from high levels in 1996 and 1997 during following years. The number of deaths approximately doubled from fishing year 1999 to 2000, having remained fairly even prior to that point. As shown in Figure 267, the trends among trawl, gillnet and longline vessels were similar to those for all fisheries. However, where injuries increased among all vessels from 1998 to 1999, they decreased among trawl, gillnet and longline vessels during this same period. Deaths on these vessels show the same trends as in all fisheries. The number of deaths more than tripled from fishing year 1999 to 2000.

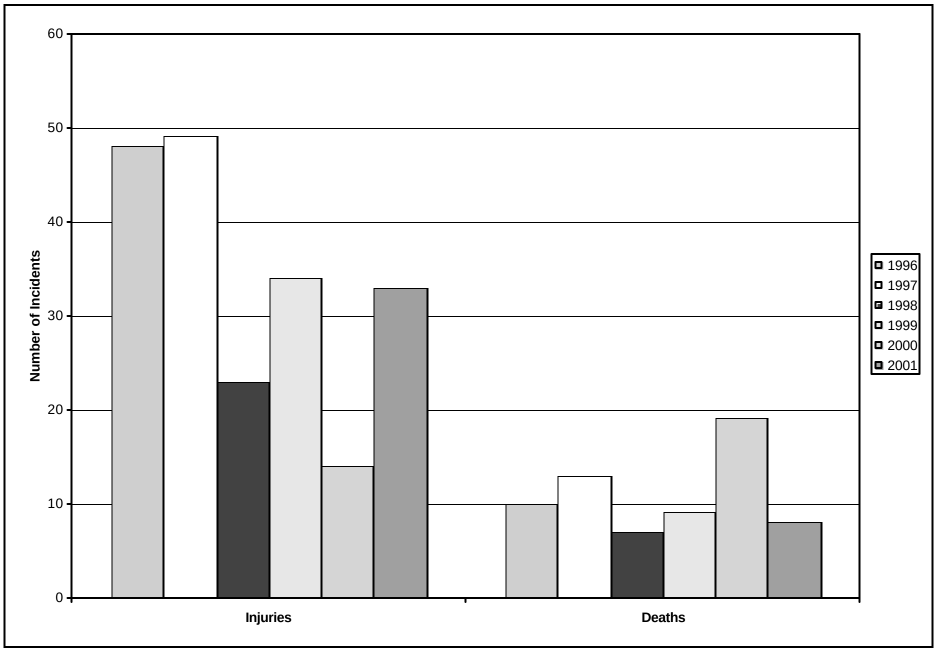

Figure 266 - Fishing vessel deaths and injuries in all fisheries
*Source Data: USCG, unpublished data. *2001 data are current through 10/31/01*
All years denote fishing years – May 1 – April 30.

*Source Data: USCG, unpublished data. *2001 data are current through 10/31/01*
All years denote fishing years – May 1 – April 30.

The number of reported injuries and deaths on trawl, gillnet, and longline vessels was further examined by vessel length (Figure 268 and Figure 269). Injury information does not reflect any clear trend. The highest number of injuries within a vessel size class in any given year occurred in 1997, with 8 injuries on vessels between 50 and 75 feet in length. For all vessel sizes, the number of deaths increased in fishing year 2000. Twelve of thirteen deaths in 2000 occurred on vessels between 30 and 75 feet in length.

All years denote fishing years – May 1 – April 30.

It is difficult to draw conclusions on the impact of groundfish regulations on the safety record of the groundfish fleet absent a closer examination of individual vessel accident investigations. The data, with some exceptions, does not include information on the fishery that the vessel was participating in at the time of the accident. For example, trawl vessels are used in a variety of fisheries in New England, and it should not be concluded that all the accidents by these vessels occurred in the groundfish fishery. While examining the data allows a determination on the number of accidents that occurred, there is no simple way to determine if accident rates have increased or declined because the data cannot be directly compared to measures of fishing effort (such as days absent, DAS, pounds landed, revenue, etc.). Some general statements, however, can be made:

- The number of deaths on trawl, gillnet and longline vessels has increased, though it is unknown in which fisheries the deaths occurred.
- The number of injuries on trawl, gillnet and longline vessels decreased marginally between 1996 and 2000. Injuries increased in 2001.

9.4.2.8 Bycatch

The M-S Act defines bycatch as fish which are harvested in a fishery, but which are not sold or kept for personal use, including economic discards and regulatory discards. Fish released alive under a recreational catch and release fishery management program are not included. Further, the M-S Act requires that, to the extent practicable, bycatch should be minimized and the mortality of bycatch that cannot be avoided should be minimized. In order to consider whether these objectives are being met, bycatch must be reported and assessed. To this end, the M-S Act requires that a standardized reporting methodology assess the amount and type of bycatch occurring in a fishery. The primary tools used to report bycatch in the multispecies fishery are the Vessel Trip Report system (VTR) and the seas sampling/observer program. Each permitted vessel is required to report catch and landings in VTRs submitted on a periodic basis. The seas sampling/observer program places personnel on boats to observe and estimate the amount of discards on a haul-by-haul basis. A federal judge recently ruled that the NMFS acted arbitrarily, capriciously, and contrary to law when it did not adopt new measures to report and assess bycatch after passage of the Sustainable Fisheries Act (*Conservation Law Foundation et al. v. Donald Evans*) in 1996.

The amount of bycatch in Northeast Region fisheries is routinely estimated on a stock-by stock and calendar year basis in the assessments conducted as part of the stock assessment workshops (SAW) reviewed by the stock assessment review committee (SARC). Generally, the estimates of discards can be divided into three broad categories: stocks for which no estimates are possible, stocks for which estimates are possible but are not included in the catch-at-age matrix (for a variety of reasons), and stocks for which estimates are available and are included in the catch-at-age matrix. These broad categories are not unchanging, in that the precisions of discard estimates for any given stock may change over time. This can be due to many reasons, such as changes in sampling, in the level of observer coverage, or in the level or quality of reporting through VTRs.

Most discard estimates are categorized according to gear, as opposed to other criteria such as target species. There are exceptions to this general rule, however, as estimates are generated for specific small mesh fisheries (shrimp and whiting are the two primary examples). Estimates for recreational fisheries are also included in assessments for some stocks. Information on discard mortality varies on a stock-to stock basis. For most stocks managed in the multispecies fishery, reliable estimates of discard mortality are not available and the assumption used in the assessment is that all discards are dead.

While the primary sources of data for commercial fishery discard estimates are VTRs and the sea sampling/observer program, a variety of statistical methods convert the information from these systems into discard estimates. In addition, some discard estimates are generated through a statistical examination of survey data, fishing effort, and fishery selectivity patterns. These methods are described in detail in the pertinent assessment documents and various technical memoranda.

There are nineteen groundfish stocks identified as regulated groundfish managed through this action. Commercial discard estimates are available for eleven of these stocks from their most recent assessments. For some stocks, discard estimates are available for over thirty years. The summary below, however, focuses on the five to seven year period prior to adoption of Amendment 5 in 1994 and the discard estimates since that period. As suggested earlier, the precision of the estimates varies from stock to stock, as does the level of detail. For some stocks, discard estimates are available by gear and age, while for others only total commercial discards are presented in the SAW documents. Recreational estimates of discards are included in the assessments of only three stocks, and are based on Marine Recreational Fishery Statistical Sampling (MRFSS) data. While MRFSS may allow calculation of discards for other stocks, only those stocks where the information was included in the SAW are presented in this summary. The most recent estimate of discards is summarized in Table 517 and described further below. Discard estimates are also available for other species caught in the groundfish fishery. These estimates are summarized in a following section.

Table 517 – Summary of recent bycatch estimates of groundfish species
Entries in italics not used in catch at age matrix for the assessment.

9.4.2.8.1 Stocks Without Discard Estimates

Recent discard estimates (since 1994) are not available for halibut, pollock, redfish, windowpane flounder (both stocks), and ocean pout.

9.4.2.8.2 Discard Estimates Not Used in Catch-at-Age Matrix

Discard estimates are available for GB cod, GB winter flounder, white hake, and GOM haddock. These estimates are of varying reliability and were not used in catch-at-age matrices for a variety of reasons. The most current estimates are summarized below.

9.4.2.8.2.1 GB Cod

Preliminary estimates for 1989-2001 were derived from the Sea Sampling database (GARM 2002). Discard ratios were estimated for eastern and western Georges Bank, with less discarding occurring in the eastern part. Estimates were also developed using the VTR database for 1994-2001. Discarding apparently increased in 1999 (based on the VTRs), possibly due to the adoption of a trip limit, but was still at low levels relative to landings (250 mt in 2001). Discard estimates were not used in the assessment due primarily to the lack of data for 1978-1988. In addition, the sea sampling data for 1989-2000 are limited by inadequate trip coverage and few biological samples.

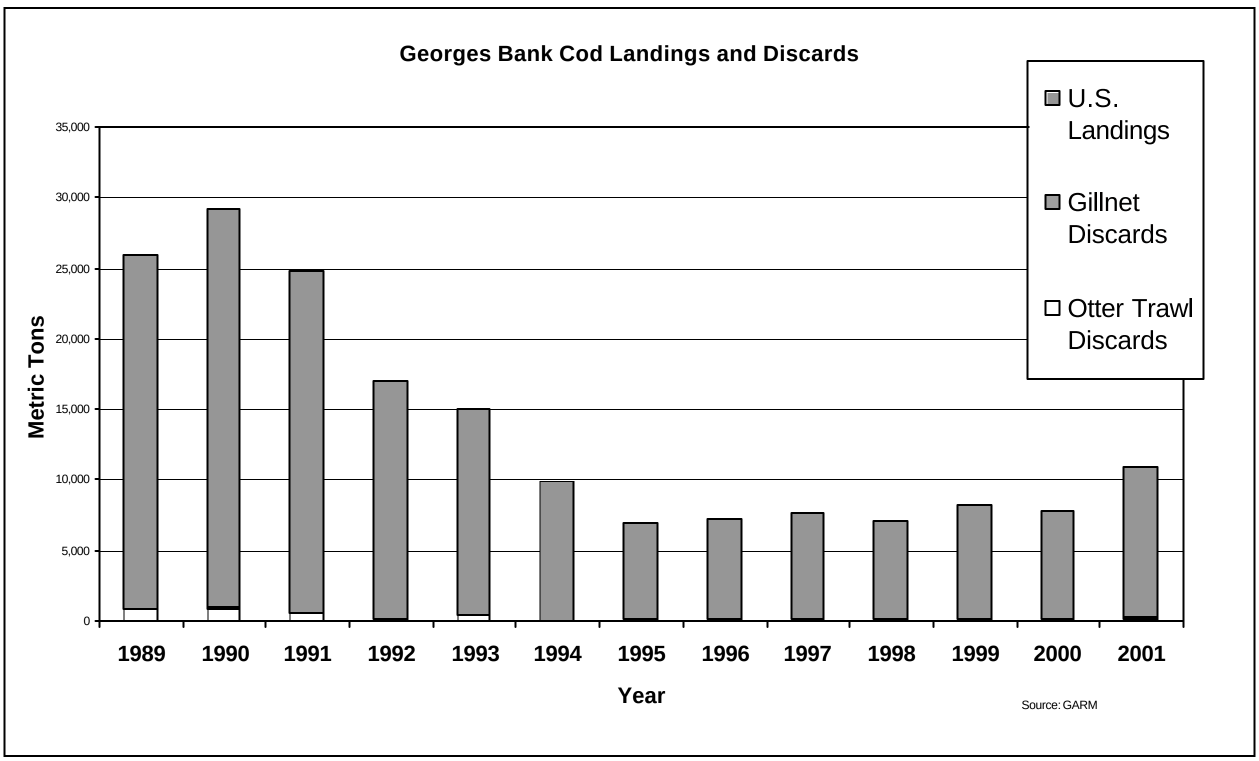

Figure 270 - Georges Bank cod landings and discards, by gear (GARM 2002)

9.4.2.8.2.2 GB Winter Flounder

Sea sampling data for 1989-2000 represent the most reliable source of information available for commercial discards. The total number of otter trawl trips sampled ranged from 3 to 17 trips annually and produced discard estimates ranging from 1.2 to 24.9 mt, less than 2 percent of the otter trawl landings.

Scallop dredge trips were more limited, ranging from 3 to 17 trips annually, and prevented even preliminary estimates. Two other approaches to estimating discards were also examined. VTR-based estimates ranged from 7 to 22 mt, or up to 3 percent of the otter trawl landings. A third approach attempted in 1999 used a combination of commercial sea sampling data and research vessel survey cruises to estimate the total number discarded at length. In summary, data from all three approaches were considered insufficient to reliably estimate the magnitude or age composition of winter flounder discards occurring in the otter trawl and scallop dredge fisheries on Georges Bank. The results, however, consistently produced low estimates of discards to landings through the entire time period. Estimates based on sea sampling data and discard ratios are shown below (SAW 34).

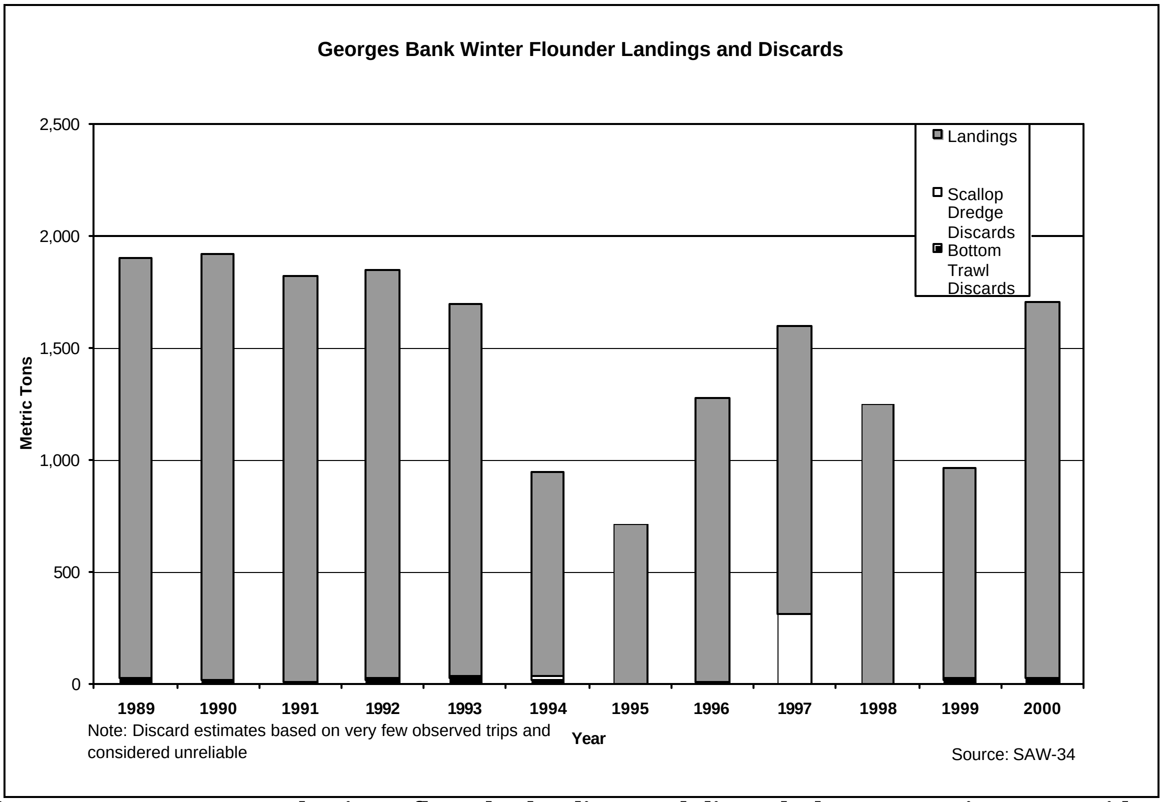

Figure 271 - Georges Bank winter flounder landings and discards, by gear. Estimates considered unreliable due to low number of observed trips (SAW 34)

9.4.2.8.2.3 White Hake

Estimates of total discards were calculated for three gear types based on data in the Domestic Sea Sampling Program. Discard rates were calculated based on the total pounds discarded/total pounds kept for each gear and semi-annual periods. To estimate discards prior to 1989, an average proportion for 1989-2000 was applied to the landings from 1964 – 1988. Estimates ranged from less than 200 mt in 1995 to more than 4000 mt in 1990. Discards appear to increase in years when there was a dominant year class. Discards at age were also estimated but were not used in the assessment as the VPA was rejected by the SARC (SAW 33).

Most discards occurred in the large mesh otter trawl fishery. In most years, discards appear to be primarily one or two year old fish. In the years of high discards that correspond with a dominant year class, some three and four year old fish are also discarded.

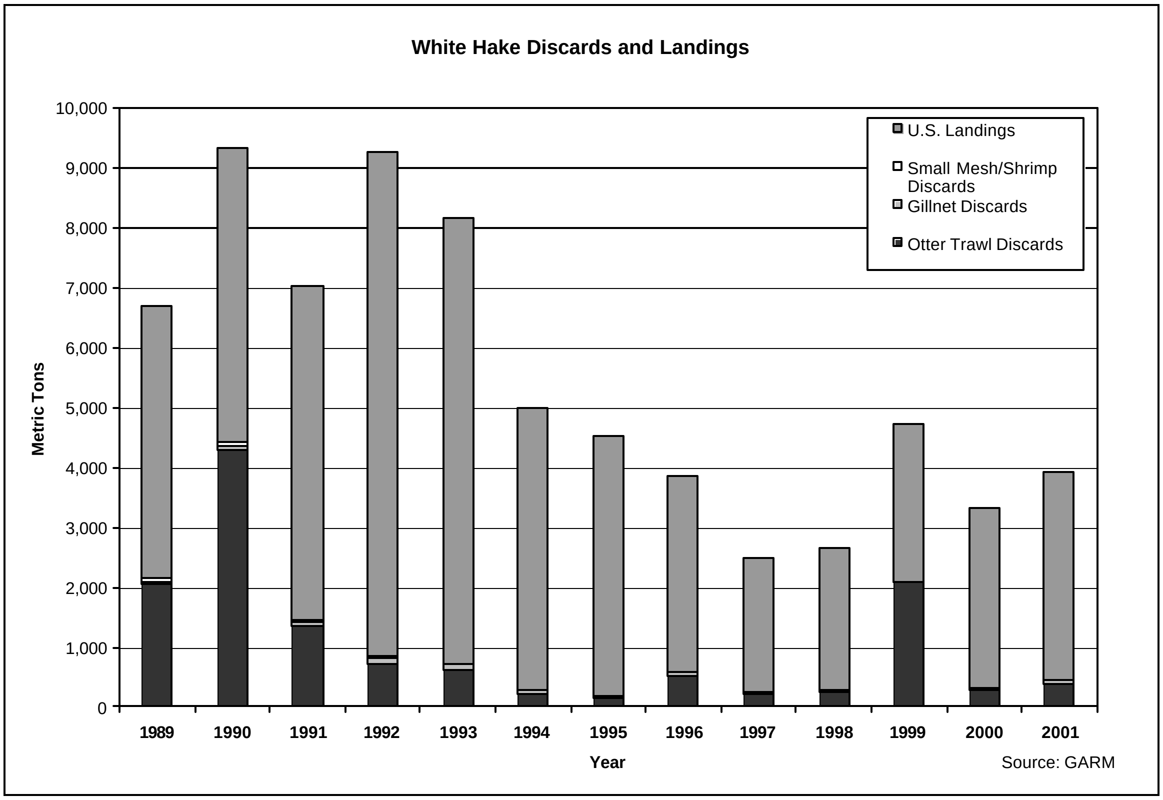

Figure 272 - White hake discards by gear and landings (metric tons) (GARM 2002)

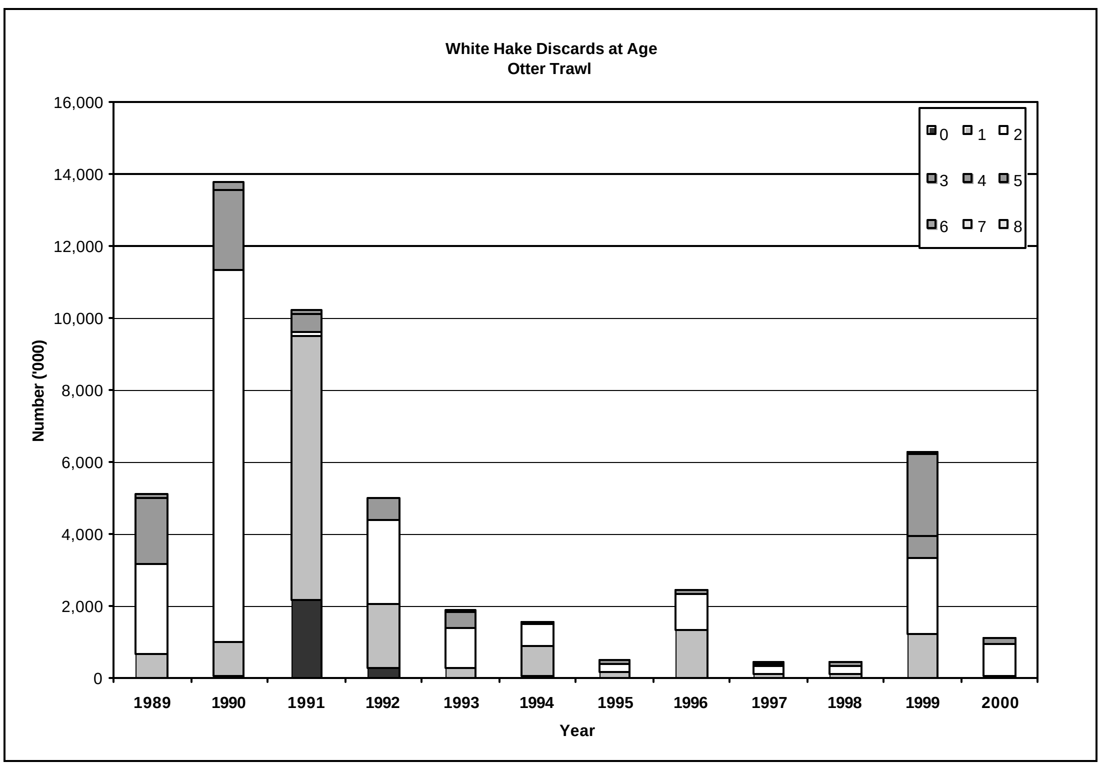

Figure 273 - White hake discards at age, numbers (‘000) of fish. (SAW 33)

9.4.2.8.2.4 GOM Haddock

The ratio of haddock discarded to haddock kept in observed sea sampling trips was calculated for otter trawl, gillnet, and longline gear in SAW-32. These ratios were not expanded to an estimate of overall discards because of few observed trips.

9.4.2.8.3 Discard estimates used in catch–at–age matrix

If there is sufficient confidence in discard estimates, and they reflect a significant amount of the total removals from a stock, the discard estimates are included in the catch used for an age-based assessment. Recent assessments for GOM cod, GB yellowtail flounder, SNE/MA yellowtail flounder, SNE/MA winter flounder, plaice, CC/GOM yellowtail flounder, GOM winter flounder, and witch flounder, included discard estimates in the catch.

9.4.2.8.3.1 GOM Cod

Prior to 2001, discard rates were routinely estimated based on the sea sampling database since 1989. Rates were calculated by quarter and gear. The problem of estimating cod discards was exacerbated by low trip limits (at one point, 30 pounds) in 1999 that resulted in additional discards, and a low number of observed trips in some quarters in both 1999 and 2000. In the last assessment for GOM cod, discard estimates were calculated in three different ways. First, rates were based on the sea sampling database. Second, a subset of available VTRs was used to estimate discards on a monthly basis. Third, a predictive economic model estimated discards in 1999 and 2000. There was no objective basis to select one method over another. The estimates of discards from all three approaches were reasonably close to each other, ranging from 2,600 mt – 3,500 mt in 1999 and 1,200 – 3,100 mt in 2000. The assessment added 2,500 mt to reported landings in 1999 and 1,000 mt to reported landings in 2000. GARM 2002 added 1,500 mt to landings in 2001. For recreational vessels, discards (numbers of fish) were estimated through the MRFSS database (SAW 33). Estimates for 2001 were developed in the GARM (2002) using similar methods.

Commercial discards of GOM cod were at very low levels from 1994 through 1998, then increased dramatically with the imposition of restrictive trip limits. Discards continue to increase, probably because the stock is rebuilding and the trip limits have not been adjusted accordingly. Recreational discards are roughly equal to recreational harvest since 1989.

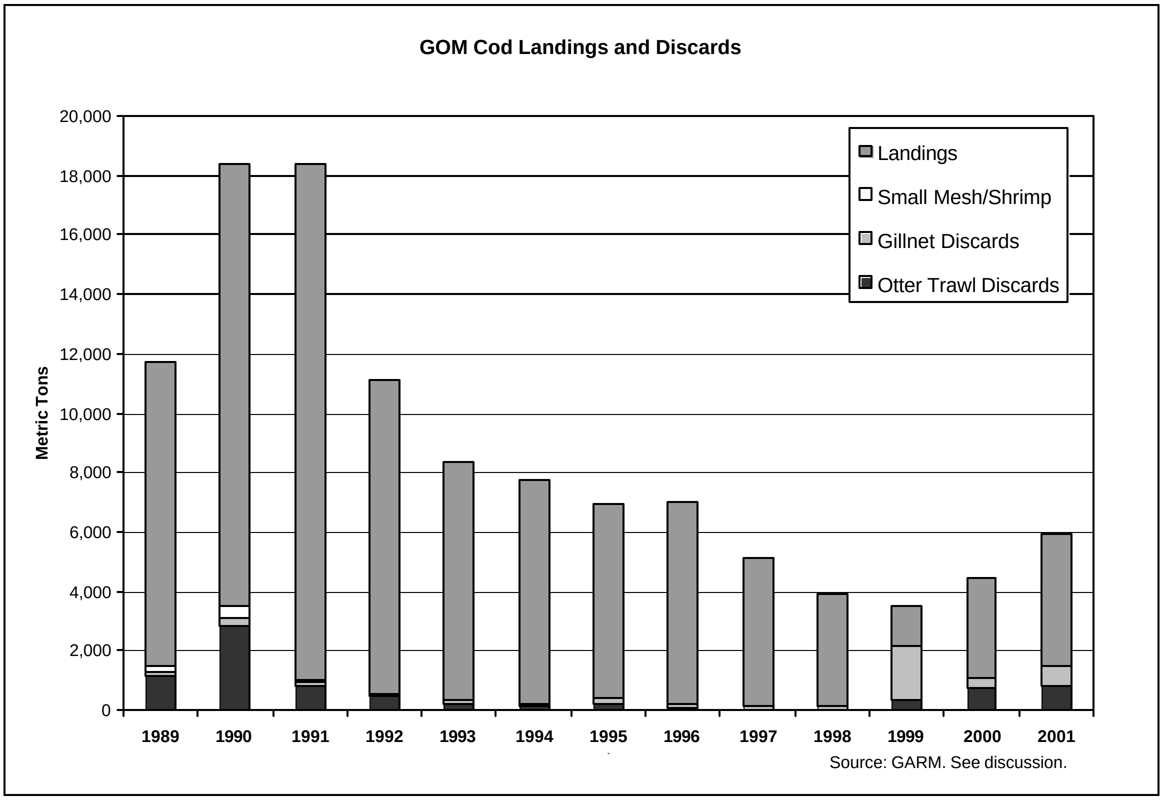

Figure 274 - GOM cod commercial landings and discards. Estimates shown based on sea sampling data, see text for additional discussion. (GARM 2002)

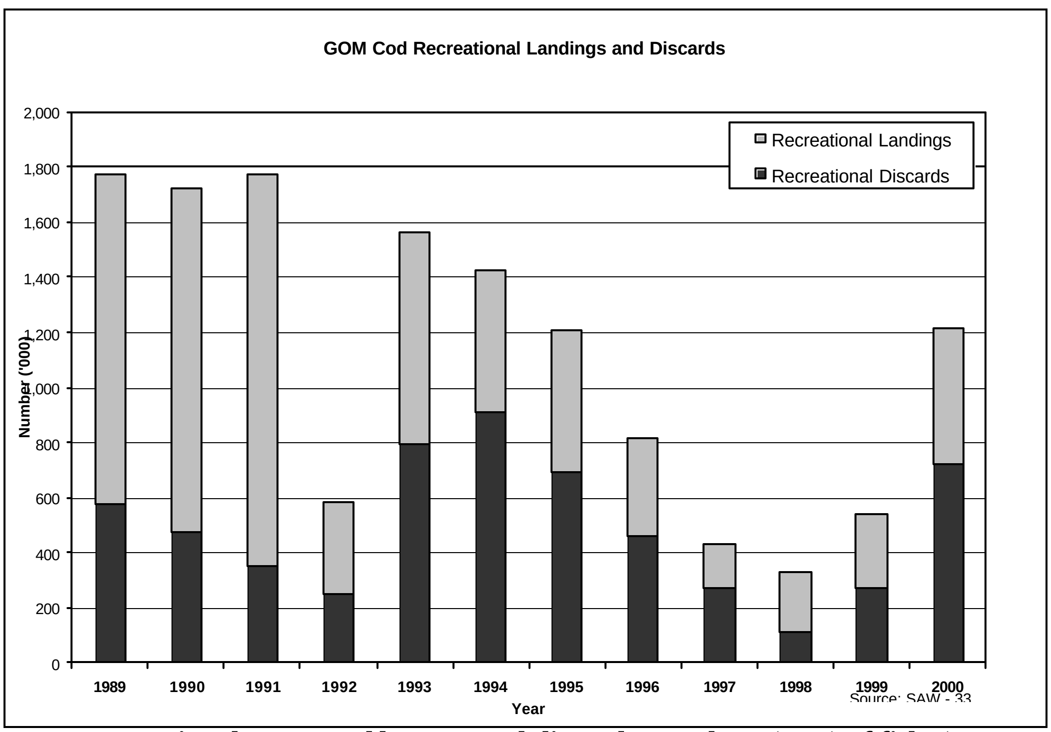

Figure 275 - Recreational GOM cod harvest and discards, numbers ('000) of fish. (MRFSS, SAW 33)

9.4.2.8.3.2 GB Haddock

Georges Bank haddock discards have been estimated periodically and added to the catch when discard levels were significant. The most recent assessment (TRAC 2001) estimated regulatory discards resulting from trip limits during 1994-1998. Discards were assumed low and not estimated for 1999 through 2001 (GARM 2002). With the increase of trip limits as GB haddock has rebuilt and the adoption of large mesh in 1996, discards have declined to an insignificant level for this stock.

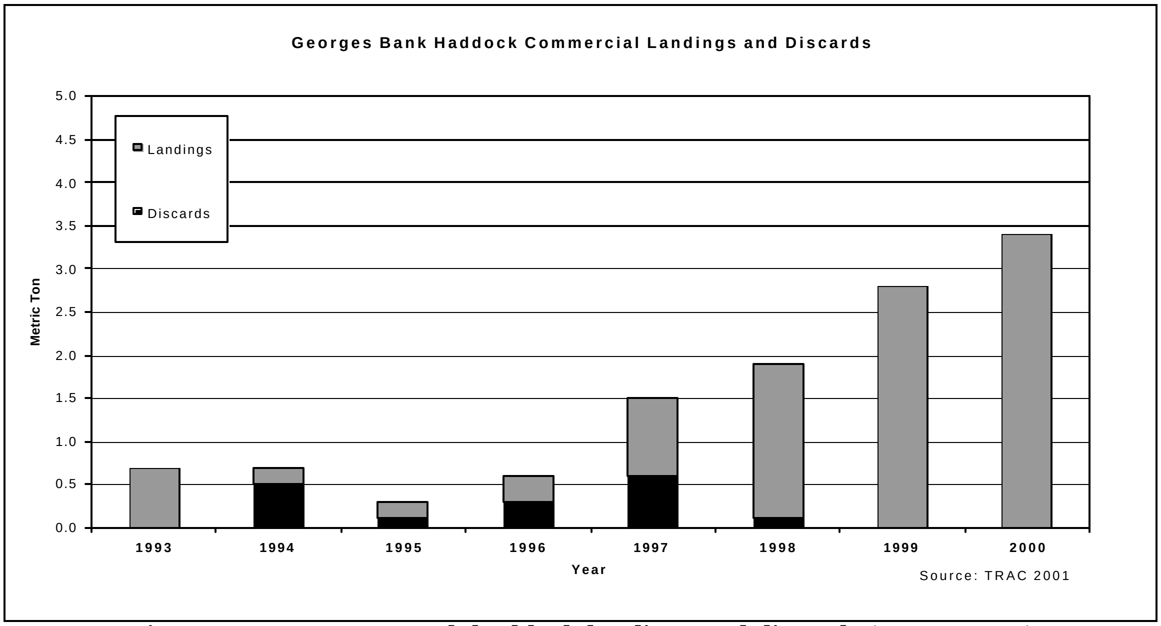

Figure 276 - Georges Bank haddock landings and discards (TRAC 2001)

9.4.2.8.3.3 Georges Bank Yellowtail Flounder

GB yellowtail flounder discard estimates were based on sea sampling data for otter trawl and sea scallop gear. Discarding of small ye llowtail flounder has been an important source of mortality due to fishing pressure, discrepancies between minimum size limits and gear selectivity, and trip limits imposed on the scallop fishery. Scallop discards in 2001 are estimated at 301 mt, while otter trawl discards are estimated at 57 mt (TRAC 2001). Discards declined significantly in 1994, probably due to declines in stock size and reduced fishing effort as a result of management restrictions, and improved gear selectivity because of mesh size increases. Discards in recent years have increased as the stock size and landings increased, but have not returned to the levels observed before 1994. While age 1 fish were a significant part of discards prior to 1994, since 1994 their presence in discards has been negligible. The majority of discards occurred in the scallop fishery in 2000 and 2001.

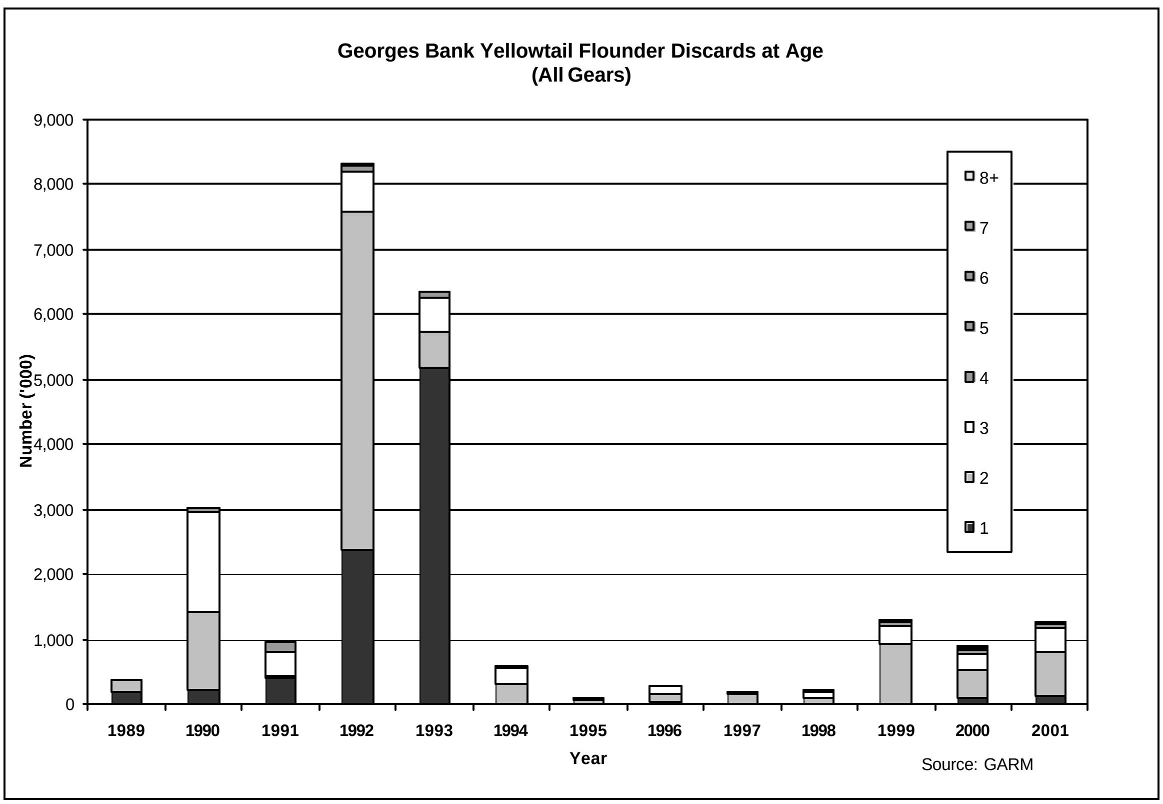

Figure 278 - GB yellowtail flounder discards at age, numbers ('000) of fish. (GARM 2002)

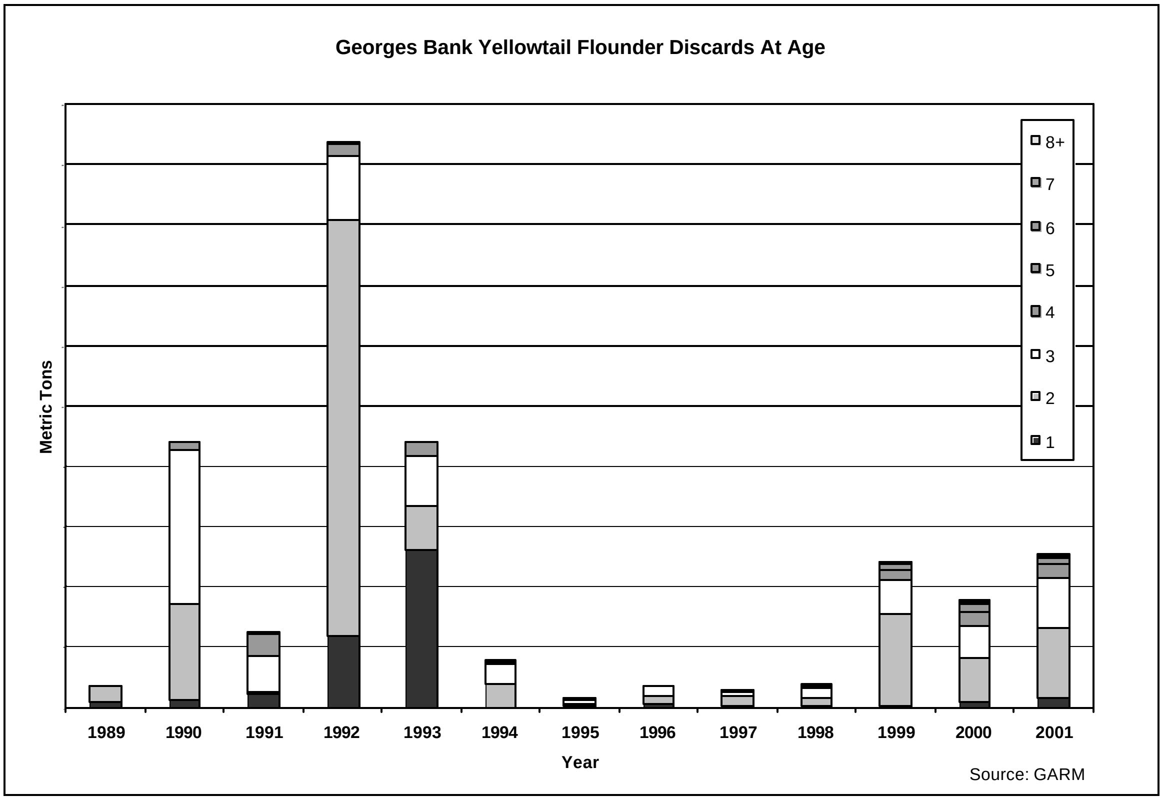

Figure 279 - GB yellowtail flounder discards at age, metric tons. (GARM 2002)

9.4.2.8.3.4 SNE/MA Winter Flounder

Commercial fishery discard estimates have been calculated using a variety of statistical techniques. Discards for 1985 through 1993 were estimated using a combination of survey, commercial port sampling, and mesh selectivity information (SAW 21). For later years, this method, sea sampling data, and VTRs were examined, and VTRs were determined to provide the most reliable data. The number of fish discarded at length was multiplied by 50 percent in both methods to represent the assumed mortality rate. Recreational discards assume a 15 percent mortality rate. Recreational estimates are based on the MRFSS data (SAW 36).

Commercial discards declined from 1989 through 1995, then increased slightly in 1998 as the commercial catch increased, but declined since 1999, probably due to mesh increases. Discards are primarily fish age 3 or younger. Recreational discards have been at low levels since 1989.

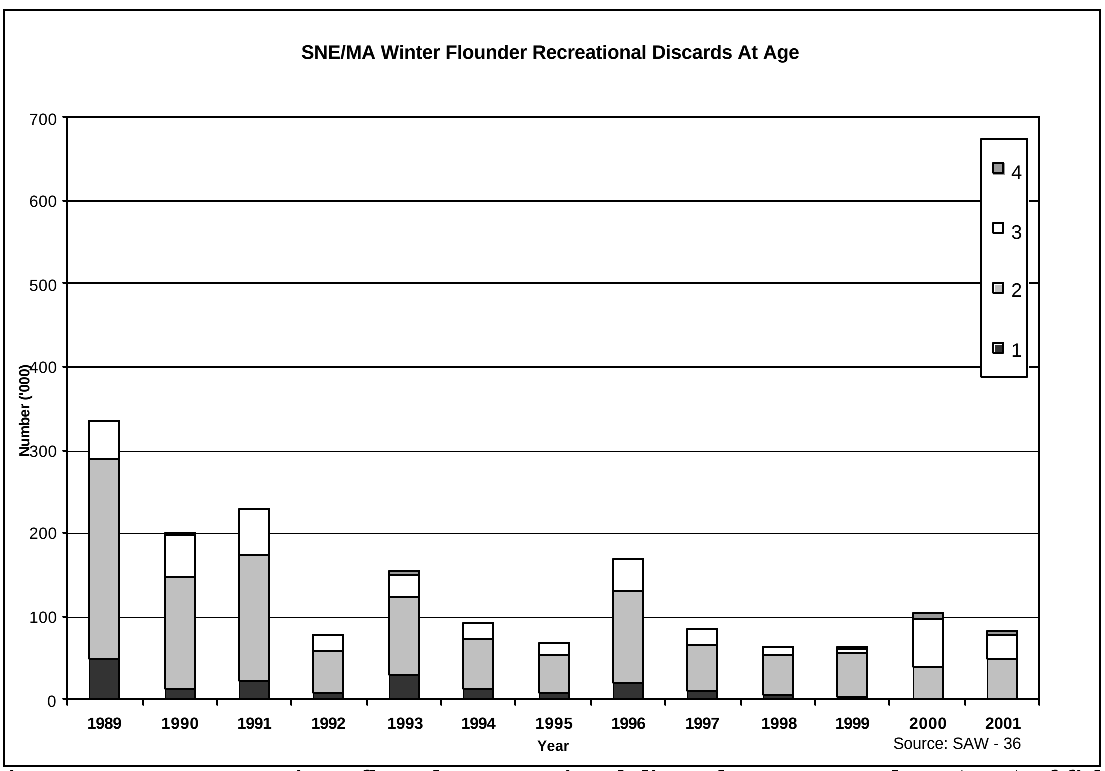

Figure 283 - SNE/MA winter flounder recreational discards at age, numbers ('000) of fish. (SAW 36)

9.4.2.8.3.5 American Plaice

Commercial fishery discards were estimated for the large mesh otter trawl fishery and the northern shrimp fishery. For the shrimp fishery, an indirect method was used for the period s 1980 – 1988 and 1998 – 1999, while a direct method estimating discards per trip from the sea sampling database was used for 1989 – 1997. A survey method was used for the large mesh otter trawl fishery. A method for the small mesh fisheries has not been developed (SAW 32).

Plaice discards declined significantly between 1995 and 1996, likely due to mesh increases and reductions in fishing effort. Since then, discards have remained steady in spite of fluctuations in landings. In the otter trawl fishery, discards are primarily fish age 4 or older. Prior to 1995, however, age 2 and 3 fish were a noticeable component of otter trawl discards, but mesh increases in 1994 and 1996 have almost eliminated discards of these young fish. In the northern shrimp fishery, discards of age 4 and older fish declined with the imposition of the nordmore grate. Most discards are now age 2 and younger. Discards in the shrimp fishery are at low levels in the latest years of the series, due to use of the nordmore grate and reduced effort in the fishery.

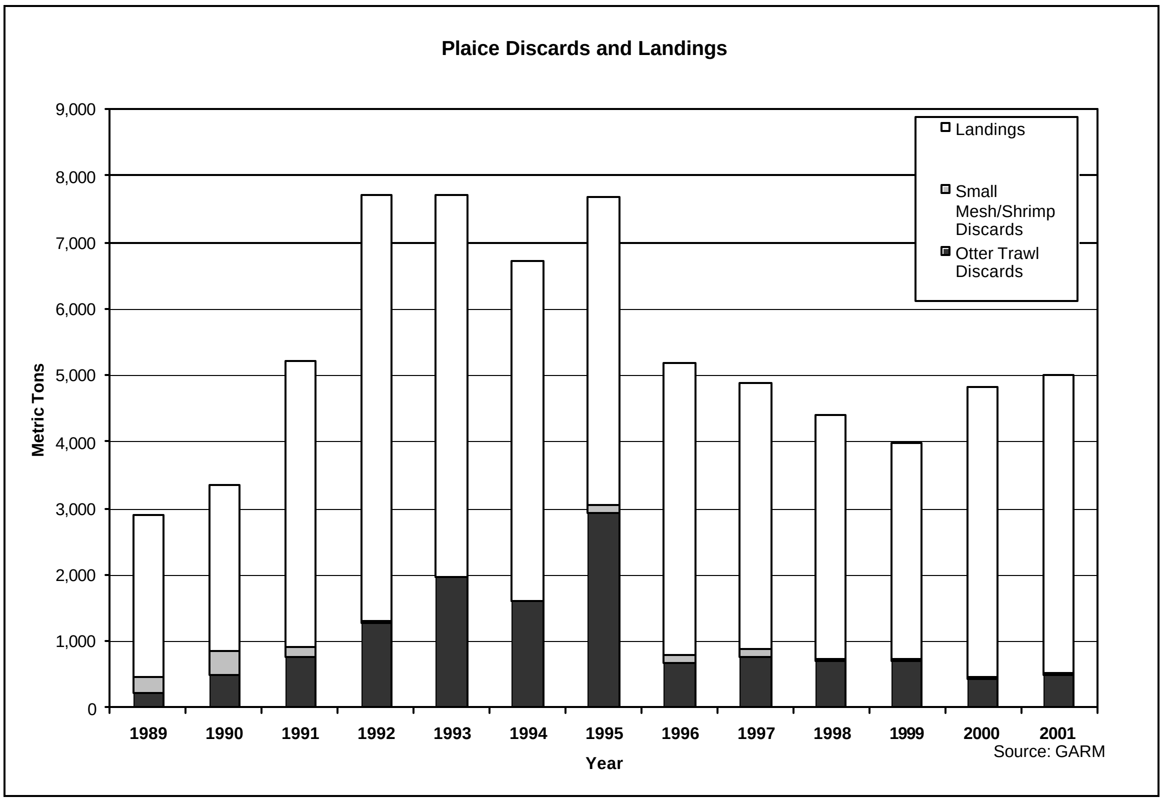

Figure 284 - American plaice discards by gear and landings, metric tons. (GARM 2002)

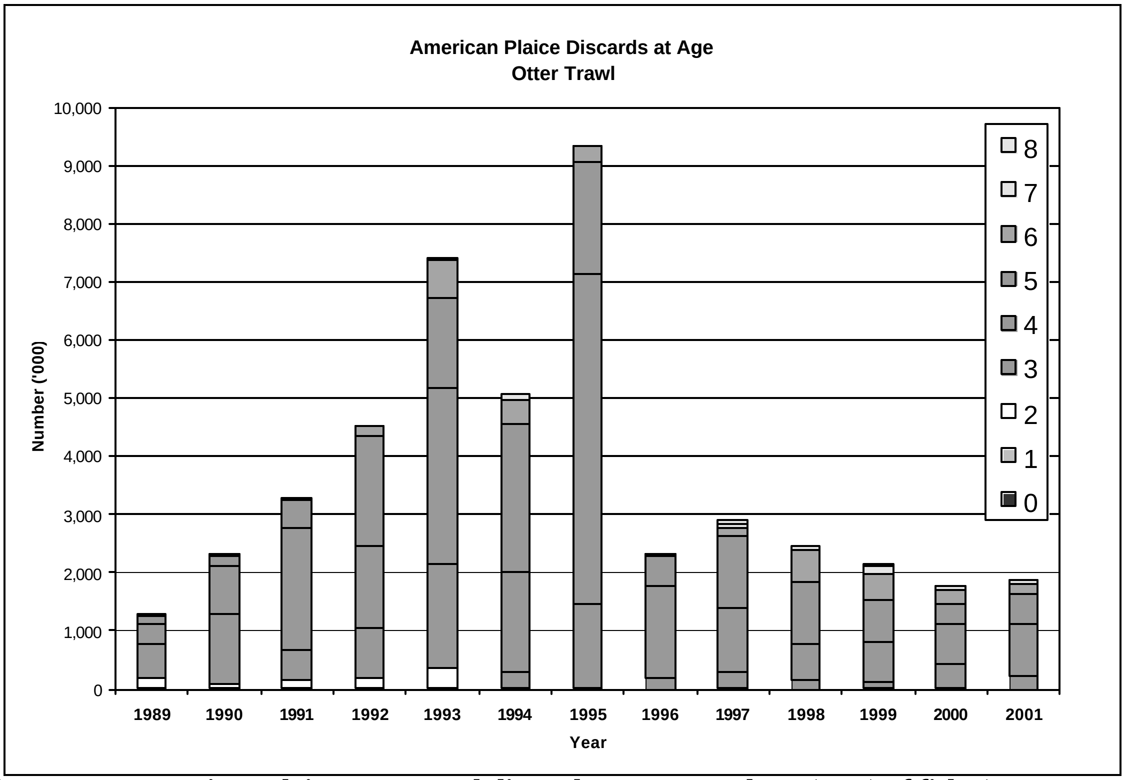

Figure 285 - American plaice otter trawl discards at age, numbers ('000) of fish. (GARM 2002)

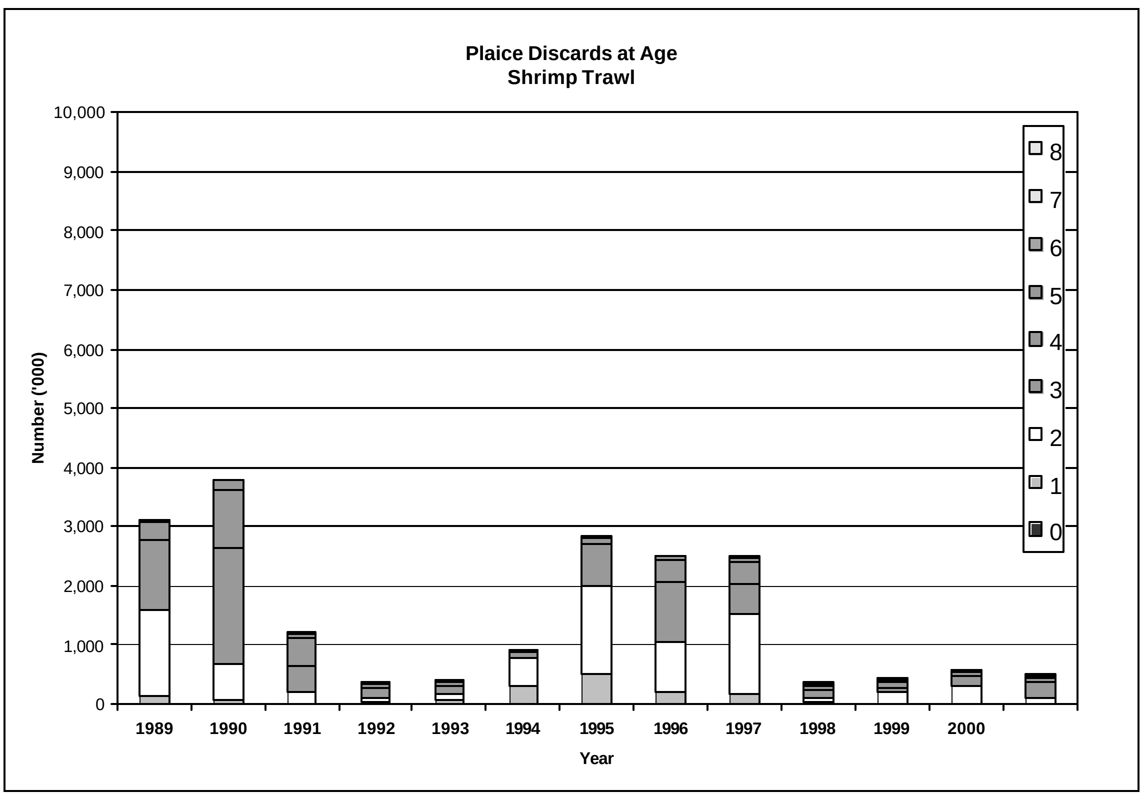

Figure 286 - American plaice northern shrimp fishery discards at age, numbers ('000) of fish. (GARM 2002)

9.4.2.8.3.6 Witch Flounder

Discards in the large-mesh otter trawl fishery and the shrimp fishery were estimated for witch flounder. The primary data source was the sea sampling database for the shrimp fishery, supplemented by various statistical methods in areas with limited data. Because of a lack of observed trips, estimates for the otter trawl fishery were based on a method that uses survey and commercial length at age, gear retention ogives, and information on culling practices (SAW 37) from 1982 – 1994. Since 1995, discards are estimated based on observer data..

Estimates of total witch flounder discards have been 500 mt or less throughout the time period. There does not appear to be a clear trend or major changes in the weight of discards between 1994 and 1999. Discarded weight increased each year from 2000 to 2002. Numbers of discarded fish in both the otter trawl and shrimp fisheries are lower than in 1993/1994. The age of discarded fish also changed, as age 3 fish do not appear in the large mesh otter trawl discards in significant numbers since 1996. Some Age 1 and 2 fish are still caught in the northern shrimp fishery in spite of the required use of the nordmore grate.

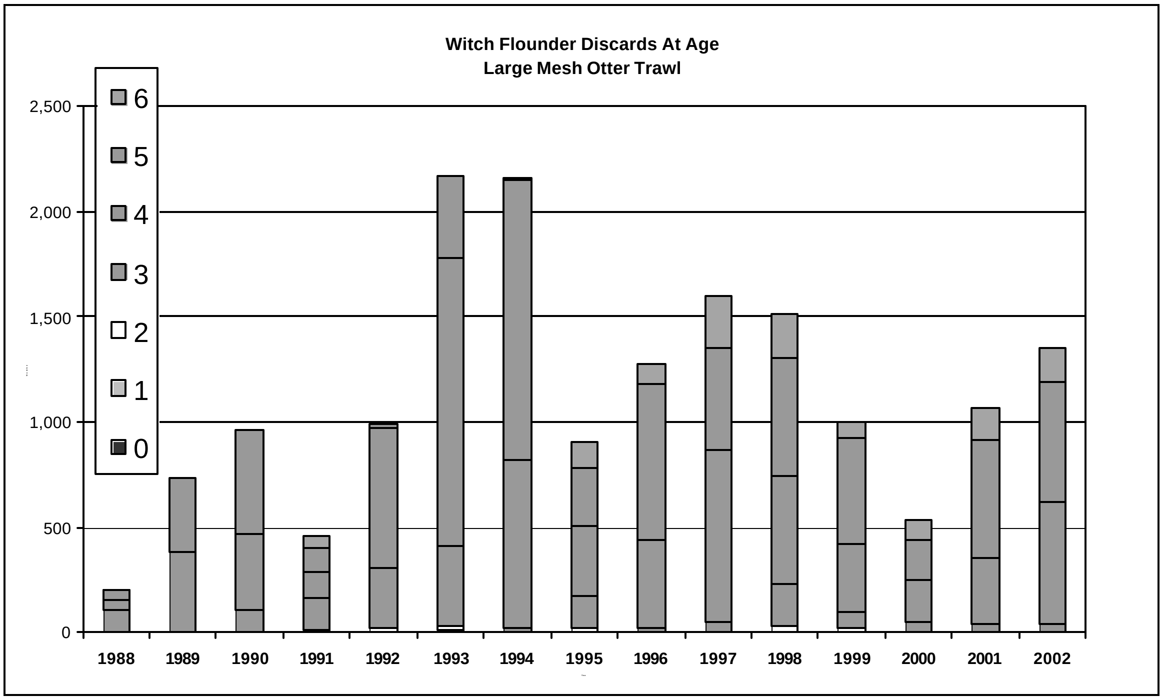

Figure 288 - Witch flounder large mesh otter trawl discards at age, numbers ('000) of fish. (SAW 37)

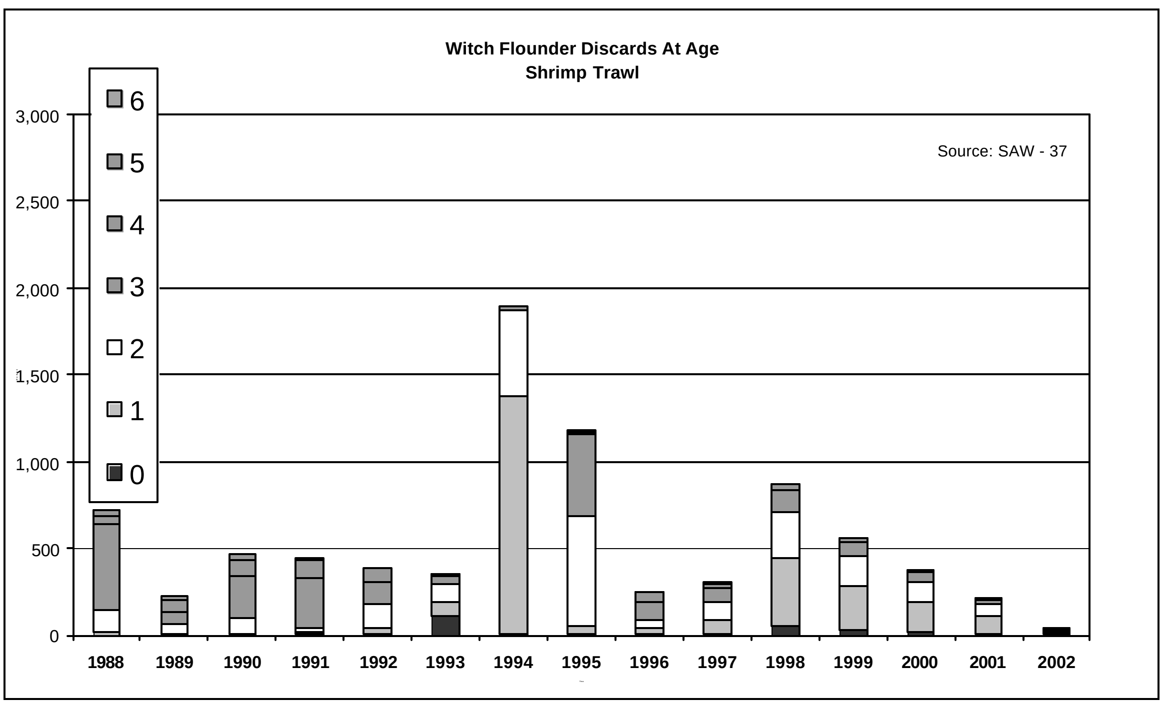

Figure 289 - Witch flounder northern shrimp fishery discards at age, numbers ('000) of fish. (SAW 37)

9.4.2.8.3.7 Cape Cod/GOM Yellowtail Flounder

Prior to SAW – 36, this stock was called Cape Cod Yellowtail Flounder and did not include landings or discards from other areas of the Gulf of Maine Discard estimates were developed since 1963 using a variety of techniques: interviews with vessel captains, observer data when available, and application of selectivity estimates to survey size frequencies. Discards for the recent period of 1989-1997 using the ratio of discarded to landed catch based on sea sampling observations. Discard estimates for all small-mesh trips were combined during the periods 1989 – 1992 Since 1993, shrimp fisheries discards were treated differently than other small mesh fisheries because of different regulations. Large mesh trawl trips were estimated separately (SAW 28).

Estimated discards of CC/GOM yellowtail flounder averaged 22 percent of total catch by weight from 1963 to 1997 (SAW 28). Recent (through 2001) discard estimates are about 20 percent of the catch, with otter trawl gear accounting for about 40 percent of discards, 30 percent from the exempted whiting fishery, and 30 percent from the scallop fishery. Discards declined from 1997 through 2000 with the implementation of the whiting raised footrope trawl, increase in scallop dredge twine top requirements, and changes in trawl mesh requirements. Otter trawl discards increased dramatically to 415 mt in 2001 (from 74 mt in 2000), but the reasons for the increase are not clear.

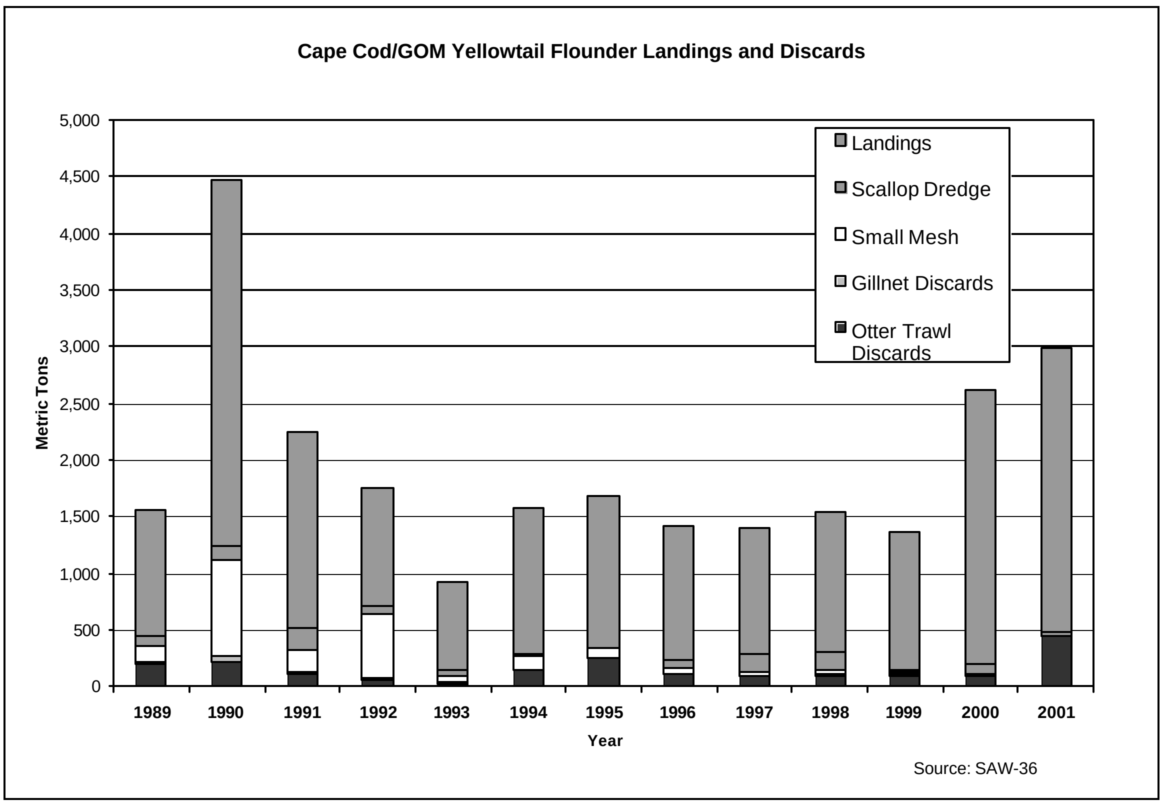

Figure 290 – CC/GOM yellowtail flounder landings and discards by gear, metric tons. (SAW 36)

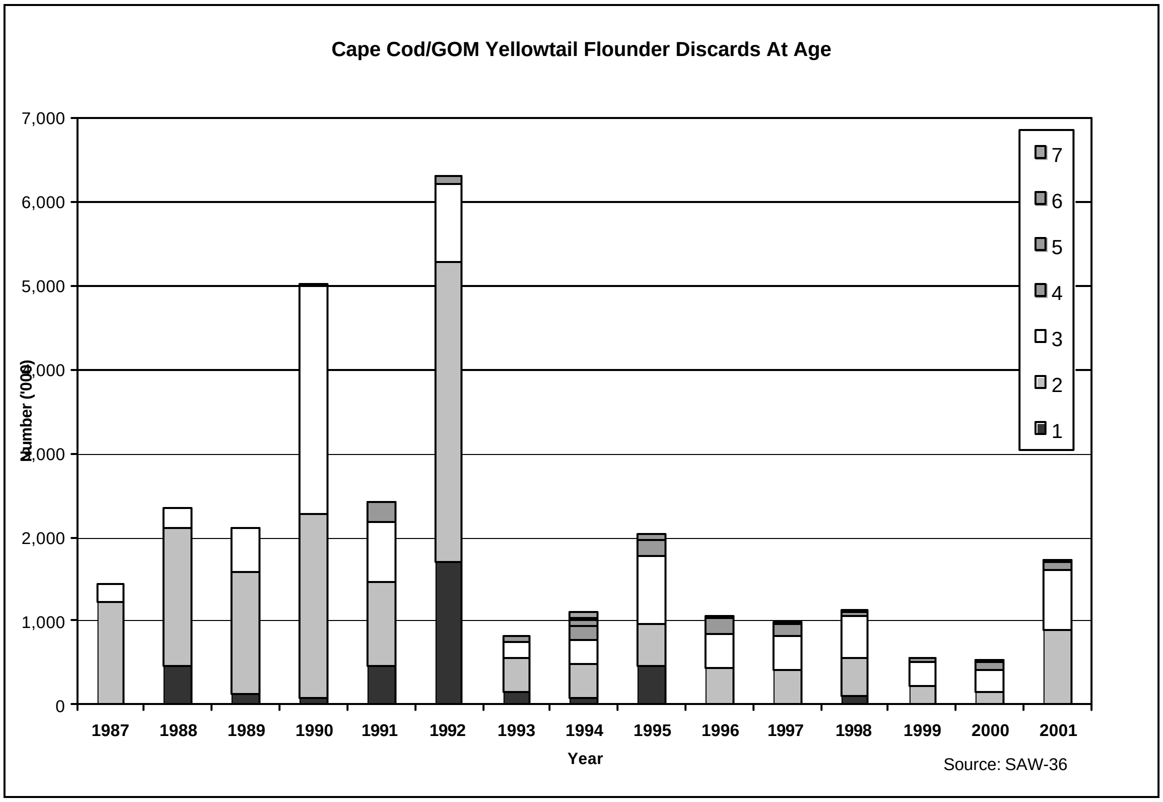

Figure 291 - CC/GOM yellowtail flounder discards at age, numbers ('000) of fish. (SAW 36)

9.4.2.8.3.8 Southern New England/Mid-Atlantic Yellowtail Flounder

Southern New England and Mid-Atlantic yellowtail flounder were assessed as two separate stocks until SAW – 36 (2002). Information on discards is available from a variety of sources, with varying degrees of reliability. SAW 27 estimated SNE yellowtail founder otter trawl discards for the period 1994 – 1997 by using discard ratios from VTRs and pooled length composition from sea sampling. Scallops discards were also estimated using VTRs for the same period (SAW 27).

A major discard event occurred between 1989 – 1991 as a result of a very large incoming year class, lack of appropriate minimum mesh size regulations, and a failure of the management system to react to these circumstances. Discards in 1990 were over 9,000 metric tons. Discard at age estimates for this period clearly show the dominant year class moving through the fishery and being wasted. Both discards and landings declined to low levels in 1993, making it difficult to determine if mesh increases in the trawl fishery, and twine top regulations in the scallop fishery, have reduced discards from this stock.

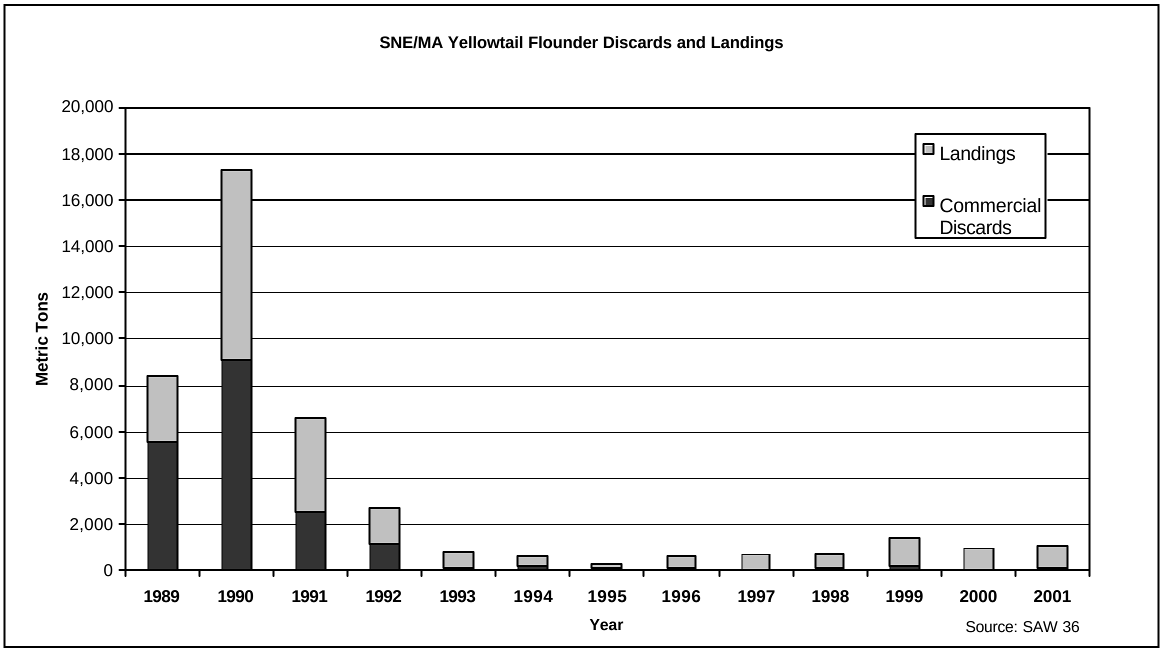

Figure 292 - SNE/MA yellowtail flounder discards and landings, metric tons. (SAW 36)

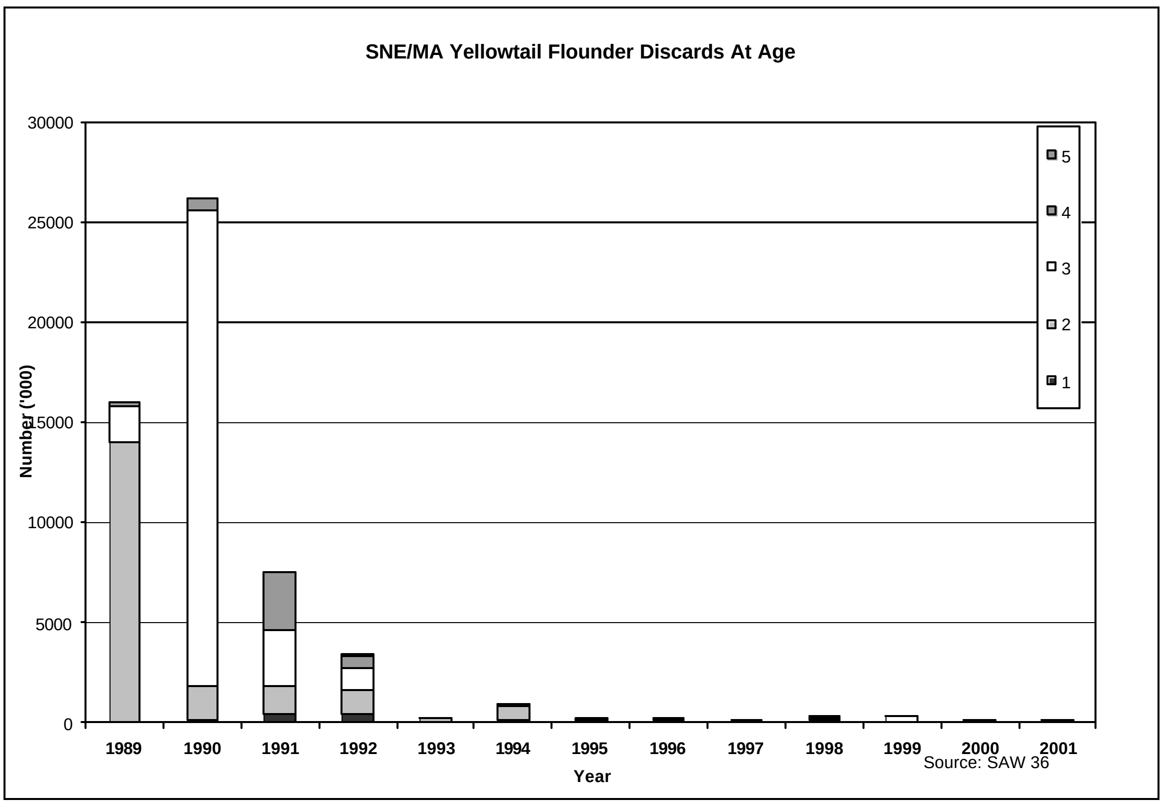

Figure 293 - SNE/MA yellowtail flounder discards at age, numbers ('000) of fish. (SAW 36)

9.4.2.8.3.9 Gulf of Maine Winter Flounder

Discard estimates were developed for both commercial (by gear) and recreational fishing in SAW 36. Commercial discard estimates are based on VTRs, while recreational estimates are based on MRFSS data. Both commercial and recreational discards are adjusted to account for survival of a portion of discarded fish. (SAW – 36)

Commercial discards have been at very low levels since 1993, and have shown little increase (weight) in recent years even as landings have increased. There was a slight increase in the numbers of fish discards in 2001. Discarded fish are primarily age 2 or 3 since 1997. Recreational discards are also at very low levels (numbers), but reflect a broader age disstribution as fish ages 1 through 4 are evenly represented in the recreational discards.

9.4.2.8.4 Other Species

Several other species are discarded by gear capable of catching groundfish.

9.4.2.8.4.1 Skates

Estimates of skate discards were calculated in SAW 30 using discard rates calculated from the Domestic Sea Sampling program applied to landings of target species. While there are seven species in the skate complex, discards were estimated for the entire complex due to the difficulty in skate identification. Discards were also calculated by gear and target species, a level of detail not usually found in other assessments. Skate discards from all fisheries are estimated to be two to eight times the reported total skate landings. The commercial fishery discard mortality, and therefore the total magnitude of skate discard mortality, are unknown.

Figure 298 illustrates skate discards by gear typically used to catch groundfish. The vast majority of discards occur in the otter trawl fisheries. The following tables provide discard estimates by gear and target species. These tables include the number of observed trips used to calculate discard rates. In some instances discard estimates for otter trawls are based on one or two trips. Based on these tables, skate discards from otter trawls using targeting groundfish appear to have declined since 1993.

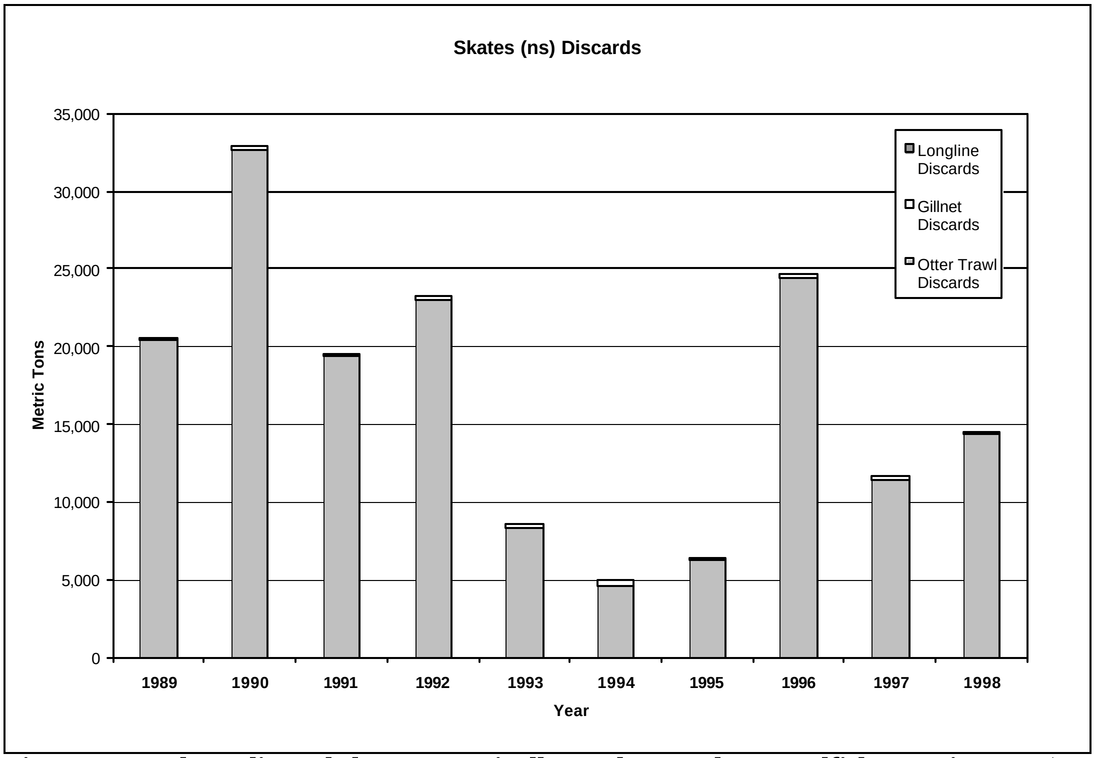

Figure 298 - Skate discards by gear typically used to catch groundfish, metric tons. (SAW 30)

Table 519 Estimated Discards of Skates on Sink Gillnet Vessels by Year and Primary Species Category

*(**Principal groundfish**: cod, haddock, pollock, and white hake; **pelagics**: herring, mackerel, butterfish, and squid; **flatfish**: summer flounder, winter flounder, American plaice, witch flounder, yellowtail flounder, windowpane flounder and unclassified flounders; **small elasmobranchs**: dogfish and skates; **small-mesh groundfish**: silver hake, red hake, and ocean pout)*

Discards are calculated as the sum of pounds of discarded skates divided by he sum of the pounds of the target species kept in each cell. Cells with zero trips are filled in with the weighted average over all years.

9.4.2.8.4.2 Monkfish

The monkfish fishery is closely linked to the groundfish fishery throughout much of its range. In the monkfish Northern Management Area, vessels fishing for monkfish usually do so while on a groundfish DAS, and they are permitted to use groundfish gear. Monkfish discard estimates by gear were calculated in SAW 34 using discard ratios from sea sampling trips applied to landings. The estimates are not based on target species. The following chart shows monkfish discards for otter trawl and gillnet gear without respect to target species (SAW 34).

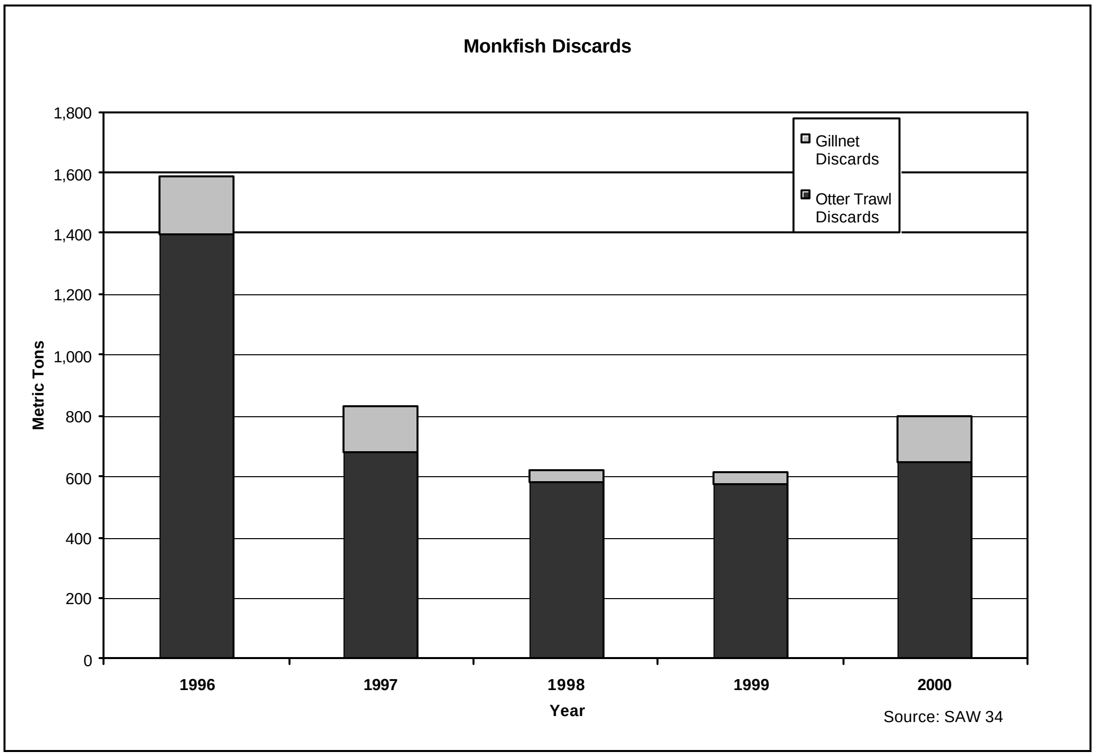

Figure 299 - Monkfish discards, otter trawl and gillnets, metric tons. (SAW 34)

9.4.2.8.4.3 Spiny Dogfish

Spiny dogfish has, in the past, been an important component of the incidental catch by trawl, gillnet, and longline vessels. Seasonal migration of dogfish influences target species for some gear, as vessel operators fish in different areas or different depths to avoid large concentrations of dogfish. Estimates of discards for otter trawl and gillnet gear (without regard for fishery) were included in the Spiny Dogfish FMP (MAFMC 1999). These estimates are shown below (Figure 300). The FMP also included estimates for gear based on target species, and shown in Table 520. These estimates are based on sea sampling data, with few sampling trips targeting some species.

Spiny dogfish discards in gillnet and trawl gear fluctuated from 4,000 to 6,200 mt from 1989 through 1997. Estimates based on target species show that most dogfish discards come from trips targetting cod, white hake, pollock, and winter flounder. There appears to be a slight decline in discards restulting from trips targeting groundfish from 1989 through 1997, perhaps due in part to reductions in fishing effort as a result of Amendment 5. It may also be due to development of a market for dogifsh. Recent management actions make it difficult to predict the trend of discards past 1997 (information that will be available in the summer of 2003). While additional reductions in fishing effort and more seasonal and year round closed areas may have reduced dogfish bycatch, the imposition of strict quotas in the Spiny Dogfish FMP may have converted landings into discards.

A new assessment with updated discard estimates was completed in July, 2003. According to SAW 37, total spiny dogfish discards (all fisheries) were as high as 47,000 mt in 1990 and 1991, considerably higher than the estimates included in the dogfish FMP. Discards declined from 14,100 mt in 1996 to 5,000 mt in 2002, values that are much closer to those reported in the dogfish FMP. These significant reductions in discards are most likely due to effort restrictions in other fisheries, including the multispecies fishery. SAW 37 included estimates of disacrds based on gear and primary species group targeted on a trip. These estimates show considerable variability in the early years of the time series, in part due to limited observer coverage, but the estimates become more stable after 1992. Dogfish discards from trips targeting principal groundfish or flatfish exceeded 30,000 mt in 1989 but have since declined to under 5,000 mt (Figure 301).

9.4.2.8.5 Measures to reduce bycatch

The SFA amendments to the M-S Act that focused additional attention to bycatch were adopted in 1996, the same year that Amendment 7 was implemented. Since 1996, a number of management measures have been implemented that affected discards and discard mortality in the groundfish fishery. Some were adopted in Amendment 7, while others have been implemented or changed through framework adjustments to the Amendment, or through court order. The impact of these changes can be seen in some of the data shown above, which suggest a shift in the amount and composition of discards beginning in 1996 for many species. In addition, the development of management plans for whiting and monkfish have likely affected discards of groundfish in those fisheries. The impacts of some of these measures cannot be determined because assessments have not been completed since their implementation.

Table 521 provides a brief overview of recent grouindfish management measures that impact discards and discard mortality. This table does not reflect management actions in other fisheries that may have increased or reduced discards.

Date	Action	Measure	Probable Impact
1996	Amendment 7	(1) GOM/GB/SNE minimum mesh size (2) Effort reduction (3) Minimum fish sizes (4) Certified bycatch fisheries program (exempted fisheries program) (5) Limit on groundfish landings by scallop vessels (6) Year round closed areas (7) Increased haddock possession limit to 1,000 pounds	(1) Reduce discards of undersized fish (2) Overall reduction in effort reduces discards of non-target species (3) Minimum fish sizes encourage compliance with mesh regulations, reduce incentive to catch small mesh (4) Established standard for small mesh fisheries, encouraging development of techniques to reduce bycatch. (5) Discouraged targeting of groundfish by scallop dredges, may have increased discards of some flounders. (6) Closed areas may have reduced discards by reducing fishing on spawning aggregations. (7) Increase in haddock possession limit reduced haddock discards as stock began to increase.
May 1, 1997	Framework 20	(1) GOM cod trip limit, included "running clock" (2) Gillnet restrictions including limits on number of nets, additional required days out of the fishery	(1) Running clock mitigated impact of GOM cod trip limit on discards by allowing landings of overages. (2) Additional gillnet restrictions may have reduced discards by limiting effort, but amount of impact uncertain
May 1, 1998	Framework 25	(1) Seasonal closures in GOM and established WGOM closed area (2) Increase to haddock trip limit, including seasonal adjustment (3) Raised footrope trawl required in small mesh areas 1 and 2	(1) By reducing fishing effort during times fish were aggregated, likely reduced discards (2) Haddock trip limit adjustment reduced discards as stock increased (3) Raised footrope trawl reduced discards in whiting fishery in a small area in the GOM
January 19, 1999	Framework 26	(1) Additional closures in inshore GOM during cod spawning	(1) Extended protection to fish (primarily cod) aggregated during spawning
May 1, 1999	Framework 27	(1) Expanded seasonal closed areas in GOM (2) Reduced GOM cod trip limit, including trigger which allowed further reductions in-season (3) Increased haddock trip limit (4) Increased minimum mesh size for square mesh in GOM/GB/SNE RMAs	(1) Extended protection to fish (primarily cod) aggregated during spawning (2) Reduction in trip limit increased cod discards (3) Haddock trip limit increase reduced discards as stock increased (4) Increase in square mesh size reduced discards

Table 521 – Recent management actions affecting discards in the multispecies fishery

Date	Action	Measure	Probable Impact
June 10, 1999	Framework 29	(1) Scallop access program to CA II, including bycatch limits, gear requirements	(1) Several measures reduced discards of yellowtail flounder in CAII access program
June 10, 1999	Scallop Framework 11	(1) Adopted requirement for 8 inch twine top on scallop dredges in all areas	(1) Large mesh twine top demonstrated reductions in groundfish bycatch in scallop dredges
July 29, 1999	Framework 30	(1) Established GB cod trip limit	(1) May have increased regulatory discards by imposition of trip limit, unless vessels able to avoid cod catches
January 5, 2000	Framework 31	(1) Increased GOM cod trip limit to 400 lbs/4000 lbs (2) Extended modified running clock (3) Additional GOM inshore closures	(1) Reduced discards as a result of low FW 27 cod trip limit (2) Change to running clock may have increased discards (3) Extended protection to fish (primarily cod) aggregated during spawning
	Amendment 12	(1) Established regulations for small mesh multispecies	(1) Measures designed to reduce mortality on small-mesh multispecies likely reduced discards of groundfish in this fishery
June 1, 2000	Framework 33	(1) Additional seasonal closures in GOM, including triggered closures (2) Seasonal May closure on GB	(1) Extended protection to fish (primarily cod) aggregated (2) Extended protection to fish (primarily cod) aggregated while spawning
June 15, 2000	Framework 34	(1) Access to groundfish closed areas for scallop dredge vessels, with gear restrictions and bycatch limits	(1) Restrictions reduced yellowtail flounder bycatch in access program
September 1, 2000	Framework 35	(1) Seasonal whiting raised footrope trawl fishery in Upper Cape Cod Bay	(1) Provided opportunity for whiting fishery while virtually eliminating groundfish bycatch
August 1, 2002	FW 33 Court Order	(1) Additional gear restrictions, including increased mesh sizes in all areas and limits on number of gillnets (2) Reduced available effort (3) Additional year round closed area in GOM (4) Yellowtail flounder trip/possession limits in SNE/MA area (5) Mandatory level of observer coverage	(1) Gear restrictions should minimize groundfish discards (2) Fishing effort declines should reduce absolute number of discards (3) Additional year round closed area may reduce discards (4) Trip/possession limits may result in increased discards unless fishermen avoid catch (5) Increased observer coverage should improve discard estimates

Table 521 **(cont.) – Recent management actions affecting discards in the multispecies fishery**

9.4.3 Recreational Harvesting Sector

Overview of Recreational Fishing in the Northeast

Recreational fishing in the Northeast region is monitored through two ongoing data collection systems: the Marine Recreational Fisheries Statistics Survey (MRFSS) and a mandatory logbook program for Federally permitted party/charter vessels. The MRFSS consists of a creel survey that identifies numbers, weight and type of species caught by fishing mode (shore, private or rental boat, and party/charter) paired with a random telephone survey of households to estimate recreational fishing participation and effort. MRFSS randomly samples the fishing activities of individual anglers in the Northeast. The mandatory logbook program, however, records activities of party/charter vessels that carry passengers for hire and that fish in the EEZ for Federally managed species. Species currently covered by mandatory reporting for party/charter vessels are summer flounder, black sea bass, scup, species managed under the multispecies FMP, bluefish, and species managed under the Squid/Mackerel/Butterfish FMP.

In addition to these two ongoing recreational fishery data collection programs, there have been several recent surveys conducted in the Northeast Region that examine recreational fishing in greater depth. In 1994 a comprehensive survey of Northeast recreational anglers was conducted to ascertain angler demographics, participation (Thunberg et. al. 1999), motivations for fishing, preferences for management alternatives (Steinback et. al. 1999), and recreational fishing values (Hicks et. al. 1999). This survey was conducted as a supplement to the MRFSS survey in two regions, as defined for the purpose of the survey: North (Maine to Connecticut) and Mid-Atlantic (New York to Virginia). Although North Carolina is considered part of the Northeast region for management purposes, the MRFSS places North Carolina in the South Atlantic region, so it was not surveyed for these studies.

In examining the demographics of recreational anglers, it was revealed that the majority of recreational fishing participants in the Northeast Region (Maine to Virginia) were white male high school graduates aged 35 to 46 (Thunberg et. al. 1999). Compared to the general population, proportionally more participants held a college or post-graduate degree and had higher household income than non-participants. This was consistent across states as well as the region as a whole. The study projected that the rate of marine recreational fishing participation (the proportion of anglers to total population) will decline while the total number of marine recreational fishing participants increases (Thunberg et. al. 1999). This study will be replicated during calendar year 2002 to identify sources of demographic change among recreational anglers and to update participation forecasts based on 2000 Census data.

In the Northeast Region approximately 50% of anglers reported owning at least one boat that was used for recreational fishing. At least 60% of anglers indicated that fishing was more important than alternative recreational outdoor activities (Steinback et. al. 1999). Most anglers described their motivations for recreational fishing as non-catch (or at least non-keep) related. Approximately 88% of anglers reported that they fish recreationally to enjoy nature and the outdoors. Others fish to relax and escape the daily routine (approximately 84%) and to spend time with friends and family (about 84%). Recreational anglers in the Northeast Region showed greatest support for management measures that establish minimum fish sizes (93%) bag limits (90%), fishing seasons (78%), and limits on areas fished (67%).

In addition to general demographic and attitudinal information, summary data were also collected on recreational fishing expenditures (Steinback et. al. 1999). As a follow-up to the 1994 study, a more detailed survey of recreational fishing expenditures was conducted in 1998 (Steinback and Gentner 2001). In this latter survey, detailed data were collected on trip related expenses (i.e. items that are consumed on a given fishing trip–bait, food, ice, lodging, etc.), purchases that are expected to be used over several fishing trips or seasons (rods, reels, tackle etc.), and items that may be used over many fishing seasons (boats, electronics, vehicles, etc.). Based on these data, a total of $4.2 billion was spent on fishing activities and equipment in 1998 throughout the Northeast Region. Expenditures by coastal state residents were found to be significantly higher than non-coastal resident spending and that recreational participants in Massachusetts, Maryland, and New Jersey had the greatest recreational fishing expenditures.

Expenditures by recreational anglers represent a direct impact on state economies but additional economic impacts are generated including indirect and induced effects. Direct impacts are associated with fishing related retail purchases of goods and services by anglers. Indirect impacts occur as retailers purchase fishing supplies from wholesalers; wholesalers purchase commodities from manufacturers and so on until these "ripple" effects become negligible. Induced effects are associated with changes in household purchasing as the direct and indirectly affected industries pay their employees. The total impact is the sum of direct, indirect, and induced impacts.

The impact of recreational fishing expenditures on total sales, income, and employment was estimated for the Northeast region from the 1998 expenditure survey data (Steinback, Gentner, and Castle; forthcoming). Using IMPLAN Pro (an input-output modeling system) the authors found that the total local economic impact of recreational fishing was less than total local expenditures. This finding is due to the fact that a large portion of the value of retail sales was imported from outside the local area. For example, a fishing rod may be purchased at a retail store in Delaware but if the retailer purchased it from a distributor located in New Jersey then the amount of economic impact that stays in Delaware is a fraction of the retail value. The local area sales impact ranged from a low of $0.44 per $1 in fishing expenditures in Rhode Island to a high of $0.64 in New Jersey.

The studies described above were based on broad-scale data collection for the North and Mid-Atlantic regions. Additional studies have focused on recreational fishing activities for specific states. Salz et. al. (in press) conducted a survey of anglers in Massachusetts. Massachusetts anglers indicated a variety of motivations for fishing, many of which were non-catch related including relaxing and being outdoors. Party/charter anglers tended to place greater emphasis on the social aspects of fishing than private boat or shore anglers. At least 50% of individual anglers agreed that a trip could be considered "successful" even if no fish were caught. Party/charter anglers tended to place greater emphasis on catch in defining a trip's success.

Salz et. al. also investigated constraints to increased fishing activity and reasons for switching from party/charter fishing to alternative fishing modes. The major reason why people would not fish was time constraints imposed by a job or alternative recreational activities. Lack of fish or low catch rates were not often cited as reasons for fishing less frequently. Similarly, fewer than 10% of interviewed anglers stated that their fishing frequency was related to restrictive regulations.

The party and charter boat industries in Maine, New Jersey, and New York were the subject of three separate studies respectively by McCay and O'Neil (1998), McCay, O'Neil, and Velchek (1999), and McCay et. al. (1999). Each of these studies describes various social and economic characteristics of the party/charter industry and its operators. The key findings for each of these studies are summarized below.

The majority of Maine party/charter operators surveyed in 1996 were predominantly engaged in charter trips only, owned only one boat used for fishing, and indicated that operating a party/charter business was among their most favored occupations. Due to the relatively short fishing season in Maine a large percentage (89%) of surveyed operators supplemented their income with a source other than fishing. A majority of captains were between 31 and 50 years of age and had been in the party/charter business for 10 or fewer years. In 1996, survey participants in Maine averaged 27 half-day fishing trips (approximately 4 hours each) and 44 full-day trips (approximately 8 hours each). On average, five passengers were taken per trip, approximately 75% of the passengers being out-of-state residents. Among those surveyed, the primary target species was striped bass (a likely reflection of the dominance of charter captains in the sample) followed by cod, shark, tuna, and bluefish. Among those sampled, vessels that were engaged in a combination of party and charter fishing were barely breaking even on each trip while captains that specialized in charter trips only were earning a modest profit of $26 per trip. Note that these estimates were based on averages across all expense categories including fixed and operating costs so there is likely to be wide variation in profits and losses among different vessels.

In New Jersey the party/charter industry surveyed during calendar year 1997 was, as in Maine, dominated by boats that specialize in charter trips (73%). These charter vessels averaged 9 half-day and 51 full-day fishing trips in 1997. Charter boats took an average of 7 passengers per trip, more than half of these New Jersey residents. Boats that specialize in party trips only took an average of 169 half-day and 175 full-day trips in 1997. On average, these boats carried 27 passengers on half-day trips and 20 passengers on full-day trips, nearly three quarters of which were New Jersey residents. Vessels that conducted a combination of party and charter trips averaged 92 half-day trips, with 24 passengers per trip, and 108 full day trips, with 21 passengers per trip in 1997. Species targeted by New Jersey party/charter captains included fluke, bluefish, striped bass, tuna, weakfish, winter flounder, and shark. New Jersey captains indicated that these choices reflected a combination of species availability and degree of regulatory restrictions but may not necessarily reflect what they or their clients would prefer to target. As was the case in Maine, most New Jersey captains considered themselves to be part-time operators while supplementing their income with other jobs particularly during the winter season. Although the largest proportion of New Jersey operators had been in business less than 10 years, the majority of operators across the sampled region had been in continuous operations for 11 or more years, with 28% in business for more than 20 years.

The New York party/charter fleet was surveyed in 1997. The composition of the fleet was similar to that of New Jersey and Maine with the majority (69%) of captains specializing in charter trips only. Across all combinations of activity the majority (over 83%) of passengers on New York party/charter vessels were New York state residents. Boats specializing in charter trips made an average of 33 half-day and 63 full-day trips and carried approximately 7 passengers per trip. Boats specializing in party trips made an average of 190 half-day and 179 full-day trips in 1979 and carried between 22 and 26 passengers per trip. Captains that offered a mix of party and charter trips took an average of 113 half-day and 156 full-day trips and carried 22 to 24 passengers per trip. The composition of targeted species was similar to that of New Jersey boats and included fluke, striped bass, shark, tuna, winter flounder, bluefish, and cod. New York captains also had alternative income sources and noted high levels of job satisfaction in their current occupation. However, like their New Jersey and Maine counterparts, New York operators expressed concern about disagreements regarding stock status for popular recreational species, the balance of recreational and commercial interests in the fishery, and difficulty in maintaining a position on the waterfront as urbanization and competing non-water dependent activities drive up the price of docking space.

9.4.3.1 Long Term Trends in Northeast Recreational Fishing

Total combined catch (kept catch plus all discards) of all species during calendar year 2000 was the highest on record since 1986 in both the MRFSS North Atlantic (38.2 million) and Mid-Atlantic (129.1 million) regions (Table 522). Prior to calendar year 2000, total catch had been fluctuating within relatively narrow range of between 21 and 25 million fish from 1993 to 1999. In contrast, catch in the

Mid-Atlantic region has not only been significantly greater than the North Atlantic but the variability in catch has also been much greater.

		Total Fish Caught (millions)	Trips (millions)		Participants (millions)	
	North Atlantic	Mid-Atlantic	North Atlantic	Mid-Atlantic	North Atlantic	Mid-Atlantic
1981	37.0	100.8	5.8	14.0	1.0	2.3
1982	46.7	81.1	7.0	15.5	0.8	2.0

1997	24.4	103.2	7.6	17.2	1.1	1.9
1998	23.5	54.6	6.8	14.5	1.0	1.8
1999	23.4	85.9	6.5	14.1	0.8	1.7
2000	38.2	129.1	8.4	18.8	1.1	2.0
2001	33.3	114.8	9.0	21.2	1.1	2.5

Table 522 - Total catch, trips and participants in MRFSS North and Mid-Atlantic Regions (1981-2001).

Source Data: MRFSS database. Years denote calendar years. Catch and landings are expressed in numbers of fish.

The greatest total number of recreational fishing trips from 1981 to 2001 in the North Atlantic occurred in 2001 at 9.0 million. In that year, the greatest number of recreational fishing trips also occurred in the Mid-Atlantic at 18.2 million (Table 522). Since 1981, total trips in the North Atlantic states have ranged from between 5.2 and 9.0 million but the number had been relatively stable from 1993 to 1999 (between 6.2 and 7.6 million trips). The number of trips taken in the Mid-Atlantic region was also fairly stable, ranging from 14.1 million to 17.2 million over the same time period. It is not known why both catch and numbers of trips were so high in both 2000 and 2001 compared to previous years especially since the number of participants in both regions did not exceed the historically observed range.

In the North Atlantic states catch per trip fluctuated from 1981 to 1986, with a downward trend until 1992 before becoming relatively constant through 1997 (Figure 302). Catch per trip in the North Atlantic region increased three consecutive calendar years from 1998 to 2000 but dropped in 2001. The average number of trips taken per angler or participant was quite variable from 1982 to 1989, followed by a general upward trend to 1994. Since 1994, the average number of trips taken per recreational anglers has been between 7 and 8 per year but did rise to just over 8 trips in 2001. Prior to 1990, the recreational fishing partic ipation rate (number of participants/total coastal state population) was above 8% in every year except 1982, 1987, and 1988. Since 1990, the participation rate has been above 8% in only four of the eleven years (1991, 1997, 2000 and 2001).

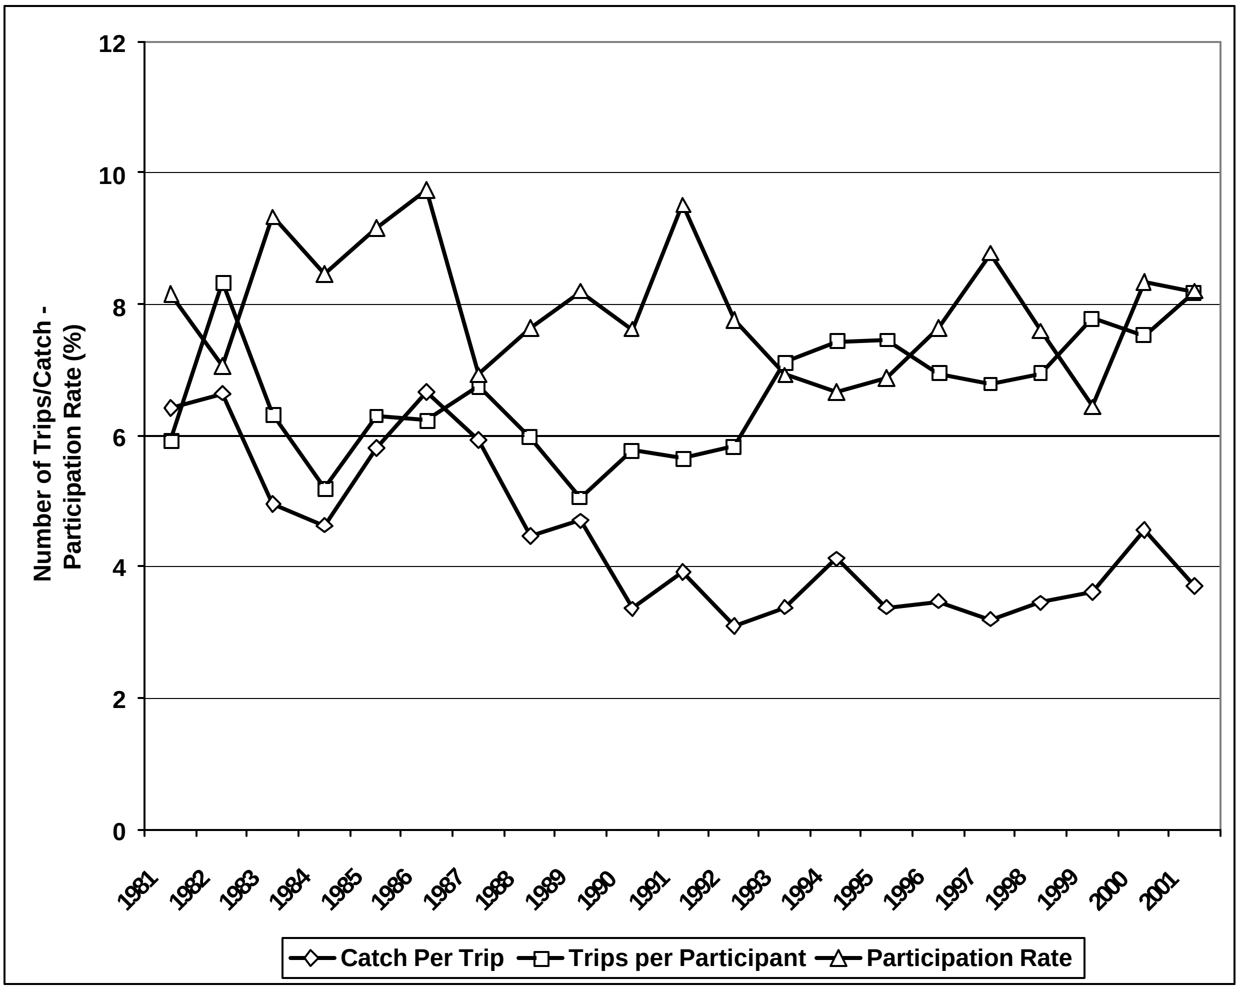

Figure 302 - Annual catch per trip, trips per angler, and participation rates for the North Atlantic States, 1981-2001

Source Data: MRFSS database. Years denote calendar years.

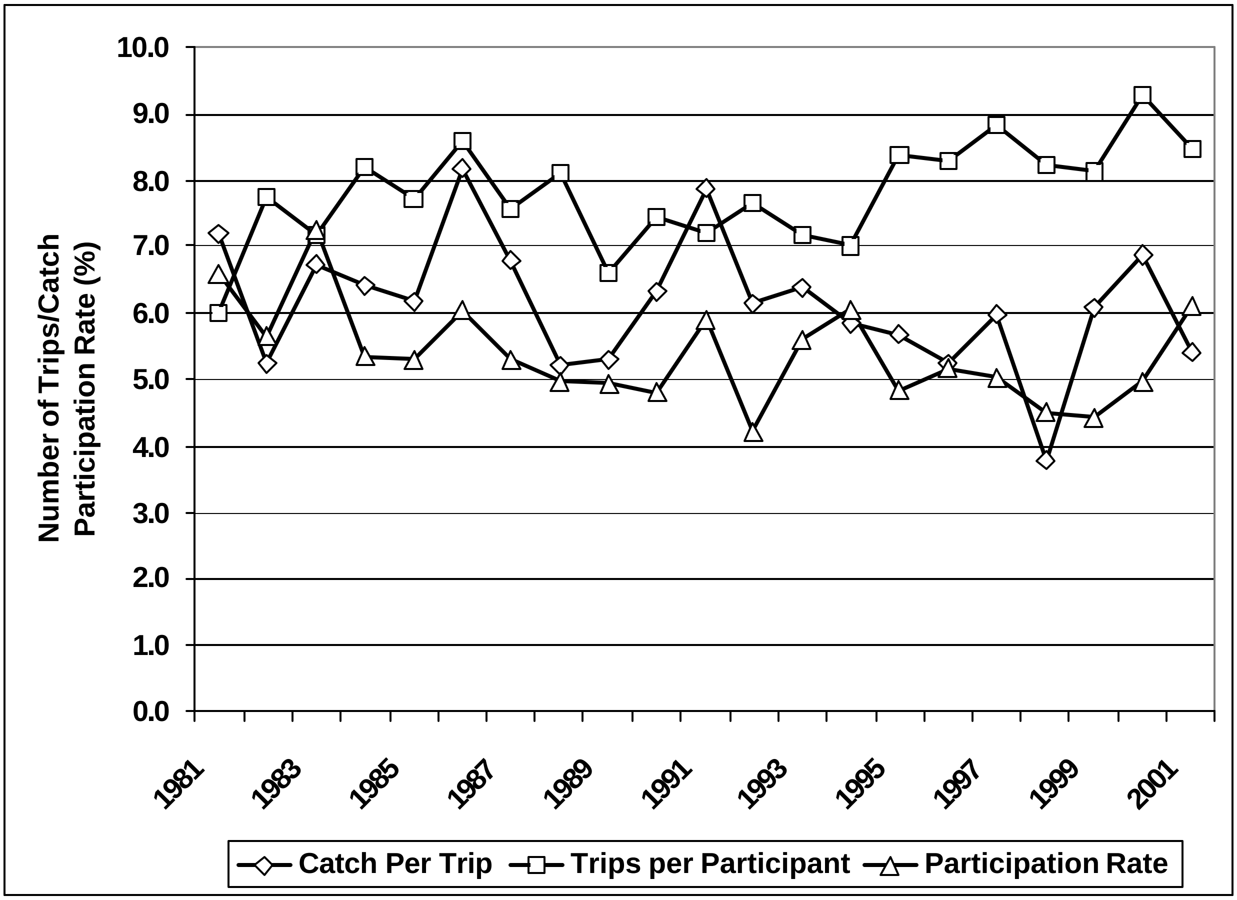

Figure 303 - Annual catch per trip, trips per angler, and participation rates for the Mid- Atlantic States, 1981-2001 ***Source Data: MRFSS database. Years denote calendar years.***

In the Mid-Atlantic states catch per trip fluctuated from 1981 to 1988, but was on a consistent downward trend from almost 8 fish per trip in 1991 with a downward trend before ending at 5.2 fish in 1996 (Figure 303). Since 1996 average catch has fluctuated with any distinct trend between a low of less than 4 fish in 1998 to a high of 7 fish in 2000. Even as average catches were declining in the early to mid-1990's the average number of trips per angler was increasing and has remained at between 8 and 9 trips per year since 1995. The Mi-Atlantic participation rate had been on a general downward trend from 1981 to 1999 falling from almost 7 percent to less than 5 percent. However, the participation rate in both 2000 and 2001 increased and was over 6 percent in 2001.

9.4.3.1.1 Trends in Recreational Catch and Trips by Group, 1990–2001

Total trips, catch, and mortality (kept catch plus discarded dead) were higher in calendar year 2000 for shore and private boat anglers than any other year since 1990 and were higher still in 2001 (Table 523). In contrast, trips, catch and mortality for party/charter vessels were higher in 2001 than in the previous three years, but were still within levels observed over the past decade. The average total number of trips from 1990 to 1995 was 2.1 million greater than the average from 1995 to 2001 for shore anglers, 0.5 million fewer for party/charter boats, and 2.2 million greater for the private boats. Total catch shows a similar pattern although average total mortality across all groups was lower from 1995 to 2001 than from 1990 to 1995. This reduction in mortality or mortality as a percent of catch appears to be consistent throughout the time period (Figure 304) and may be due to a change in management regulations that reduced the number of fish that anglers may keep. Another contributing factor may be increasing emphasis on catch-and-release fishing. Catches may continue to increase, as observed, while reducing the overall mortality. Note that this relationship may be enhanced as discard survival can be increased either by changes in catch-and-release technique or the use of less injurious fishing tackle or methods (barbless hooks and circle hooks, for example).

	Total Trips (millions)			Total Catch (millions)			Total Mortality (millions)		
Year	Shore	Party/ Charter	Private/ Rental Boat	Shore	Party/ Charter	Private/ Rental Boat	Shore	Party/ Charter	Private/ Rental Boat

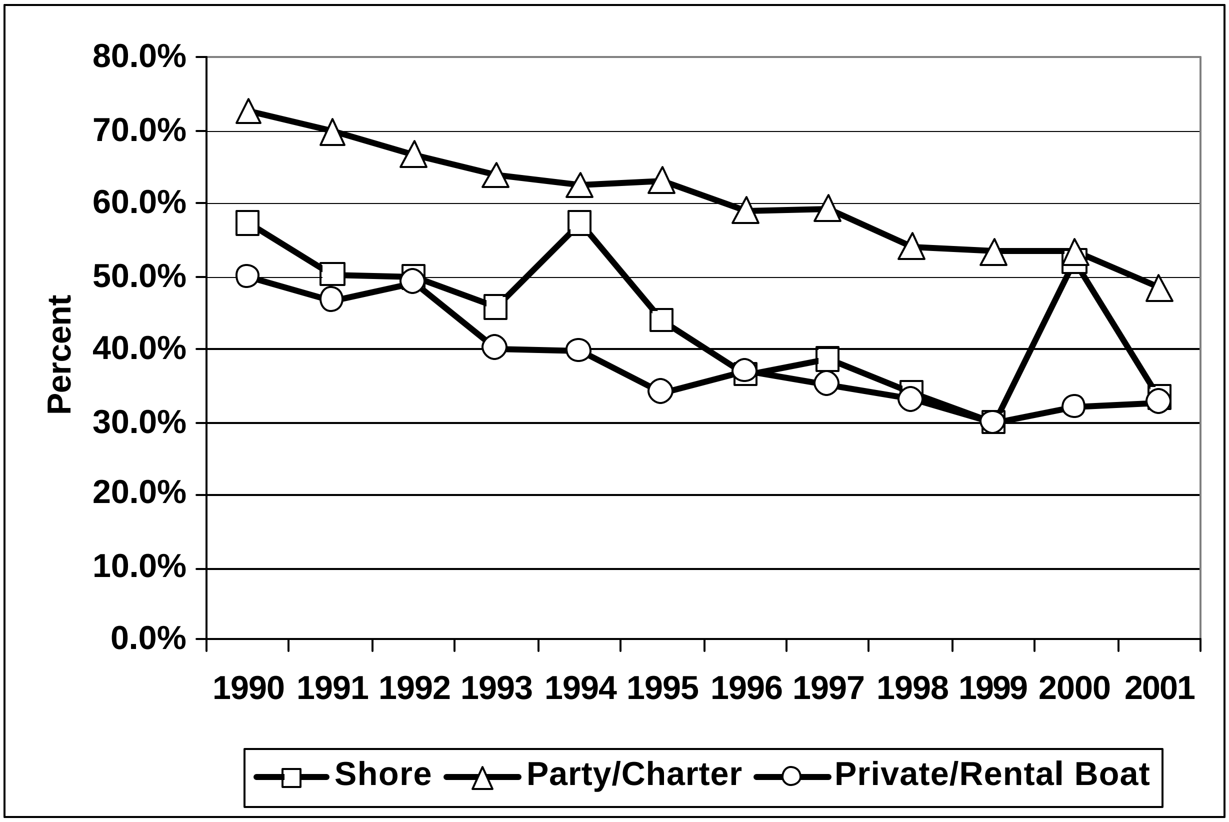

Figure 304 - Mortality as a percent of total catch by recreational fishing mode
Source Data: MRFSS database. Years denote calendar years.

The proportion of trips taken by fishing mode indicates that some switching between modes may be occurring with a general shift away from party/charter fishing toward the expanded use of private boats (Figure 305). This shift was noted by Salz et. al. (in press) in Massachusetts and may be a region-wide occurrence which appears to be more evident since 1995. Reflective of this apparent shift in fishing mode, the proportion of total recreational mortality attributed to party/charter anglers has declined while that attributed to private boats has increased since 1995 (Figure 306).

9.4.3.2 The Role of Groundfish in Northeast Region Recreational Fisheries

Since 1990, the combined recreational catch of regulated multispecies (i.e. all species regulated under the Multispecies FMP except silver hake, red hake, ocean pout, and Atlantic halibut) ranged from a high of 8.0 million in 1991 to a low of 2.8 million fish in 1999. Regulated multispecies contributed to less than 6.5% of the total recreational catch and 8% of total mortality from 1990 to 2001 (Table 524). As the total catch of all species and groundfish catch has declined so has the relative importance of regulated groundfish as a percentage of the Northeast recreational fishery. Specifically, the percentage of groundfish in total catch averaged 4.4% from 1990 to 1995 but fell to 3.0% from 1995 to 2001. This decrease in percentage of total catch was accompanied by a decline in groundfish as a percentage of total mortality. These effects may be due to a combination of factors affecting species targeting choices, including shifts in stock status (improvements in resource conditions for popular recreational species like striped bass and summer flounder with relatively poorer stock conditions for groundfish) as well as regulatory changes affecting groundfish including size and bag limits with the implementation of Amendment 7.

Year	Total Catch	Total Mortality	Total Groundfish Catch	Total Groundfish Mortality	Groundfish Percent of Total Catch	Groundfish Percent of Total Mortality
1990	121.1	65.7	7.8	5.2	6.4%	7.9%
1991	167.8	84.1	8.0	5.1	4.8%	6.1%
1992	109.1	55.8	2.7	1.6	2.4%	2.8%
1993	135.4	61.2	6.9	3.9	5.1%	6.4%
1994	147.6	69.6	5.2	2.7	3.6%	3.8%
1995	130.1	53.6	5.4	2.9	4.1%	5.3%
1996	120.5	47.3	4.5	2.5	3.7%	5.3%
1997	146.2	57.4	3.6	1.9	2.5%	3.4%
1998	125.8	43.5	2.9	1.4	2.3%	3.1%
1999	125.9	40.0	2.8	1.3	2.2%	3.4%
2000	189.5	73.6	5.7	2.8	3.0%	3.8%
2001	171.9	58.6	5.5	2.6	3.2%	4.4%
'90-'95 Avg.	135.2	65.0	6.0	3.5	4.4%	5.4%
'95-'01 Avg.	144.3	53.4	4.3	2.2	3.0%	4.1%

Table 524 - Total recreational catch and mortality of combined species and regulated groundfish in the Northeast Region.
Source Data: MRFSS database. Years denote calendar years. Catch and landings are expressed in millions of fish.

Although the proportion of groundfish catch has declined on a region-wide basis, there are important differences in the relative importance of groundfish across sub-regions and modes. As a percent of the total groundfish catch, a small majority of fish is caught by anglers in New England states (Table 525). This majority has increased slightly in terms of both catch and mortality averaging 63.2% and 58.1% respectively from 1995-2001 as compared to 53.6% and 54.0% from 1990-1995. Note that groundfish catch by Mid-Atlantic anglers comes almost exclusively from New York and New Jersey anglers.

Though New England catches represent a small majority of recreationally caught groundfish, the proportion of groundfish in New England recreational catch is greater than that in Mid-Atlantic fisheries. From 1990 to 1995 the share of groundfish in the New England catch ranged between 23.4% and 7.6%, averaging 14.6% (Table 525). In contrast, the share of groundfish in Mid-Atlantic angler catches averaged only 3.1% over the same time period. Since 1995, the proportion of groundfish in both New England and Mid-Atlantic fisheries has declined, averaging 12.2% and 1.4% respectively. This decline is most pronounced beginning in 1996, which coincides with a period of relatively depressed stock conditions as well as implementation of more restrictive measures under Amendment 7 of the Multispecies FMP. However, the share of groundfish in New England recreational fisheries increased in three consecutive years (1999-2001) so the relative share of groundfish in New England recreational may once again approach levels experienced in the early 1990's. Note the share of groundfish in total mortality in both regions follows the same general pattern described for total catch.

Year	New England Share of Northeast Region Groundfish Catch	New England Share of Northeast Region Groundfish Mortality	New England Groundfish Catch as a % of Total Catch	New England Groundfish Mortality as a % of Total Mortality	Mid-Atlantic Groundfish Catch as a % of Total Catch	Mid-Atlantic Groundfish Mortality as a % of Total Mortality
1990	55.9%	61.2%	23.4%	24.6%	3.4%	3.8%
1991	43.9%	48.0%	13.2%	13.3%	3.2%	4.1%
1992	50.9%	53.8%	7.6%	7.7%	1.4%	1.6%
1993	49.5%	48.6%	16.3%	14.3%	3.1%	4.2%
1994	59.7%	57.6%	12.1%	9.0%	1.7%	2.2%
1995	61.4%	54.7%	15.0%	15.6%	1.9%	3.0%
1996	44.3%	41.4%	8.7%	11.0%	2.6%	3.9%
1997	54.4%	49.9%	8.1%	10.3%	1.4%	2.0%
1998	76.9%	80.3%	9.6%	16.0%	0.7%	0.7%
1999	67.7%	61.3%	8.2%	9.4%	0.9%	1.7%
2000	63.1%	50.0%	9.4%	8.1%	1.3%	2.4%
2001	74.5%	69.2%	12.3%	14.8%	1.0%	1.7%
'90-'95 Avg.	53.6%	54.0%	14.6%	14.1%	2.4%	3.1%
'95-'01 Avg.	63.2%	58.1%	10.2%	12.2%	1.4%	2.2%

Table 525 - Distribution of groundfish catch by sub-region. 1990-2001.
Source Data: MRFSS database. Years denote calendar years. Catch and landings are expressed in millions of fish.

There are only small differences in the relative importance of recreationally caught groundfish across all modes in the Mid-Atlantic sub-region (Table 526). Across all modes, the relative contribution of groundfish in Mid-Atlantic angler catches averaged between 2.0% and 3.5% from 1990 to 1995 and averaged 1.5% or less from 1995 to 2001. The relative contribution of groundfish to the total catch among shore-based anglers in New England was similar to that for Mid-Atlantic anglers. In contrast, a greater proportion of groundfish was present in private boat catches in New England. Groundfish represented at least one-third of New England party/charter catches in all but two years since 1990. Further, compared to the 1990-1995 time period, while the average proportion of groundfish to total catch declined in both regions for private and shore modes and in the Mid-Atlantic party/charter mode, the contribution of groundfish in the New England party/charter mode increased from 37.8% to 41.6%.

	New England by Mode			Mid-Atlantic by Mode		
Year	**Shore**	**Party/Charter**	**Private Boat**	**Shore**	**Party/Charter**	**Private Boat**

9.4.3.3 Party/Charter Fisheries

As described earlier, information about the party/charter sector is gathered by both the MRFSS and by a logbook program for vessels that take passengers for hire that retain species that are covered under a Federal FMP requiring mandatory reporting. There are important differences between the two reporting systems that must be considered in drawing inferences about the status of the party/charter fishery and its participants.

The MRFSS is broad-based and surveys individual anglers regarding all forms of party/charter activity regardless of fishing location or species caught. In contrast, logbook data represent a census of party/charter vessel activity but is limited only to those vessels holding Federal permits requiring mandatory reporting. Therefore, the logbooks do not record party/charter vessel activity in state waters or for those targeting unregulated species. However, for the segment of the party/charter fishery that is covered by logbooks, the coverage of party/charter catch is more comprehensive than the MRFSS. This is particularly true for species that are encountered infrequently in the MRFSS intercept survey. Given that the sample size for the party/charter sector in the MRFSS is low relative to shore and private boat sampling, less frequently caught species are likely to be absent from survey data or present in very low numbers. Consequently, catch estimates can be influenced by outliers or “unusual” trips, may not be reliable due to large standard errors, and often cannot be sufficiently disaggregated by location to address issues of concern to fisheries managers. As a census of activity, logbooks overcome many of these problems but are subject to their own potential difficulties.

Logbook data is subject to human error when initially recorded by hand and later electronically recorded into a database. For party/charter trips the captain is required to report time and date sailed/returned, number of anglers, number of crew, gear used, statistical area fished, loran or latitude-longitude coordinates, and kept and discarded catch in numbers of fish by species. If properly documented, these data can provide important information about the party/charter fishery that the MRFSS cannot. For example, the number of operating vessels can be identified along with information on numbers of trips by trip type (half-day, full-day, overnight), area fished, numbers of passengers carried, etc. However, inaccuracies in reporting may misrepresent certain facets of the party/charter fishery. To date, the most common recording errors that have been identified are reporting fish in pounds instead of numbers, failing to report loran or latitude-longitude coordinates, failing to report numbers of passengers, incorrectly recording trip type, and failure to report time sailed or returned. Of these errors, the most problematic is reporting catch in pounds instead of numbers.

In addition to potential errors in properly filling out each logbook, there may also be inaccuracies (accidental or otherwise) in the information that has been provided. Unfortunately, unlike the commercial fisheries dealer reporting system there is no independent cross-check to verify the validity of the reported data except for the MRFSS which is itself less reliable for the party/charter mode than for other modes. To date, no thorough review of the party/charter logbooks has been conducted to determine error rates either in terms of missing or inaccurate information or coding errors. This means it is not possible to identify potential biases present in the party/charter logbook data other than obvious outliers. There is no particular reason to believe that the party/charter logbooks are subject to any more or less error than commercial logbooks. They are likely to provide a reasonable approximation of party/charter activity and should be a reliable indicator of trends in the party/charter fishery.

9.4.3.3.1 Party/Charter Permits

As of fishing year 2002, Federal party/charter permits were issued under the following FMPs: Summer Flounder/Scup/Black Sea Bass, Squid/Mackerel/Butterfish, Lobster, Bluefish, and Multispecies. Each of these permit categories is open access and may require mandatory reporting. With the exception of the Multispecies plan any vessel carrying passengers for hire must have a party/charter permit. Since the Multispecies plan forbids any vessel from having a limited access and any open access permits, limited access vessels may carry passengers for hire without having a specific party/charter permit to do so. In 1995 there were a total of 990 unique vessels (Table 527). In 1996 a total of 413 multispecies party/charter permits were issued, this number increased to 610 permits in fishing year 2000 and was about 650 permits in 2001 and 2002. The total number of unique vessels that were issued at least one party charter permit ranged from a high of 964 in 2000 to a low of 752 in 1998.

9.4.3.3.2 Party/Charter Trip Activity

Party/Charter vessels typically offer a range of trip types but most common are half-day, full-day, and extended or overnight trips. Using the logbook data a half-day trip was defined as any trip of 6 hours or fewer, a full-day trip was defined as a trip between 6 and 12 hours and trips in excess of 12 hours were defined as an extended trip. Extended trips may include trips that may be considered as being an “overnight” trip because they may be 24 hours or greater in duration or may span more than one calendar day. Note that an extended trip that was 18 hours but departed and returned on the same calendar day would not be considered an overnight trip under these criteria.

The total number of extended trips taken by Mid-Atlantic party/charter operators was much greater than that of Gulf of Maine operators (Table 528). However, the proportion of extended relative to total trips was similar in both areas with the Gulf of Maine generally one to two percentage points below that of the Mid-Atlantic. The proportion of overnight trips relative to total extended trips ranged between 25.2% and 30.5% from 1995 to 1999 in the Mid-Atlantic but increased to nearly 50% in 2001. By contrast, the relative proportion of overnight trips in the Gulf of Maine has never been more than 14.4% and averaged below 6% from 1996 – 2000 before increasing to almost 13% in 2001. Unlike the Mid-Atlantic region, groundfish and more specifically, cod were retained on the majority of overnight trips in the Gulf of Maine. In the Mid-Atlantic region, groundfish was retained on fewer than 10% of overnight trips.

Permit Type	1995	1996	1997	1998	1999	2000	2001	2002
Summer Flounder	774	645	585	579	619	674	691	670

Table 528 - Summary of northeast region overnight party/charter trips. 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

The number of reporting vessels ranged from 512 in 1998 to 623 in 1995 (Table 529). Note that the number of reporting operators may be influenced by a combination of changing activity levels and changes in the number of permitted vessels that have been subject to mandatory reporting. Total trips and passengers were all higher in 2001 than in any other year while the largest number of fish kept was 4.5 million in 1995. On a per trip basis, fishing year 2001 was within the range of recent historical activity in terms of passengers and numbers of fish retained. Similarly the average keep per passenger was also consistent with levels experienced over the prior six years. The distribution of activity by trip length has been relatively stable with a slight redistribution of activity away from “overnight” trips to shorter trips since 1998. Across types of trips, half-day trips tended to retain fewer fish. Keep rates per passenger were also lowest on half-day trips.

Table 529 - Summary of party/charter activity for vessels reporting taking passengers for hire 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30. Keep is expressed in numbers of fish.

In any given year, approximately half of the party/charter vessels operating in the Northeast Region report catching and keeping at least some number of regulated multispecies. Since 1995, the total number of these reporting vessels has ranged between 251 and 309 (Table 530). On average, aggregate numbers of passengers taken, trips, combined keep of all species, and groundfish keep were lower in 1998-1999 as compared to 1995-1997, although keep and passengers per trip as well as keep per passenger has remained relatively constant over the past six years.

Over the past two fishing years (2000 and 2001) total trips, passengers and groundfish keep has increased but as just noted, neither per trip nor per passenger keep rates have changed much in seven years.

The total number of extended trips reporting keeping groundfish declined four consecutive years since 1996 but was stable in fishing years 2000 and 2001. The number of half-day trips had also been declining since 1996 but increased my more than 200 trips from 2000 to 2001. The number of full-day trips had remained relatively constant at about 3,000 trips per year before increasing by 800 and 700 trips in fishing years 2000 and 2001 respectively. With the exception of half-day trips in 2001, the number of passengers per trip was similar across all trip types ranging from 19 to 25 passengers over the seven year period. Unlike the Northeast region as a whole, where there was little difference in keep per trip or keep per passenger between full-day and extended trips, there were substantial differences in keep rates for party/charter vessels landing groundfish particularly since 1998. Specifically, the groundfish keep per trip for full-day trips is more then twice that of half-day trips and in many years more than doubles again for overnight trips. Similarly, groundfish keep per passenger was only slightly more than one fish from 1996-2001 on half-day trips, but was almost 4 fish on full day trips in 2000 and 2001, and exceeded 10 fish on overnight trips in 2001.

9.4.3.3.3 Composition of Party/Charter Catch

Party/charter vessels in the Northeast region target a variety of different species. The top five federally regulated species kept by vessels operating out of New England are cod, scup, bluefish, pollock, and haddock (Figure 307). Of these species, the proportional keep of cod had been declining since 1996 but increased in both 2000 and 2001. The relative proportion of Scup keep had also been declining but has been increasing every year since 1998. For vessels operating out of Mid-Atlantic ports, the top five species are black sea bass, bluefish, scup, summer flounder, and striped bass (Figure 308). While groundfish species comprise 40% or more of total kept catch in New England, groundfish tends to be less than 1% of total kept catch for Mid-Atlantic party/charter vessels. Of the groundfish species most frequently kept cod, haddock and pollock represent nearly 98% of total kept catch (Figure 309).

9.4.3.3.4 Party/Charter Vessel Dependence on Passenger Income

In the Northeast, Party/Charter vessels may elect to take passengers for hire or, provided they possess appropriate permits, may elect to fish commercially. Total annual income was estimated by adding all commercial gross revenues as reported in the dealer data with total income from passenger fees. Passenger fees by state were estimated as the average reported party/charter fee by anglers interviewed during the 1998 Northeast region angler expenditure survey (Steinback and Gentner 2001). Party/charter vessels also receive income from equipment rental and sales of food and merchandise. Therefore, the total income of a given party/charter business may be underestimated.

The majority (an average of 78%) of party/charter vessels operating in the Northeast region depend exclusively on passenger fees for total operating revenues (Table 531). Since 1995, there have been no notable changes in the relative proportion of vessels that may have switched from commercial activity to carrying passengers for hire. On average, 7.4% of party/charter vessels relied on passenger fees for 25% or less of total business income.

	= 25%	25% < I = 50%	50%< I = 75%	75% < I < 100%	100%

For party/charter vessels that kept some quantity of groundfish income dependence on passenger fees was only slightly less than that for Northeast Region party/charter operators (Table 532).

9.4.3.3.5 Party/Charter Ports or "Centers of Activity"

McCay et. al. (1999) and McCay, O'Neil and Velcheck (1999) identify several ports in New Jersey and New York as places where party/charter vessels are concentrated. Party/charter vessels that reported keeping some groundfish were from ports in New England, New York and New Jersey (Table 533). The majority of these vessels operate out of Massachusetts, Maine, Rhode Island and New Hampshire. Since 1996 there has been a contraction in the number of party/charter vessels from Connecticut, New York, and New Jersey that either targeted or encountered groundfish. The number of ports in Connecticut, New York and New Jersey in which party/charter vessels are located has also decreased (Table 534). The number of ports in which party/charter vessels that land groundfish are located has remained relatively stable in Maine, New Hampshire, Massachusetts, and Rhode Island and has declined in Connecticut.

	1995	1996	1997	1998	1999	2000	2001

There were only 12 ports (defined by principal port on the annual permit application) in the Northeast that have maintained a party/charter fleet (defined as 4 or more vessels) that reported landing groundfish while taking passengers for hire in every year from 1995 to 2001(Table 535). There were no ports in Maine or Connecticut that met this criterion and only one port in Rhode Island (Point Judith), New Hampshire

(Hampton) and New York (Montauk). Only Massachusetts (Gloucester, Green Harbor, Newburyport, Plymouth, and Salisbury) and New Jersey (Atlantic Highlands, Barnegat Light, Belmar, and Point Pleasant) had more than one port with four or more party/charter operators in every year.

9.4.3.3.6 Effectiveness of Management Regulations (1997-2001)

With the implementation of Amendment 7 a bag limit of 10 fish of combined cod and haddock was established and the recreational size limit for cod and haddock was increased from 19 to 21 inches over two years. Although the size limit applied to all recreational anglers, only private boats and shore anglers are subject to the bag limits. Beginning in fishing year 2000, party/charter vessels were required to obtain a letter of authorization to fish in any one of the GOM closed areas or the Nantucket Lightship closure. Note that these regulations apply to Atlantic cod and haddock while fishing in Federal waters. Fish harvested from state waters are subject to state regulations that may or may not be in conformance with Federal laws so that evaluation of the effectiveness of Federal regulations is clouded by these inconsistencies. Thus, the following was developed in terms of conformance with Federal regulations since non-compliance is not readily discernible.

To evaluate the effectiveness of recreational measures established in Amendment 7, the kept catch and size distributions by stock area and mode were constructed from MRFSS data. Due to the relatively infrequent sampling of haddock catch, only size distributions for Atlantic cod were constructed. Kept catch distributions for cod were based on expanded estimates from the raw MRFSS intercept data and were modified to account for portions of kept catch that were filleted. The latter adjustment was necessary because filleted catch is usually treated as discards (or Type B1 catch) under MRFSS reporting procedures. Given the fact that filleting fish is one of the services that many party/charter operators offer their customers, omission of filleted catch would misrepresent the actual party/charter kept catch.

Although both numbers and length of cod are recorded as part of the intercept survey the available sample size for fish lengths is smaller than the sample size for numbers of cod. Length measurements are not always taken at the time fish are counted for a variety of reasons. Filleted fish are not measured. Anglers may permit the interviewer to count fish but may refuse to allow the interviewer to take biological samples (weight and length measurements). In other instances the interviewer may not take biological samples because of time constraints at a particularly busy site.

For the reasons outlined above, in combination with a general decline in recreational catches there have not been sufficient length samples in any fishing mode to construct a size distribution for Georges Bank cod in any year since 1998. For the private boat mode there have not been enough measured fish to estimate a size distribution of the Georges Bank cod catch sine 1996. Thus, an assessment of conformance with the Amendment 7 Georges Bank cod size regulations is not possible.

Size limit conformance in the Gulf of Maine differs markedly between recreational fishing modes. On average, about 9% of party charter kept cod was not in conformance with Federal size regulations in effect (19”) from 1993 to 1996 (Figure 310). From 1997 to 2000 less than 4% of cod kept by party/charter passengers was below the Federal size limit (20” in 1997 and 21” thereafter) but was 16% in calendar year 2001. Compared to the 1993-1996 average non-conformance rate, the average rate since implementation of Amendment 7 has improved to 6% or equivalently, 94% of cod retained by party/charter anglers has been at or above the Federal size limit.

By contrast, 23% of the private boat kept cod was not in conformance with the Federal size limit prior to Amendment 7 and was at least that much in 1997, 1999, and 2000 (Figure 311). The non-conformance rate was about 8% and 10% in 1998 and 2001 respectively. Compared to the 1993-96 average, the 1997-2001 average non-conformance rate improved to about 19%; still more than three times as great as that of party/charter anglers.

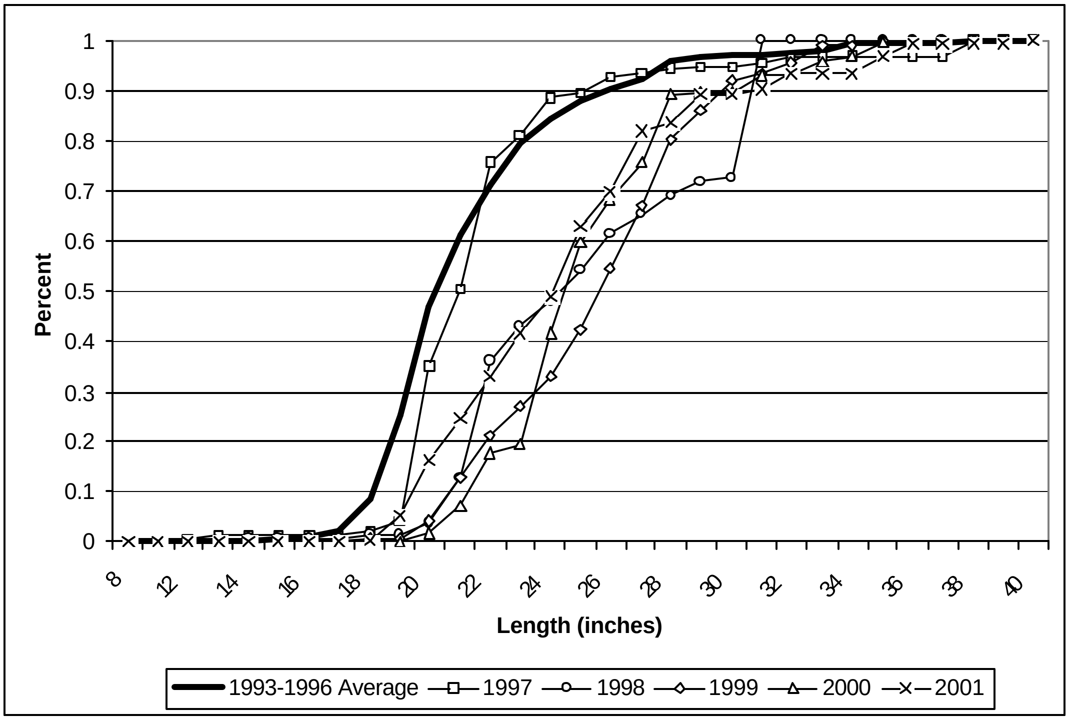

Figure 310 - Cumulative percent of Gulf of Maine cod kept by size class for party/charter mode. 1993-2001.
Source Data: NMFS MRFSS database. Years denote calendar years.

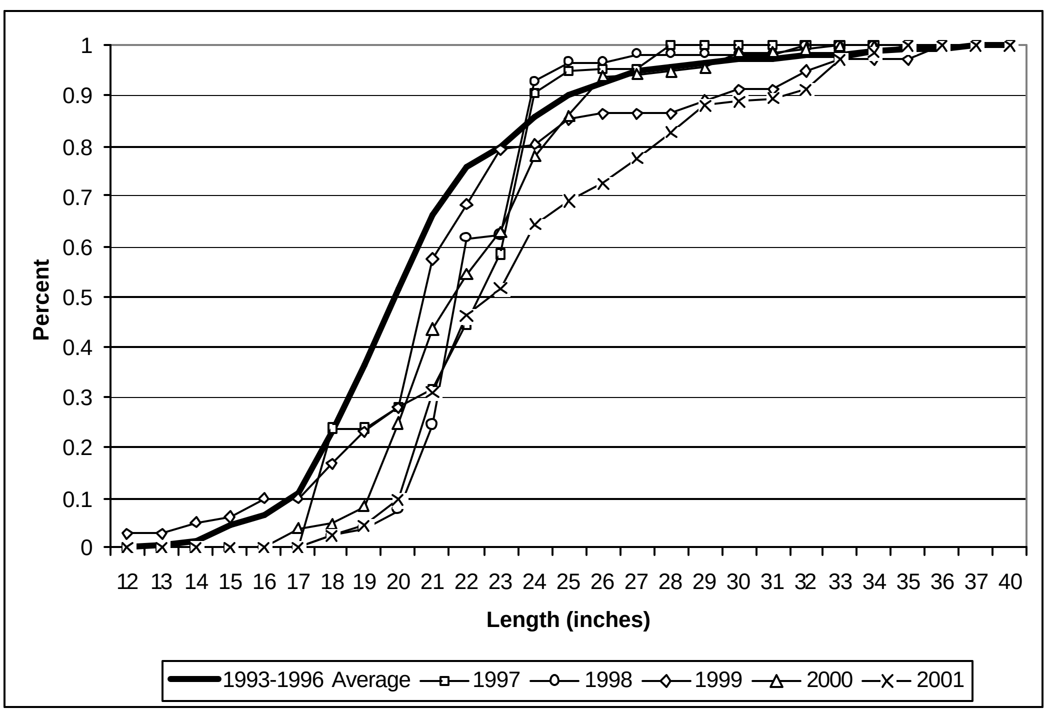

Figure 311- Cumulative percent of Gulf of Maine cod kept by size class for private boat. 1993-2001.
Source Data: NMFS MRFSS database. Years denote calendar years.

Due to low sample sizes for Georges Bank cod in the private boat mode the effectiveness of the cod trip limit is difficult to assess. However, on average, 21% of total Georges Bank cod was retained from 1993 to 1996. Available data indicate that the proportion of Georges Bank cod retained above the 10 fish limit has likely declined but it is not possible to determine whether this improvement may be due to compliance or to declining stock conditions.

Conformance by Gulf of Maine private boat anglers has resulted in a decline in the proportion of retained fish in excess of the 10 fish bag limit (Figure 312). From 1993 to 1996 approximately 33% of cod was retained on trips where more than 10 fish were kept. From 1997 to 1999 less than 4% of cod was on trips that kept more than 10 fish. In both 2000 and 2001 proportionally more fish were retained above the bag limit (12% and 18% respectively). These proportions indicate that private boat non-conformance in the Gulf of Maine may be increasing but the proportion of kept cod above the bag limit is still well below pre-Amendment 7 levels.

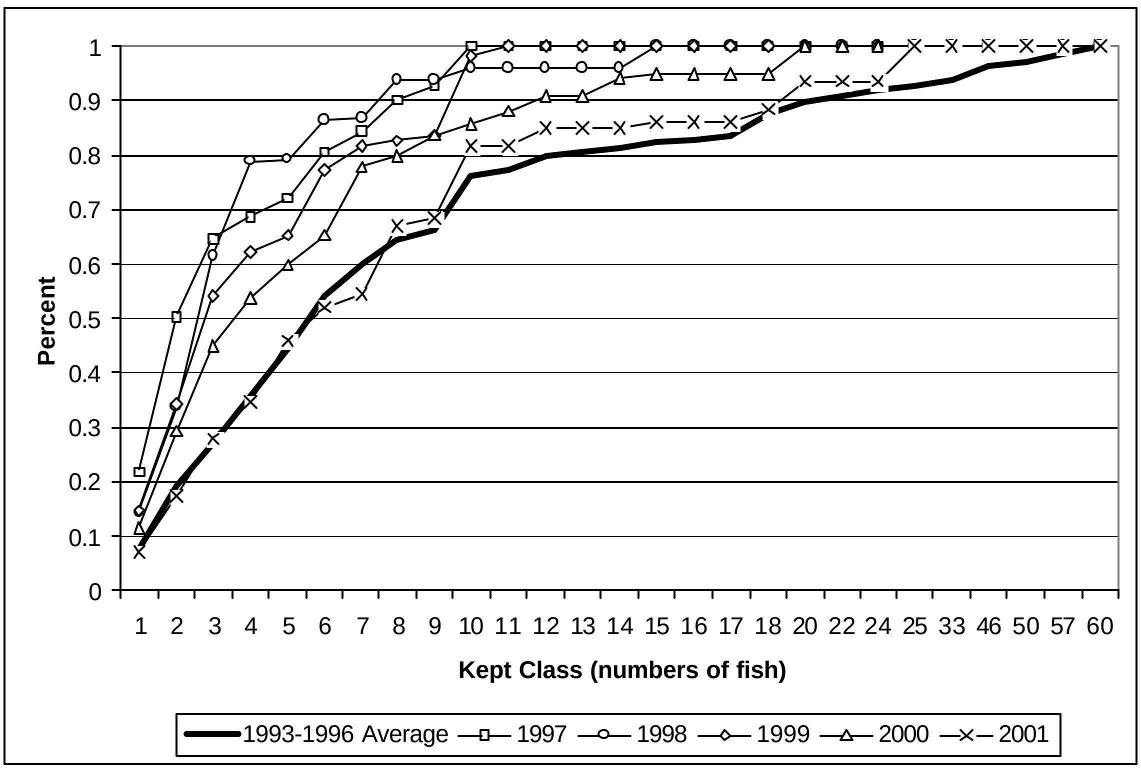

Figure 312 - Cumulative percent of Gulf of Maine cod kept by kept class for private boat. 1993-2001.
Source Data: NMFS MRFSS database. Years denote calendar years.

The private boat mode is subject to both bag and size limit regulations. The average combined non-conformance rate in this mode for Gulf of Maine cod was about 20% of which 17% was associated with a propensity to retain fish below the Federal minimum size of 21". In more recent years, combined non-conformance has been 34% and 26% in calendar years 2000 and 20001 respectively.

There are a number of reasons why the Gulf of Maine cod private boat recreational catch does not conform to Federal regulations. From 1997 to 2001 state landings laws were not consistent with Federal regulations in all Gulf of Maine states. Anglers may know the landings laws in their own state but may not know what the Federal regulations are even if they are fishing in Federal waters. Still other anglers may simply choose not to comply. Whatever the reason, at least some conservation benefit would be obtained through improved conformance with Federal size and bag limits without any changes in existing regulations. Note that the magnitude of any such conservation gains would be partially dampened by release mortality.

9.4.3.3.7 Party/Charter Fishing in the Gulf of Maine

The total number of trips taken in the Northeast region and number of anglers on those trips where any regulated groundfish were caught declined in consecutive years from 1996 to 1999 (Table 536). However, the number of trips has increased by more than 1,500 (600 in 2000 and another 900+ in 2001). Much of this increase has occurred in the Gulf of Maine as numbers of trips and passengers fishing on Georges Bank and southward has been gradually declining since 1996.

	Georges Bank/SNE		Gulf of Maine		All Areas	
Fishing Year	**Anglers**	**Trips**	**Anglers**	**Trips**	**Anglers**	**Trips**

Table 536 - Party/charter anglers and trips by fishing year. Fishing years 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

At least 94% of party/charter trips catching groundfish in the Gulf of Maine caught one or more cod (Table 537). Cod accounted for 55% or more total fish kept and has been nearly 70% of groundfish kept in every year except 1998. In the Gulf of Maine, party/charter activity associated with groundfish and cod generally declined from 1995 to 1997, followed by increases in all subsequent years. Total cod catch increased in every year from 1997 to 2001; reaching time series highs in consecutive years (2000 and 2001).

Catch and landings are expressed in <u>numbers</u> of fish.

The annual trend in Gulf of Maine cod keep indicates a downward trend in 1996 and 1997 followed by annual increases in kept cod from 1998 through 2001 (Figure 313). This pattern coincides with implementation schedule for size increases prescribed by Amendment 7. Size limits were increased in one-inch increments from 19" to 20" in 1996 and to 21" in 1997. These changes in size limits would have affected the total number of cod that could be retained by party/charter anglers. While the annual trend indicates a consistent rise in recreational catches, kept cod did not exceed that of 1995 levels until fishing year 2000.

Party/charter boats (with a letter of authorization) and private recreational boats have been exempted from the Gulf of Maine area closures. These exemptions have been contentious and have lead to suggestions that party/charter effort has increased particularly during earlier parts of the year. Gulf of Maine cod party/charter activity has increased and there has been an extension of effort into early spring months (March/April) (Table 538). However, compared to 1995-97 averages, the cumulative percent of trips taken prior to May was only about 3% higher in 1998, 1999, and 2001 but was about 9% higher in 2000 (Figure 314). By June, the cumulative percent of party/charter trips catching cod from 1998-2000 was approximately equal to that in 1995-1997 (43%).

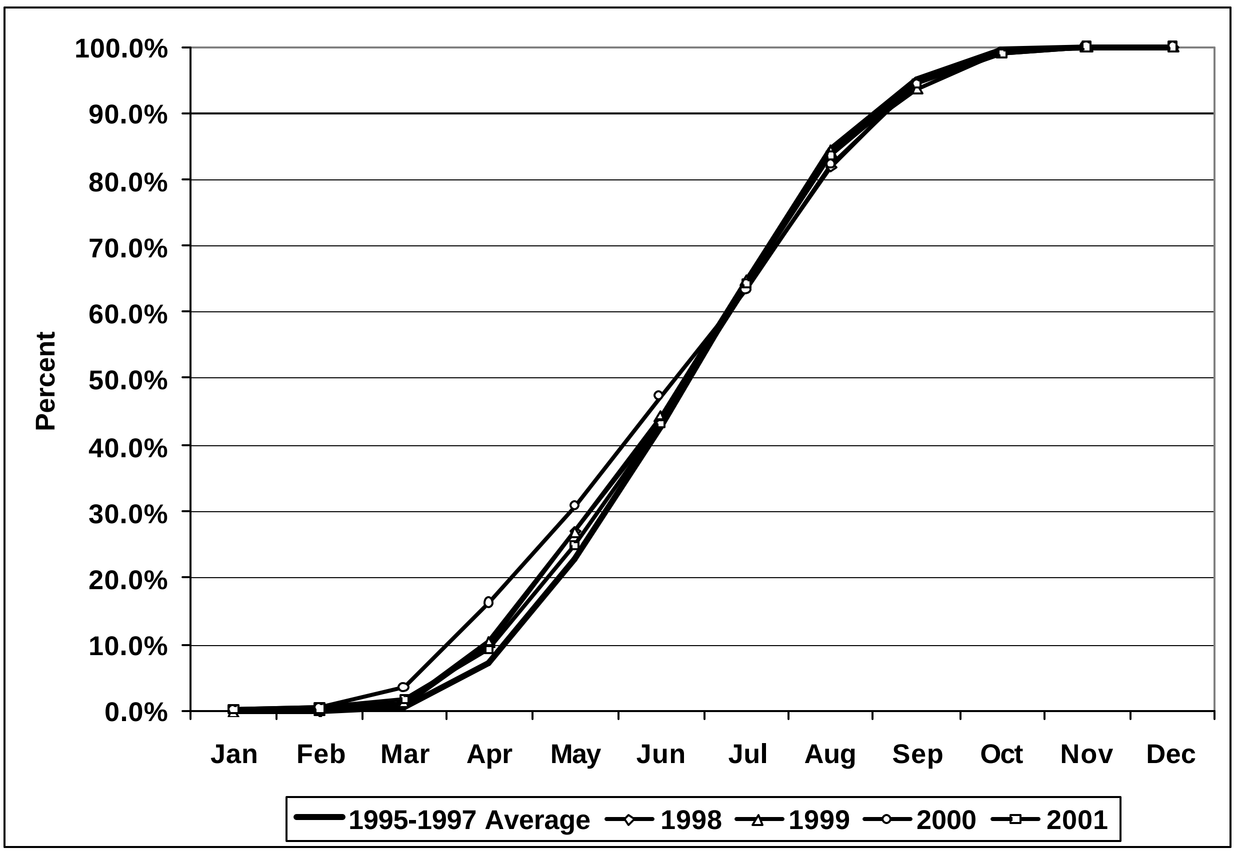

Figure 314 - Cumulative percent of party/charter trips catching cod by month. 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

In contrast to the relative distribution of trips, total Gulf of Maine cod catch shows a more distinct separation between cumulative percent of catch in March and April (approximately 25%) during fishing years 1998 and 1999 as compared to the 1995-1997 average (14%) (Figure 315). The separation in fishing year 2000 was even more pronounced (37% of total kept cod). During each of these years, much of this increase occurred in the month of April. Thus, a larger proportion of cod catch was taken in the early spring in fishing years 1998, 1999, and 2000 than in previous years, but this trend did not repeat itself in fishing year 2001. During fishing year 2001, the distribution of cod catch across months was virtually identical to that of the 1995-97 average.

Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

Keep rates per trip and per passenger follow similar trends for Gulf of Maine cod (Figure 316). In every case, keep rates declined from 1995 to 1997 followed by increased keep rates in all subsequent years. Average keep rates per angler bottomed out at about 4 cod in 1997 but had risen to nearly 7 cod in 2001. Similarly, average kept cod per trip was lowest in 1998 at about 48 fish and increased by more then 27 fish in 2001.

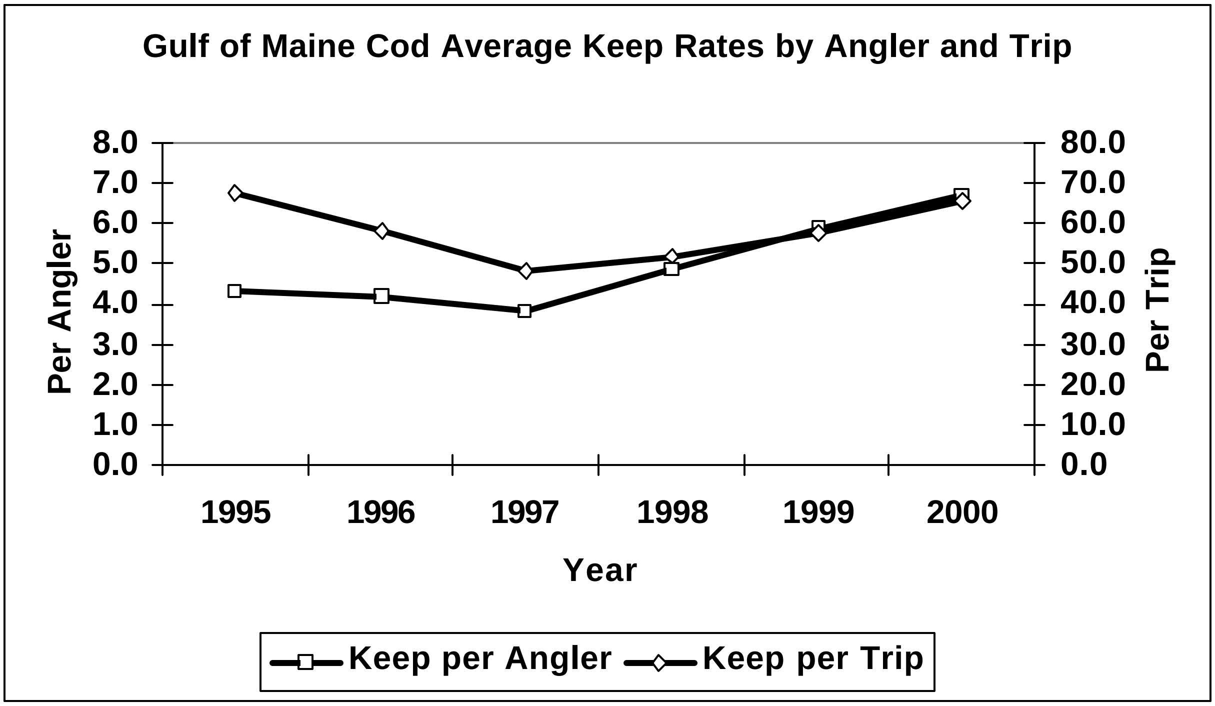

Figure 316 - Gulf of Maine average cod keep per party/charter angler and per trip 1995-2000.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.
Catch and landings are expressed in *numbers of fish.*

Although average keep rates may have been between 5 and 7 fish from 1999-2001 keep rates on any given trip may vary considerably depending on time of year and fishing location. During fishing years 1999-2001 about 48% of all party/charter trips averaged 2 or fewer kept cod per passenger (Figure 317). Nearly 90% of all trips landed 10 or fewer cod and 93% of all trips landed 15 or fewer cod per angler. Of the total number of passengers taken, 68% were on trips that landed 2 or fewer cod per passenger, 91% were on trips that landed 5 or fewer and 98% were on trips that landed 15 or fewer cod. In terms of kept cod, 18.5% of total keep occurred on trips that kept 2 or fewer fish. This means that nearly half of the trips and 68% of party/charter passengers accounted for less than 20% of total landed cod. Similarly, 88% of trips and 96% of passengers landed 10 or fewer fish but these trips and passengers accounted for 63% of total kept cod. Conversely, only 12% of trips and 6% of Gulf of Maine party/charter passengers accounted for 37% of total cod kept, and these trips averaged more than 10 fish per passenger.

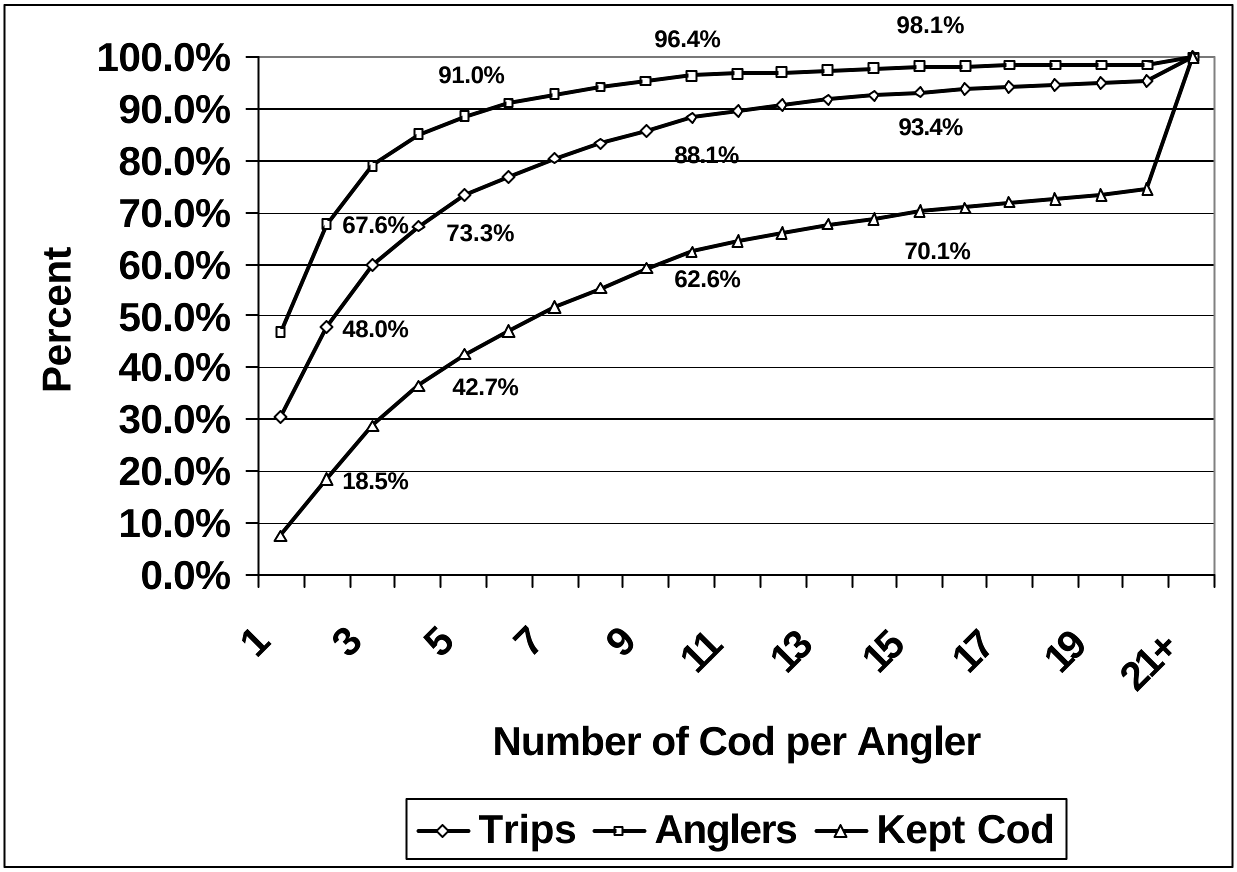

Figure 317 - Cumulative percent of party/charter trips, anglers, and Gulf of Maine cod kept catch by keep class. Fishing year 1999-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

There were a total of 140 vessels reporting taking one or more party/charter trips that caught cod during fishing year 2001. Of these vessels, 20% (28 vessels) accounted for 64% of party/charter trips, 75% of passengers, and almost 82% of total Gulf of Maine cod catch (Figure 318). Note that the 2001 fishing year was not unusual in that similar proportions were found for consecutive fishing years 1997 through 2000. Thus, in any given year, 20% of operators have accounted for the majority of party/charter activity catching Gulf of Maine cod in any given year.

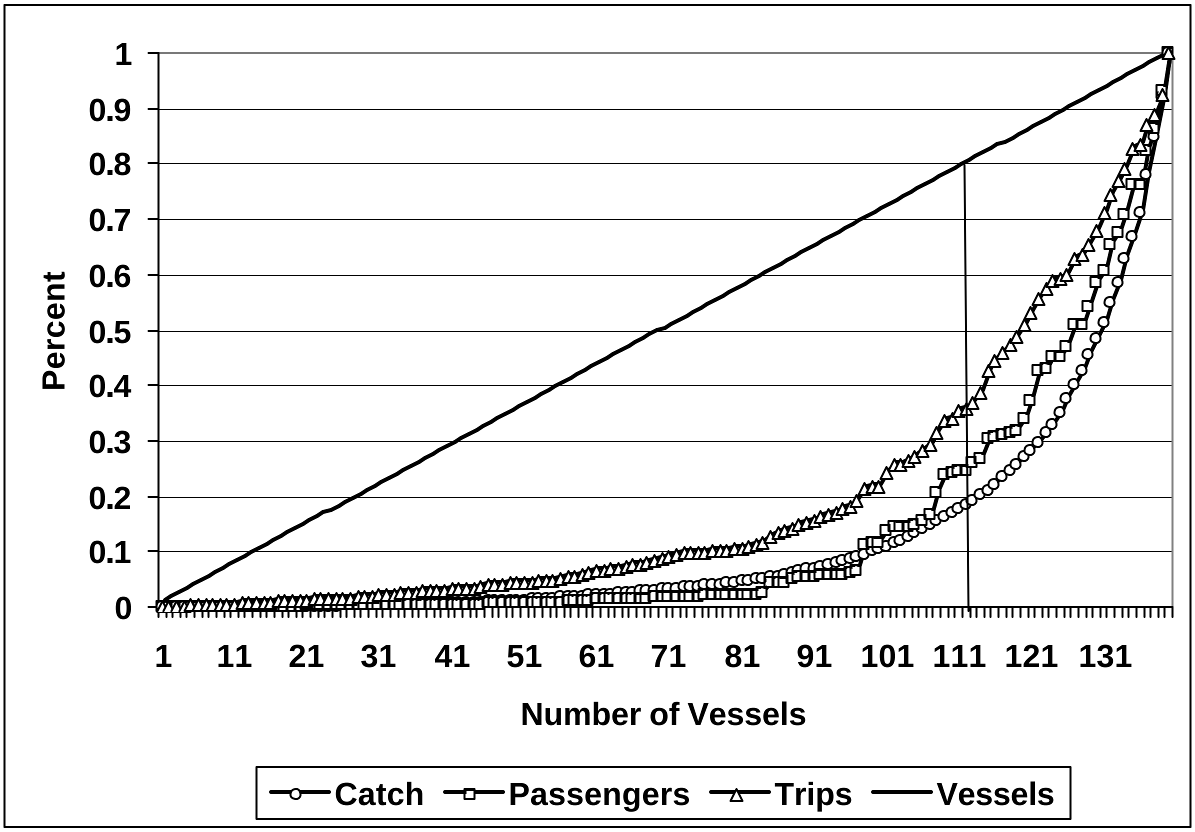

Figure 318 - Cumulative percent of party/charter trips, passengers, and Gulf of Maine cod catch. Fishing year 2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

Of the party/charter activity catching cod in the GOM, the majority (approximately 98% of both total trips and catch) have occurred in either statistical area 513 or 514 in every year since 1995. However, the relative share of activity in these two areas did undergo some changes. In 1995 the proportion of total trips taken in the two areas was almost 1:1 but the proportion of trips taken to area 513 increased in the following years reaching nearly 57% in 1997 (Figure 319). In subsequent years a shift in recreational effort seems to have occurred away from area 513 back to area 514 and in appears to have stabilized since 1999 at about a 48%/52% split between the two areas.

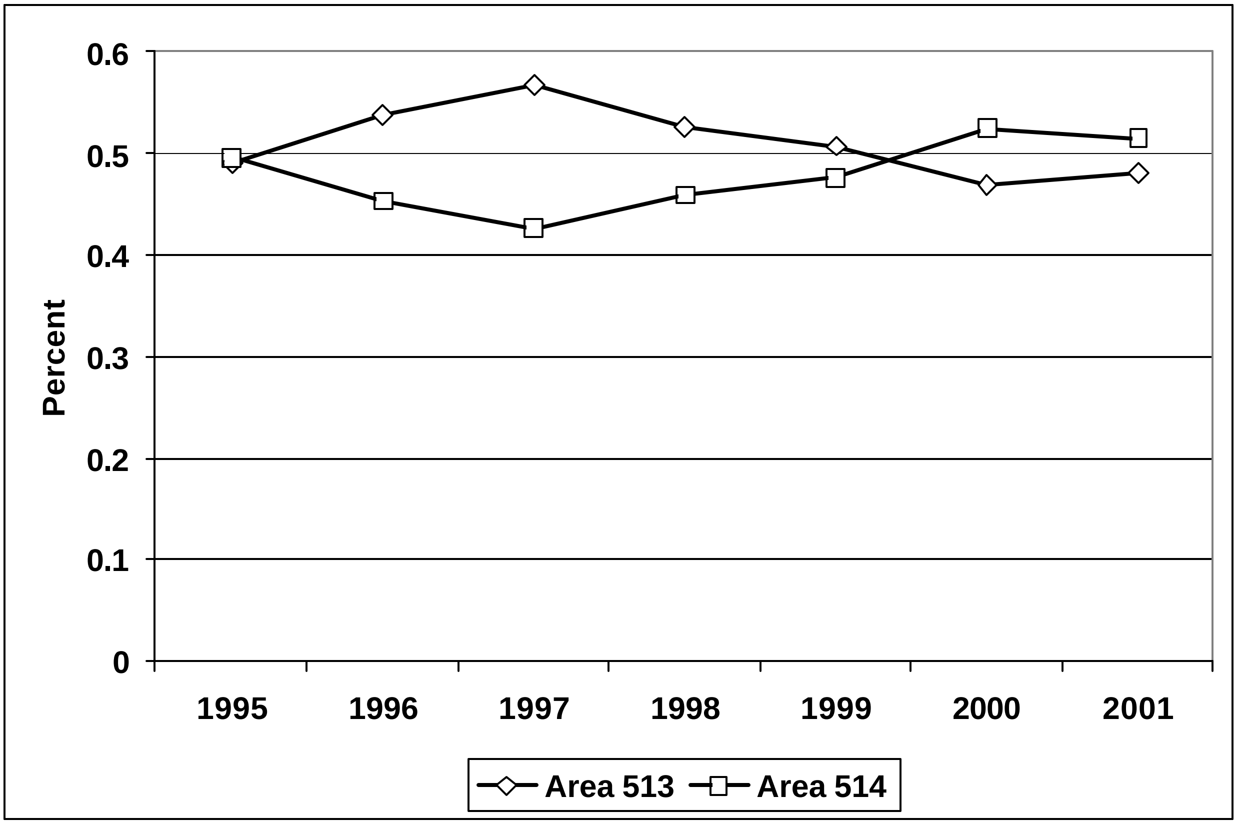

Figure 319 - Percent of Total Party/Charter trips Taken in the Statistical Areas 513 and 514. Fishing years 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

Even though the proportional number of trips was approximately equal in 1995, 59% of GOM cod catch came from area 514 while 41% of catch came from area 513 (Figure 320). With a shift toward area 513 in 1996 to 1998, the proportion of cod catch from area 514 declined to approximately 50% in 1998. After 1997, effort in area 514 increased, while it declined in area 513. Over the past two fishing years about 62% of kept cod came from area 514 and 38% from area 513. The apparent shift toward area 514 may be a response to increased availability of the resource to recreational fishermen, as commercial fishing is restricted by area and seasonal closures. If this is the case, then one would expect to observe both an increase in the amount of effort in area 514 associated with early spring months coupled with an increase in catch.

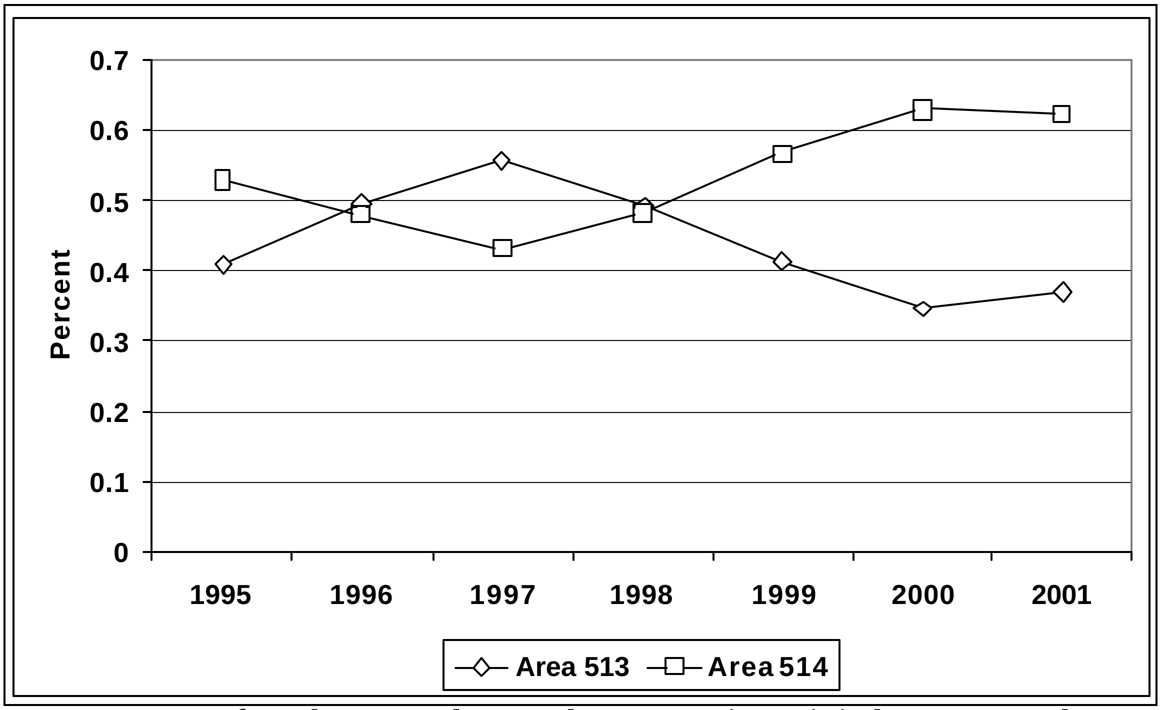

Figure 320 - Percent of Total GOM Cod Party/Charter Keep in Statistical Areas 513 and 514. Fishing years 1995-2001.
Source Data: NMFS VTR database. Years denote fishing years – May 1 to April 30.

Party/Charter GOM kept cod in area 514 does show a shift toward the early spring months as compared to the rest of the year (Figure 30). Compared to the 1995-97 average (17%), the proportion of total annual catch in area 514 during March and April more than doubled in 1998 (35%), 1999 (41%), and 2000 (52%). However, the relative distribution of kept cod in 2001 was nearly identical to that of the 1995-1997 baseline. Also, with the exception of fishing year 2000, the relative distribution of effort either in terms of trips or passengers from 1998-2001 was nearly identical to that of the 1995-97 averages (Figure 322 and Figure 323). Thus, the increase in the proportion of GOM cod catch in area 514 is more likely to be associated with improved catch rates in the spring months rather than to a shift in effort specifically targeting cod during this time of year. In fact, the general increase in number of trips and passengers on party/charter vessels represents a general increase in effort distributed throughout the year rather than in any specific time period.

9.4.3.4 Synthesis

Recreational Activity
Recreational fishing participation in the North Atlantic region (Maine to Connecticut) has remained nearly constant over the last 20 years. Over this time period catch per trip declined from 1981 to 1992 and has fluctuated without trend from 1992 onward yet the number of trips taken per participant has increased since 1989. Although participation in the Mid-Atlantic region has exhibited greater variability over time the trends in catch and trips per participant are similar to that of the North Atlantic with increasing trip taking behavior despite relatively flat changes in catch rate and in the face of an increasing regulatory framework. Thus, at least in aggregate, recreational trip demand in the Northeast region appears to be relatively robust with respect to changing stock conditions and regulatory regime.

Over the past six years the sum of all regulated groundfish in the Northeast region has accounted for about 3% of total recreationally caught fish. However, the relative contribution of groundfish to total recreational catch varies among fishing modes and regions. In the North Atlantic region groundfish accounted for about 10% of total catch but was more than 40% of total catch in the party/charter mode. Groundfish catches were about 8% of the North Atlantic private boat catch and 3% of the shore mode. By contrast, regulated groundfish comprised less than 2% of recreational catch across all fishing modes in the Mid-Atlantic region. This means that changes in groundfish regulation would affect a relatively small component of Northeast region recreational fisheries as a whole, but the impact would be greatest on party/charter anglers fishing from sites in New England.

From 1995 to 2001 approximately half (250 to 300) of all party/charter operators subject to mandatory reporting report landing regulated groundfish at some time during the year. Fishing activity by these vessels in fishing year 2001 was a seven-year high in terms of numbers of trips, passengers, total keep, and total groundfish keep. However, average groundfish keep per trip and groundfish keep per angler was similar to that of fishing year 2000 and was within the range of observed levels since 1995.

The majority (98%) of groundfish catch by New England party/charter operators is comprised of cod, haddock, and pollock. Of these three species cod has averaged about 70% of total groundfish keep from 1998 to 2001. In the Gulf of Maine at least 94% of all trips catching groundfish caught at least one cod with keep rates increasing from 4 cod per angler in 1995 to nearly 7 fish in 2001. However, these averages do not adequately capture the potential effect of regulatory changes on Gulf of Maine party/charter anglers. During fishing years 1999-2001 about 48% of all party/charter trips averaged 2 or fewer kept cod per passenger (Figure 317). Nearly 90% of all trips landed 10 or fewer cod and 93% of all trips landed 15 or fewer cod per angler. Of the total number of passengers taken, 68% were on trips that landed 2 or fewer cod per passenger, 91% were on trips that landed 5 or fewer and 98% were on trips that landed 15 or fewer cod. In terms of kept cod, 18.5% of total keep occurred on trips that kept 2 or fewer fish. This means that nearly half of the trips and 68% of party/charter passengers accounted for less than 20% of total landed cod. Similarly, 88% of trips and 96% of passengers landed 10 or fewer fish but these trips and passengers accounted for 63% of total kept cod. Conversely, only 12% of trips and 6% of Gulf of Maine party/charter passengers accounted for 37% of total cod kept, and these trips averaged more than 10 fish per passenger.

Party/Charter Operators

Throughout the Northeast region the total number of unique vessels issued a Federal permit to carry passengers for hire in any given fishery ranged from a high of 990 in 1995 to a low of 752 in 1998. Exclusive of limited access permit holders that may also take passengers for hire, the number of party/charter permits issued under the multispecies FMP was approximately 500 from 1997 to 1999 but increased to about 650 in both FY2001 and 2002. The number of vessels actually reporting party/charter activity for groundfish has ranged between 250 and 300 vessels from 1995 to 2001, about half the number of permitted vessels.

Massachusetts has the largest number of federally permitted party/charter vessels reporting groundfish catches followed by New Jersey, New York, New Hampshire and Maine. Note that groundfish catch for New Jersey and New York vessels represents a very small proportion of fishing activity. Thus even though there may be 40-50 vessels in each of these states that landed some groundfish the impact of groundfish management on these vessels is likely to be minor. In Massachusetts party/charter operators hailed from 31 different home ports with notable concentrations in the ports of Gloucester, Green Harbor, Newburyport, Plymouth and Salisbury. The majority of New Hampshire vessels operated from the ports of Hampton and Portsmouth while Maine operators were based in Boothbay Harbor, Kennebunkport, Kittery, and Portland (two vessels each in FY2001).

A large majority (about 75%) of party/charter operators that landed groundfish earn 100% of annual fishing income from passenger fees and nearly 85% of vessels earned at 75% or more of annual fishing income from passenger fees. Thus, only a small number of vessels have diversified into both commercial and recreational fishing business activity. Even though most party/charter operators depend on passenger fees for fishing income there are wide differences among the fleet in terms of level of activity particularly with respect to Atlantic cod. In the Gulf of Maine about 20% of operating vessels account for more than 60% of all trips that kept cod, more than 70% of all passengers taken on these trips, and reported over 80% of total kept cod. Since cod is typically caught on more 95% of party/charter trips in the Gulf of Maine, 20-30 vessels conduct the majority of party/charter business in the Gulf of Maine. This also means that while recreational management measures for groundfish will affect the entire fleet the impact of those regulations will not be uniformly distributed but will fall on a relatively small number of vessels.

Effectiveness of Regulations (1997 to 2001)
Due to low sample sizes for Georges Bank cod, the effectiveness of bag and size limits that had been in effect since from 1997 to 2001 could not be evaluated. Limited data indicate that for the private boat mode the proportion of Georges Bank cod retained above the 10 fish limit has likely declined but it is not possible to determine whether this improvement may be due to compliance or to declining stock conditions. Unfortunately, there were not enough measured fish to ascertain whether the size limit for the party/charter and private boat modes were effective.

Size limit conformance in the Gulf of Maine differs markedly between recreational fishing modes. On average, about 9% of party/charter kept cod was not in conformance with Federal size regulations in effect (19") from 1993 to 1996. From 1997 to 2000 less than 4% of cod kept by party/charter passengers was below the Federal size limit (20" in 1997 and 21" thereafter) but was 16% in calendar year 2001. Compared to the 1993-1996 average non-conformance rate, the average rate since implementation of Amendment 7 has improved to 6% or equivalently, 94% of cod retained by party/charter anglers has been at or above the Federal size limit.

By contrast, 23% of the private boat kept cod was not in conformance with the Federal size limit prior to Amendment 7 and was at least that much in 1997, 1999, and 2000. The non-conformance rate was about 8% and 10% in 1998 and 2001 respectively. Compared to the 1993-96 average, the 1997-2001 average non-conformance rate improved to about 19%; still more than three times as great as that of party/charter anglers.

Conformance by Gulf of Maine private boat anglers has resulted in a decline in the proportion of retained fish in excess of the 10 fish bag limit. From 1993 to 1996 approximately 33% of cod was retained on trips where more than 10 fish were kept. From 1997 to 1999 less than 4% of cod was on trips that kept more than 10 fish. In both 2000 and 2001 proportionally more fish were retained above the bag limit (12% and 18% respectively). These proportions indicate that private boat non-conformance in the Gulf of Maine may be increasing but the proportion of kept cod above the bag limit is still well below pre-Amendment 7 levels.

The private boat mode is subject to both bag and size limit regulations. The average combined non-conformance rate in this mode for Gulf of Maine cod was about 20% of which 17% was associated with a propensity to retain fish below the Federal minimum size of 21". In more recent years, combined non-conformance has been 34% and 26% in calendar years 2000 and 20001 respectively.

There are a number of reasons why the Gulf of Maine cod private boat recreational catch does not conform to Federal regulations. From 1997 to 2001 state landings laws were not consistent with Federal regulations in all Gulf of Maine states. Anglers may know the landings laws in their own state but may not know what the Federal regulations are even if they are fishing in Federal waters. Still other anglers may simply choose not to comply. Whatever the reason, at least some conservation benefit would be obtained through improved conformance with Federal size and bag limits without any changes in existing regulations. Note that the magnitude of any such conservation gains would be partially dampened by release mortality.

9.4.4 Processing and wholesale trade sector

Fresh fish processing and frozen fish processing are two separate industries in New England, each with its own customers, firms, and industrial organizations (Georgianna and Dirlam 2000). Fresh fish processors buy whole fresh supplies from fishermen locally and at other New England ports, and they bring in fresh supplies from other parts of the U.S., Canada and other countries. They process the product (for example, cutting fish into fillets) and sell it to wholesalers, retailers, restaurants, and other users. Groundfish processors in the United States buy frozen imports from Canada, Iceland, Norway, and other nations around the world. These products, mainly frozen blocks of fillets, are processed into frozen portions, sticks, and other products for sale to supermarkets, restaurants, and institutions. Frozen products keep for a long time and are not subject to the same time constraints as fresh products. Prices are less volatile, markets more impersonal, and business relations more competitive. Frozen groundfish plants are also much larger than fresh groundfish plants, and they operate longer through the day and through the year. Few fresh groundfish processors produce frozen product, and those that do sell special orders to institutions, usually government agencies, which are sometimes required to purchase U.S. product (Georgianna and Dirlam 2000). Wholesale firms do not process fish, but buy from processors and sell to retail outlets, institutions and other buyers.

Data Sources

Employment and landings data for the wholesale and processing sectors was provided by NMFS for calendar years 1995 through 1999. Additional employment data is reported from the County Business Patterns (CBP) database of the U.S. Census Bureau for 1998 to 2001, and provides information on the number of establishments within fishing industry sectors. In this section, industry sectors are reported by North American Industry Classification System (NAICS) code for each state. More detailed information on fishing industry sector employment is provided at the county level in Section 9.4.5. See section 9.4.5.5 for a comprehensive description of Census data and an overview of the NAICS codes highlighted in this document.

Discussion

According to NMFS unpublished data, the number of processing firms in New England has declined since 1995, while wholesaling firms have increased in number (Figure 325). There was an increase in processing sector employment until 1997, followed by a decline. Wholesale sector employment had the opposite trend with a decline until 1997, followed by an increase to its highest level in 1999 (Figure 324).

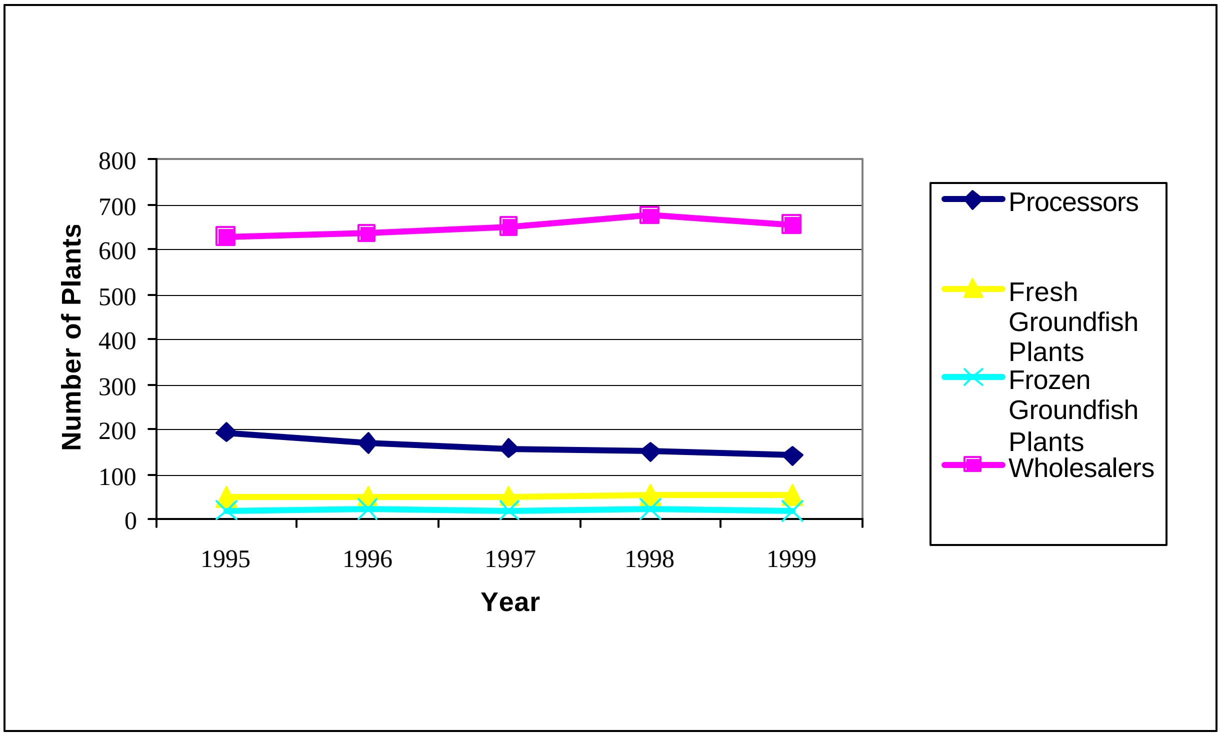

Figure 324 - New England processing and wholesale sector employment, 1995-1999.
Source Data: NMFS unpublished data. Years denote calendar years.

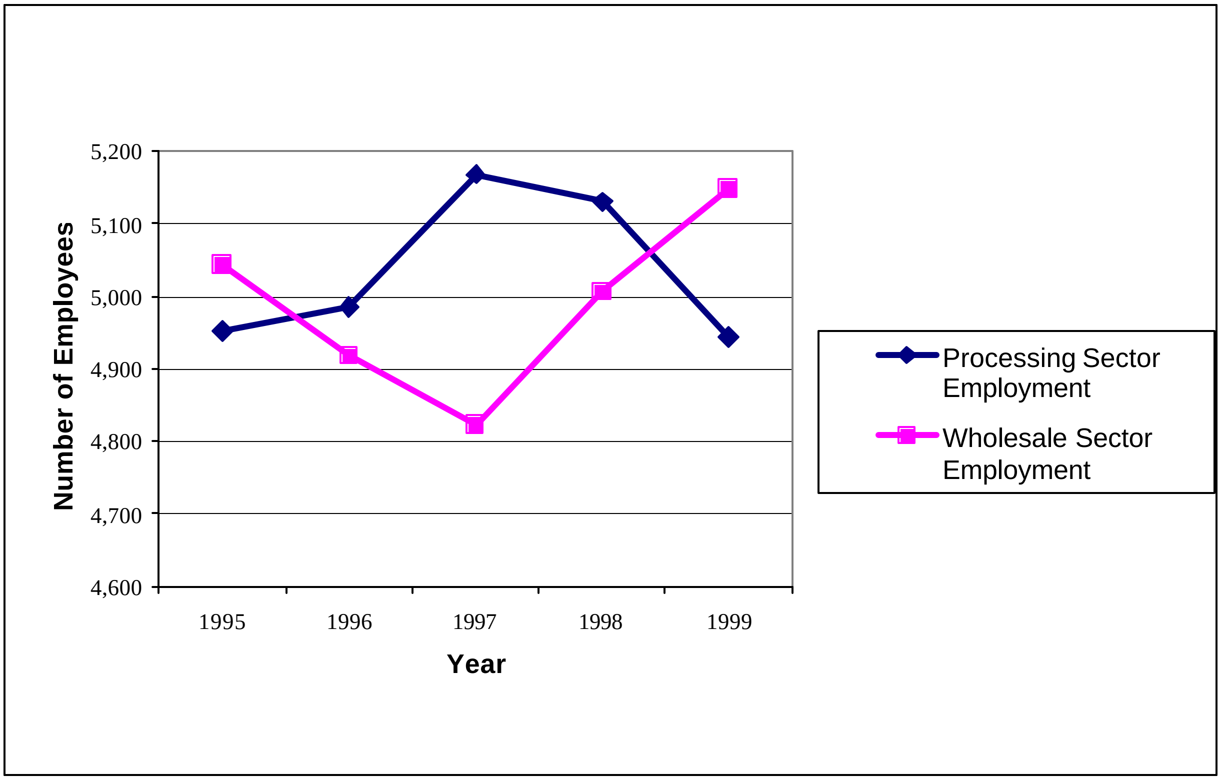

Figure 325 - Number of employees in wholesale and processing sectors in New England, 1995-1999.
Source Data: NMFS unpublished data. Years denote calendar years.

It is estimated that more than one-third of the fresh processing firms in business in 1992 are no longer operating, although the number of plants has been stable since 1995 (Figure 325). Surviving firms are now paying more attention to the their net revenues (Georgianna and Dirlam 2000). Most groundfish landed in New England is sold into the fresh fish market, and landings since 1995 have been less than the total volume of processed products in terms of live weight (Figure 328). This has led fresh fish processors in the Northeast to acquire additional products from Canada and the west coast of the United States. Recently, processors increased imports from Iceland because air cargo routes into Logan airport were being used less frequently by Canadian suppliers. Both the inflation-adjusted value of fresh groundfish processed and the average volume have declined since 1995 (Figure 329). Firms have compensated for this decline by expanding their product line to substitute species such as farmed salmon, shark, tilapia, mahi mahi, orange roughy and catfish (Georgianna and Dirlam 2000). The majority of these processing facilities are in Massachusetts. Plants located in Massachusetts have a distinct competitive advantage because of their proximity to Boston's Logan airport (Georgianna and Dirlam 2000).

According to CBP data, in both New England (ME, NH, MA, RI, and CT) and the Mid-Atlantic (NY, NJ, DE, MD, VA, and NC) the number of seafood product preparation and packaging (processing) establishments remained stable from 1998 to 2001. In both regions, the number of fish and seafood wholesale establishments declined slightly across the period. However, the number of wholesale establishments exceeded the numbers of processing and market establishments in all four years. Fish and seafood markets outnumbered processing establishments in New England and the Mid-Atlantic, this number increasing slightly from 1998 to 2001 (Table 539, Figure 326, and Figure 327). The number of establishments in these sectors is generally lower than those reported by NMFS. The discrepancies are likely a result of differences in the ways in which processing and wholesale sectors were defined and data were collected and compiled by NMFS and the U.S. Census Bureau. The relative numbers of processing and wholesale establishments are similar in CBP and NMFS data, and indicate a more dominant presence of wholesalers over processors in New England.

NAICS Sector Participation by State

Table 540 – Table 549 report the number of establishments and annual payroll by state for NAICS industry sectors 3117 – Seafood Product Preparation and Packaging (includes 311711 – Seafood Canning, and 311712 – Fresh and Frozen Seafood Processing); 42246 – Fish and Seafood Wholesalers; and 44522 – Fish and Seafood Markets.

Maine and Massachusetts reported the greatest number of seafood product preparation and packaging establishments in New England, with Connecticut reporting the smallest number from 1998 to 2001 (Table 540). This sector generally remained stable across the period, with some increase in Maine in 1999 and 2000.

A greater number of fresh and frozen seafood processing establishments (311712) was reported in New England states than seafood canning establishments (311711) from 1998 to 2001. The majority of seafood canning establishments were reported in Maine, this sector diminishing for all states across the time period (Table 541). Fresh and frozen seafood processing establishments were relatively stable during these years, with some overall fluctuation (Table 542). Massachusetts reported the greatest number of processing establishments, followed by Maine.

The number of seafood product preparation and packaging establishments declined overall in the Mid-Atlantic states from 1998 to 2001 (Table 543). This sector increased slightly in New York and New Jersey over the period, remained stable in Delaware at one establishment, and declined further south

(Maryland, Virginia and North Carolina). Virginia reported the greatest number of processing establishments in all years.

The number of seafood product preparation and packaging establishments exceeded the number of seafood canning establishments in Mid-Atlantic states from 1998 to 2001. Seafood canning establishments increased in number while processing establishments decreased (Table 544 and Table 545). The number of seafood canning establishments in the Mid-Atlantic states was much lower than that reported in New England, while the number of processors was about the same. Virginia reported the greatest number of seafood preparation and packaging establishments in the Mid-Atlantic.

In New England, Massachusetts reported the highest number of fish and seafood wholesale establishments, followed by Maine (Table 546). Wholesalers declined in number in New England from 1998 to 2001, particularly in Maine. Mid-Atlantic states reported slightly fewer wholesale establishments than New England states, with New York reporting the greatest number, followed by Virginia (Table 547).

The number of fish and seafood markets increased in both New England and Mid-Atlantic states from 1998 to 2001 (Table 548 and Table 549). The Mid-Atlantic reported a higher number of markets than New England, with the majority of these establishments in New York. In New England, Massachusetts reported the greatest number of fish and seafood markets during this period.

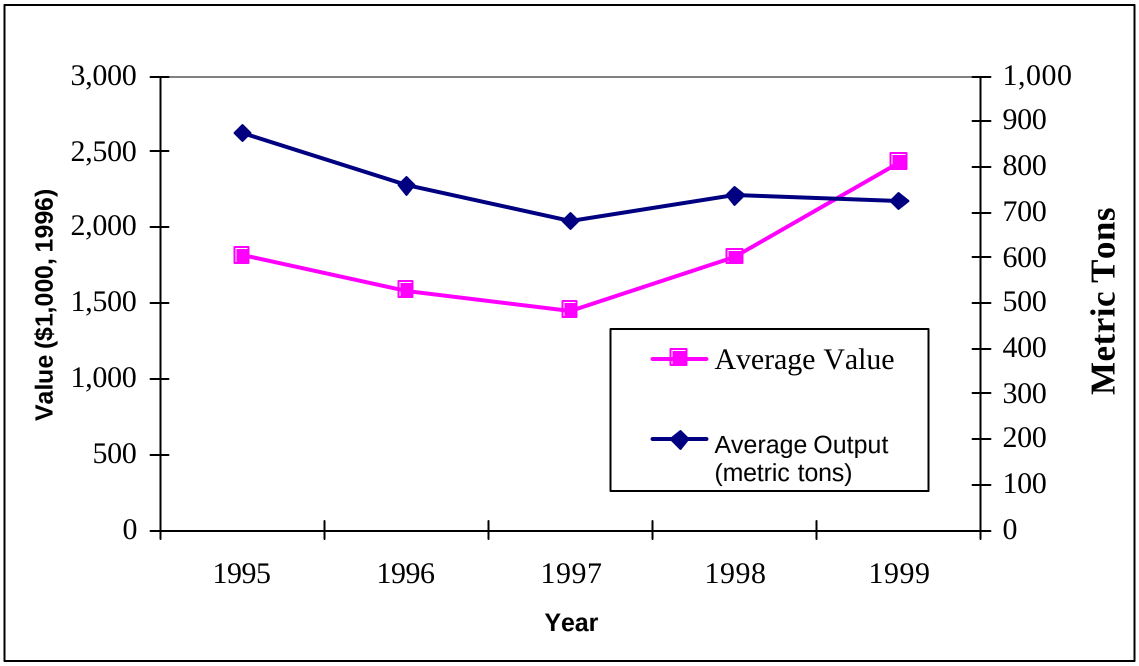

Figure 330 - Average value and output of New England frozen groundfish processed product, 1995-1999.

Source Data: NMFS unpublished data. Years denote calendar years.

Frozen groundfish processing has also declined in the region, and has been similarly impacted by a shortage of groundfish supply. However, most of this has been caused by a decline in Canadian landings after the closure of the Grand Banks to cod fishing in 1991. Rarely, if ever, are New England groundfish landings processed into frozen blocks. As imports of cod blocks declined, imports of pollock blocks increased and processors substituted pollock for cod in the production of breaded cooked fillets, portions and nuggets (Georgianna and Dirlam 2000). Since 1995 the number of frozen groundfish processing plants has remained stable, however, the average output of groundfish products per plant has declined. The average value of production declined until 1997 and then increased to its highest level in 1999, indicating increased demand for these products. Whether this trend will continue is uncertain. According to Georgianna and Dirlam (2000), consumer demand for fish sticks and portions has been declining since the mid-1980s.

As the processing sector diminished, the wholesale sector increased due to opportunistic processors who transferred their attention from the struggling processing sector to wholesaling. Imports of new products have offered profit potential to existing wholesalers and the potential to expand their product line. It is difficult to predict whether the wholesale sector will remain strong if inroads are made by firms that specialize in internet-marketing.

These trends correspond to those described by Georgianna and Dirlam (2000), who concluded the following about the current condition of the processing and wholesale trade sectors in New England:

1. *Boston processing firms have reinforced their position as the leading processing center in New England with all the associated brokerage, packing, transport and wholesaling activities that support processing.*

2. *With the possible exception of Gloucester, processors in other ports have not fared as well as those in Boston. Processors in smaller ports have either disappeared or now supply only small amounts to local customers. The same is true for Portland processors, who have not gained much from the success of the Portland display auction. Some New Bedford processors switched to monkfish, dogfish, and skate when landings of these species increased, selling them to a different set of customers from those that bought groundfish fillets. New Bedford has lost its dominance in flounder production, and Boston firms produce much of the port's fresh groundfish fillets with plants in New Bedford. Gloucester has maintained its small niche in fresh fillet production.*

3. *Long-term relationships or loyalties between processors, their suppliers, and their customers have continued to erode, contributing to the day to day variability of ex-vessel input prices on the one hand, and wholesale prices on the other. As we noted in 1993, when loyalties vanish, hard bargaining takes their place. Although operating and profit margins may not have changed radically on an annualized basis for the firms that still process groundfish, profit margins have become increasingly difficult to maintain in each transaction and over time.*

4. *The survival techniques we noted in 1993, including importing fresh fillets, exploiting niches, substituting for groundfish, focusing more on wholesaling, and closely watching the bottom line, have been extended, and became essential features of successful processors' purchasing and marketing strategies. Whereas in 1993, West Coast whole cod was something of a novelty, many processors today buy frozen whole fish from the West Coast and Alaska as a matter of course. And other new sources have been tapped to replace the shrinking supply of Canadian whole groundfish. As the shortage of the major groundfish species persisted and became accentuated, consumers have become willing to accept domestic and imported substitutes. Those firms that adapted to or promoted the change have been able to diversify their output and maintain volume. Many small processors, however, which were the most dependent on a relatively stable price structure and easy availability of whole groundfish, have not been able to finance the initiation and successful maintenance of these innovative strategies and have quit the industry. The number of processors has, accordingly, continued to decline.*

5. *Boston's advantages in transport costs and clustering far outweigh access to local landings of processors in other ports. Processors at other ports, dependent on local landings, have not found it easy to implement any of these survival strategies.*

6. *As the smaller firms have turned to wholesaling or simply vanished, not only are there fewer, and typically larger firms, but the processors' markets have become even more concentrated than in 1992. Market buying power has not, however, increased to the same extent. As far as we can tell, collusion among a few buyers, if it exists, has not been able to distort the auction process by depressing prices. In the wholesale and retail markets, small-scale customers, such as fish markets, have disappeared due to customer preference for convenience. The larger processing firms now compete among themselves for orders from even larger and more powerful super markets and food service companies. Increasing concentration in this declining market has not given large processing firms market power.*

7. *Though no processor can be said to enjoy an assured supply of whole fish, large firms are better able to draw on widely scattered geographic sources, and adapt to display auctions, now an indispensable source of domestic whole fish. The forces that are reshaping the structure of the processing industry are, therefore, real economies of scale.*

8. *In our previous report, we assumed that increased supplies of underutilized species such as monkfish, skate, and dogfish would very likely lead to intense price competition for a small share of established markets. This did not occur. Demand expanded for these and other species, followed by intensive fishing and then stock declines. These formerly underutilized stocks are now severely depleted, and U.S. Department of Commerce is preparing restrictive management plans for these species.*

9. *In our previous report, we observed an increase in the number of wholesaling firms and wholesaling employment, which we attributed to some firms switching from cutting fillets to simply buying and selling whole fish or previously processed fillets. We predicted that many of these entries into wholesaling were temporary, because some of the firms that switched from processing to wholesaling could not survive competitive pressure in the wholesaling sector. There is some but not conclusive evidence for this. Massachusetts Division of Employment and Training data show a decline in the rate of increase in the number of firms and an absolute decline in wholesaling employment.*

10. *An increase in groundfish stocks and landings resulting from stock recovery, could stabilize or may even reverse declines in employment and in the number of processing firms. Many of the changes in structure of groundfish processing due to supply shortages, for example, the dominance of Boston firms, the growing importance of display auctions, and weakened customer loyalty, will probably not be affected by increases in landings, when and if stocks recover.*

9.4.5 Fishing Community Information

9.4.5.1 Defining a Fishing Community

National Standard 8 requires the consideration of impacts on fishery dependent communities, where a fishing community is "a community which is substantially dependent on or substantially engaged in the harvesting or processing of fishery resources to meet social and economic needs, and includes fishing vessel owners, operators, and crew and United States fish processors that are based in such community." Current guidance on National Standard 8 specifies that communities are place-based: geographic units such as towns and cities that might fit the Census Bureau's definition of a "place." But actual methodological guidelines are still in the process of refinement and resources have not been directed towards the systematic and long-term collection of the kinds of baseline data needed to make such determinations in an empirically grounded way. For example, the weigh-out data and the permit files document landing and home ports, but these are not necessarily the same places where people live, where specific styles of and knowledge about fishing are practiced, or where the impacts of management are most strongly felt. It is important to note that fishing communities are not bounded or separated from the commerce and institutional apparatus of the larger cities and towns in which they are located. In fact, most fishing communities rely on a rather complicated network of business and social ties that extend well beyond the boundaries of their communities and often into other communities in the region.

In terms of the keywords "substantially dependent" and "substantially engaged," some have suggested, for example, that "substantial dependence" be measured in terms similar to the U.S. Department of Agriculture's criteria for determining whether rural communities are dependent on agriculture or logging. The Economic Research Service of the USDA, for example, classifies counties as farming dependent given a certain percentage of economic activity, in this case labor and proprietor income. Some of the sources of data to consider in making determinations of fishing dependence are thus supplied in current guidance, such as landings information or numbers of participants, and the sociocultural importance of the fishery. With respect to determining whether a community is "substantially engaged" in the harvesting or processing of a fishery, existing guidance does not provide clear criteria. While the application of a percentage of economic income activity may be an appropriate way to determine "substantial dependence", there may be other valid criteria for determining "substantial dependence." For example, it could be based on some minimum absolute level of activity (such as landings, number of vessels, etc.), or the presence of particular type of infrastructure (auctions, co-ops, state fish piers), or level of fishing activity (revenues, landings in weight, time spent fishing) that indicate a community is "substantially engaged" in fishing. This approach is used in this document to identify fishing communities that are "substantially engaged" in fishing.

This AHE and the SIA also discuss ports and groups based on gear or other characteristics in order to meet the requirements of the fishery impact statements to examine the impacts to all the individuals, communities, and other groups that participate in the fishery. However, assessment of the impacts of the measures proposed in this amendment includes not only those communities that meet the strict interpretation of fishing communities, but also other ports or port groups that will certainly experience impacts from the proposed action, for the impacts of Amendment 13 are predicted to be large in scale, affecting most places engaged in the groundfish fishery. Not all of these port groups necessarily meet the legal definition of a fishing community as promulgated through National Standard 8, which can be considered a subset of the broader ports and groups involved in the groundfish fishery. The Northeast Region has begun to make some headway in collecting the kinds of information and performing the kinds of analyses to support National Standard 8 determinations, most notably the Marine Fisheries Initiative (MARFIN) project on fishing communities and fishing dependency in New England (Hall-Arber, *et. al* 2001) and an updated port-profiles report for the Mid-Atlantic (McCay and Cieri, 2000). While some of these efforts include discussions of communities at larger levels than a "place," they still usefully provide context and background for understanding the impacts that fishing communities defined by National Standard 8 might experience. However, they do not identify all the fishing dependent communities that may require action under National Standard 8, an exercise which is still in progress. The SIA does, however, identify fishing communities based on a criteria for determining they are "substantially engaged" in harvesting or processing fish.

9.4.5.2 Identification of Amendment 13 Community Groups

In this amendment, coastal communities throughout the Northeast region are organized into primary and secondary *port groups* based on participation in the groundfish fishery since the 1994 fishing year. The port groups are assembled in such a way that additional information about them can be obtained by cross-referencing information about the sub-regions in the MARFIN Report (see 0 for a description of the MARFIN Report). The port groups identified in this document are essentially subsets of the sub-regions identified in the MARFIN Report. Since social and demographic statistics are often compiled at the county level, the port groups are divided by county or adjacent counties, depending on how the MARFIN sub-regions are structured, so that county-level data may be used to characterize changes in these communities and ports.

The port groups in this document are separated into primary and secondary groups. ***Primary groups*** are those communities that are substantially engaged in the groundfish fishery, as explained above, and which are likely to be the most impacted by groundfish management measures. ***Secondary groups*** are those communities that may not be substantially dependent or engaged in the groundfish fishery, but have demonstrated some participation in the groundfish fishery since the 1994 fishing year (FY94). Because of the size and diversity of the groundfish fishery, it is not practical to examine each secondary port individually, which is why most secondary ports are grouped with others in the same county or in geographically adjacent counties.

To identify primary and secondary port groups, groundfish landings by port were examined for the time period 1994-1999 from the dealer weighout database. Primary port groups represent the most active ports (currently) in the groundfish fishery and were selected based on groundfish landings greater than one million pounds annually since 1994 and/or the presence of significant groundfish infrastructure (auctions and co-ops, for example). In this Amendment and in the absence of specific guidance, these ports are considered fishing communities (as defined by the MSFCMA) because they have demonstrated a continued substantial engagement in fishing, here in particular the groundfish fishery. Secondary port groups consist of groups of ports in which some level of groundfish activity has been observed since 1994. This approach provides a way to consider the impacts of the Amendment 13 management measures on every port in which some amount of groundfish has been landed since 1994, and identifies some as fishing communities (as defined by NS8) based on substantial engagement. Though the analysis does not identify those fishing communities that meet the "substantial dependence" criteria, it is unlikely that the analysis misses any port which may be a fishing community based on the substantial dependence criteria because the impacts of the amendment are considered on nearly every port that has groundfish activity,.

It is important to remember that because significant geographical shifts in the distribution of groundfish fishing activity have already occurred, the characterization of some ports as primary or secondary ports may not reflect their historical participation in and dependence on the groundfish fishery. A good example is Rockland, Maine. Historically, Rockland would have been considered a primary groundfish port, landing large quantities of redfish, flounders, and other groundfish, and serving as an important groundfish processing port, and would have met the test for "substantial engagement." In recent years, however (since the establishment of the Hague Line in 1984 and the decline of groundfish stocks in the early 1990s), fishing activity in Rockland has shifted from groundfish to other species like lobster and herring. This also reflects the apparent concentration of the groundfish fishery around Portland, Maine and the loss of the fishery to many coastal communities in northern Maine.

The outline below lists the Amendment 13 primary and secondary port groups. Additional information about each of these groups appears in the following subsections. Primary multispecies ports are considered fishing communities under NS8.

I. DOWNEAST MAINE – WASHINGTON COUNTY

A. Primary Multispecies Port
1. None

B. Secondary Multispecies Ports
1. Downeast Maine: Jonesport, West Jonesport, Beals Island, Milbridge, Machias, Eastport, and Dyers Bay

II. UPPER MID-COAST MAINE – HANCOCK, WALDO, AND KNOX COUNTIES

A. Primary Multispecies Ports
1. None

B. Secondary Multispecies Communities
1. Upper Mid-Coast 1: Rockland, Port Clyde, Sprucehead, Owls Head, Friendship, Friendship Harbor, Camden, and Vinalhaven
2. Upper Mid-Coast 2: Stonington and Sunshine/Deer Isle
3. Upper Mid-Coast 3: Winter Harbor, Southwest Harbor, Bar Harbor, Northeast Harbor, and Northwest Harbor

III. LOWER MID-COAST MAINE – LINCOLN, SAGADAHOC, AND CUMBERLAND COUNTIES

A. Primary Multispecies Ports
1. Portland

B. Secondary Multispecies Ports
1. Lower Mid-Coast 1: New Harbor, Bristol, South Bristol, Boothbay Harbor, East Boothbay, Medomak, Southport, and Westport
2. Lower Mid-Coast 2: Cundys Harbor, Orrs Island, Yarmouth, Harpswell, East Harpswell, South Harpswell, Bailey Island, and Cape Elizabeth
3. Lower Mid-Coast 3: Sebasco Estates, Small Point, West Point, Five Islands, and Phippsburg

IV. SOUTHERN MAINE – YORK COUNTY

A. Primary Multispecies Ports
1. None

B. Secondary Multispecies Ports
1. Southern Maine: York, York Harbor, Camp Ellis, Kennebunkport, Kittery, Cape Porpoise, Ogunquit, Saco, and Wells

V. OTHER MAINE – all other coastal Ports in Maine

VI. STATE OF NEW HAMPSHIRE – ROCKINGHAM AND STRAFFORD COUNTIES

A. Primary Multispecies Ports
1. Portsmouth

B. Secondary Multispecies Ports
1. NH Seacoast: Rye, Hampton/Seabrook, Hampton, and Seabrook

VII. OTHER NEW HAMPSHIRE – all other coastal Ports in New Hampshire

VIII. GLOUCESTER AND NORTH SHORE – ESSEX COUNTY

A. Primary Multispecies Ports

1. Gloucester

B. Secondary Multispecies Ports

1. The North Shore: Rockport, Newburyport, Beverly/Salem, Beverly, Salem, Marblehead, Manchester, and Swampscott

IX. BOSTON AND SOUTH SHORE – MIDDLESEX, SUFFOLK, NORFOLK, AND PLYMOUTH COUNTIES

A. Primary Multispecies Ports

1. Boston

B. Secondary Multispecies Ports

1. The South Shore: Scituate, Plymouth, and Marshfield (Green Harbor)

X. CAPE AND ISLANDS – BARNSTABLE, DUKES, AND NANTUCKET COUNTIES

A. Primary Multispecies Ports

1. Chatham/Harwichport

B. Secondary Multispecies Ports

1. Provincetown
2. Other Cape Cod: Sandwich, Barnstable, Wellfleet, Woods Hole, Yarmouth, Orleans, and Eastham
3. The Islands: Nantucket, Oak Bluffs, Tisbury, and Edgartown

XI. NEW BEDFORD COAST – BRISTOL COUNTY

A. Primary Multispecies Ports

1. New Bedford/Fairhaven

B. Secondary Multispecies Ports

1. Other Bristol County: Dartmouth, and Westport

XII. OTHER MASSACHUSETTS – all other coastal Ports in Massachusetts

XIII. STATE OF RHODE ISLAND – WASHINGTON AND NEWPORT COUNTIES

A. Primary Multispecies Ports

1. Point Judith

B. Secondary Multispecies Ports

1. Western RI: Charlestown, Westerly, South Kingstown (Wakefield), and North Kingstown (Wickford)
2. Eastern RI: Newport, Tiverton, Portsmouth, Jamestown, Middletown, and Little Compton

XIV. OTHER RHODE ISLAND – all other coastal Ports in Rhode Island

XV. STATE OF CONNECTICUT – NEW LONDON, MIDDLESEX, NEW HAVEN, AND FAIRFIELD COUNTIES

A. Primary Multispecies Ports

1. None

B. Secondary Multispecies Ports

1. Coastal CT: Stonington, New London, Noank, Lyme, Old Lyme, East Lyme, Groton, and Waterford

XVI. OTHER CONNECTICUT – all other coastal Ports in Connecticut

XVII. LONG ISLAND, NEW YORK – SUFFOLK, NASSAU, QUEENS, AND KINGS COUNTIES

A. Primary Multispecies Ports
   1. Eastern Long Island: Montauk, Hampton Bay, Shinnecock, and Greenport

B. Secondary Multispecies Ports
   1. Other Long Island: Mattituck, Islip, Freeport, Brooklyn, Other Nassau County, and Other Suffolk County

XVIII. OTHER NEW YORK – all other coastal Ports in New York

XIX. NORTHERN COASTAL NEW JERSEY – MONMOUTH AND OCEAN COUNTIES

A. Primary Multispecies Ports
   1. None

B. Secondary Multispecies Ports
   1. Northern Coastal NJ: Point Pleasant, Belford, Long Beach/Barnegat Light, Barnegat, Highlands, Belmar, Sea Bright, and Manasquan

XX. SOUTHERN COASTAL NEW JERSEY – ATLANTIC AND CAPE MAY COUNTIES

A. Primary Multispecies Ports
   1. None

B. Secondary Multispecies Ports
   1. Southern Coastal NJ: Cape May, Wildwood, Burleigh, Sea Isle City, Ocean City, Stone Harbor, and Avalon

XXI. OTHER NEW JERSEY – all other coastal Ports in New Jersey

XXII. DELAWARE

XXIII. MARYLAND

XXIV. VIRGINIA

XXV. NORTH CAROLINA

9.4.5.3 Available Information

New information about the ports involved in multispecies fisheries has been made available since Amendment 7 and is utilized to the extent possible to analyze the impacts of the management alternatives under consideration in Amendment 13.

While it is not practical to include all of the newly available social and community information in this document, appropriate references are included in the various sub-sections for each community group so that readers and reviewers can access any additional materials in which they are interested. Most of these additional materials can be obtained by contacting the Council office.

Council Staff Initiatives

To improve the quantity and quality of social and economic data available for analyzing the impacts of groundfish management measures, the New England Fishery Management Council staff conducted a comprehensive query of fishery data for multispecies permit holders and hosted a series of ten social impact informational meetings throughout the region. Fishery data were gathered for multispecies permit holders from the permit, logbook, and dealer databases to generate a comprehensive database that provides fishery information (landings and revenues) from the 1994 fishing year to present by species group, multispecies permit category, vessel size, gear type, and port. These data were used to develop the description of the commercial harvesting sector in this document. These data will also be used in the Amendment 13 FSEIS to characterize fishing activity in the identified community groups.

The Social Impact Informational Meetings were intended to provide an opportunity to retrospectively discuss the social impacts of groundfish regulations since Amendment 5 with residents of affected fishing ports. Through this process, qualitative social impact information was obtained from more than 300 residents of affected fishing ports. In addition, a total of 61 comment sheets and four written letters were received from November 1, 2000 – January 7, 2001. This information was summarized and presented in a report from Council staff, which is referenced in this document. The information gleaned from the social impact informational meetings was derived from a non-representative sample of participants who chose to attend the meetings, which therefore cannot be considered necessarily representative of the views of all groups of stakeholders. However, this information can be used to identify general trends and perceptions of impacts.

Other Initiatives

Madeleine Hall-Arbor et al. received funding for a cooperative research project funded by the Saltonstall-Kennedy program and the Northeast Consortium. The program uses "community-based panels" composed of knowledgeable residents to provide socioeconomic information about the situation in which they live. While the results collected from community panel meetings should be considered non-random data (if the membership varies from meeting to meeting, and participants comprising the panels in each location do not necessarily represent the interests of all stakeholder groups), these panels may ultimately provide new/additional community information, review available information for accuracy and comprehensiveness, and provide insight useful for social impact assessment and resource management decision-making. In its early stages, a pilot program was funded for the communities of Gloucester, Downeast Maine, and South Shore of Massachusetts. Additional funding has recently been obtained to establish panels in Chatham and New Bedford, MA and Point Judith, RI.

A preliminary report for the panels project is included in the public comment section of this document. The themes of this initial report include concern over long-term regulatory impacts, lack of flexibility, impact on vessel condition/safety, impacts on shoreside businesses (infrastructure), impacts on supply and prices, economic costs, concerns and visions for the future. Gloucester panel members expressed concern over a likely domino effect that would occur to the commercial infrastructure resulting from cutbacks due to Amendment 13. Further concerns include a future inability to harvest stocks once they are rebuilt. The report on commercial infrastructure, although prepared by the Gloucester panel, is relevant for other ports concerned about the consequences of loss of commercial waterfront.

MARFIN and Other Community Profiles

Madeleine Hall-Arber et al. recently completed a report entitled, "*Fishing Communities and Fishing Dependency in the Northeast Region of the United States*" as part of a grant received through the Marine Fisheries Initiative (MARFIN). This MARFIN Report serves to lay the groundwork for regional and community data sharing among managers, fishing industry participants, and fishing communities. One unique feature of the MARFIN Report is that it attempts to characterize and quantify fishing dependence in various coastal communities. Measuring fishing dependence is complicated and requires consideration of fishing history, infrastructure, social institution, gentrification, etc.. These and other issues are described in the MARFIN Report.

While it is not practical to include the MARFIN Report as part of the Amendment 13 document (it is more than 400 pages), it should be noted that the MARFIN Report serves as an important reference for Amendment 13. Much of the community information presented in the MARFIN Report was referenced and utilized to the extent possible in the analyses and should be referenced accordingly in the review of this document. It is noted in the subsections below when additional information can be obtained by referencing the MARFIN Report as well as other relevant materials.

The MARFIN Report updates economic, social, and cultural data for fishing communities in New England (Maine – Connecticut), but does not include Mid-Atlantic states. Bonnie McCay et al. recently received funding to conduct similar research for the Mid-Atlantic states. McCay et al. propose to use demographic, ethnographic, survey, and participatory methods to develop community profiles for Mid-Atlantic fishing communities that are comparable in structure and scope to those used by Hall-Arber et al. This, combined with the MARFIN Report for the New England states, should provide a baseline database that can be used to assess the impacts of changes in the regulatory environment on fisheries and fishing communities now and in the future. Since the MARFIN and McCay et al. work is intended to represent a starting point for the systematic collection of social and community information, the data should be updated regularly as more information becomes available. The McCay et al. research is currently underway, and if available, will be included in the Final EIS for Amendment 13.

McCay and Cieri did recently complete general updates to port profiles for the Mid-Atlantic region as work funded by the Mid-Atlantic Council (McCay and Cieri, 2000). Resources were limited, but McCay and Cieri utilized NMFS landings data, 1990 census information, brief visits to ports and interviews with key informants, and other materials where available to characterize fishing ports in the Mid-Atlantic region. This information will serve as the most recent information for these ports until additional work is completed. Again, while it is not practical to include this report as part of the document, it should be noted that this report serves as an important reference and was utilized to the extent possible for Amendment 13 analyses. It is noted in the subsections below when additional information can be obtained by referencing the McCay and Cieri 2000 report.

Two additional reports containing social information and fishing community profiles serve as useful references for this document:

In October 1996, Aguirre International completed a report entitled, *An Appraisal of the Social and Cultural Aspects of the Multispecies Groundfish Fishery in New England and the Mid-Atlantic Regions*. This report was intended to be the result of the first phase of a comprehensive assessment of the social and cultural characteristics of fishing communities involved in the multispecies fishery. The recently completed MARFIN Report builds on the information presented in the Aguirre Report and includes more information about dependence, gentrification, and other important issues. However, the Aguirre Report is still useful for some historic information and for a snapshot of some fishing communities around the time of implementation of Amendments 5 and 7. The communities profiled in the Aguirre Report include:

- **Primary Ports:** Portland, ME; Gloucester, MA; Chatham, MA; New Bedford, MA; Point Judith, RI
- **Secondary Ports:** Stonington and Downeast, ME; Portsmouth, NH and southern Maine ports; Provincetown, MA; Newport, RI; Montauk, NY; Ocean City, MD; Tidewater, VA; Wanchese, NC.

Bonnie McCay et al. completed a report for the Mid-Atlantic Council detailing aspects of fishing communities in the Mid-Atlantic region in December 1993. This report was intended to serve as a source document for social and economic impact assessments and contains useful information about the fisheries in which vessels in these communities participate. While it does not include much social and community information (demographics, cultural information, etc.), the economic and fisheries information is helpful to characterize communities' involvement in and dependence on various fisheries, including the multispecies fishery. The report provides information on communities throughout the Mid-Atlantic area, including ports in New York, New Jersey, and Rhode Island, as well as Stonington, CT, New Bedford and Chatham, MA, Wanchese, NC, Ocean City, MD, and Hampton Roads, VA.

9.4.5.4 Conservation Law Foundation et al. v. Evans (Framework 33 Lawsuit)

Section 9.4.2.4.6 summarizes the potential cumulative impacts of the gear restrictions and area closures implemented through the settlement agreement on groundfish fishing activity based on port of landing in FY2000. Groundfish landings in some smaller ports, especially in Maine, are predicted to be affected 100%. Other ports with landings that are likely to be most significantly affected include Gloucester MA, Newburyport MA, Provincetown MA, Newport RI, Point Judith RI, New London CT, Stonington CT, and almost all major ports in New York and New Jersey. These impacts are based on observed landings in FY2000; actual impacts will depend on the ability of fishermen in the affected communities to find new areas in which to fish and adapt to the gear restrictions.

State	Port Landed	No. of vessels	% of total groundfish affected	Total groundfish landed	State	Port Landed	No. of vessels	% of total groundfish affected	Total groundfish landed
Maine	Bar Harbor	4	**100.0**	150,529	Massachusetts	New Bedford	150	**73.3**	30,729,098
	Boothbay Harbor	4	**79.3**	156,550		Newburyport	12	**85.5**	370,398

Source: NMFS Interim Action EA, June 2002, Table 6.30. Information is based on the 2000 fishing year.

9.4.5.5 Data Sources and Caveats

9.4.5.5.1 Landings and Revenues

Landings and Revenues By Port of Landing

Landings and revenues by multispecies permit holders as reported in the dealer weighout database are summarized in each section. These data are reported by dealers based on the area in which the fish were landed. This information is useful for characterizing the fishing activity occurring in specific ports and regions, as well as the relative importance of the areas as groundfish ports of landing. These data only reflect fishing activity by multispecies permits holders.

Total number of active multispecies vessels as reported in each Port of Landing section in the following discussion represents the total number of vessels holding multispecies permits and landing fish. For every given year, a certain number of these vessels did not demonstrate activity in the multispecies fishery. Total active multispecies vessels are associated with total landings, while multispecies vessels landing groundfish are associated with groundfish landings. The number of active multispecies vessels landing groundfish are a subset of the total number of active multispecies vessels, and represent the group of vessels that reported landings of groundfish in a particular region, county, or port.

Landings and revenues are reported for each port group and fishing community and grouped in the following categories:

- **Groundfish** includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.
- **Small Mesh Multispecies** includes silver hake, red hake, offshore hake, and ocean pout.
- **Small Mesh Non-Multispecies** includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.
- **Other Species** includes monkfish, fluke, dogfish, skates, cusk and all other species.
- **High Value Species** includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

Landings and revenues for less than three vessels were not reported for confidentiality reasons.

Landings and Revenues By Homeport

Fishing activity by permitted multispecies vessels is also summarized by home port. Home port, as described in the commercial harvesting section, home port is indicated on the permit and represents the port and state in which the associated vessel resides. The data were generated through a combination of the permit and dealer weighout databases. Two assumptions are made when examining these data:

1. Owners/captains of the vessels homeported in the community group live in the community group as well.
2. Revenues from the vessels homeported in the community group are returned to that same community group, no matter where the fish are landed and sold.

To the extent that the above assumptions hold true, these data better reflect the community's participation in and dependence on the multispecies fishery. For this discussion, dependence is defined as multispecies revenues as a percentage of total revenues from federally permitted vessels in a particular region, county, or port. For years in which fewer than three vessels reported groundfish landings, dependence was not reported as an exact percentage. Instead, the values calculated were rounded to nearest whole percentage points and reported as estimates. Again, these data do not reflect activity for vessels that do not possess any federal permits. As for data reported by port of landing, landings and revenues by home port were not reported for less than three vessels for confidentiality reasons.

The number of permitted multispecies vessels reported in each Homeport section represents the total number of vessels with multispecies permits, *including inactive vessels which did not report landings of any species*. The number of active vessels associated with total landings and revenues and groundfish-only landings and revenues are also reported. Again, the number of permitted multispecies vessels homeported in a particular place and reporting groundfish landings is low compared to the number of permitted multispecies vessels landing *any* species or the total number of vessels with multispecies permits.

9.4.5.5.2 U.S. Census

The decennial U.S. census, taken by the Census Bureau in years ending in 0 (zero), is a comprehensive census of population and housing in the United States. Article I of the Constitution requires that a census be taken every ten years for the purpose of reapportioning the U.S. House of Representatives. 1990 and 2000 census data are reported here to show changes in population, educational attainment, poverty and unemployment for counties within each port group. Population by race in each county is shown for 2000 only.

9.4.5.5.3 Fishing Industry Employment Data

Data on employment in the fishing industry is reported by North American Industry Classification System (NAICS) sectors for each county. Two databases provide data on number of establishments (businesses), annual payroll and other relevant information on business activity in specific industry sectors. These are the County Business Patterns and Nonemployer Statistics. Both databases use the same industry classification codes, described below.

North American Industry Classification System (NAICS)
The North American Industry Classification System was developed by representatives from the United States, Canada, and Mexico, and replaces each country's separate classification systems with one uniform system for classifying industries. In the United States, NAICS replaces the Standard Industrial Classification (SIC), a system that federal, state, and local governments, the business community, and the general public used from the 1930s until 1998.

Data on NAICS Sector 1141 (Fishing) was derived from the Nonemployer Statistics database, while data on NAICS Sectors 3117 (Seafood product preparation and packaging), 311711 (Seafood canning), 311712 (Fresh and frozen seafood processing), 42246 (Fish and seafood wholesaler), and 44522 (Fish and seafood markets) was taken from the County Business Patterns database. While CBP provides information on the Fishing sector, these data substantially underestimate the number of participants in fish harvesting industry, due to the large number of self-employed individuals. Likewise, the number of employers reported in the Nonemployer Statistics within the seafood processing, packaging, sales and marketing sectors is far lower than the actual number of active businesses, since most of these are incorporated businesses and thus would not be considered nonemployers.

The following industry sectors are discussed in relation to fishing communities and port groups that will be affected by Amendment 13. These NAICS code descriptions are provided by the U.S. Census Bureau:

NAICS 1141: Fishing
This industry comprises establishments primarily engaged in the commercial catching or taking of finfish, shellfish, or miscellaneous marine products from a natural habitat, such as the catching of bluefish, eels, salmon, tuna, clams, crabs, lobsters, mussels, oysters, shrimp, frogs, sea urchins, and turtles.
Data source in Amendment 13: Nonemployer Statistics

NAICS 3117: Seafood Product Preparation and Packaging
This NAICS Industry Group includes establishments classified in NAICS Industry 31171, Seafood Product Preparation and Packaging. Note that Industry Sectors 311711 (Seafood Canning) and 311712 (Fresh and Frozen Seafood Processing) are subsets of 3117.
Data source in Amendment 13: County Business Patterns

NAICS 31171: Seafood Product Preparation and Packaging
This industry comprises establishments primarily engaged in one or more of the following: (1) canning seafood (including soup); (2) smoking, salting, and drying seafoods; (3) eviscerating fresh fish by removing heads, fins, scales, bones, and entrails; (4) shucking and packing fresh shellfish; (5) processing marine fats and oils; and (6) freezing seafood. Establishments known as "floating factory ships" that are engaged in the gathering and processing of seafood into canned seafood products are included in this industry.
Data source in Amendment 13: County Business Patterns

NAICS 4224: Grocery and related product wholesalers
This NAICS Industry Group includes establishments classified in the following NAICS Industries: 42241, General line grocery wholesalers; 42242, Packaged frozen food wholesalers; 42243, Dairy product (except dried or canned) wholesalers; 42244, Poultry and poultry product wholesalers; 42245, Confectionery wholesalers; **42246, Fish and seafood wholesalers**; 42247, Meat and meat product wholesalers; 42248, Fresh fruit and vegetable wholesalers; 42249, Other grocery and related products wholesalers.
Data source in Amendment 13: County Business Patterns

NAICS 44522: Fish and Seafood Markets
This industry comprises establishments primarily engaged in retailing fresh, frozen, or cured fish and seafood products.
Data source in Amendment 13: County Business Patterns

9.4.5.5.3.1 County Business Patterns

County Business Patterns provides data on the total number of establishments, mid-March employment, first quarter and annual payroll, and number of establishments by nine employment-size classes by detailed industry for all counties in the United States and the District of Columbia.

CBP data are extracted from the Business Register, the Census Bureau's file of all known single and multiestablishment companies. The Annual Company Organization Survey and quinquennial Economic Censuses provide individual establishment data for multi-location firms. Data for single-location firms are obtained from various programs conducted by the Census Bureau, such as the Economic Censuses, the Annual Survey of Manufactures, and Current Business Surveys, as well as from administrative records of the Internal Revenue Service (IRS), the Social Security Administration (SSA), and the Bureau of Labor Statistics (BLS).

An establishment is a single physical location at which business is conducted or services or industrial operations are performed. It is not necessarily identical with a company or enterprise, which may consist of one or more establishments. When two or more activities are carried on at a single location under a single ownership, all activities generally are grouped together as a single establishment. The entire establishment is classified on the basis of its major activity and all data are included in that classification.

Total payroll includes all forms of compensation, such as salaries, wages, reported tips, commissions, bonuses, vacation allowances, sick-leave pay, employee contributions to qualified pension plans, and the value of taxable fringe benefits. Payroll is reported before deductions for Social Security, income tax, insurance, union dues, etc.

9.4.5.5.3.2 Nonemployer Statistics

Nonemployer Statistics summarizes the number of establishments and sales or receipts of companies with no paid employees. These nonemployers are typically self-employed individuals or partnerships operating businesses that they have not chosen to incorporate. A nonemployer business is one that has no paid employees, has annual business receipts of $1,000 or more ($1 or more in the construction industries), and is subject to federal income taxes. (Self-employed owners of incorporated businesses typically pay themselves wages or salary, so that the business is an employer.) Nonemployers do not get census questionnaires and are not reflected in any of the other Core Business Statistics reports or detailed sector-specific reports.

The universe of nonemployer establishments is created annually, in part, as a by-product of identifying the Census Bureau's business employer universe. The business employer universe is known as the Business Register. The Business Register attempts to cover all businesses in the United States with paid employees. If the Census Bureau receives information about a particular business establishment through administrative records, but does not receive any indication that it has paid employees, it becomes part of the potential nonemployer universe. Name, address, industry classification, and receipts are available for each potential nonemployer record. These data are obtained chiefly from the annual business income tax returns filed with the Internal Revenue Service (IRS).

All of the Agriculture, Forestry, Fishing, and Hunting sector, except crop and animal production, are covered in nonemployer statistics; these industries typically are not covered in other Census Bureau economic programs.

In accordance with U.S. Code, Title 13, Section 9, no data are published that would disclose the operations of an individual business. For U.S.- and state-level data, the number of establishments and receipts in a data cell is published only if it contains three or more nonemployer businesses. For county- and MSA-level data, the number of establishments and receipts in a data cell is published only if it contains ten or more nonemployer businesses. According to Census Bureau disclosure rules, when a small number of nonemployer businesses have a dominant share of receipts in a data cell, establishments and receipts are suppressed to protect the dominant businesses.

Receipts includes gross receipts, sales, commissions, and income from trades and businesses, as reported on annual business income tax returns. Business income consists of all payments for services rendered by nonemployer businesses, such as payments received as independent agents and contractors.

Generally, an establishment is a single physical location at which business is conducted or services or industrial operations are performed. However for nonemployers, each distinct business income tax return filed by a nonemployer business is counted as an establishment.

9.4.5.6 Maine

This section summarizes available information about fishing communities in the state of Maine and includes references to the appropriate documents, which are not included as part of this document.

In 1998, the Maine Department of Marine Resources (ME DMR) contracted for a series of focus group meetings to discuss the impacts of Amendments 5 and 7 on various communities throughout the state. Focus group meetings were conducted in Portland, Wiscasset, Rockland, Stonington, and Jonesport, and the report from these meetings is included as part of an overall report entitled, *Perspectives from Five Ports: Impacts of Amendments 5 and 7 to the Northeast Multispecies Fishery Management Plan*. This report provides some useful information about these communities, including perspectives from residents in the communities about the impacts of Amendments 5 and 7. The larger report also includes information about this history of Maine's groundfish fishery, economic aspects of the fishery, the composition of Maine's fishing fleet, the role of the Portland Fish Exchange, support from the city of Portland, and the performance of Maine's groundfish industry over time.

Health care and the ability for the fishing industry to find and keep affordable health insurance is an important social issue. In the Spring of 1999, Caritas Christi Health Care System funded the development of a report entitled, *Health Survey of the Fishing Population in Maine*. The survey project in the state of Maine was part of a regional effort to determine the need for more affordable heath insurance for fishing families. It was initiated by leaders in the Massachusetts Fishermen's Partnership and was part of a continuing effort to expand the benefits of the Fishing Partnership Health Plan to other states in the region. A random sample of 2,500 permit holders in the state were selected for the survey, and 168 surveys were returned, providing information on 308 adults and 169 children. The survey was conducted in the Summer of 1998, and based on the results, approximately 44% of the fish harvesting population in the state were without health insurance at that time. This Report can be referenced for additional important information about fishing families in many communities throughout Maine, including information about employment and household characteristics, health insurance status, cost of health care, and other information related to the use of health services.

ME DMR completed a report in 2001 detailing a developmental strategy for the Maine seafood industry, which also provides additional useful socio-economic information. This report, entitled, *Maine Seafood Harvesting and Processing: A Developmental Strategy*, was intended to serve not only as a reference for impact assessments, but also for Maine's Joint Standing Committee on Business and Economic Development. It presents information about the fishing industry in Maine and provides the industry's perspectives on the barriers and opportunities for future growth in the state. The report provides a useful overview of Maine's most important fisheries; recommendations in the report are not those of ME DMR, but of residents of various fishing communities throughout the state.

Recently, ME DMR contracted with Market Decisions, Inc. to conduct a survey about the impacts of recent groundfish regulations in the state of Maine. In August 2002, Market Decisions released a Research Report entitled, *DMR Groundfish Regulation Impact Survey*, includes a substantial amount of important and helpful information to consider when analyzing the social and community impacts of future groundfish regulations. The impact survey is based on telephone interviews conducted during August 2002 with 168 vessel owners, shoreside business owners, and hired captains and crew in Maine's groundfish industry. Response rates were estimated to be no lower than 55.6%. In terms of sampling error, the percentages reported for the vessel owners are estimated to be within +/- 8% of all active groundfish permit holders in the state of Maine. The sampling error among shoreside business owners is estimated at +/- 8.8%. The data for the captains and crew is less comprehensive and should be considered in a qualitative sense, suggesting trends rather than absolute percentages.

The results from the Market Decisions survey provide useful descriptive fishery, social, and economic information, including: vessel and crew characteristics; port of landing; business practices; income; dependence on groundfish; impacts of recent groundfish regulations; priorities for assistance programs; and health insurance. Some of the key findings of this survey include:

- A large majority of vessel owners, captains, and crewmembers indicated that groundfish regulations have a negative impact on their businesses.
- Most often, vessel owners employ 1-2 people, and most shoreside owners employ more than 10 people in their business year-round.
- After May 1, 2002, only 30% of vessels were allocated more than 80 DAS.
- Under the new regulations, 75% of vessels lost more than 20 DAS.
- About 75% of shoreside business owners fully depend on the fishing industry.
- More than 75% of vessel owners invested in new gear to meet the 2002 regulations, and 7% invested in new groundfish permits.
- To finance their business, many vessel owners and shoreside business owners use alternative means of financing, including the use of family and personal savings, home equity loans, and personal credit cards.
- A majority of respondents are covered by health insurance – 69% of vessel owners, 79% of shoreside business owners, and 62% of hired captains and crew). A majority of spouses are also covered by health insurance.
- Just 5% of vessel owners provide health insurance for their employees; less than half of shoreside business owners provide health insurance to their employees.
- Forty percent of vessel owners indicted that they need at least 88 DAS to break even in their groundfish business.
- More than 1/3 of respondents had income from non-fishing activities (37% of vessel owners, 47% of shoreside business owners, and 33% of hired captains and crew). These activities cover a wide range of occupations.
- Twenty-seven percent of respondents receive income from just groundfishing (23% of vessel owners, 32% of shoreside business owners, and 38% of hired captains and crew).
- A majority of respondents thought that new groundfish regulations would make them get out of the industry or make their work more difficult.
- More than 1/3 of vessel or shoreside business owners are considering relocating their business, with most considering a move to Massachusetts.

Market decisions identified two prominent groups of respondents:

(1) a group consisting of smaller vessels with businesses that employ fewer people and have less business-related debt and investment. This group of individuals is more likely to have been allocated less than 88 DAS and fish less than 88 DAS. They are less likely to offer their employees health insurance and more likely to derive income from other marine and non-marine activities. This group represents about 20-30% of the survey respondents. The impacts on this group are likely to be more personal. The overall effect on this group will be to make a situation where many are doing whatever possible to hold onto their groundfish business even more difficult.

(2) a group consisting of larger vessels with businesses that employ more people and have larger business-related debt and investment. This group of individuals is more likely to have been allocated more than 88 DAS and actually fished more than 88 DAS (the percentage increases as the amount of debt and investment rises). They are more likely to offer their employees health insurance and less likely to derive income from other marine and non-marine activities. This group represents about 20-30% of respondents and more of the people who are directly involved in the groundfish fishery. They are investing in the business for better or worse and have significantly more business debt. The impact on this group will go beyond the direct financial impact on themselves and their family. It will lead to a reduction in household income, but it will also affect others in their business. It will also affect the larger business community, as it will become more difficult for them to pay off loans they have taken out on their business. They are more dependent on their groundfish business as their sole source of income, reducing the ability to use other sources of income to offset any losses. Much of this group is likely to relocate to other areas, potentially only shifting the problem to new ports or having to leave the industry due to factors such as the inability to pay off their debt and bankruptcy. This will have repercussions for other industries including shoreside businesses.

The state of Maine has established an informative website with information about the state's fisheries and fishing-related industries. A directory of fishing-related businesses can be accessed, as well as a species-specific database of related industries and products. The "news" and "links" on the website are also useful and informative. This information can be obtained at www.maineseafood.org.

Demographic Profile of Maine

MAINE	1990		2000		Percent change
Population (total individuals)	1,227,928		1,274,923		3.8%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	78.8%		85.4%		Difference = 6.6%

Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	40,722	6.6%	31,165	4.8%	-23.5%

Table 551 - Population, education, poverty and unemployment statistics for the state of Maine (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Maine increased by 3.8% from 1990 to 2000 (Table 551). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 6.6% over the course of a decade. While the number of families below the poverty level increased slightly (1.1%), the unemployment rate declined, from 6.6% to 4.8% of the civilian labor force, aged 16 years and older.

Table 552 - Population by race in Maine counties, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

The population of Maine is 96.9% white, with 1% of the individuals being of two or more races and just over 2% represented by all other races combined (Table 552). The population in Washington County (Downeast Maine) is 93.5% white, 4.4% American Indian and Alaska Native, 1.1% of two or more races, and under 1% black/African American, Asian, Hawaiian/Pacific Islander, other races, and Hispanic/Latino of any race. Washington has the highest percentage of non-whites of any of the Maine counties. Hancock, Waldo, and Knox counties, comprising Upper Mid-Coast Maine, are among the counties with the highest percentage of white individuals in the population, with whites composing 97.6%, 97.9% and 98.3% of their populations, respectively. Lincoln County has the highest percentage of whites of all counties in Maine, at 98.5%. Cumberland and Sagadahoc counties, which together with Lincoln compose the Lower Mid-Coast Maine group, are slightly more racially diverse. In Cumberland, 95.7% are white, 1.1% black/African American, 1.4% Asian, and 1.1% of two or more races. In Cumberland and Sagadahoc counties, 1% or more of the total populations are composed of Hispanic/Latino individuals of all races. York County, which is considered Southern Maine for the purposes of these analyses, has a population with a similar racial profile to those of Hancock and Waldo counties.

9.4.5.6.1 Downeast Maine

The downeast Maine port group is a secondary multispecies port group that includes Jonesport, West Jonesport, Beals Island, Milbridge, Machias, Eastport, and Dyers Bay. All of these ports are in Washington County.

MARFIN – The MARFIN Report provides profiles for several communities in the Downeast Maine group including Beals Island, Jonesport, and Eastport. It also includes a general profile of Washington County and the Downeast Maine sub-region. These profiles should be referenced for social and demographic data not contained in this document.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Ellsworth, Maine on December 7, 2000, and residents from several downeast communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of downeast communities relate to the loss of flexibility, long-term community impacts from the loss of fishing-related infrastructure, and a feeling of dislocation from the federal fisheries management process. The groundfish regulation that has produced the most significant social impacts for this community group may be a regulation that has not even been implemented yet. Those who commented at the social impact informational meeting are extremely concerned about the potential long-term social and community impacts of any action designed to reduce latent effort in the groundfish fishery. Please reference the complete meeting report for additional discussion of these and other important social impact issues.

Washington County	1990		2000		Percent change
Population (total individuals)	35,308		33,941		-3.9%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	73.2%		79.9%		Difference = 6.7%
Poverty* (Number of families)	1,444		1,319		-8.7%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	1,614	10.8%	1,312	8.5%	-18.7%

Table 553 - Population, education, poverty and unemployment statistics for Washington County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

While the total population of Maine increased from 1990 to 2000, the population in Washington County (Downeast Maine) declined 3.9% during this period (Table 553). The increase in Washington high school graduates or higher from 1990 to 2000 mirrored the state-wide increase. However, the total percentage of Washington County citizens 25+ years who graduated from high school or higher was lower than the state-wide percentage in both 1990 and 2000, with 85.4% of the total population in Maine and 79.9% of the total population in Washington County reaching this education level. The number of families below the poverty level decreased nearly 9% across the decade and unemployment fell 18.7%. Despite this decrease in unemployment, the unemployment level in Washington County remained high, at 10.8% of the civilian labor force unemployed in 1990 and 8.5% in 2000. Further loss of jobs and income related to Amendment 13 may have particularly strong effects in Downeast Maine.

Fishing Industry Employment in Downeast Maine

The number of individuals employed in fishing (harvesting fish) in Downeast Maine (Washington County) increased 14% from 1997 to 2000 (Table 554). The average annual payroll for nonemployers in the fishing sector (i.e., individual fishermen) in Washington County was about $33,529 in 2000. The fish and seafood wholesale sector had the greatest number of establishments after fishing in all years from 1998 to 2001. The number of establishments in this sector decreased nearly 22%, from 32 in 1998 to 25 in 2000, with an average annual payroll of $51,680 per establishment in 2000. Seafood product preparation and packaging establishments ranged from 8 to 10 during the time period. The number of establishments in fresh and frozen seafood processing and seafood canning remained relatively constant from 1998 to 2000, not exceeding five establishments in either of the sectors during a given year. There was only one fish and seafood market reported in Washington County during each year.

NAICS Code and Description		1997	1998	1999	2000	2001

Fishing Activity in Downeast Maine

By Port of Landing

Table 555 summarizes landings and revenues by multispecies permit holders in Downeast Maine from the dealer weighout database. In Downeast Maine, there are many more non-multispecies permitted boats (e.g. state waters boats, lobster boats), so overall fishing activity in the area is much greater than these data suggest.

The number of permitted multispecies vessels landing fish in Downeast Maine remained relatively consistent from 1994 to 2001, with some decline towards the later years of the time period. Of these vessels, few were active in the groundfish fishery, this number declining across the time period from four in 1994 to one in 2001.

Total landings in Downeast Maine generally increased at an average annual rate of 10.3%. Total revenues increased at an even greater rate due to a dramatic increase in landings of high value species. From 1994 to 2001, the highest landings were generally composed of "other species," which *may* include monkfish, fluke, dogfish, skates, cusk or species not included in the categories described below (Table 555). Groundfish landings and revenues fluctuated from year to year, with an overall declining trend from 1994 to 2001. Groundfish were the second greatest component of the total landings throughout the time period, after Other Species.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 555 - Landings and Revenues from Multispecies Permit Holders in Downeast Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

Table 556 summarizes fishing activity by vessels homeported in Downeast Maine. The number of permitted multispecies vessels homeported in Downeast Maine and reporting groundfish landings is low compared to the number of permitted multispecies vessels landing *any* species or the total number of vessels with multispecies permits.

Total landings by vessels homeported in Downeast Maine fluctuated from 1994 to 2001, with an overall increasing trend. The greatest change occurred from 1994 and 1995, when landings more than doubled. Total revenues exhibit a similar trend. Groundfish landings and revenues also fluctuated from 1994 to 2001, with a generally increasing trend across the time period. The greatest declines in groundfish landings occurred from 1998 to 2000, when the number of permitted multispecies vessels landing groundfish and homeported in Downeast Maine decreased. Groundfish dependence in Downeast Maine declined from 45.2% to near-zero in 2000, with a slight increase to 5.3% in 2001. The number of permitted multispecies vessels landing groundfish decreased from 1994 to 2001, while the total number of active permitted multispecies vessels (landing any species) remained relatively stable across the time period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.6.2 Upper Mid-Coast Maine

The port groups in Upper Mid-Coast Maine fall within three counties – Hancock, Waldo and Knox counties. The following is a description of the population, education, poverty, unemployment and fishing industry participation in these counties.

Hancock County	1990		2000		Percent change
Population (total individuals)	46,948		51,791		10.3%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	83.3%		87.8%		Difference = 4.5%
Poverty* (Number of families)	855		997		16.6%

Table 557 - Population, education, poverty and unemployment statistics for Hancock County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Hancock County includes the ports of Stonington and Sunshine/Deer Isle (Upper Mid-Coast 2), and Winter Harbor, Southwest Harbor, Bar Harbor, Northeast Harbor, and Northwest Harbor (Upper Mid-Coast 3). The total population in Hancock County increased more than 10% between 1990 and 2000 (Table 557). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 83.3% in 1990 to 87.8% in 2000, a rise of 4.5 percentage points over the period. The number of families living in poverty increased 16.6%. Unemployment remained low relative to Washington County but increased 3.4% over the decade.

Waldo County	1990		2000		Percent change
Population (total individuals)	33,018		37,252		12.8%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	77.4%		84.6%		Difference = 7.2%

	1,504	9.6%	1,040	5.7%	-30.9%

Table 558 - Population, education, poverty and unemployment statistics for Waldo County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

While the total population in Waldo County is smaller than that in Hancock County, it expanded at a greater rate from 1990 to 2000, with a 12.8% increase (Table 558). The percent of the population 25 years and over graduating from high school and above increased from 77.4% to 84.6%, but remained below the educational attainment level in Hancock County. Number of families in poverty decreased 3.8% and unemployment decreased substantially, from 9.6% of the civilian labor force in 1990 to 5.7% in 2000.

Knox County	1990		2000		Percent change
Population (total individuals)	36,310		39,618		9.1%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	80.8%		87.5%		Difference = 6.7%
Poverty* (Number of families)	806		695		-13.8%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	1,258	7.2%	676	3.4%	-46.3%

Table 559 - Population, education, poverty and unemployment statistics for Knox County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Knox County includes the ports of Rockland, Port Clyde, Sprucehead, Owls Head, Friendship, Friendship Harbor, Camden and Vinalhaven (Upper Mid-Coast 1). In Knox County, a county with a similar population size as Waldo County, population increased about 9%, from 36,310 to 39,618 between 1990 and 2000 (Table 559). Educational attainment (high school or higher) increased about 6.7 percentage points over the decade. Relative to Waldo County, Knox has a low poverty rate and the number of families in poverty decreased nearly 14% from 1990 to 2000. The number of unemployed also decreased more than 46% to a low level of 676, or 3.4% of the civilian labor force, in 2000. Based on these data, it appears that Knox County has experienced economic and social growth since 1990.

Fishing Industry Employment in Upper Mid-Coast Maine

Hancock County
The number of individuals employed in fishing (1141) remained relatively consistent from 1997 to 2000, averaging 1,244 during that period (Table 560). The average annual payroll for individuals in the fishing sector was $44,524 in 2000. Of the remaining fishing-related industry sectors, the fish and seafood wholesale sector comprised the greatest number of establishments, with an average of 37 establishments from 1998 to 2000, and a decrease to 33 in 2001. Seafood product preparation and packaging and seafood canning remained stable but small sectors, with 3-5 establishments each in every year from 1998 to 2001. One establishment was reported in the fresh and frozen seafood processing sector in 1998-2000, increasing to 2 in 2001. No fish and seafood markets were reported in Hancock County in 1998 and 1999, and only 1 in 2000 and 2001. In general, the fishing industry has remained an active, stable presence in Hancock County since the late 1990s.

NAICS Code and Description		1997	1998	1999	2000	2001

Waldo County

The number of reported establishments in the fishing sector is much lower in Waldo County than in Hancock or Knox counties, increasing from 129 in 1997 to 146 in 2000 (Table 561). The average annual payroll for an individual in the fishing sector was $37,760 in 2000, lower than the average in Hancock County. The number of fish and seafood wholesale establishments declined 50%, from 8 in 1998 to 4 in 2001. Other seafood and fishing related sectors have a very limited presence in Waldo County, although participation in seafood product preparation and packaging and fish and seafood markets increased slightly or remained stable between 1999 and 2001. Overall, the fishing industry in Waldo County is small, with the harvesting sector increasing slightly, fish and seafood wholesale declining, and other sectors remaining relatively stable.

NAICS Code and Description		1997	1998	1999	2000	2001
1141* Fishing	Sum of Total Establishments	129	144	139	146	NA

Data source: U.S. Census Bureau – Nonemployer Statistics (NES) and County Business Patterns (CBP)

Knox County

The number of individuals employed in the fishing sector in Knox is similar to that in Hancock, increasing steadily (an annual average of about 1%) from 1,252 in 1997 to 1,293 in 2000 (Table 562). However, the average annual payroll for fishers in Knox County greatly exceeds that of Hancock and Waldo counties, at $61,061 in 2000. The primary target stocks for the port group Upper Mid-Coast 1 (Knox County) are small-mesh non-multispecies, these being primarily herring, while multispecies permit holders in Upper Mid-Coast 2 and 3 (Hancock County) have a greater dependence on groundfish as a percentage of their total revenues from fishing. The fish and seafood wholesale sector, which has a greater number of establishments than other fishing-related sectors (besides the harvesting sector) in Knox County, decreased in size, declining 17% 1998 to 2001. No seafood canning establishments were reported in Knox County. The number of establishments reported in each year for the seafood product preparation and packaging, fresh and frozen seafood processing, fish and seafood markets sectors ranged from 2 to 3 from 1998 to 2001.

NAICS Code and Description		1997	1998	1999	2000	2001
1141* Fishing	Sum of Total Establishments	1,252	1,269	1,277	1,293	NA

9.4.5.6.2.1 Upper Mid-Coast 1, Maine

The Upper Mid-Coast 1, Maine group is a secondary multispecies port group that includes Rockland, Port Clyde, Sprucehead, Owls Head, Friendship, Friendship Harbor, Camden, and Vinalhaven. All of these communities are in Knox County.

MARFIN – The MARFIN Report provides detailed profiles for several communities in the Upper Mid-Coast 1 group including Rockland and Vinalhaven. The Report also includes a general profile of the Upper Mid-Coast Maine sub-region, Waldo County, Knox County, and Hancock County, the counties in which the communities in the Upper Mid-Coast groups are located. These profiles should be referenced for social and demographic data not contained in this document.

Upper Mid-Coast 1, Maine is not a primary port group for groundfish activity, but is one of the areas of particular interest in this document, primarily because concerns about and impacts on this community group are likely to be reflective of many communities throughout Maine. Knox county is the smallest county in Maine, but has the largest commercial fishing industry. Rockland was first known as “shore village” until it was incorporated as Rockland in 1854. The MARFIN report describes that in the late 1800s, Rockland was a leading port for the export of lime rock.

Rockland used to be an important groundfish and harvesting port, with two offshore fleets that fished in Canadian waters. After the Hague Line was established in 1984 and US fishermen were excluded from Canadian fishing grounds, these offshore fleets eventually disappeared. According to the MARFIN Report, Rockland used to be renowned for redfish, before the stock collapsed. Today, herring and lobster are the primary fisheries in Rockland. MARFIN found that there are about 30 lobster boats in Rockland, 5 purse seiners fish for herring, and a few groundfish trawl and gillnet vessels. MARFIN reported that some individuals with larger boats and groundfish permits have developed innovative ways to use different gear at sea to harvest groundfish, scallops and shrimp. Some former groundfish fishermen have switched to lobstering when possible.

The 1990 Census determined that 7,972 people lived in Rockland, and only 63 were non-white. Estimates varied greatly in the MARFIN Report related to the number of fishermen in the Rockland area (40 to 250). Employment that is indirectly dependent on fishing such as trucking and bait supply is high. Rockland has lost several processing plants over the years, and now the city is principally a depot for the transport of fish and lobster to other places. Although there are numerous outlets for employment in the area, the MARFIN Report considers Rockland an essential provider to the fishing industry due to it's role as a major transporter of herring as lobster bait and transshipment of lobsters. Fishing is considered to be very important in Rockland, and lobster landings are the highest in the state. MARFIN cited that there are numerous fishery-related groups in the area. For example, the Maine Sea Grant Cooperative Extension at the University of Maine is active with outreach programs and industry members in the area. Rockland is not considered to be a popular recreational fishing center, mostly because the fishing grounds are relatively far from shore.

Vinalhaven is the other major port in the Upper Mid Coast 1 region of Maine. Vinalhaven is an island community 15 miles off the coast. The MARFIN Report found that seafood has always played a major role in the economy of this island, and in the days of tub trawling and dragging, Vinalhaven was a major groundfish port. Effort from foreign factory trawlers in the 1960s was blamed for the demise of the Vinalhaven groundfish fleet in the MARFIN Report. Currently, there is no groundfish activity in Vinalhaven. Today, 8-10 % of all lobsters landed in Maine are from Vinalhaven, and many of them are being frozen for shipment around the US and worldwide. In addition to lobsters, some rock crab, sea scallops, and herring are also landed here.

Recent interviews in the MARFIN Report suggest that there are about 1,200 residents in Vinalhaven, and as many as 2,400 visitors in the summer. Two-thirds of the population is employed as lobstermen, and the rest are involved in tourism. MARFIN reported that fishing is the center of life in Vinalhaven. It is estimated that two-thirds of the residents are members of fishing families. There are about 300 relatively small lobster vessels, a few urchin divers, and two purse seiners. In 1997, 58 vessels homeported in Vinalhaven held federal permits. There is little extra room for recreational vessels in Carver Harbor in Vinalhaven, so recreational fishing effort is non-existent.

Social Impact Informational Meetings – Council staff conducted social impact informational meetings in Ellsworth, Maine on December 7, 2000 and Portland, Maine on November 13, 2000. A few residents from communities in Upper Mid-Coast 1 attended these meetings and submitted comments. The summary from these meetings can be found in Appendix I.

Fishing Activity in Upper Mid-Coast 1, Maine

By Port of Landing

The total number of active permitted multispecies vessels landing fish in Upper Mid-Coast 1 ranged from 26 to 30 in each year from 1994 to 1999, increasing in 2000 and 2001 (Table 563). Approximately half of these permitted vessels reported landings of regulated multispecies between 1994 and 2001, the number of multispecies vessels landing groundfish increasing about 67% from 1994 to 2001. Landings in all species categories generally increased from 1994 to 2001. Total landings rose from 1,745,000 pounds in 1994 to a peak of 42,739,000 pounds in 1997, declined 40.8% from 1997 to 1998, and remained relatively stable until 2001. Groundfish landings, which typically made up the second greatest component of total landings across the time period, increased or remained steady across the time period. Small mesh non-multispecies, which generally comprised the greatest percentage of the total landings across the time period, increased dramatically from 862,400 pounds in 1994 to 41.5 million pounds in 1997. Small mesh non-multispecies landings, most likely dominated by herring, declined about 42% from 1997 to 1998 and remained fairly steady 1998 through 2001. Landings of other species generally increased across the time period, with 2001 landings 2.3 times greater than 1994 landings. High value species landings increased from 1994 to 1995 but generally declined from 1995 through 1999, with a slight increase in 2000 and 2001. Small mesh multispecies were the smallest component of total landings in Upper Mid-Coast 1 throughout this period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001
Total Number of Active Multispecies Vessels	26	30	30	25	27	28	43	38

Table 563 - Landings and Revenues from Multispecies Permit Holders in Upper Mid-Coast 1, Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The total number of permitted multispecies vessels homeported in Upper Mid-Coast 1 peaked at 88 vessels in 1996, decreasing by about 50% in the following year as a result of the Amendment 7 capacity reduction efforts (Table 564). From 1997 to 2001, the number of multispecies permits in Upper Mid-Coast 1, Maine, increased 42%, from 45 to 64. The number of multispecies vessels landing any species increased as a percentage of total permitted vessels, from 38% of the total number in 1994 to 53% in 2001. The number of active vessels declined from 1996 to 1997, remained stable throughout the next three years, and increased in 2001. The landings by these vessels increased an annual average of 53.8%, while total revenues increased only 5.2% due to a decrease in landings of high value species.

The number of permitted multispecies vessels in Upper Mid-Coast 1 reporting landings of groundfish remained consistent from 1994 to 2000, averaging about 17 vessels in each year. Twenty-three Upper Mid-Coast 1 vessels landed groundfish in 2001. Groundfish landings and revenues increased from 1994 to 1995, declined 51.6% from 1995 to 1996, and generally increased after 1996 to a peak of 2,231,800 pounds in 2001. Dependence on groundfish as a component of total fishing revenues by multispecies permit holders in Upper Mid-Coast 1 averaged 33.7% across the time period, dropping from around 50% in 1995 to 23% in 1996, and increasing to 36.6% in 2001. The decline in dependence in 1996 coincides with the lowest groundfish landings of the time period reported during that year and an increase in reported landings of small mesh non-multispecies (herring).

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.6.2.2 Upper Mid-Coast 2, Maine

The Upper Mid-Coast 2, Maine group is a secondary multispecies port group that includes Stonington and Sunshine/Deer Isle. These communities are in Hancock County.

MARFIN – The MARFIN Report provides a detailed profile for Stonington and Deer Isle. It also includes a general profile of the Upper Mid-Coast Maine sub-region and Hancock County, the county in which Stonington and Deer Isle are located. These profiles should be referenced for social and demographic data not contained in this document.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Ellsworth, Maine on December 7, 2000, and residents from Stonington and Deer Isle attended and submitted comments. The summary from this meeting can be found in Appendix I.

Additional Community Information – In 1999, the Stonington Fisheries Alliance produced an inventory of the fishing industry in Stonington and Deer Isle, which includes quite a bit of interesting information. The inventory includes a narrative that describes changes that have occurred in the Stonington/Deer Isle fishing industry over throughout the last decade, an overview of the history of Deer Isle as it relates to the importance of the fishing industry in the last century, and detailed data on the various fisheries, support services, and ancillary businesses in the area. According to the inventory, over 50% of the resident population of Stonington and Deer Isle (total population estimated to be 3,134) is involved in some aspect of the fishing industry.

Fishing Activity in Upper Mid-Coast 2, Maine

By Port of Landing

Fewer multispecies vessels landed fish in Upper Mid-Coast 2 than Upper Mid-Coast 1, the number declining from 1994 to 2001 (Table 565). In 1994, 10 out of 12 active multispecies vessels landed groundfish; by 2000 the number of multispecies vessels landings groundfish had fallen to 3, out of a total of 6 active vessels. After a general decline from 1994 to 1999, total landings increased dramatically from 101,600 pounds in 1999 to 12,270,800 pounds in 2001. Total revenues increased in the later years of the period as well, but not as dramatically. Groundfish landings fluctuated, with an average annual decline of 2.1%. Groundfish made up the majority of total landings in all years except 2000 and 2001, when small mesh non-multispecies landings increased dramatically, contributing to over 95% of the total landings in those years.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001
Number of Active Multispecies Vessels	12	18	15	8	10	5	6	9

Table 565 - Landings and Revenues from Multispecies Permit Holders in Upper Mid-Coast 2, Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport
Total number of permitted multispecies vessels with homeports in Upper Mid-Coast 2, Maine, declined from 1996 to 1997, remained relatively steady at 15-17 vessels until an increase to over 20 in 2000 (Table 566). Of these, approximately half reported landings of any species. Vessels reporting landings of groundfish declined from 10 in 1994 to just 4 in 2001. Total landings by vessels homeported in Upper Mid-Coast 2 declined 27.6% on average each year. Groundfish landings fluctuated in the beginning of the time period and generally decreased from 1996 to 2001. Groundfish contributed to just under half of the total revenues from 1994 to 1997, increasing steadily to 82.2% of the total in 2000. Multispecies revenues as a percent of total revenues fell to a period low of 33.6% in 2001, a year in which other species and high value species experienced increases in landings.

9.4.5.6.2.3 Upper Mid-Coast 3, Maine

The Upper Mid-Coast 3, Maine group is a secondary multispecies port group that includes Winter Harbor, Southwest Harbor, Bar Harbor, Northeast Harbor, and Northwest Harbor. These communities are located in Hancock County.

MARFIN – The MARFIN Report provides general profiles for the Upper Mid-Coast sub-region and Hancock County, the county in which the communities in this group are located. These profiles should be referenced for social and demographic data not contained in this document.

Fishing Activity in Upper Mid-Coast 3, Maine

By Port of Landing
The number of active multispecies vessels landing fish in Upper Mid-Coast 3 ranged from 21 to 28 between 1994 and 2001, with a peak of 44 vessels in 1996 (Table 567). Total landings decreased from 1994 to 1998, nearly doubled in the following year, and continued to increase through 2001. Total revenue trends were driven by landings of high value species – in some years where total landings increased, total revenues decreased because of declines in landings of high value species. The number of multispecies vessels landing groundfish generally decreased, with some fluctuation between 1994 and 2001. Groundfish landings declined six-fold from 1994 to 1998, then tripled from 1998 to 2001. Groundfish made up the greatest

fraction of total landings, followed by high value and other species, small mesh non-multispecies, and small mesh multispecies.

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels with home ports in Upper Mid-Coast 3, Maine, decreased from 40 to 23 between 1996 and 1997 but remained stable throughout the remainder of the period (Table 568). The number of multispecies vessels landing any species peaked at 20 (50% of the total number of permitted multispecies vessels) in 1996, and ranged from 10 to 13 during the following years. Total landings increased from 1994 to 1998, dropping by over 100% in the following year, and fluctuating during 2000 and 2001. Total revenues declined consistently from 1994 to 2001 due to a drop in landings of high value species. The number of permitted multispecies vessels landing groundfish averaged 11 from 1994 to 1998, decreasing to 5 in 2001. Groundfish landings remained relatively stable, with a slight overall average decline. The relative importance of groundfish revenues to Upper Mid-Coast 3 fishermen declined in the early years, from 42.6% of total revenues in 1994 to 22.2% in 1996, fluctuating around an average of 32% from 1997 to 2000, and increasing to a peak of 47% in 2001.

9.4.5.6.3 Lower Mid-Coast Maine

The port groups in Lower Mid-Coast Maine fall within three counties – Lincoln, Sagadahoc, and Cumberland counties. The following is a description of the population, education, poverty, unemployment and fishing industry participation in these counties.

Lincoln County	1990		2000		Percent change
Population (total individuals)	30,357		33,616		10.7%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	81.4%		87.9%		Difference = 6.5%
Poverty* (Number of families)	542		636		17.3%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	923	6.3%	721	4.3%	-21.9%

Table 569 - Population, education, poverty and unemployment statistics for Lincoln County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Lincoln County includes the ports of New Harbor, Bristol, South Bristol, Boothbay Harbor, East Boothbay, Medomak, Southport, and Westport (Lower Mid-Coast 1). The total population in Lincoln County increased nearly 11% between 1990 and 2000 (Table 569). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 81.4% in 1990 to 87.9% in

2000, a rise of 6.5 percentage points over the period. The number of families living in poverty increased 17.3%. Unemployment declined from 6.3% of the labor force in 1990 to 4.3% in 2001.

Sagadahoc County	1990		2000		Percent change
Population (total individuals)	33,535		35,214		5.0%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	81.1%		88.0%		Difference = 6.9%
Poverty* (Number of families)	541		673		24.4%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	842	5.1%	604	3.3%	-28.3%

Table 570 - Population, education, poverty and unemployment statistics for Sagadahoc County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Sagadahoc County includes the ports of Sebasco Estates, Small Point, West Point, Five Islands, and Phippsburg (Lower Mid-Coast 3). Total population is similar in size to Lincoln County but demonstrated a smaller increase (5%) from 1990 to 2000 (Table 570). Educational attainment increased from 81.1% in 1990 to 88% in 2000. The number of families living in poverty increased more than 24% over the decade, while the number of unemployed declined 28.3% and the unemployment dropped to a very low rate of 3.3% in 2000.

Cumberland County	1990		2000		Percent change
Population (total individuals)	243,135		265,612		9.2%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	85.0%		90.1%		Difference = 5.1%
Poverty* (Number of families)	3,601		3,527		-2.1%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	6,786	5.2%	5,296	3.7%	-22.0%

Table 571 - Population, education, poverty and unemployment statistics for Cumberland County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Cumberland County includes the ports of Portland (Primary Multispecies Port in Lower Mid-Coast Maine) and Cundys Harbor, Orrs Island, Yarmouth, Harpswell, East Harpswell, South Harpswell, Bailey Island, and Cape Elizabeth (Lower Mid-Coast 2). Total population in Cumberland County is approximately seven times greater than that in Lincoln and Sagadahoc counties and also demonstrated an increase from 1990 to 2000 (Table 571). The percent of individuals 25+ years who graduated from high school or higher increased five percentage points from 1990 to 2000, reaching 90.1%. Number of families in poverty and unemployment both declined in Cumberland. Cumberland County experienced economic improvement and educational growth in the decade from 1990 to 2000.

Fishing Industry Employment in Upper Mid-Coast Maine

Lincoln County

The number of individuals employed in fishing (1141) declined slightly from 1997 to 2000, averaging 925 during that period (Table 572). The average annual payroll for individuals in the fishing sector was $36,322 in 2000. The fish and seafood wholesale sector comprised the greatest number of establishments after the fishing sector, with an average of 24 establishments from 1998 to 2001. No establishments were reported in the seafood canning sector. Seafood product preparation and packaging, fresh and frozen seafood processing, and fish and seafood markets sectors remained small but stable. These data demonstrate that the fishing industry has remained an active, stable presence in Lincoln County since the late 1990s.

NAICS Code and Description		1997	1998	1999	2000	2001
1141* Fishing	Sum of Total Establishments	929	938	925	908	NA

Sagadahoc County

The number of fishing establishments in Sagadahoc County averaged 292 from 1997 to 2000, decreasing slightly over the time period (Table 573). The average payroll for fishers in Sagadahoc was $33,552 in 2000. All other fishing-related sectors reported between 1 and 4 establishments in each year from 1998 to 2001. These sectors remained stable across the time period, fluctuating very little in the number of establishments reported each year.

NAICS Code and Description		1997	1998	1999	2000	2001
1141* Fishing	Sum of Total Establishments	299	309	290	268	NA

Cumberland County

The number of fishers in Cumberland County exceeded that in Lincoln and Sagadahoc due to Portland's participation in the fishing industry in this county (Table 574). Portland is regarded as a "primary multispecies port" in Maine because of the high level of activity in the fishing industry there. The average payroll for fishers in Cumberland County was $53,847 in 2000, exceeding the average in Sagadahoc and Lincoln counties. The number of fish and seafood wholesale establishments declined from 39 in 1998 to 35 in 2001, while the number of fish and seafood markets increased from 11 to 14 over the time period. Seafood product preparation and packaging and fresh and frozen seafood processing averaged about 12 establishments in each year from 1998 to 2001. Two seafood canning establishments were reported in each year from 1999 and 2001.

9.4.5.6.3.1 Portland, Maine

Portland, Maine has been identified as a primary multispecies port. Portland is the only primary multispecies port in the state of Maine. Information obtained from industry members in Portland and throughout the state suggests that the majority of Maine's groundfish fishery has concentrated in Portland since the implementation of Amendments 5 and 7. As previously discussed, this concentration has occurred primarily for economic reasons. The emergence of the Portland Fish Exchange in 1986 and its evolution since that time have allowed Portland to become a marketing center for groundfish and other seafood products. In addition, increased regulations in groundfish and other fisheries have led to an industry downsizing in many smaller communities. Ice facilities, cutting houses, vessel repair services, and other related industries have gone out of business in smaller communities, leaving Portland as one of the only ports in the state where a vessel can unload and access most of the necessary services in-between trips. Unloading in Portland also reduces transportation costs, as trucking fish to the Exchange becomes unnecessary. The Exchange services approximately 300 vessels and handles 20-30 million pounds of seafood products annually.

MARFIN – The MARFIN Report provides a detailed profile of Portland as well as a general demographic profile of Cumberland County, the county in which Portland is located. These profiles should be referenced for social and demographic data not contained in this document.

Maine became a state in 1820, and Portland became the capital. Portland has a rich history in commercial fishing, and it is considered an active port still today. Revenues from the commercial fishing industry may only represent about ten percent of the city's gross product, but commercial fishing is considered culturally important to the city. Portland showed its support for the presence of a strong commercial fishing industry when it helped establish the Portland Fish Exchange in 1987. Portland then became the first city on the East Coast with a display auction for the sale of fresh fish. After a somewhat rocky start, the Portland Fish Exchange has been very successful, and about 90% of groundfish landed in Portland goes through the auction.

According to the 1990 Census, 64,358 people lived in Portland in 1989. The racial and ethnic background of Portland citizens has been primarily English, French, and Irish, but experts predict that these figures will radically change in the 2000 Census. MARFIN reported that Portland has 21 processors of fresh and frozen seafood. Respondents estimated that 300-400 households are directly dependent on commercial fishing and about 1,500-2,000 households are indirectly dependent. MARFIN found that the majority of fishermen from Portland are from Maine and are year-round harvesters. It is interesting to note that the limiting factor in the growth of fish processing in Maine seems to be due more to labor shortages than lack of fish.

MARFIN reports that trawlers, longliners, and gillnetters have traditionally worked out of Portland. According to 1992 NMFS permit data, 68 commercial vessels were homeported in Portland, and in 1997 that number fell to 51. When groundfish fishermen faced cut backs in days-at-sea regulations, a number of large groundfish vessels switched to the herring, mackerel, and squid fisheries. Some smaller groundfish vessels turned to lobster fishing instead. The groundfish industry in Portland seems to be recuperating, and in 2000 there were at least 18 large groundfish boats. Another shift in the groundfish fleet has been in the pattern of ownership. The MARFIN Report found that before DAS limitations, most vessels in Portland were owner-operated; today more of Portland's groundfish fleet is comprised of owners of two and three vessels. Some key informants in the MARFIN survey indicated that the cumulative impacts of Amendment 5 and 7 are what has affected Portland the most. The top ten species landed in Portland in 1997 according to the MARFIN Report (in order of pounds landed) were: herring, lobster, shrimp, plaice, cod, witch flounder, pollock, monkfish, white hake and silver hake. The recreational fishing industry seems to be limited in Portland, but it was reported that there are five marinas in South Portland.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Portland, Maine on November 13, 2000, and residents from Portland and surrounding communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Portland relate to the apparent polarization of the fishing industry in Portland (big boat/small boat, Individual DAS/Fleet DAS), a loss of new entrants in the fishery and problems finding and keeping crew, and concerns about safety resulting from adaptations that fishermen are making in the face of increasing regulations. The groundfish regulations that residents feel have produced the most significant social impacts in this community are the DAS allocations and reductions in DAS since Amendment 5. This community is home to many vessels with Individual DAS permits, and these boats have experienced a 50% reduction in their allocated DAS since Amendment 5. Comments concerning the social impacts of the DAS reductions relate to the loss of opportunity and flexibility for boats that are primarily dependent on the groundfish fishery and not involved in many alternative fisheries. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Additional Community Information – The Portland Fish Exchange (PFE) publishes an annual report that details activity at the Exchange. These reports include information about prices, annual and monthly landings, cull sizes, and other important economic information. Information about the PFE can be obtained from its website, www.portlandfishexchange.com.

Fishing Activity in Portland, Maine

The number of active multispecies vessels landing fish in Portland peaked at 193 in 1996, but declined 27.5% overall from 1994 to 2001 (Table 575). The greatest decline in number of active vessels was 25.5%, from 1997 to 1998. Total landings in Portland increased greatly from 1994 to 1997, declining in the following year, and increasing continuously to a maximum of over 75 million pounds in 2001. The number of multispecies vessels landing groundfish increased as a percentage of the total number of active multispecies vessels from 1994 to 2001, but decreased overall during this period. Groundfish landings decreased from around 17 million pounds in 1994 to under 12 million in 1999, followed by a general increase from 1999 to 2001. Landings of small mesh non-multispecies (primarily herring) increased substantially from 3.7 million pounds in 1994 to 53.6 million pounds in 2001. Landings of other species remained consistent, while high value species landings generally declined.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 575 - Landings and Revenues from Multispecies Permit Holders in Portland, Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

Total number of vessels homeported in Portland declined substantially from 117 in 1994 to 76 in 2001 (Table 576). The number of active vessels from Portland landing any species also declined by 39% over this period, and active vessels landing groundfish decreased 29%. Total landings by Portland vessels decreased from 1994 to 1997, increased in the following year, and remained relatively stable after 1999, with landings slightly below the level in 1994. Groundfish landings declined through 1998, and increased afterwards. Dependence on groundfish as a percentage of total fishing revenues by multispecies vessels from Portland averaged 64.4% from 1994 to 2001.

9.4.5.6.3.2 Lower Mid-Coast 1, Maine

The Lower Mid-Coast 1, Maine group is a secondary multispecies port group that includes New Harbor, Bristol, South Bristol, Boothbay Harbor, East Boothbay, Medomak, Southport, and Westport. These communities are located in Lincoln County.

MARFIN – The MARFIN Report provides detailed profiles of South Bristol, Boothbay, Boothbay Harbor, and Southport. It also includes a general profile of the Lower Mid-Coast Maine sub-region and Lincoln County, the county in which the Lower Mid-Coast 1 communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Social Impact Informational Meetings – Council staff conducted social impact informational meetings in Portland, Maine on November 13, 2000 and Ellsworth, Maine on December 7, 2000. A few residents from Lower Mid-Coast 1 communities attended the meeting in Portland and submitted comments. While attendance from these communities was not overwhelming, the information collected at these two social impact meetings may reflect, at least in part, the perspectives of the residents of these communities. The summary from these meetings can be found in Appendix I.

Fishing Activity in Lower Mid-Coast 1, Maine

By Port of Landing

The number of active permitted multispecies vessels in Lower Mid-Coast 1 declined steadily from 89 vessels in 1994 to 33 in 2001 (Table 577). The number of multispecies vessels landing groundfish declined overall, fluctuating throughout the time period. However, the number of multispecies vessels landing groundfish increased as a percentage of total active vessels, from 42% in 1994 to nearly 82% in 2001. Total landings in Lower Mid-Coast 1 generally decreased from 1994 to 2001. Groundfish landings declined from 1994 to 1999, followed by a large increase from 1999 to 2001 to a level comparable to that landed in 1995. Small mesh non-multispecies landings were relatively stable from 1994 to 1999 with a peak in 1996, followed by a steep decline after 1999. Small mesh non-multispecies landings made up the greatest proportion of total landings in most years, followed by groundfish. Small mesh multispecies landings dropped from about 53.8 million pounds in 1994 to zero in 2001, while other species landings were relatively stable. High value species also declined to zero landings by 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Data source: NMFS Permit and Dealer databases

By Homeport

The total number of permitted multispecies vessels homeported in Lower Mid-Coast 1 decreased over the period from 90 in 1994 to 48 in 2001 (Table 578). Of these, active vessels landing any species and those reporting landings of groundfish declined as well. Despite the decline in number of active vessels, total landings increased from 4.3 million pounds in 1994 to 6.2 million pounds in 1996. After 1996, landings decreased steadily. Groundfish landings fluctuated but remained relatively steady, with two low periods in 1997 and 1999. Groundfish landings were highest in 1994, at 1.8 million pounds. Dependence on revenues from groundfish was lowest in 1997, at 30.8% of total revenues and highest in 2001, at 58.2%.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.6.3.3 Lower Mid-Coast 2, Maine

The Lower Mid-Coast 2, Maine group is a secondary multispecies port group that includes Cundys Harbor, Orrs Island, Yarmouth, Harpswell, East Harpswell, South Harpswell, Bailey Island, and Cape Elizabeth. These communities are located in Cumberland County.

MARFIN – The MARFIN Report provides detailed profiles of Harpswell, including South Harpswell and Cundys Harbor. It also includes a general profile of the Lower Mid-Coast Maine sub-region and Cumberland County, the county in which the Lower Mid-Coast 2 communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Fishing Activity in Lower Mid-Coast 2, Maine

By Port of Landing

As in Lower Mid-Coast 1, the number of active multispecies vessels landing groundfish in Lower Mid-Coast 2 declined by over 50% from 1994 to 2001 (Table 579). Unlike the vessels landing groundfish in Lower Mid-Coast 1, however, the number of vessels landing groundfish in Lower Mid-Coast 2 increased from zero in 1994 to 14 in 2001, 82% of the total number of active multispecies vessels in that year. Total landings and revenues generally declined. Groundfish landings increased from zero in 1994 to 344,100 pounds in 2001, making up the majority of total landings in that year. Landings of small mesh non-multispecies, which composed the majority of total landings in most years, declined across the period as did high value species landings. As groundfish increased as a component of total landings in Lower Mid-Coast 2, high value and small mesh non-multispecies decreased.

Table 579 - Landings and Revenues from Multispecies Permit Holders in Lower Mid-Coast 2, Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

The numbers of total permitted multispecies vessels and those reporting landings of any species declined from 1994 to 2001, while the number of multispecies vessels landing groundfish increased over the period (Table 580). Total landings were relatively stable during the first two years of the time period, with a two-fold increase from 1996 to 1997, and a three-fold increase in landings from 1997 to 1998. Landings increased more gradually after 1998. Total revenues do not reflect this trend. Revenues remained fairly constant, with a slight downward trend overall, likely due to a decrease in landings of high value species. Groundfish landings decreased in the first two years and fluctuated for the remainder of the time period, with a slight overall positive trend. Dependence on groundfish by vessels homeported in Lower Mid-Coast 2 increased from 37% to 71% across the period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.6.3.4 Lower Mid-Coast 3, Maine

The Lower Mid-Coast 3, Maine group is a secondary multispecies port group that includes Sebasco Estates, Small Point, West Point, Five Islands, and Phippsburg. These communities are located in Sagadahoc County.

MARFIN – The MARFIN Report provides a profile of Phippsburg, Maine. It also includes a general profile of the Lower Mid-Coast Maine sub-region and Sagadahoc County, the county in which the Lower Mid-Coast 3 communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Fishing Activity in Lower Mid-Coast 3, Maine

By Port of Landing
The total number of active multispecies vessels landing fish in Lower Mid-Coast 3 declined 90% from 58 vessels in 1994 to only 6 in 2001 (Table 581). The number of multispecies vessels landing groundfish increased during the late 1990s, then declined to four vessels in 2001. As a percentage of total active vessels, vessels landing groundfish increased substantially, from 5% in 1994 to 67% in 2001. Total landings in Lower Mid-Coast 3 increased substantially from 1994 to 1995, then decreased continually in the following years, with an average annual percent decrease after 1995 of 34.6%. Revenues decreased from 1994 to 2001. After a dramatic increase in groundfish landings from 1994 to 1995 (36-fold increase), landings generally decreased in the following years. Small mesh non-multispecies landings followed a similar trend to groundfish landings, while high value species declined throughout the time period. While groundfish landings are increasing in Lower Mid-Coast 3, landings of other species groups appear to be declining.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 581 - Landings and Revenues from Multispecies Permit Holders in Lower Mid-Coast 3, Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

The total number of permitted multispecies vessels as well as the numbers of multispecies vessels landing any species and those reporting landings of groundfish all declined from 1994 to 2001 (Table 582). Total landings and revenues decreased constantly, with only a very small increase in 2001. Groundfish landings declined through 1999 then increased through 2001, the 2001 landings only half the level reported in 1994. Dependence on groundfish increased over the period, as other species and high value species landings declined, from 21% in 1994 to 64% in 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.6.4 Southern Maine

The Southern Maine group is a secondary multispecies port group that includes York, York Harbor, Camp Ellis, Kennebunkport, Kittery, Cape Porpoise, Ogunquit, Saco, and Wells. These communities are located in York County.

MARFIN – The MARFIN Report provides detailed profiles of Kennebunkport and Cape Porpoise, Maine. It also includes a general profile of York County, the county in which the Southern Maine communities are located. These profiles should be referenced for social and demographic data not contained in this document.

The following is a description of the population, education, poverty, unemployment and fishing industry participation in York County.

York County	1990		2000		Percent change
Population (total individuals)	164,587		186,742		13.5%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	79.5%		86.5%		Difference = 7.0%
Poverty* (Number of families)	2,158		2,999		39.0%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	5,398	6.3%	3,429	3.5%	-36.5%

Table 583 - Population, education, poverty and unemployment statistics for York County, ME (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in York County increased 13.5% between 1990 and 2000 (Table 583). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 79.5% in 1990 to 86.5% in 2000, a rise of 7 percentage points over the period. The number of families living in poverty increased 39%, while the number of unemployed decreased 36.5% from 1990 to 2000. The unemployment rate declined from 6.3% of the labor force in 1990 to 3.5% in 2001.

Fishing Industry Employment in Southern Maine

York County

The number of individuals employed in fishing (1141) declined slightly from 1997 to 2000, averaging 390 during that period (Table 584). The average annual payroll for individuals in the fishing sector was $49,478 in 2000. The fish and seafood wholesale sector comprised the greatest number of establishments after the fishing sector, with an average of 20 establishments from 1998 to 2001. Only one establishment was reported in the seafood canning sector from 1998 to 2000, and zero in 2001. Seafood product preparation and packaging, fresh and frozen seafood processing, and fish and seafood markets sectors remained small but stable. These data demonstrate that the fishing industry remained an active, stable presence in York County during the late 1990s.

NAICS Code and Description		1997	1998	1999	2000	2001

Fishing Activity in Southern Maine

By Port of Landing

The number of active multispecies vessels (landing any species and groundfish) declined from 1994 to 2001 (Table 585). 100% of the active multispecies vessels reported landings of groundfish in 2001 (17 vessels). Total landings and revenues generally declined from 1994 to 2001, with some fluctuation. Groundfish landings fluctuated, dipping in 1995-1996, increasing through 1998, dropping again in 1999, and increasing to the highest landings of the period in 2000 and 2001. Small mesh non-multispecies, which made up almost 70% of total landings in 1994, declined substantially during the following years. Small mesh multispecies landings also declined, reported at low levels in all years. Landings of high value species fluctuated, with the highest reported landings in 2000 at 99.8 million pounds and the lowest in 2001, at zero.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 585 - Landings and Revenues from Multispecies Permit Holders in Southern Maine (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The numbers of permitted multispecies vessels and those reporting landings of any species declined slightly from 1994 to 2001, while multispecies vessels reporting landings of groundfish increased in number over the period (Table 586). Half of the total number of active vessels reported landings of groundfish in 1994, while 100% of the active vessels landed groundfish in 2001. Total landings remained relatively consistent from 1994 to 2001, with a small overall decline across the period. After a slight decline from 1994 to 1995, groundfish landings increased from 499,800 pounds in 1996 to 1.4 million pounds in 2001. The greatest increase in landings occurred between 1996 and 1997 (85%). Dependence on groundfish revenues fluctuated to some extent across the period though generally increasing, reaching 74.7% of total revenues by 2001.

9.4.5.6.5 Other Maine

Data are reported for other ports in Maine that do not fall into Primary or Secondary Multispecies Port groups.

Fishing Industry Employment in Other Maine
The number of fishing establishments increased from 169 in 1997 to 185 in 1998, falling back to 169 in 1999 and increasing in 2000 (Table 587). For these other ports in Maine, average annual payroll for harvesters was low relative to other regions in Maine, at $19,954 in 2000. The fish and seafood wholesale and fish and seafood markets sectors remained stable, each with four establishments in nearly all years. There were three or fewer seafood product preparation and packaging and fresh and frozen seafood processing sectors. Seafood canning reported no establishments in all but one year from 1997 to 2000.

NAICS Code and Description		1997	1998	1999	2000	2001
1141* Fishing	Sum of Total Establishments	169	185	169	174	NA

Fishing Activity for Other Maine

By Port of Landing

The number of multispecies vessels landing fish decreased 72% from 137 in 1994 to 38 in 2001 (Table 588). The number of multispecies vessels landing groundfish also declined, to only 6 vessels in 2001. Total landings increased from 2.1 million pounds in 1994 to 771,000 pounds in 1996, but demonstrated a 19-fold increase in the following year to 14.6 million pounds. Landings fluctuated from 1998 to 2001, with a peak during the period of 31.6 million pounds (1999). Groundfish landings declined from 1994 to 1997, doubled from 1997 to 1998, and declined again in the following years. Small mesh non-multispecies landings composed the majority of the total landings in all years and heavily influenced the total landings trend. Landings of groundfish, other species and high value species made up similar proportions of total landings. Small mesh multispecies landings dropped rapidly to zero after 1994, when they composed the second greatest percentage of the total landings.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Data source: NMFS Permit and Dealer databases.

By Homeport

As with the numbers of vessels landing fish in other Maine ports, the number of vessels homeported in these places also declined (Table 589). Total landings increased nearly 6-fold from 1994 to 2001. Groundfish landings generally increased as well, though the magnitude of the increase was much smaller. Dependence on groundfish in Other Maine remained fairly consistent throughout the time period, with an annual average of 25.7%.

9.4.5.6.6 Maine Summary

Maine's downeast coastal counties experienced the greatest economic declines, with increases in poverty and unemployment from 1990 to 2000. South of Hancock County, poverty and unemployment levels declined. Groundfish are among the most substantial components of total landed catch in Maine, together with Other Species, High Value Species (lobster) and Small Mesh Non-multispecies (herring). Landings of small mesh non-multispecies generally increased in Maine. As a percentage of total revenues generated by multispecies vessels, groundfish revenues decreased in the regions furthest to the northeast and increased to the southwest. Portland, one of Maine's primary groundfish ports, experienced a marked decline in the number of active multispecies vessels landing fish and the number of multispecies vessels homeported there. However, groundfish revenues as a percentage of total revenues increased, demonstrating an increase in dependence on groundfish in Portland. Maine more nonemployer establishments in the fishing sector than any other state from 1997 to 2000. The fish and seafood wholesale sector reported the second greatest number of establishments after the fishing sector in Maine. As in other states, multispecies permit holders have increased their activity in the groundfish fishery since 1994.

9.4.5.7 New Hampshire

Demographic Profile of New Hampshire

NEW HAMPSHIRE	1990		2000		Percent change
Population (total individuals)	1,109,252		1,235,786		11.4%

Table 590 - Population, education, poverty and unemployment statistics for the state of New Hampshire (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Total population in New Hampshire increased 11.4% from 1990 to 2000, a greater percent increase than in the state of Maine (Table 590). By 2000, total population in NH was comparable to that in ME. The percentage of individuals 25+ years graduating from high school or higher also increased in New Hampshire over the decade. The number of families in poverty increased 8.6% but unemployment dropped from 6.2% of the civilian labor force to 3.8% between 1990 and 2000.

Table 591 - Population by race in New Hampshire counties, 2000
Counties examined in Fishing Communities section of AHE in bold type.

Data source: U.S. Census Bureau

The population of New Hampshire is 96% white, with 1.1% of the individuals being of two or more races, 1.7% Hispanic of any race, and just under 3% represented by all other races combined (Table 591). The racial profiles of Rockingham and Strafford counties are similar, although the total population of Rockingham is over twice that of Strafford. The population of each county is just over 96% white, with 0.6% black/African American, 0.2% American Indian and Alaska Native, 1.1-1.4% Asian, 0.9-1.1% of two or more races, and 1-1.2% Hispanic/Latino of any race. There are no native Hawaiians and other Pacific Islanders, and 0.3-0.4% other races. In New Hampshire, Rockingham and Strafford counties are among those with the highest percentage of non-whites, after Hillsborough and Grafton counties.

Rockingham County	1990		2000		Percent change

Table 592 - Population, education, poverty and unemployment statistics for Rockingham County, NH (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Portsmouth, Rye, Seabrook and Hampton are located in Rockingham County. The total population in Rockingham County increased 12.8% between 1990 and 2000 (Table 592). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 86.2% in 1990 to 90.5% in 2000, a rise of 4.3 percentage points over the period. The number of families living in poverty increased 9.7%, while the number of unemployed decreased over 50% from 1990 to 2000. The unemployment rate declined from 6.0% of the labor force in 1990 to 2.7% in 2001.

Strafford County	1990		2000		Percent change
Population (total individuals)	104,233		112,233		7.7%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	79.8%		86.4%		Difference = 6.6%

	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
Unemployment (Pop. 16 yrs and over)	3,748	6.6%	2,351	4.1%	-37.3%

Table 593 - Population, education, poverty and unemployment statistics for Strafford County, NH (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Total population of Strafford County is about half that of Rockingham County and increasing at a slower rate (Table 593). Educational attainment is lower than that in Rockingham, with 79.8% of the population 25 years and older graduating from high school or higher in 1990, increasing to 86.4% in 2000. The number of families living in poverty increased nearly 5%, while number of unemployed fell about 37%. Unemployment rate declined from 6.6% to 4.1% from 1990 to 2000.

Fishing Industry Employment in Rockingham and Strafford Counties

Rockingham County

The number of individuals/establishments employed by fishing in Rockingham County declined 14% (34 establishments) from 1997 to 2000 (Table 594). In 2000, the average payroll for members of the fishing sector was $87,604. The second largest fishing-related sector in Rockingham County is the fish and seafood wholesale sector, with 12 establishments in 1998 declining to 9 in 2001. Seafood product preparation and packaging and fish and seafood markets each reported 5 to 6 establishments in each year. There were four establishments in fresh and frozen seafood processing from 1998 to 2000, this number decreasing to three in 2001. Two establishments were reported in the seafood canning sector in all years from 1998 to 2001. Most fishing-related sectors remained stable during this period.

Strafford County

The fishing industry has far less of a presence in Strafford County, without major ports like those situated in Rockingham County. The number of individuals or establishments in fishing was not reported in 1997, and demonstrated relative stability from 1998 to 2000, numbering from 34 to 41 in each of those years (Table 595). The average annual payroll in fishing during 2000 was $33,073, far lower than the average in Rockingham. Seafood product preparation and packaging and fresh and frozen seafood processing sectors reported one establishment in each year from 1998 to 2001. Fish and seafood wholesale reported two establishments annually from 1998 to 2000 and one in 2001. After 1998, there were no reported fish and seafood markets in Strafford County.

9.4.5.7.1 Portsmouth, NH

Portsmouth, New Hampshire has been identified as a primary multispecies port and is located in Rockingham County.

MARFIN – The MARFIN Report provides a detailed profile of Portsmouth, New Hampshire. It also includes a general profile of the New Hampshire Seacoast sub-region and Rockingham County, the county in which Portsmouth is located. These profiles should be referenced for social and demographic data not contained in this document.

Portsmouth sits near the mouth of the Piscataqua River, which divides NH and Maine. Portsmouth has a long maritime history, and by 1820 there were approximately 500 men fishing on 150-200 vessels based out of Portsmouth. Portsmouth is the largest fishing port along New Hampshire's eighteen-mile coastline. The primary components of the fishing infrastructure are the State Pier and adjoining fish co-op. In general, the city of Portsmouth is supportive of the commercial fishing sector, recognizing its cultural significance and its waterfront attraction for tourists. MARFIN reported that Portsmouth does have a concentrated amount of support services including four lobster bait houses, two boat builders, two boat yards, five fish retailers, and many other indirect commercial fishing industries.

MARFIN found that about 26 finfish vessels and 50 lobster boats are from Portsmouth. It was estimated that 200 households are directly dependent on commercial fishing, and 300 or so are indirectly dependent on commercial fishing. Aquaculture is becoming a significant industry in this port. GreatBay Aquafarms, Inc. focuses on raising fluke and summer flounder; it employs roughly six full-time employees and six part-time employees. New Hampshire Sea Grant has an extension office in Portsmouth and they work closely with the fishing industry on a number of research programs.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Portsmouth, New Hampshire on November 6, 2000. Several residents of Portsmouth and other NH Seacoast communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meeting, the most important social impact issues for residents of Portsmouth and other NH Seacoast communities relate to a loss of morale in the fishing industry (primarily from regulatory discarding), stress from uncertainty and the inability to plan business, problems finding and keeping crew, and safety concerns. The groundfish regulations that residents feel have produced the most significant social impacts are the Gulf of Maine rolling closures and the low Gulf of Maine cod trip limits, all of which have occurred since the start of the 1998 fishing year. Please see the complete meeting report in Appendix I for additional discussion of these and other important social impact issues.

Additional Community Information – Portsmouth's fishing industry is supported by a state pier and an adjoining fish cooperative. In August of 2000, Council staff had the opportunity to interview the general manager and the president of the Portsmouth Co-op. The bullets below summarize some interesting information about activity at the co-op (from August 2000 Council staff interview with president and general manager of co-op):

- The Portsmouth Fishermen's Co-op was established in 1978. It was the first co-op in New Hampshire.
- Membership in the co-op is at about 28, and this has remained relatively consistent over time. The total number of boats serviced by the co-op is about 38 (28 member boats and 10 non-member boats). Eight boats that fish out of Rye, NH truck their fish to the co-op, and three boats from York, ME use the co-op (two of them tie-up at the co-op instead of York).
- Sixteen members dock their boats at the co-op. Dock space is pretty tight because it is limited by the depth of the harbor. The harbor is not deep enough to dock a vessel greater than about 60 feet in length (without additional dredging).
- Member vessels in the co-op are about 50% gillnetters and 50% draggers, with about 4-5 boats that switch between the two gear types on a seasonal basis. All of the member boats are between 40-60 feet in length. The draggers tend to be the more "inshore" boats (about four of them fish offshore), and the gillnetters tend to be the more "offshore" boats. All inshore trips are day trips (less than 24 hours), and the offshore trips run about 3-7 days. There are currently no hook boats at the co-op, although many inshore boats used to hook fish on Jeffreys in the wintertime (this practice stopped with the establishment of the western Gulf of Maine closure).
- About 12 of the member boats are truly "offshore boats" – they usually work with four people on board, including the captain. The "inshore" draggers tend to work alone (just the captain), and the gillnetters tend to work with 2-3 people, including the captain.
- The president and general manager noted that many of the co-op boats have learned to adapt to increasing regulations in groundfish and other fisheries. Many of their members have opted to fish farther offshore or find another way to make a living (some have made fishing a part-time job). They

have also seen some of their members upgrade their vessels to make them capable of going offshore (at least one per year).

- The general manager noted a problem in finding employees for the co-op, and he cited the current status of the economy as one reason. He is having a hard time finding anyone who wants to work at the co-op when other, less labor-intensive jobs are available for similar or more money. He also noted that there are not very many young people entering the industry anymore, and it is becoming increasingly difficult to find relatively inexpensive labor. Sometimes, the co-op cannot handle the volume of fish that is landed because of the timing of the landings and the lack of a sufficient number of employees. When this happens, many boats have to wait for long periods of time to unload.
- The general manager also noted that the volume of fish landings has increased in the past year or so (not necessarily groundfish), and that this has been a problem not only for the co-op (in terms of having the employees to handle the volume), but also for the auctions, buyers, and processors. No one is currently prepared to handle the increase in volume, and as a result, the prices for fish have been very low. In fact, he noted that during the month of July 2000, volume could have been double what it was, but a lot of people tied-up and didn't fish because the prices were so bad.
- The biggest change since Amendment 5 that the general manager and president noted was the transition of about ½ of their member boats from inshore dayboats to offshore trip boats without an increase in vessel size (a lot of these boats made safety, etc. upgrades to go further offshore, but very few made length upgrades). They also noted that this has resulted in the co-op "losing its edge" on some of the fresh fish markets it used to be heavily involved with because these markets are seeking "day old" fish.
- Other services at the co-op (for members and non-members) include ice, fuel, and bait. There is also a gear storage area and a haul-out across the river in Kittery. The haul-out is likely to be sold in the near future for condo development, and the general manager and president are concerned because it is the only nearby place that is equipped to handle commercial vessels. There are two other nearby places to haul-out, but vessel owners are required to use specific sub-contractors at those places, and they are much more equipped for yachts and pleasure boats. They feel that this could be a problem for the Portsmouth commercial fleet in the near future.

Fishing Activity in Portsmouth, NH

By Port of Landing

The total numbers of permitted multispecies vessels reporting landings of any species and those reporting groundfish landings in Portsmouth increased overall from 1994 to 2001 (Table 596). The number of active vessels declined from 1995 to 1998, increased 1998 to 2000, and declined slightly in 2001. The number of multispecies vessels reporting landings of groundfish increased 50% from 46 in 1994 to 69 in 2001. Total landings were relatively stable from 1994 to 1996, declined from 1996 to 1999, and increased again in 2000. Overall, reported landings during this time period demonstrated a relatively flat trend. Groundfish landings made up the majority of the total landings in Portsmouth. The lowest groundfish landings were reported in 1998 and 1999 and landings demonstrated a general decline overall. Landings of small mesh multispecies, small mesh non-multispecies, and other species did not demonstrate any strong positive or negative trends, fluctuating across the period. High value species landings increased substantially from 1999 to 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 596 - Landings and Revenues from Multispecies Permit Holders in Portsmouth, NH (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homemport

The number of vessels homeported in Portsmouth remained relatively stable from 1994 to 2001 (Table 597). There was a slight decline in active vessels after 1994, with an increase back to 1994 levels around 1999. Total landings were stable from 1994 to 1999, then demonstrated a four-fold increase from 1999 to 2000, increasing an additional 78% from 2000 to 2001. Groundfish landings fluctuated very little from 1994 to 2001, exhibiting a slightly positive overall trend during this period. Dependence on groundfish declined over the period, with a peak of 74% in 1998. Portsmouth multispecies vessels exhibited the lowest dependence in 2000 and 2001 due to an increase in landings of small mesh non-multispecies and high value species during those years.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.7.2 NH Seacoast

The New Hampshire Seacoast group is a secondary multispecies port group that includes Rye, Hampton, and Seabrook. These communities are located in Rockingham County.

MARFIN – The MARFIN Report provides detailed profiles of Hampton and Seabrook, NH. It also includes a general profile of the NH Seacoast sub-region and Rockingham County, the county in which the NH Seacoast communities are located. These profiles should be referenced for social and demographic data not contained in this document.

MARFIN ranked the NH Seacoast with a low overall economic dependence on fishing due to the intense coastal development and diversified economic activity in the area. However, the Hampton/Seabrook port has a vibrant commercial fishing industry. Furthermore, MARFIN documented that Rye is still a significant fishing port with 24 or more vessels, 2-10 groundfish and over 12 lobster vessels. One important factor that has helped many New Hampshire ports survive is their close proximity to rich fishing grounds compared to other ports in the North Atlantic.

Hampton Beach and Seabrook are located just north of the Massachusetts border. This area is known as a "summer vacation community." The year-round population is 13,100, and the summer visitors are estimated to reach 150,000 individuals. The recreational sector is not considered a dominant activity in this area; however, the party/charter sector in both Rye and Hampton is significant. There are substantial support services in the area such as ice supplies, bait houses, and a local netmaker for repairs. MARFIN estimated that 70 families are directly dependent on commercial fishing in the Hampton/Seabrook area. About 40% of those individuals sought seasonal work outside of the industry when fishing restrictions were imposed, but returned when restrictions were lifted. MARFIN reported an important difference when the fishermen returned however – now most fishermen work alone, whereas before the restrictions, almost all vessels had at least one crewmember.

In 1978, there were 35 lobster boats and a dozen or so gillnetters, bottom trawlers, and purse seine vessels working out of Hampton Harbor. MARFIN determined that twenty years later, the number of vessels has remain essentially unchanged; today, there are 36 lobster boats, four gillnetters, and ten draggers. It is important to note that six out of ten draggers have become inactive due to closures and other restrictions on catch. There is less groundfishing in the area, but shrimping has increased to the extent allowed, and lobstering has boomed. Both the fleet and the local coop have diversified significantly over time to stay in business. In 1997, the Newburyport Co-op merged with the local co-op, and today the Yankee Co-op in Seabrook has 59 members. MARFIN reported that most of the product from the Co-op is sold to regional buyers in Boston, Gloucester, and Saugus. No one interviewed in this area by MARFIN encourages his or her children to go into the commercial fishing business because of the economic uncertainty.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Portsmouth, NH on November 6, 2000. A few residents from NH Seacoast communities attended and submitted comments. The summary from these meetings can be found in Appendix I.

Fishing Activity on the NH Seacoast

By Port of Landing

The number of active multispecies vessels declined from 1994 to 1996, increasing to 36 active vessels in 2001, 29 of these reporting groundfish landings (Table 598). Total landings declined substantially from 1.4 million pounds in 1994 to only 4,000 pounds in 1996. Landings generally increased after 1996 to almost 1.2 million pounds in 2001. Groundfish landings declined rapidly from 359,000 pounds in 1994 to zero in 1996, and generally increased from 1996 to 2001. Landings of all species declined to zero in 1996, with the exception of high value species.

Table 598 - Landings and Revenues from Multispecies Permit Holders in NH Seacoast Group (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.
Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.
Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.
Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.
High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.
C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**
Data source: NMFS Permit and Dealer databases.

By Homeport
The number of permitted multispecies vessels from the New Hampshire Seacoast group declined from 1994 to 2001 (Table 599). While the total number of active vessels declined over the time period, the fraction of these reporting groundfish landings increased, with all but two of the 53 active vessels landing groundfish in 2001. Total landings and revenues generally declined from 1994 to 2001. Groundfish landings declined each year from 1994 to 1999, then doubled from 1999 to 2001. The percent of groundfish revenues making up the total revenues in 1994 was 38.7%, and increased to about 50% in 1998. After a one-year decline in 1999, dependence increased to over 60% in 2001. Groundfish have become a more important source of income to New Hampshire Seacoast fishermen.

9.4.5.7.3 Other New Hampshire

Fishing Industry Employment in Other New Hampshire
The number of individuals engaged in fishing in all other coastal regions of New Hampshire declined from 1997 to 1999 and was stable from 1999 to 2000 (Table 600). The annual payroll for fishing individuals/establishments was $21,196 in 2000. All other sectors reported between 1 and 4 establishments in each year from 1998 to 2001. No seafood canning establishments were reported in any years from 1998 to 2001.

NAICS Code and Description		1997	1998	1999	2000	2001

Fishing Activity in Other NH

By Port of Landing

The number of active multispecies vessels declined from 80 in 1994 to 61 in 2001 (Table 601). Out of these active vessels, the number landing groundfish increased from 38 in 1994 to 47 in 2001, or 77% of total active vessels. Total landings declined from 1994 to 1997, increasing in subsequent years. From 1997 to 2001, landings increased 400%. The change in revenues was much less dramatic, the trend remaining relatively flat across the time period. The rise in total landings resulted from a substantial increase in small mesh non-multispecies landings from 1998 to 2001; this increase did not greatly affect total revenues since small mesh non-multispecies are low value species. Groundfish landings remained very stable from 1994 to 1999, increasing 79% from 1999 to 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

By Homeport

Total number of permitted multispecies homeported in Other NH decreased from 1994 to 1998, remained steady for the next two years, and increased slightly in 2001 (Table 602). The number of active vessels, including those landing groundfish, declined as well. Total landings decreased from 1994 to 2001, with an annual average reduction of 13.7%. Groundfish landings declined gradually from 1994 to 1996, then dropped substantially in 1997, a 67% decline from the previous year. Landings of groundfish remained somewhat stable for the duration of the period. Dependence on groundfish generally fluctuated, with a high of 73% in 1994 and a low of 33% in 1997.

9.4.5.7.4 New Hampshire Summary

In New Hampshire, the total population increased to a greater extent than in Maine, with educational attainment rising and a small increase in poverty. The unemployment rate declined to below the national average in 2000. With a smaller coastline, New Hampshire reported fewer vessels and fewer fishing participants than other states. Fishing activity by groundfish vessels in Portsmouth, New Hampshire's primary port, was relatively stable throughout the 1990s. In other New Hampshire ports, groundfish dependence increased.

9.4.5.8 Massachusetts

This section summarizes available information about fishing communities in the state of Massachusetts and includes references to the appropriate documents, which are not included as part of this document.

Health care and the ability for the fishing industry to find and keep affordable health insurance is an important social issue. In November of 1996, Caritas Christi Health Care System and the Massachusetts Fishermen's Partnership funded the development of a report entitled, *Health Survey of the Fishing Population in Massachusetts*. The survey project in the state of Massachusetts was the beginning of a regional effort to determine the need for more affordable heath insurance for fishing families. It was initiated by leaders in the Massachusetts Fishermen's Partnership and provided information to support the much-needed Fishing Partnership Health Plan, which was initiated in 1997. A random sample of 3,500 permit holders in the state were selected for the survey, and 485 surveys were returned, providing information on 1,400 adults and children associated with the fishing industry in Massachusetts. The survey was conducted in the Spring and Summer of 1996, and based on the results, approximately 43% of the fish harvesting population in the state were without health insurance at that time. This Report can be referenced for additional important information about fishing families in many communities throughout Massachusetts, including information about employment, income, household characteristics, health insurance status, cost of health care, and other information related to the use of health services.

Demographic Profile of Massachusetts

MASSACHUSETTS	1990		2000		Percent change

Table 603 - Population, education, poverty and unemployment statistics for the state of Massachusetts (1990 and 2000)

** data shown for 1989 and 1999*

Data source: U.S. Census Bureau

The total population in Massachusetts increased by 5.5% from 1990 to 2000 (Table 603). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 4.8% over the course of a decade, from 80% in 1990 to 84.8% in 2000. While the number of families below the poverty level increased slightly (2.8%), the unemployment rate declined, from 6.7% to 4.6% of the civilian labor force, aged 16 years and older.

Table 604 - Population by race in Massachusetts counties, 2000

Counties examined in Fishing Communities section of AHE in bold type.

Data source: U.S. Census Bureau

Massachusetts has a much larger total population than both Maine and New Hampshire. The population of Massachusetts is 84.5% white, with 5.4% black/African American, 3.8% Asian, 2.3% of two or more races, and just under 4% represented by all other races combined (Table 604). 6.8% of the population is Hispanic/Latino of any race. The population in Essex County (Gloucester and North Shore) is 86.4% white, 2.6% black/African American, 2.3% Asian, 2.1% of two or more races, under 1% Indian and Hawaiian/Pacific Islander, and 6.2% of other races. Essex County has the third highest percentage of Hispanic/Latino of any race, at 11% of the total county population. Boston and the South Shore port group is composed of Middlesex, Suffolk, Norfolk and Plymouth counties, which are among the Massachusetts counties with the largest total populations. Boston is in Suffolk County, which has the highest percentage of non-whites (42.2%) of any of the counties in Massachusetts. The population is 22.2% black/African American, 7% Asian, 4.4% of two or more races, and 8-9% all other races. Suffolk has the highest percentage of Hispanic/Latino of any race, at 15.5% of the total population. The total populations of Middlesex, Norfolk, and Plymouth counties are between 86% and 89% white, 3.2-4.6% black/African American, 1-6% Asian, 1.4-2.5% of two or more races, and 1-3% of all other races. Barnstable, Dukes and Nantucket counties make up the Cape and Islands port group. The populations of Barnstable and Dukes are over 90% white, with approximately 2% black/African American, 1.7-3.2% of two or more races, and 2-4% all other races combined. Nantucket is 87.8% white, 8.3% black/African American, and below 2% of each of the other races. The New Bedford Coast port group is in Bristol County, which is also predominantly white.

9.4.5.8.1 Gloucester and the North Shore

Gloucester and other North Shore communities discussed in this document are located in Essex County.

Essex County	1990		2000		Percent change
Population (total individuals)	670,080		723,419		8.0%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	80.2%		84.6%		Difference = 4.4%
Poverty* (Number of families)	13,193		12,233		-7.3%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	24,625	6.9%	16,880	4.6%	-31.5%

Table 605 - Population, education, poverty and unemployment statistics for Essex County, MA (1990 and 2000)

** data shown for 1989 and 1999*

Data source: U.S. Census Bureau

The total population in Essex County increased 8.0% between 1990 and 2000 (Table 605). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 80.2% in 1990 to 84.6% in 2000, a rise of 4.4 percentage points over the period. The number of families living in poverty decreased about 7%, and the number of unemployed decreased 31.5% from 1990 to 2000. The unemployment rate declined from 6.9% of the labor force in 1990 to 4.6% in 2001.

Fishing Industry Employment in Gloucester and the North Shore

Essex County

The number of reported fishing establishments increased 5.4% from 816 in 1997 to 860 in 1998, and declined 7% between 1998 and 2000 (Table 606). The average payroll for individuals in the fishing sector was $48,395 in 2000. The number of establishments in the seafood product preparation and packaging, fresh and frozen seafood processing, and fish and seafood markets sectors increased from 1998 to 2001. The number of seafood canning establishments remained small but stable after 1998, with two reported establishments in each year. Fish and seafood wholesale reported the greatest number of establishments after the fishing sector, and was the only other sector besides fishing to report a decline in numbers (66 in 1998 to 47 in 2001).

NAICS Code and Description		1997	1998	1999	2000	2001

9.4.5.8.1.1 Gloucester, MA

Gloucester, Massachusetts has been identified as a primary multispecies port.

MARFIN – The MARFIN Report provides a detailed profile of Gloucester. It also includes a general profile of the North Shore sub-region and Essex County, the county in which Gloucester and the North Shore communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Gloucester has been a fishing port since it was founded in 1623. One individual told MARFIN researchers, "everyone in Gloucester knows a fisherman." It is a tight community where fishing is still an honorable profession. It was mentioned in the MARFIN Report that Gloucester is probably diversified enough to sustain itself without fishing, but it is hard to imagine a city like Gloucester without commercial fishing.

Gloucester's inner harbor is a "designated port area," thus legally bound to maintaining marine dependent uses.

The 1990 Census reported that 28,716 individuals lived in Gloucester, and in 1996, that number increased to 29,267. In 1997, there were 226 federally-permitted vessels in Gloucester. One respondent from the MARFIN Report estimated that 90% of the fleet was born in the Gloucester area, and sixty percent of those individuals have fishing in their family history. Gloucester is the original home of frozen fish thanks to Gloucester native, Clarence Birdseye, who developed the technique of freezing fish. Today, Gloucester is still the leader in processing frozen fish, but most of the fish is imported from Canada, Iceland, and Norway. Gloucester has a large infrastructure for commercial fishing including dealers, trucking companies, the Gloucester Display Auction, and several fuel companies. In 1997, it was estimated that there were 1,581 employees earning $58 million in the seafood processing and wholesaling industry in Gloucester.

Most fishermen in Gloucester are full-time, but due to fishery regulations many have supplemented their income with other land-based jobs such as mechanics or construction workers. The MARFIN Report found that most fishermen from Gloucester are full-time groundfish fishermen or lobstermen. There are numerous fishing-related organizations in Gloucester, and many of them have been active in the regional fisheries management process. The communication between the fishing industry and government representatives is said to be "strong" in Gloucester. The presence of recreational fishing is growing, and whale watching is another active industry in this port.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Gloucester, Massachusetts on November 1, 2000, and many residents from Gloucester and surrounding communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Gloucester relate to impacts on children and the younger generation in the community from stress, uncertainty, and changes in the family structure as well as safety issues associated with adaptations that fishermen are making in response to decreased fishing opportunities (less crew, less maintenance, more risk-taking). The groundfish regulations that Gloucester residents feel have produced the most significant social impacts in this community are the Gulf of Maine area closures, both year-round and seasonal. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Additional Community Information – Gloucester's fishing industry is supported by a seafood display auction. In August of 2000, Council staff had the opportunity to interview the general manager of the Gloucester Seafood Display Auction. The bullets below summarize some interesting information about activity at the auction (from August 2000 Council staff interview with general manager of the auction):

- The Gloucester Display Auction (GDA) opened its doors in December of 1997. The GDA was founded partially as a response to increasing regulations and partially as a business venture to increase marketing opportunities for local vessels. The GDA facility is about 40,000 square feet.
- Over the course of a year, the GDA services more than 300 vessels. Most of the vessels are local (from Gloucester and surrounding areas), although there is some crossover with vessels from ME, and there is an offshore vessel fleet from Rhode Island that offloads at the auction seasonally.
- Currently, the GDA employs 15-20 people year-round, and an additional 20-30 people seasonally, totaling about 40-50 people on an annual basis. This should increase as the auction continues to expand its capabilities.
- In general, the GDA is heavily dependent on groundfish. Primary species on the auction floor include haddock, cod, pollock, and hake. The GDA doesn't handle as much monkfish and flatfish as the Portland Fish Exchange.

- Cod regulations have impacted business at the GDA greatly because there are fewer boats dayfishing. In order to make a trip, vessels have been "fishing through cod" to catch enough flatfish. The result has been a lower quality flatfish product.
- The general manager also discussed the notion that the rolling closures put too much pressure on one area that is open at a time (inshore areas). The rolling closures have resulted in shifts of effort and concentrations of effort that have devastated the price of some species. Effort becomes concentrated in small areas, and the vessels all pound an area, pound the bottom, decrease the quality of the product, and flood the market with too much product. Processors, facing decreased local product and uncertainty about the future, have contracted for international products and are in the frozen H&G market now. Frozen product has a set price and consistent supply. Processors cannot stop their operations to take fresh product when there is a glut and hope that they can process it quickly enough before it spoils. In turn, the price for locally-caught fresh fish has plummeted.

In 1999, the City of Gloucester published a Harbor Plan designed to rejuvenate Gloucester's waterfront and maintain the social and cultural infrastructure to allow this port community to continue to grow and evolve to meet the needs of its residents. The 1999 Gloucester Harbor Plan, developed by an 18 member Committee representing harbor user groups and citizens, was accepted by the Mayor and the City Council in March 1999 and approved by the Massachusetts Secretary of Environmental Affairs on July 6, 1999. The Plan includes a three-pronged strategy to meet the community's goals:

1. Rebuild Harbor Infrastructure
2. Strengthen the Traditional Port
3. Celebrate Historical and Cultural Assets

Copies of the Gloucester Harbor Plan are available through the City of Gloucester as well as the Gloucester Fisheries Commission. This Plan should be referenced for additional information about the community of Gloucester as well as to emphasize the importance of fishing and fishing-related businesses to the city.

Fishing Activity in Gloucester, MA

By Port of Landing

The number of active permitted multispecies vessels decreased 18% from 350 in 1994 to 286 in 1995, and increased to 321 in 1998 (Table 607). Since 1998, this number generally declined, reaching 301 in 2001. The number of multispecies vessels landing groundfish decreased from 1994 to 1996, generally increasing afterwards. While the total number of vessels reporting groundfish landings remained relatively stable over the time period, this number increased as a proportion of the total number of vessels reporting landings of any species, from 75% in 1994 to 87% in 2001. Total landings in Gloucester doubled from 1994 to 1998, declined 63% from 1998 to 1999, and remained stable from 1999 to 2000, more than doubling in the following year. Revenues remained relatively stable from 1994 to 2001. Groundfish landings declined about 17% from 1994 to 1995, then increased from 1995 to 2001. Revenues followed a similar trend except from 1999 to 2000, when revenues decreased while landings increased. Small mesh non-multispecies composed the majority of total landings, increasing four-fold from 1994 to 1998, followed by a decline through 2000. Landings of small mesh multispecies, high value species and other species generally declined throughout the time period. Groundfish comprised the second greatest proportion of total landings across the period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001
Number of Active Multispecies Vessels	350	286	297	292	321	280	314	301
Number of Multispecies Vessels Landing Groundfish	264	229	192	197	221	216	279	261

Table 607 - Landings and Revenues from Multispecies Permit Holders in Gloucester, MA (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels homeported in Gloucester remained relatively stable from 1994 to 2001, with some decline through the late-1990s (Table 608). The numbers of active vessels landing any species and those landing groundfish declined approximately 14% and 10%, respectively during this time period. Total landings and revenues generally increased from 1994 to 1998 then dropped in subsequent years. 2001 landings were 58% lower than landings reported in 1994. Groundfish landings remained relatively stable across the time period, fluctuated around a mean of 10 million pounds from 1994 to 2000 and increasing 23.6% from 2000 to 2001. Groundfish dependence remained stable from 1994 to 2000, averaging 63% each year, and increased to 71.4% in 2001.

9.4.5.8.1.2 The North Shore of Massachusetts

The North Shore of Massachusetts is a secondary multispecies port group that includes Rockport, Newburyport, Beverly, Salem, Marblehead, Manchester, and Swampscott. These communities are located in Essex County.

MARFIN – The MARFIN Report provides detailed profiles of Rockport and Marblehead, Massachusetts. It also includes a general profile of the Gloucester/North Shore sub-region and Essex County, the county in which the North Shore communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Gloucester, MA on November 1, 2000. A few residents from North Shore communities attended and submitted comments. While attendance from these communities was not overwhelming, the information collected at these two social impact meetings may reflect, at least in part, the perspectives of the residents of these communities, especially because some of these communities are very closely connected to Gloucester. The summary from these meetings can be found in Appendix I.

Fishing Activity on the North Shore

By Port of Landing
The number of active multispecies vessels and those reporting landings of groundfish on the North Shore increased from 1994 to 2001 (Table 609). By 2000, 100% of the active multispecies vessels were reporting groundfish landings. Total and groundfish landings increased from 1994 to 1995, declined 1995 to 1999, and increased in the last two years of the time period. Small mesh non-multispecies landings demonstrated a steep decline from 1994 to 2001, while small mesh multispecies landings fluctuated during this period. Groundfish landings increased nearly 46% from 1994 to 2001, and made up the greatest percentage of total landings in all years.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 609 - Landings and Revenues from Multispecies Permit Holders in the North Shore Group (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels declined from 1994 to 1999 and increased in the following two years (Table 610). Total active and those reporting groundfish declined throughout the time period. Total landings by vessels homeported on the North Shore declined steadily, with an average decrease of 4.5% each year. Revenues followed a similar trend. Groundfish landings declined from 1994 to 1999, demonstrating a substantial increase from 2000 to 2001. The groundfish landings in 2001 were 15% lower than those reported in 1994. Dependence on groundfish changed little throughout the time period, averaging 56.8% each year.

9.4.5.8.2 Boston and the South Shore

Boston and other south shore communities discussed in this document are located in Middlesex, Suffolk, Norfolk, and Plymouth counties.

Middlesex County	1990		2000		Percent change
Population (total individuals)	1,398,468		1,465,396		4.8%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	84.3%		88.5%		Difference = 4.2%
Poverty* (Number of families)	14,831		15,740		6.1%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	46,588	5.8%	27,660	3.4%	-40.6%

Table 611 - Population, education, poverty and unemployment statistics for Middlesex County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Middlesex County increased 4.8% between 1990 and 2000 (Table 611). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 84.3% in 1990 to 88.5% in 2000, a rise of 4.2 percentage points over the period. While the number of families living in poverty increased about 6%, the number of unemployed decreased 40.6% from 1990 to 2000. The unemployment rate declined from 5.8% of the labor force in 1990 to 3.4% in 2001.

Suffolk County	1990		2000		Percent change
Population (total individuals)	663,906		689,807		3.9%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	75.4%		78.1%		Difference = 2.7%

Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	30,099	8.3%	25,017	7.1%	-16.9%

Table 612 - Population, education, poverty and unemployment statistics for Suffolk County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Suffolk County, which includes the city of Boston, is the most urban county in this community group. The total population in Suffolk County increased 3.9% between 1990 and 2000 (Table 612). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 75.4% in 1990 to 78.1% in 2000, a rise of 2.7 percentage points over the period. While the number of families living in poverty increased 4%, the number of unemployed decreased nearly 17% from 1990 to 2000. The unemployment rate declined from 8.3% of the labor force in 1990 to 7.1% in 2001. The unemployment rate in Suffolk County is nearly double the rate in Norfolk, Middlesex and Plymouth counties. Educational attainment is also lower than that in other counties on the south shore.

Norfolk County	1990		2000		Percent change
Population (total individuals)	616,087		650,308		5.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	88.0%		91.3%		Difference = 3.3%
Poverty* (Number of families)	4,919		4,824		-1.9%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force

Table 613 - Population, education, poverty and unemployment statistics for Norfolk County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Norfolk County increased 5.6% between 1990 and 2000 (Table 613). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 88% in 1990 to 91.3% in 2000, a rise of 3.3 percentage points over the period. The number of families living in poverty decreased about 2%, and the number of unemployed decreased 42.7% from 1990 to 2000. The unemployment rate declined from 5.5% of the labor force in 1990 to 3.2% in 2001.

Plymouth County	1990		2000		Percent change
Population (total individuals)	435,276		472,822		8.6%

Table 614 - Population, education, poverty and unemployment statistics for Plymouth County, MA (1990 and 2000)

** data shown for 1989 and 1999*

Data source: U.S. Census Bureau

The total population in Plymouth County increased 8.6% between 1990 and 2000 (Table 614). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 83.8% in 1990 to 87.6% in 2000, a rise of 3.8 percentage points over the period. While the number of families living in poverty increased about 2%, and the number of unemployed decreased 39% from 1990 to 2000. The unemployment rate declined from 7.1% of the labor force in 1990 to 4.1% in 2001.

Fishing Industry Employment in Boston and the South Shore

Middlesex County

The number employed in the fishing sector was reported at 84 in 1999, but could not be reported in other years from 1997 to 2000 due to confidentiality reasons (Table 615). The fish and seafood wholesale had the greatest number of establishments after fishing, with an average of 17 in each year from 1998 to 2001. Between 14 and 15 fish and seafood markets were reported each year from 1998 to 2001, increasing to 18 in 2001. Seafood product preparation and packaging and fresh and frozen seafood processing sectors reported 1-2 establishments each year, remaining stable throughout the time period. There were no seafood canning establishments reported in Middlesex County.

Suffolk County

The number of individuals employed in fishing increased from 80 in 1997 to 88 in 1998 and remained stable through 2000 (Table 616). The average payroll for fishing sector establishments was $60,375 in 2000. Between 44 and 49 establishments were reported in the fish and seafood wholesale sector in 2000. With around ten establishments in each year from 1998 to 2001, the seafood product preparation and packaging and fresh and frozen seafood processing sectors remained stable throughout the time period. Fish and seafood markets numbered, on average, 12 each year. No establishments were reported in the seafood canning sector.

Norfolk County

The fishing sector reported 141 establishments in 1997 and 1998, increasing to 158 in 1999, and declining to 149 in 2000 (Table 617). The average annual payroll was $43,691 for individuals in this sector. The fish and seafood wholesale sector reported 8-9 establishments each year from 1998 to 2001, and the fish and seafood markets sector reported 6-7 during this period. Other sectors were reported in low numbers.

Plymouth County

Total fishing establishments increased over 13% from 502 in 1997 to 569 in 1999, followed by a decrease to 531 in 2000 (Table 618). The average payroll during 2000 for individuals in this sector was $48,339. After 1998, the fish and seafood markets sector remained stable, reporting 13 establishments in each year. The number of establishments in the fish and seafood wholesale sector averaged 20 per year across the period. Other sectors remained small but stable from 1998 to 2001.

9.4.5.8.2.1 Boston, MA

Boston, Massachusetts has been identified as a primary multispecies port. It is located in Suffolk County.

MARFIN – The MARFIN Report provides a detailed profile of Boston, Massachusetts. This profile should be referenced for social and demographic data not contained in this document.

Boston has historically been a harbor dominated by maritime industries such as fishing, shipbuilding, trade, and commerce. Although Boston is no longer considered a fishing-dependent community with high annual landings, it still provides numerous support services for smaller ports all over New England. MARFIN categorizes Boston as an essential provider to the regional industry. Today, Boston is the major center of international transshipment of fishing products from all over New England. Boston has a container cargo port, rail accesses, major highways and an international airport. MARFIN notes that while the number of processors and fish harvesters have declined, fishing has remained a critical component of Boston's economy. It is interesting to note that the Boston Auction used to handle about one million pounds of fish each day; today, the average is 50,000 pounds each day. Respondents explained to MARFIN that due to the regulations that require vessels to take their nets apart when transiting the closed areas, fishermen decided to land in outlying ports instead of Boston.

MARFIN concluded that Boston specializes in fresh fish production and wholesale marketing, which employs roughly 1,063 individuals earning $40 million in 1997. The workforce in the fishing industry in Boston is rather diverse; some processor employees are first-generation immigrants from regions like Guatemala and Mexico, lobstermen are predominantly English, Irish, and Scottish, and draggers are primarily Polish or Italian-Americans. MARFIN found that there are about 12 draggers left in the port of Boston and 20-30 lobster boats, together employing about 100 fishermen. The average income per fishermen in 1997 was $23,000. The majority of vessels were found to be owner-operated. MARFIN received feedback that recreational sailing seems to be more prominent in this harbor than recreational fishing.

Social Impact Informational Meetings – Council staff conducted an impromptu social impact informational meeting in Boston, Massachusetts on December 4, 2000, and many residents from Boston and surrounding communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Boston relate to employment stability, the loss of year-round fishing opportunities, and concerns about safety as fishermen adapt to regulations by trying to maximize their available DAS and fish farther from shore and in more extreme weather. The groundfish regulations that Boston residents feel have produced the most significant social impacts in this community are the Amendment 5/7 DAS allocations and reductions. Many vessels in Boston have Individual DAS permits, and meeting participants noted the loss of opportunity and flexibility that resulted from the 50% reduction in Individual DAS. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Fishing Activity in Boston, MA

By Home Port State

The number of active permitted multispecies vessels peaked in 1997 at 92 vessels, with an overall decline across the time period from 77 vessels in 1994 to 39 vessels in 2001 (Table 619). Those landing groundfish also declined in number, from 76 vessels in 1994 to 35 vessels in 2001. The percentage of active multispecies vessels reporting landings of groundfish remained high throughout the time period, ranging from 76-100% of the total active vessels. Total landings in Boston declined gradually across the time period, except for a 57.6% increase from 2000 to 2001. Revenues declined constantly from 1994 to 2001. Groundfish landings and revenues declined as well, the 1994 landings nearly twice that in 2001. Groundfish made up the greatest proportion of the total landings during the time period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 619 - Landings and Revenues from Multispecies Permit Holders in Boston, MA (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

The number of permitted multispecies vessels, active vessels, and those reporting landings of groundfish declined from 1994 to 2001 (Table 620). Total landings remained relatively stable, except for a peak in 1997 at 8 million pounds. Overall, total landings exhibit a slight positive trend. Groundfish landings rose from 1994 to 1997, declined 1997 to 1999, increasing afterwards. Dependence on groundfish did not change dramatically, averaging 62.4% per year.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.8.2.2 The South Shore of Massachusetts

The South Shore of Massachusetts is a secondary multispecies port group that includes Scituate, Plymouth, and Marshfield (Green Harbor). These communities are located in Middlesex, Norfolk and Plymouth counties.

MARFIN – The MARFIN Report provides detailed profiles of Plymouth and Scituate, Massachusetts. It also includes a general profile of Plymouth County, the county in which the South Shore communities are located. These profiles should be referenced for social and demographic data not contained in this document.

The Pilgrims landed in Plymouth in 1620, and it became the first permanent settlement in New England. Plymouth is about five miles north of the Cape Cod Canal and attracts thousands of tourists each summer; however, the area still maintains a diverse commercial fishery. Scituate is a small to mid-sized community located equidistant from Boston and Plymouth. There are two piers in Plymouth, one reserved for the Mayflower, and the other reserved for commercial use. The local community has agreed to protect 15% of total dockage space for the commercial fleet, while recreational boats use the remaining 85%. Fishery dependence in Plymouth is based on the lobster industry. MARFIN found that there are 50 lobster vessels in Plymouth as well as four stern draggers and four gillnetters. Four stern draggers is a significant decline from 30 or so draggers that used to harvest dogfish in Plymouth just five years ago. Key respondents in the MARFIN report estimated that there are 200 households directly dependent on fishing in Plymouth, and another 50-100 indirectly dependent. The majority of fishermen from this area were born to fishing families, but fewer children seem to be getting into the industry. There are limited fish dealers and support services in Plymouth. There are substantial businesses that support the recreational sector including five boat yards, marinas and hotels.

Scituate used to have many commercial boats in its harbor, but today there are only four mid-sized trawlers, five gillnet vessels, and about 50 lobster boats. MARFIN determined that before the groundfish regulations, there were 15-18 draggers that now go lobstering instead. Seventy-five to one hundred vessels were homeported in Marshfield, and fifteen of them were charter boats. Dogfish used to be a major species for Marshfield vessels, but recent regulations have eliminated that fishery. Similar to Plymouth, there are no processing facilities in Scituate, and little infrastructure to support the commercial fishing industry. Marshfield on the other hand, is a center for tuna landings, with infrastructure for processing and transporting tuna to Logan Airport in Boston. MARFIN reported that about 300 fishermen live in the Scituate/Marshfield area, and another 100 households are indirectly dependent on commercial fishing.

Respondents in Scituate told MARFIN researchers that the economic condition of the fishing industry was "excellent" ten years ago. "Everyone had the freedom to fish and some chose to take the pressure of groundfish" and went after dogfish. Today, fishermen from this believe the closures in blocks 124 and 125 put Scituate boats at a disadvantage. MARFIN reports that a lot of boats have gone out of business and some have switched from finfishing to lobstering.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Scituate, Massachusetts on December 4, 2000, and many residents from Scituate, Plymouth and surrounding South Shore communities attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of South Shore communities relate to stress and loss of morale resulting from regulatory discarding and uncertainty, employment stability, and conflicts resulting from perceived inequities in the regulations (big boat/small boat, commercial/recreational). The groundfish regulations that South Shore residents feel have produced the most significant social impacts in this community are the Gulf of Maine rolling closures. These closures were cited for eliminating year-round fishing opportunities, reducing flexibility, and compromising safety as small vessels adapt by fishing with less crew and/or farther from shore. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Fishing Activity on the South Shore

By Port of Landing

The number of vessels landing fish in south shore ports increased almost 28% from 1994 to 1995, generally declining afterwards to 70 vessels in 2001 (Table 621). The number of vessels landing groundfish remained more stable, with a dip in 1997 to 58 vessels, averaging 73 in all other years. Total landings nearly doubled from 1994 to 1995, remained stable in the following year, and declined 74% from 1996 to 2001. This trend was driven by landings of Other Species, which made up the greatest proportion of total landings in most years. Groundfish landings increased, with an average annual increase of 11.8%. Small mesh multispecies landings fluctuated throughout the time period, while small mesh non-multispecies remained low throughout the period, with a peak of 128,000 pounds in 1998. High value species landings were low and relatively consistent until 2000, when landings increased 441% from the previous year.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 621 - Landings and Revenues from Multispecies Permit Holders in the South Shore Group (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels on the south shore remained fairly stable from 1994 to 2001, averaging 167 vessels throughout the period (Table 622). The number of active vessels remained fairly consistent from 1994 to 1999, and declined in 2000 and 2001. Active vessels reporting landings of groundfish increased in number, from 38 in 1994 to 53 in 2001, remaining stable from 1995 to 1999 with an average of 48 vessels during these years. Total landings by vessels homeported in the south shore fluctuated, with a generally increasing trend across the time period while revenues declined slightly. Groundfish landings fluctuated as well but the trend did not reflect that for total landings. Groundfish dependence changed very little, averaging 48% from 1994 to 2001.

9.4.5.8.3 Cape Cod and The Islands

Cape Cod and the islands in proximity to the Cape are located in Barnstable, Dukes and Nantucket counties.

Barnstable County	1990		2000		Percent change
Population (total individuals)	186,605		222,230		19.1%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	88.4%		91.8%		Difference = 3.4%
Poverty* (Number of families)	3,030		2,833		-6.5%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	6,314	7.1%	5,483	5.2%	-13.2%

Table 623 - Population, education, poverty and unemployment statistics for Barnstable County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Barnstable County increased more than 19% between 1990 and 2000 (Table 623). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 88.4% in 1990 to 91.8% in 2000, a rise of 3.4 percentage points over the period. The number of families living in poverty declined 6.5%, and the number of unemployed decreased 13.2% from 1990 to 2000. The unemployment rate declined from 7.1% of the labor force in 1990 to 5.2% in 2001.

Dukes County	1990		2000		Percent change
Population (total individuals)	11,639		14,987		28.8%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	90.4%		90.4%		Difference = 0%
Poverty* (Number of families)	121		192		58.7%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	380	6.1%	221	2.7%	-41.8%

Table 624 - Population, education, poverty and unemployment statistics for Dukes County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Dukes County is very small and demonstrated a greater increase than that of Barnstable County, rising 28.8% between 1990 and 2000 (Table 624). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school was 90.4% in 1990 and was reported at the same percentage in 2000. It is likely that this value was reported in error in the source database, given that the proportion of the adult population graduating from high school or higher has increased since 1990 in nearly all other counties examined. While the number of families living in poverty increased about 58.7%, the number of unemployed decreased 41.8% from 1990 to 2000. The unemployment rate declined from 6.1% of the labor force in 1990 to 2.7% in 2001.

Nantucket County	1990		2000		Percent change
Population (total individuals)	6,012		9,520		58.3%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	89.4%		91.6%		Difference = 2.2%
Poverty* (Number of families)	40		63		57.5%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	75	2.1%	244	4.3%	225.3%

Table 625 - Population, education, poverty and unemployment statistics for Nantucket County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

Nantucket County has the smallest population in Massachusetts, with an increase from about 6,000 to about 9,500 individuals over the past decade, representing a 58.3% increase from 1990 to 2000 (Table 625). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 89.4% in 1990 to 91.6% in 2000, a rise of 2.2 percentage points over the period. Both poverty and unemployment increased since 1990. The number of families living in poverty increased about 57.5% from 1990 to 2000, while the number of unemployed increased over 225% during this period. The unemployment rate rose from 2.1% of the labor force in 1990 to 4.3% in 2001. Despite the increase, unemployment remains low in Nantucket County.

Fishing Industry Employment in Cape Cod and The Islands

Barnstable County

The number of fishing establishments increased almost 10% from 1997 to 2000, averaging $36,670 per establishment in 2000 (Table 626). Fish and seafood wholesale establishments declined from 30 in 1998 to 24 in 2001, while the number of fish and seafood markets remained relatively stable over the period, averaging 21 establishments per year. There were no reported establishments in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

NAICS Code and Description		1997	1998	1999	2000	2001

Dukes County

The number employed in the fishing sector increased from 1997 to 2000, averaging $20,172 per establishment in 2000 (Table 627). The fish and seafood wholesale sector reported three establishments in each year from 1998 to 2001. The fish and seafood markets sector also demonstrated stability over the time period, reporting one establishment each year. There were no reported establishments in the fresh and frozen seafood processing, seafood product preparation and packaging and seafood canning sectors.

9.4.5.8.3.1 Chatham/Harwichport, MA

Chatham/Harwichport, Massachusetts has been identified as a primary multispecies port group. Because of their proximity and similarity in fisheries, Chatham and Harwichport will be examined as one primary community group. Chatham and Harwichport are located in Barnstable County.

MARFIN – The MARFIN Report provides a detailed profile of Chatham, Massachusetts. It also includes a general profile of the Cape and Islands sub-region and Barnstable County, the county in which Chatham and Harwichport are located. These profiles should be referenced for social and demographic data not contained in this document.

Chatham, MA is a small coastal town on Cape Cod that is primarily known as a tourist destination. In addition to great beaches and quaint shops, another major attraction for tourists in Chatham is the opportunity to view fishermen unload their catch on the Town Pier. Chatham is a geologically diverse area that supports a vast number of different fisheries. According to the 1990 Census, the year-round population was 6,600 in 1989, but it is estimated that this number is increasing significantly in recent years. Close to half of the homes in Chatham are vacant in the winter months, and roughly one-third of the population is over 65. The population of Chatham in 1989 was 98.6% white, and the median household income was $31,315. The largest category of employed residents is in 1995 was the "services" category, and fishing made up 12% of this category, representing a significant portion of the overall employment in Chatham.

According to Chatham harbormaster documents, there are 279 commercial vessels at the Chatham Fish Pier and Stage Harbor mooring areas. It is estimated that about two-thirds of these vessels are small skiffs used for shellfishing. MARFIN found that there are currently 64 vessels with docking permits for the Town Pier; 22 gillnets, 17 longliners, 5 combination, 8 lobster vessels, several handline vessels, several draggers, and four party/charter boats. The Town Pier facilities are maintained by the Town and are dedicated solely to commercial fishing interests. In addition to the Town Pier, the majority of finfish activity actually takes place on the two private docks adjacent to the Town's facility. MARFIN found that the fleet in Chatham primarily targets Georges Bank stocks of groundfish and dogfish. The major species landed are codfish, dogfish, monkfish, haddock, bluefin tuna, and lobster. Chatham also has a substantial shellfish industry. There are numerous support services for the fishing industry in Chatham such as fish buyers, cutters, gear workers, and shellfish shuckers. Some fishermen in this area only fish part of the year, and others switch their gear to fish for longer periods of time. MARFIN found that the majority of vessels in Chatham are owner-operated.

The recreational sector is growing in Chatham. MARFIN determined that the favorite species for recreational fishermen in Chatham were striped bass, followed by bluefish, scup and cod. MARFIN found many fishing related organizations in Chatham and some of them are very active in supporting Chatham fishermen and representing their voice in fisheries management. All fishermen interviewed by MARFIN believe there has been a change in effort over the past ten years, accept for shellfish, which has remained stable over the years. Some Chatham fishermen voiced that they want to diversify, but they cannot get the permits to do it.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Chatham, Massachusetts on November 2, 2000, and many residents from Chatham and Harwichport attended and submitted comments. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Chatham relate to frustration with the federal fisheries management process, the loss of flexibility for the small-boat fleet, and the loss of quality of life and sense of community resulting from turning fishing into a "numbers game." The groundfish regulation that Chatham residents feel have produced the most significant social impacts in this community is the May closure on Georges Bank for Georges Bank cod. This closure was cited for reducing fishing opportunities and flexibility. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Fishing Activity in Chatham/Harwichport, MA

By Port of Landing

The number of active multispecies vessels and those landing groundfish generally decreased from 1994 to 1998 and fluctuated during the following years, with an increase in 2001 (Table 629). Overall, the number of active vessels demonstrated a declining trend from 1994 to 2001. Total landings in Chatham/Harwichport exhibited a slight downward trend with little fluctuation across the time period. Groundfish landings increased slightly from 1994 to 2001, with the greatest decline during the time period from 1997 to 1998 (26.5% decrease). Small mesh multispecies landings declined substantially from 1994 to 1995, gradually increasing during subsequent years. Small mesh non-multispecies landings increased almost seven-fold from 1995 to 1997, declined 92% in the following year, increased steeply from 1998 to 1999, then remained stable at the end of the time period. Other species comprised the majority of total landings in Chatham/Harwichport across the period, and demonstrated a generally declining trend.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 629 - Landings and Revenues from Multispecies Permit Holders in Chatham/Harwichport, MA (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

After a 55% increase from 1994 to 1995, total landings decreased at an average of 8% per year from 1995 to 2001 (Table 630). Groundfish landings increased, from 4.3 million pounds in 1994 to 5.9 million pounds in 2001. The percentage of total revenues made up by groundfish revenues ranged from 49% (1995) to 74% (2000), fluctuating across the time period.

9.4.5.8.3.2 Provincetown, MA

Provincetown, MA has been identified as a secondary multispecies port. Provincetown was examined as a separate community group because of its geographic isolation, unique fleet and industry characteristics, and its potential to be significantly impacted by changes to groundfish management measures. Provincetown is located in Barnstable County.

MARFIN – The MARFIN Report provides a detailed profile of Provincetown, Massachusetts. It also includes a general profile of the Cape and Islands sub-region and Barnstable County, the county in which Provincetown is located. These profiles should be referenced for social and demographic data not contained in this document.

Provincetown, often referred to as "P-town," is located at the tip of Cape Cod. MARFIN documented that it grew very slowly during the 18th century and its population fluctuated with the price of fish. By the mid 1800s as whaling became a major industry in New England, Provincetown transformed into "the largest and safest natural harbor on the New England coast." However, MARFIN reported that in the last 15 or so years, the commercial fishing industry in Provincetown has experienced a major downturn due to inshore area closures and declines in fish stocks. Because P-town did not diversify in its industry's development, the vessels have not been able to recover. Furthermore, there is little support from local representatives and the community at large to preserve the commercial fleet in Provincetown. MARFIN reports another disadvantage for P-town is its geographical location. Although Provincetown is the second deepest natural harbor in the world, its location is too far from major fish markets. The Portuguese community and influence in Provincetown is still very strong, but in the last 25 years, many more successful Portuguese fishermen have left and moved to New Bedford.

MARFIN documented that in 1996, there were 28 large vessels and 19 small jig boats, and only 17 of the 28 larger vessels were in safe working condition. In 2001, only eight of the 28 large vessels are reported to be in operation, along with twelve small longlining/jigging/lobstering boats. The MARFIN Report estimates that 25 individuals are involved in groundfish fishing, 20 in lobstering, and ten in other small-scale fisheries. It is predicted that these 55 individuals affect 26 households in Provincetown. MARFIN found that fishermen from Provincetown believe that closures in nearby waters, including Stellwagen, and limited DAS restrictions are the measures that have impacted fishermen most. MARFIN concludes that, "Provincetown epitomizes what can go wrong in a port highly reliant on one fishery albeit a multispecies fishery."

Fishing Activity in Provincetown, MA

By Port of Landing

The number of active multispecies vessels landing fish in Provincetown generally declined over the period from 1994 to 2001 (Table 631). Total landings decreased 54% from 1994 to 1995, generally increasing afterwards. Groundfish landings gradually declined from 1994 to 1999, with a sharp increase of around 87% from 1999 to 2000, followed by a 12% decline in the last year of the period. Small mesh non-multispecies landings declined substantially from 1994 to 1995, gradually increasing in the following years. Other species, which made up the bulk of total landings throughout the time period, declined through 1997, increased to a peak of 1.5 million pounds in 1998, and declined again afterwards.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 631 - Landings and Revenues from Multispecies Permit Holders in Provincetown, MA (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/reve nues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

The number of permitted multispecies vessels increased slightly from 1994 to 1995, then generally declined in the following years (Table 632). The number of active vessels was stable in the first three years of the period, generally decreasing after 1996. 26 vessels landed groundfish in 1994 and 1995, this number declining to 23 in 1996 and remaining relatively stable through 2001. Total landings declined from 1994 to 1995, followed by a gradual upward trend through 2001. Revenues were relatively stable from 1994 to 2000, with a 79% increase from 2000 to 2001. Groundfish landings and revenues fluctuated, with an overall negative trend over the period. Groundfish revenues as a percentage of total revenues generally decreased from 55.4% in 1994 to 30.5% in 2001, with a peak of nearly 70% in 1995.

9.4.5.8.3.3 Other Cape Cod, MA

The Other Cape Cod, MA group is a secondary multispecies port group that includes Sandwich, Barnstable (Hyannis), Wellfleet, Woods Hole, Yarmouth, Orleans, and Eastham. These communities are located in Barnstable County.

MARFIN – The MARFIN Report provides detailed profiles of Hyannis and Sandwich, Massachusetts. It also includes a general profile of the Cape and Islands sub-region and Barnstable County, the county in which the Other Cape Cod communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Fishing Activity in Other Cape Cod, MA

By Port of Landing

The number of active multispecies vessels declined after a stable period from 1994 to 1996 and increased again in 2001 (Table 633). Those vessels landing groundfish declined in number from 1994 to 1999, and increased rapidly in the last two years of the time period. Total landings and revenues generally declined from 1994 to 2001, although there was a small increase in 1998 due to increased landings of other species. Groundfish landings declined steeply from 1994 to 1996, followed by a sharp increase from 1996 to 1998. Landings again declined for two years and increased to the highest landings of the time series in 2001, at around 173,000 pounds. Landings of small mesh multispecies were zero or near-zero for all years. Landings of small mesh non-multispecies were also zero or near-zero in all years except for 1994. Other species landings declined from 1994 to 1995, increased from 1996 to 1998, and declined afterwards. High value species landings demonstrated a gradual decline over the period.

By Homeport

The number of permitted multispecies vessels homeported in Other Cape Cod decreased from 131 in 1994 to 91 in 1997, remained stable through 1998, and increased to 137, the maximum number of vessels for the time period, in 2001 (Table 634). The number of active vessels followed a similar trend, reaching 66 in 2001. The number of vessels landing groundfish was relatively stable from 1994 to 1996, declined in 1997, and increased in the following years. From 2000 to 2001, the number of vessels reporting groundfish landings increased 53%. Total landings declined slightly through the late 1990s and increased to the highest level of the time period in 2001, at 3.9 million pounds. Groundfish landings decreased from 1.6 million pounds in 1994 to 730,000 pounds in 1997, increasing in the following years. Dependence on groundfish declined from 46% in 1994 to 27% in 1997, generally increasing in the following years to 38% in 2001.

9.4.5.8.3.4 The Islands, MA

The Islands, MA group is a secondary multispecies port group that includes Nantucket, Oak Bluffs, Tisbury, and Edgartown. These communities are in Nantucket and Dukes counties.

MARFIN – The MARFIN Report provides a detailed profile of Tisbury (Vineyard Haven), Massachusetts. It also includes a general profile of the Dukes County, the county in which the Islands communities are located. These profiles should be referenced for social and demographic data not contained in this document.

Fishing Activity on The Islands
By Port of Landing
The number of active multispecies vessels fluctuated from 1994 to 2001, reaching a maximum of 40 vessels in 1996 (Table 635). The number of multispecies vessels landing groundfish was relatively stable from 1994 to 1997, averaging 13 vessels during that period. No vessels reported landings of groundfish in 1999. Total landings fluctuated between 1994 and 2001, peaking in 1996 and 1999. The highest revenues were reported in 2000, as a result of an increase in landings of high value species during that year. Groundfish landings and revenues declined rapidly after 1996 and none were reported in 1999. In general, landings and revenues of all species groups on the islands nearby Cape Cod fluctuated from 1994 to 2001, and remained low throughout the period.

By Homeport

The number of permitted multispecies vessels decreased from 33 in 1994 to 24 in 2001, with relative stability from 1998 to 2000 (Table 636). The number of vessels homeported in The Islands reporting landings increased from 15 vessels in 1994 to 24 vessels in 1995, declining afterwards and remaining relatively stable in the latter half of the time period. The number of vessels reporting landings of groundfish remained low throughout the period from 1994 to 2001, peaking at 7 vessels in 2000. Total landings increased by almost 90% from 1994 to 1995. After 1995, landings gradually declined until 1999, after which landings increased at an average of 42% per year. Groundfish landings were stable from 1994 to 1995 and peaked in 1996, constantly declining in the following years. Groundfish dependence declined overall, from nearly 28% in 1994 to 10% in 2001, averaging 14.6% over the time period.

9.4.5.8.4 New Bedford/Fairhaven, MA

New Bedford/Fairhaven, Massachusetts has been identified as a primary multispecies port group. These communities are located in Bristol County.

MARFIN – The MARFIN Report provides detailed profiles of New Bedford and Fairhaven, Massachusetts. It also includes a general profile of Bristol County, the county in which the New Bedford and Fairhaven are located. These profiles should be referenced for social and demographic data not contained in this document.

The New Bedford/Fairhaven region was the largest whaling area in the United States, and turned to harvesting and processing finfish and shellfish in the late 1880s. In 1997, the New Bedford Chamber of Commerce said that 60% of the city's economy was supported by the fishing industry. MARFIN noted that a 1999 report found that the seafood industry contributed nearly $609 million in sales and 2,600 jobs, 90 and 70 percent of the sales and employment harborwide. MARFIN found that in the New Bedford/Fairhaven area, there are roughly 75 seafood processors, and wholesale fish dealers, and 200 other shoreside industries; together these businesses employ around 6,000-8,000 additional workers.

Historically, scallops and yellowtail flounder made up the majority of landings in this area. New Bedford is a very industrial waterfront and while it dwarfs Fairhaven in size, there are numerous boat yards and marinas in Fairhaven as well. According to the 1990 Census, 99,922 people lived in New Bedford and 16, 132 in Fairhaven. New Bedford has the largest percentage of Portuguese population in the United States. MARFIN found that the majority of the dragger fleet is Portuguese, while the Norwegian population in New Bedford/Fairhaven work on scallop boats.

MARFIN found that New Bedford has the most developed infrastructure for groundfishing, and is the first port in New England for groundfish landings and revenues. MARFIN determined that there are roughly 250 fishing vessels in New Bedford; close to 100 of these are scallop vessels, and the majority of the rest are groundfish and monkfish vessels. The fleet in Fairhaven is mostly scallopers, but the size is about half of what it was before the groundfish and scallop Amendments were implemented. MARFIN estimates the numbers of fishermen to range from 1,800 to 3,000 for the area over time. The majority of boats in the area are owner-operated, and several owners have small fleets of vessels. The MARFIN Report found that it is more likely to find family members working together on groundfish vessels than on scallop vessels. There are numerous fishing-related organizations in the area, and they have a significant role in providing support the fishing community. MARFIN found that both federal and state legislators generally support the fishing industry in this area, and communication with these representatives is good.

When Georges Bank closed, many fishermen in this area went south to fish for fluke. Most fishermen interviewed in the later part of the MARFIN survey agreed that DAS is the regulation with the most impact on scallopers and groundfishermen. Fishermen are becoming more selective with their fishing effort, getting the most out of every fishing day possible, but some of the older fishermen are finding it difficult to adapt. MARFIN concluded that the uncertainty in the fishing industry and it's future is what most fishermen in this area are concerned about. Most fishermen who responded said they hoped their children would not go into fishing, due to the difficulties associated with constantly changing regulations and lack of financial security.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in New Bedford on November 8, 2000. Residents from New Bedford and Fairhaven attended and submitted comments about the impacts of groundfish regulations since Amendment 5. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of New Bedford relate to the loss of family traditions and the younger generation of fishermen due to uncertainty and instability, and safety concerns. The groundfish regulations that residents feel have produced the most significant social impacts in this community are the DAS allocations and reductions in DAS since Amendment 5. This community is home to many vessels with Individual DAS permits, and these boats have experienced a 50% reduction in their allocated DAS since Amendment 5. Comments concerning the social impacts of the DAS reductions relate to the loss of opportunity and flexibility as full-time operations were converted to part-time. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Bristol County	1990		2000		Percent change
Population (total individuals)	506,325		534,678		5.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	65.0%		73.2%		Difference = 8.2%

Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	21,423	8.1%	15,859	5.8%	-26.0%

Table 637 - Population, education, poverty and unemployment statistics for Bristol County, MA (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Bristol County increased 5.6% from 1990 to 2000 (Table 637). The percentage of individuals 25+ years graduating from high school or higher increased in the county over the decade, from 65% to 73.2%. This educational attainment level is low compared to other New England counties. The number of families in poverty increased 8.5% but unemployment dropped from 8.1% of the civilian labor force to 5.8% between 1990 and 2000.

Fishing Industry Employment in Bristol County, MA

The number employed in the fishing sector decreased from 940 in 1997 to 882 in 1999, increasing to 916 in 2000 (Table 638). The average payroll for those in the fishing sector was nearly $60,000, higher than that for most other counties in New England. The fish and seafood wholesale sector reported the second greatest number of establishments, but declined over the period, from 57 in 1998 to 43 in 2001. The number of establishments in the seafood product preparation and packaging sector remained relatively stable from 1998 to 2001, averaging 14 over the period. The number of fresh and frozen seafood establishments was also stable, averaging 13 from 1998 to 2001. Fish and seafood markets declined from 12 in 1998 to 10 in 2001, while the number of seafood canning establishments remained stable but was reported as a single establishment in the last three years of the period.

Fishing Activity in New Bedford/Fairhaven, MA

By Port of Landing

More permitted multispecies vessels land groundfish in the ports of New Bedford and Fairhaven than in any other New England port group. This number generally increased, from 329 active vessels in 1994 to 386 vessels in 2001 (Table 639). The number of vessels reporting landings of groundfish decreased from 1994 to 1995, remained relatively stable for the next three years, decreased in 1998, increased to a peak of 290 vessels in 1999, and declined to the lowest reported number of the period in 2001. On average, 76% of active vessel reported landings of groundfish in each year from 1994 to 2001. Total landings and revenues increased consistently in New Bedford and Fairhaven from 1994 to 2001. Landings increased 78% from 1994 to 2001, with an average increase of 9.3% each year. Groundfish landings doubled between 1994 and 2001, from approximately 18.5 million pounds to 40.8 million pounds. Groundfish composed the majority of total landings in all years during the time period. Landings of other species, which made up the second greatest proportion of total landings, declined about 32% from 1994 to 2001. High value species landings increased gradually from 1994 to 1998, followed by a sharp increase during the later years of the time series. Landings of small mesh multispecies remained at a relatively constant low level for much of the period, increasing dramatically from around 195,000 pounds in 1999 to 2.8 million pounds in 2001. Small mesh non-multispecies landings rose to a sharp peak in 1998, then dropped in the following years.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 639 - Landings and Revenues from Multispecies Permit Holders in New Bedford/Fairhaven, MA (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of multispecies vessels permitted in New Bedford and Fairhaven declined, from 293 in 1994 to 255 in 2001 (Table 640). The number of active vessels and those reporting landings of groundfish also declined, active vessels landing groundfish dropping almost 43% from 1994 to 2001. Total landings more than doubled from 1994 to 2001, with an average annual rise of 14.2%. Groundfish landings demonstrated a less dramatic increase over the time period. Dependence on groundfish decreased, from 30.5% in 1994 to 24.6% in 2001.

Fishing Activity in Other Bristol County, MA

By Port of Landing

The number of multispecies vessels landing fish in other communities in Bristol County was small, increasing slightly from 1994 to 1995, declining in 1996 and remaining stable for the next three years, and increasing slightly at the end of the time period (Table 641). The number of vessels landing groundfish increased from 6 to 12 vessels between 1994 and 1995 and declined afterwards, reaching a low of 2 vessels in 2001. Total landings increased after a period of decline from 1996 to 1997. Landings in 1995 and 1996 were the highest of the time series, at 1.2 million pounds and 1.4 million pounds, respectively. Groundfish landings demonstrated a large decline from 36,000 pounds in 1996 to 6,000 pounds in 2001. No small mesh multispecies were reported in Other Bristol County, and very low landings of small mesh non-multispecies. Other species and high value species composed the majority of total landings throughout the time period. Both species groups declined in the beginning of the time period and increased afterwards.

By Homeport

The number of permitted multispecies vessels homeported in Other Bristol County decreased from 40 vessels in 1994 and 1995 to 31 in 1997 (Table 642). This number did not change until 2000, with an increase to 36 vessels. The number of active vessels demonstrated a similar trend, increasing to a maximum of 14 vessels in 2001. Few vessels reporting landings of groundfish were homeported in this port group, increasing from 6 vessels in 1994 to 10 in 1996 and decreasing afterwards, with a local maximum of 7 vessels for the period from 1997 to 2001. Total landings increased from 1994 to 2001, with an average annual rise of 16%. Landings peaked in 1996 at 1.8 million pounds. Landings by vessels homeported in Other Bristol County were generally higher than those by vessels landing their catch in this region. Groundfish landings fluctuated across the time period, with a peak of around 89,000 pounds in 1999. The percent of total revenues comprised of groundfish revenues generally decreased, from 10% in 1994 to 2% in 2001. Groundfish dependence in this port group is low compared to other port groups in Massachusetts.

9.4.5.8.5 Other Massachusetts

Fishing Industry Employment in Other Massachusetts

In other ports in Massachusetts, the sum of fishing establishments increased about 43% from 1997 to 1998, decreased to a low of 132 vessels in 1999, then increased again in 2000 (Table 643). The annual payroll for fishing establishments averaged just over $32,000 in 2000. Fish and seafood markets remained stable from 1998 to 2001, averaging 13 establishments over this period. There were 8 fish and seafood wholesale establishments in 1998 and 1999, this number decreasing to 5 in 2000 and 2001. No establishments were reported in fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning.

Fishing Activity in Other Massachusetts

By Port of Landing

The number of active multispecies vessels increased from 1994 to 1996, decreased through 2000, and rose again in 2001 (Table 644). Active vessels demonstrated a generally declining trend across the period. The number of multispecies vessels landing groundfish increased from 78 in 1994 to 140 in 2001, with a rapid rise at the end of the time period. Total landings remained relatively stable over the time period, while groundfish landings fluctuated with a generally increasing trend. Landings of other species composed the bulk of total landings throughout the period, and demonstrated a small overall decline.

By Homeport

The number of permitted multispecies vessels homeported in other Massachusetts ports averaged 396 from 1994 to 2001, decreasing slightly over the time period (Table 645). The number of active vessels and those reporting landings of groundfish decreased after 1994. In 2000, the number of vessels landing groundfish was only 22% of the total number of permitted multispecies vessels. Total landings decreased from 1994 to 2001, the greatest decline occurring from 1996 to 1998. Groundfish landings increased over the period, with a small decline from 1998 to 1999. Groundfish dependence remained low in all years, but increased from nearly 9% in 1994 to around 29% in 2001.

9.4.5.8.6 Massachusetts Summary

Massachusetts has the largest population of all coastal New England states. The unemployment rate in Massachusetts was higher than the national average and the number of families in poverty increased slightly from 1990 to 2000. The North shore, Boston area, and South shore demonstrated increases in groundfish dependence, while on Cape Cod, the Islands, and southeastern Massachusetts groundfish dependence declined. The fishing sector reported the greatest number of nonemployer establishments in Massachusetts from 1997 to 2000, with fish and seafood wholesale and fish and seafood markets sectors following. In southeastern MA and Cape Cod, no canning and few processing, preparation and packaging establishments were reported. In Massachusetts, multispecies permit holders have increased their activity in the groundfish fishery since 1994.

9.4.5.9 Rhode Island

Demographic Profile of Rhode Island

RHODE ISLAND	1990		2000		Percent change
Population (total individuals)	1,003,464		1,048,319		4.5%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	72.0%		78.0%		Difference = 6.0%
Poverty* (Number of families)	17,867		23,608		32.1%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	34,690	6.6%	29,859	5.6%	-13.9%

Table 646 - Population, education, poverty and unemployment statistics for the state of Rhode Island (1990 and 2000)

** data shown for 1989 and 1999*

Data source: U.S. Census Bureau

The total population in Rhode Island increased by 4.5% from 1990 to 2000 (Table 646). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 6% over the course of a decade. While the number of families below the poverty level increased substantially (32.1%), the unemployment rate declined, from 6.6% to 5.8% of the civilian labor force, aged 16 years and older.

Table 647 - Population by race in Rhode Island counties, 2000

Counties examined in Fishing Communities section of AHE in bold type.

Data source: U.S. Census Bureau

The total population of Rhode Island was around 1 million in 2000, just under that of Maine and New Hampshire (Table 647). Rhode Island is 85% white, 4.5% black/African American, 2.3% Asian, 2.7% of two or more races, and 5% other races. Less than 1% of the population is represented by American Indians and Alaska natives and native Hawaiians and other Pacific islanders. 8.7% of the state's population is

Hispanic or Latino of any race. Newport and Washington counties are over 90% white. While the total population of Washington County is larger than that of Newport County, Newport has a higher percentage of non-whites than Washington. Fishing regulations in Rhode Island are not likely to affect large minority populations.

9.4.5.9.1 Point Judith, RI

Point Judith, RI has been identified as a primary multispecies port. Point Judith is located in Washington County.

MARFIN – The MARFIN Report provides a detailed profile of Point Judith, Rhode Island. It also includes a general profile of Washington County, the county in which Point Judith is located. These profiles should be referenced for social and demographic data not contained in this document.

The MARFIN Report summarizes many important aspects of fishing communities in New England including demography, fisheries profiles, and social and economic trends in these communities. The following discussion highlights some of the important information about Point Judith that is presented in the MARFIN Report. The Point Judith/Galilee fishing village developed in the mid-1800s, with the first commercial fishermen using hook and line, beach seines, and floating fish traps. Today, Galilee is a major commercial fishing port. Tourism and gentrification are said to be forcing the fishing industry into the economic background in South County, RI. However, Pt. Judith is the second largest port in New England after New Bedford. Therefore, this port has remained a significant commercial fishing region despite pressures from the recreational sector and the tourism industry.

Point Judith is within the Narragansett township, and based on 1990 Census data, there were 14,985 people in this community, the median income in 1989 was $35,545, and the number of fishermen that live in this town has remained fairly constant over time. The MARFIN Report describes the Point Judith fleet as very diverse and adaptable. Overall, the fleet is fairly modern and in good repair due to the willingness of boat owners to innovate and use different gears and participate in different fisheries. When MARFIN collected their data, there were 134 commercial vessels in this port, ranging from 45-90 ft, with most being ground trawlers. The majority of larger vessels from Point Judith harvest squid, herring, and whiting. There were 40 inshore and 10 offshore lobster boats at the time MARFIN conducted their research. There are many support industries along the waterfront in Point Judith including dockside fuel pumps, restaurants, bait shops, commercial and recreational marine suppliers, and vessel repair shops. The Town Dock employs 50 people and 20-50 part-time employees.

The Town Dock receives a variety of groundfish, but about seven years ago, there was a decrease in landings of groundfish, and the processors shifted their focus. This has caused problems for the few fishermen that still target groundfish in the area. The MARFIN Report found that there are approximately 500 households involved in commercial fisheries in Point Judith, and another 400 indirectly dependent households. The majority of fishermen from Point Judith are first-generation white males. Most fishermen live within a 20-mile radius from the port. MARFIN concluded that the major issues facing this port include gear conflicts, area restrictions, and competition for resources with the recreational sector.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Point Judith on November 9, 2000. Residents from Point Judith attended and submitted comments about the impacts of groundfish regulations since Amendment 5. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Point Judith relate to the loss of employment stability and year-round fishing opportunities and the long-term impacts of the loss of the community's fishing-related infrastructure. The groundfish regulations that residents feel have produced the most significant social impacts in this community are gear restrictions and DAS reductions since Amendment 5. Gear restrictions contribute to difficulty planning business and produce an immediate economic cost for impacted vessels. DAS reductions have reduced flexibility and the ability for Point Judith's vessels to shift effort into groundfish as restrictions in other fisheries increase.

Washington County	1990		2000		Percent change

Table 648 - Population, education, poverty and unemployment statistics for Washington County, RI (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Washington County increased 12.3% between 1990 and 2000 (Table 648). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 82.8% in 1990 to 88.6% in 2000, a rise of 5.8 percentage points over the period. The number of families living in poverty increased almost 31%, and number of unemployed increased as well. The unemployment rate dropped from 5.6% of the civilian labor force in 1990 to 5.1% in 2000.

Fishing Industry Employment in Point Judith, RI

Washington County
The number of reported fishing establishments increased 11% from 1997 to 1999, dropping slightly in 2000 (Table 649). The average payroll for individuals in the fishing sector was $68,134 in 2000. This is among the highest reported average annual payrolls for the fishing sector in New England counties. Fish and seafood wholesale reported a from 14 to 18 establishments in each year from 1998 to 2001. The number of establishments in the seafood product preparation and packaging, fresh and frozen seafood processing, and fish and seafood markets sectors remained small but stable over the period from 1998 to 2001. No seafood canning establishments were reported in Washington County during these years.

Fishing Activity in Point Judith, RI

By Port of Landing

The number of active vessels averaged 200 from 1994 to 1996, declining afterwards and remaining relatively stable from 1996 to 2000, increasing again in 2001 to the level close to that in 1994 (Table 650). The number of vessels landing groundfish declined 20% from 1995 to 1996 and declined more gradually in the following years. Total landings declined about 50% from 1994 to 2001, while groundfish landings increased steadily through 2000 before declining in the final year of the period. Small mesh non-multispecies made up the bulk of the total landings for most of the time period but declined almost 70% from 1994 to 2001. Of all the species groups, only groundfish and other species landings increased.

Table 650 - Landings and Revenues from Multispecies Permit Holders in Point Judith, RI (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases.

By Homeport

The number of permitted multispecies vessels homeported in Point Judith declined in a stepwise fashion from 1994 to 2001, demonstrating the most stability towards the end of the time period, with a reported 124 vessels in 1999-2001 (Table 651). The numbers of active vessels and those landing groundfish fluctuated little from 1994 to 2001. Total landings by vessels homeported in Point Judith increased from 1994 to 1997, declining afterwards at an average of 13% each year through 2001. Groundfish landings increased over the time period, with a slight decline from 2000 to 2001. Groundfish dependence increased from 5.7% in 1994 to 21.4% in 2001.

9.4.5.9.2 Western Rhode Island

Western RI is a secondary multispecies port group that includes Charlestown, Westerly, South Kingstown (Wakefield), and North Kingstown (Wickford). These communities are located in Washington County.

Fishing Activity in Western Rhode Island

By Port of Landing
The total number of active multispecies vessels generally fluctuated from 1994 to 2001, reaching a maximum of 27 vessels in 2000 (Table 652). The number of vessels landing groundfish increased from zero in 1994 to 6 in 1996, fluctuating in the following years and reaching a maximum of 8 vessels in 2000. Total landings increased five-fold from 1994 to 1995, declining an average of 10% each year through 2001. Groundfish landings comprised a very small percentage of total catch, and fluctuated during the time period with the maximum landings of the period at 11,000 pounds in 1996. Small mesh non-multispecies landings made up the large majority of total landings, peaking in 1995 at nearly 40 million pounds.

By Homeport

The number of permitted multispecies vessels decreased from 48 in 1994 to 35 in 2001, while the total number of active vessels remained relatively consistent, averaging 21over the time period (Table 653). Active vessels landing groundfish declined in number, from 16 in 1994 to 11 in 2001. Total landings dropped sharply from 1996 to 1997 then remained relatively constant through 2001. Groundfish landings increased consistently after 1995, with an average annual rise of 22%. Groundfish dependence increased from 4-5% early in the time series to nearly 28% by 2001.

9.4.5.9.3 Eastern RI

The Eastern RI group is a secondary multispecies port group that includes Newport, Tiverton, Portsmouth, Jamestown, Middletown, and Little Compton. These communities are located in Newport County.

MARFIN – The MARFIN Report provides detailed profiles of Newport, Tiverton, and Jamestown, Rhode Island. These profiles should be referenced for social and demographic data not contained in this document.

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Point Judith, Rhode Island on November 9, 2000. While meeting participants were primarily from Point Judith, they discussed fishing activity in Newport, RI. Most thought that while the Newport fleet is much smaller than the Point Judith fleet, it is currently more dependent on groundfishing. One person believed that the Newport fleet, which consists primarily of smaller, family-owned vessels, has been more negatively affected by the groundfish regulations than the Point Judith fleet. He said that only two fish buyers remain in Newport, and while most of the landings are trucked to Boston, some of the smaller fishing operations have been "caught in the middle" and are left with few opportunities in the fishery. In addition, of three large trap companies that used to be located in Newport (scup, squid), only one marginal operation remains. The summary from this meeting can be found in Appendix I.

Newport County	1990		2000		Percent change
Population (total individuals)	87,194		85,433		-2.0%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	82.8%		87.7%		Difference = 4.9%
Poverty* (Number of families)	1,241		1,212		-2.3%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	2,691	6.3%	2,310	5.3%	-14.2%

Table 654 - Population, education, poverty and unemployment statistics for Newport County, RI (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Newport County decreased 2% between 1990 and 2000, one of the few county populations in New England to undergo a reduction (Table 654). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 82.8% in 1990 to 87.7% in 2000, a comparable rise to that in Washington County, RI. The number of families living in poverty decreased over 2%, and number of unemployed decreased around 14%. The unemployment rate dropped from 6.3% of the civilian labor force in 1990 to 5.3% in 2000.

Fishing Industry Employment in Eastern RI

Newport County

The number of fishing establishments remained stable from 1997 to 1998, at 291 in each of those years. Fishing establishments declined to a small extent from 1998 to 2000 (Table 655). The average annual payroll for the fishing sector in 2000 was $53,450. Fish and seafood wholesale reported 11 establishments in 1997, this number declining to 8 in 2001. There were three fish and seafood markets in each year from 1998 to 2001, and one seafood product preparation and packaging establishment in those same years. There were no establishments reported in fresh and frozen seafood processing or seafood canning sectors.

Fishing Activity in Eastern Rhode Island

By Port of Landing

The number of multispecies vessels landing fish in eastern RI declined by over 50% from 1994 to 1996, generally increasing afterwards (Table 656). The number of vessels landing groundfish ranged from 37 (1996) and 66 (1999) during the period from 1994 to 2001. Total landings and revenues generally increased, while groundfish landings fell in the second year of the period, rose steadily from 1995 to 2000, and dropped slightly from 2000 to 2001. As for western RI, landings of small mesh non-multispecies composed the majority of total landings from 1994 to 2001. High value species landings declined most dramatically, dropping by 50% in two years (1995-1997).

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001
Number of Active Multispecies Vessels	110	85	52	75	82	98	102	98

Table 656 - Landings and Revenues from Multispecies Permit Holders in Eastern RI (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.
Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.
Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.
Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.
Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.
High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.
C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**
Data source: NMFS Permit and Dealer databases

By Homeport

The total number of permitted multispecies vessels homeported in eastern RI remained relatively stable from 1994 to 2001, with a slight decline through the late-1990s (Table 657). The number of active vessels and those landing groundfish exhibited similar trends. The number of active vessels landing groundfish was about half the total number of permitted multispecies vessels throughout the time period. Total landings did not change dramatically between 1994 and 2001, and the general trend was slightly positive throughout the period. Groundfish landings more than doubled from 1994 to 2001, and groundfish revenues as a proportion of total revenues averaged about 16% over the time series but was somewhat inconsistent from year to year.

9.4.5.9.4 Other Rhode Island

Fishing Industry Employment in Other Rhode Island

The number of fishing establishments in all other RI counties generally increased from 1997 to 2000 (Table 658). The average annual payroll for fishing establishments was $20,598 in 2000. The number of fish and seafood wholesale establishments decreased from 20 in 1998 to 17 in 2001, while the number of fish and seafood markets rose, from 16 in 1998 to 20 in 2001. Seafood product preparation and packaging and fresh and frozen seafood processing establishments declined slightly after 1998, with three establishments reported in each of the following years. No seafood canning establishments were reported in any year.

Fishing Activity in Other Rhode Island

By Port of Landing

The number of active multispecies vessels declined from 1994 to 1999 and increased during the following two years, with a 35% overall decline across the period (Table 659). Multispecies vessels landing groundfish numbered 33 in 1994, declining 76% to 8 in 2001. Total landings declined, with the steepest drop from 1994 to 1995. Groundfish landings increased slightly from 1994 to 1996, then declined steeply from 145,000 pounds in 1996 to 39,000 pounds in 1997, continuing to decrease to very low levels in the later years of the time period. Small mesh non-multispecies, which comprised the majority of total landings from 1994 to 2001, declined rapidly as well, falling 81% from 1994 to 1995.

By Homeport

The number of permitted multispecies vessels homeported in Other RI generally declined from 1994 to 2001, as did the number of active vessels and those landing groundfish (Table 660). Total landings dropped after 1994 but doubled between 1996 and 1998, followed by a gradual decline of around 11% per year from 1999 to 2001. Groundfish landings increased steadily throughout the time period from 283,000 pounds in 1994 to 1.4 million pounds in 2001. Dependence on groundfish as a percentage of total revenues was low in all years but increased across the time period from 2% in 1994 to 17% in 2001.

9.4.5.9.5 Rhode Island Summary

Rhode Island, though much smaller in area, has a total population comparable to that in the states of Maine and New Hampshire. In Rhode Island, most county business establishments were reported in fish and seafood wholesale. No canning and few processing establishments were reported from 1998 to 2001. Groundfish landings were not as substantial a component of total landings in Rhode Island as landings of small mesh non-multispecies and other species. In Rhode Island, multispecies permit holders have increased their activity in the groundfish fishery since 1994.

9.4.5.10 Connecticut

Demographic Profile of Connecticut

CONNECTICUT	1990		2000		Percent change

Table 662 - Population by race in Connecticut counties, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

The total population of Connecticut was around 3.4 million in 2000, just over half that of Massachusetts (Table 662). 81.6% of Connecticut's population is white, with just over 9% black/African American, 2.4% Asian, 2.2% of two or more races, and less than 5% other races. The population is 9.4% Hispanic/Latino of any race. Fairfield and New Haven counties have very similar demographic profiles, with populations of over 800,000 composed of around 79% whites, 10-11% blacks/African Americans, 2.3-3.3% Asians, 2.2-2.5% of two or more races, and over 4.5% other races. 10-12% of the total populations in these counties are Hispanic/Latino of any race. The populations of Middlesex and New London counties are less racially diverse but demonstrate similar racial distributions to Fairfield and New Haven counties.

9.4.5.10.1 Coastal CT

The Coastal CT group is a secondary multispecies port group that includes Stonington, New London, Noank, Lyme, Old Lyme, East Lyme, Groton, and Waterford. These communities are located in Fairfield, Middlesex, New Haven, and New London counties.

MARFIN – The MARFIN Report provides detailed profiles of New London and Stonington, Connecticut. It also includes a general profile of the Connecticut sub-region. These profiles should be referenced for social and demographic data not contained in this document.

New London County	1990		2000		Percent change

Table 663 - Population, education, poverty and unemployment statistics for New London County, CT (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in New London County remained relatively stable between 1990 and 2000, increasing only 1.6% over the decade (Table 663). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 80.9% in 1990 to 86% in 2000, a rise of 5.1 percentage points over the period. The number of families living in poverty decreased 4.2%, while the number of unemployed decreased nearly 30% from 1990 to 2000. The unemployment rate declined from 6.0% of the labor force in 1990 to 4.1% in 2001.

Middlesex County	1990		2000		Percent change
Population (total individuals)	143,196		155,071		8.3%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	82.6%		88.7%		Difference = 6.1%

Table 665 - Population, education, poverty and unemployment statistics for New Haven County (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in New Haven County increased just 2.5% from 1990 and 2000 (Table 665). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 77.5% in 1990 to 83% in 2000, a rise of 5.5 percentage points over the period. The number of families living in poverty increased nearly 17%, while the number of unemployed decreased slightly (~1%) from 1990 to 2000. The unemployment rate increased from 5.8% of the labor force in 1990 to 5.9% in 2001.

Fairfield County	1990		2000		Percent change
Population (total individuals)	827,645		882,567		6.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	81.0%		84.4%		Difference = 3.4%
Poverty* (Number of families)	9,889		11,488		16.2%
	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
Unemployment (Pop. 16 yrs and over)	24,559	5.4%	21,306	4.8%	-13.2%

Table 666 - Population, education, poverty and unemployment statistics for Fairfield County (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Fairfield County increased 6.6% from 1990 and 2000, the greatest percent increase of all counties in the Coastal CT port group (Table 666). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 81% in 1990 to 84.4% in 2000, a rise of 3.4 percentage points over the period. The number of families living in poverty increased nearly 16.2%, while the number of unemployed decreased 13.2% from 1990 to 2000. The unemployment rate increased from 5.4% of the labor force in 1990 to 4.8% in 2001.

Fishing Industry Employment in Coastal Connecticut

New London County

The number of fishing establishments in New London County increased about 4% from 1997 to 1998, decreasing 10% in the following year and remaining stable from 1999 to 2000 (Table 667). The average payroll for fishing establishments in the county was $43,686 in 2000. Fish and seafood wholesale establishments and fish and seafood markets numbered between 3 and 5 from 1998 to 2001, remaining stable throughout the period. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

Middlesex County

Fewer fishing establishments were reported in Middlesex County than New London County, decreasing over the period from 1997 to 2000 (Table 668). The average payroll for individuals employed in the fishing sector was $29,237 in 2000. Between 1 and 2 establishments were reported in the fish and seafood wholesale and fish and seafood markets sectors from 1998 to 2001. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

New Haven County
The number of fishing establishments reported in New Haven County fluctuated slightly from 1997 to 2000, averaging 83 over the period (Table 669). The average payroll for each fishing sector participant was $24,506 in 2000. Between 6 and 8 establishments were reported in the fish and seafood wholesale sector from 1998 to 2001. Eight fish and seafood markets were reported in all years from 1998 to 2001, except for a peak of twelve establishments in 1999. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

Fairfield County
The composition of reported establishments in fishing and related industries in Fairfield County closely mirrored that of New Haven County (Table 670). Fishing establishments averaged 79 from 1997 to 2000, with an average payroll of $33,767 in 2000. Fish and seafood wholesale establishments numbered between 6 and 8 from 1998 to 2001, while 11 to 13 fish and seafood markets were reported in these years. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

Fishing Activity in Connecticut

Note on Connecticut commercial fishery data:

Landings and revenues for the state of Connecticut are reported from CT state dealer records, rather than in the NMFS commercial fisheries dealer database. Because Connecticut landings and revenues are reported as aggregate records to NMFS, it was not possible to examine CT fishing activity by county/sub-region or by vessels homeported in the state. Landings and revenues are available from 1995 through 2000.

The number of permitted multispecies vessels declined 44% from 168 in 1995 to 94 in 2000 (Table 671). Total landings remained relatively stable from 1995 to 2000, falling slightly in 1997 and 1998. Groundfish landings more than doubled over this time period, from 406,000 pounds in 1995 to 1.1 million pounds in 2000. Landings of small mesh multispecies composed the majority of total landings over the time period and remained stable, with a peak of 7 million pounds in 1999. Small mesh non-multispecies and other species landings were fairly stable from 1995 to 2000 while high value species landings increased about 48% during these years. In general, despite the decrease in number of multispecies vessels in Connecticut, landings of all species remained relatively stable or increased between 1995 and 2000.

Table 671 - Landings and Revenues from Multispecies Permit Holders in Connecticut (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data Source: CT State Dealer Records

9.4.5.10.2 Other Connecticut

Fishing Industry Employment in Other Connecticut Counties

Fishing establishments remained stable from 1997 to 2000, averaging 51 over the period (Table 672). The average annual payroll for these establishments increased substantially from $10,200 from 1997 to 1999, to $25,118 in 2000. Between 6 and 8 establishments were reported for the fish and seafood wholesale and fish and seafood markets sectors from 1998 to 2001. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging, and seafood canning sectors.

9.4.5.10.3 Connecticut Summary

In Connecticut, Other Species landings composed the majority of total landings for all years from 1994 to 2001. Groundfish landings increased, although the number of permitted multispecies vessels declined over this period. The number of nonemployer establishments reported in the fishing sector generally remained stable from 1997 to 2000. No canning, processing, preparation and packaging establishments were reported in Connecticut.

9.4.5.11 New York

This section summarizes available information about fishing communities in the state of New York and includes references to the appropriate documents, which are not included as part of this document.

In May 2001, TechLaw Inc. prepared a report for New York Sea Grant entitled, *The Economic Contribution of the Sport Fishing, Commercial Fishing, and Seafood Industries to New York State*. This study t estimate the economic importance of these industries to the state was sponsored by New York Sea Grant and conducted in consultation with an Advisory Committee of stakeholders from industry and government. Economic contribution is expressed in terms of 1999 dollar value and employment, which includes employment in the industries themselves and equivalent jobs created as an impact of the economic activity within the industries. The estimates of economic contribution were made using an econometric model. Basic expenditures for each industry were inputs to the model, and they were derived from the IMPLAN input/output model.

The overall economic contribution of these three industries to the state of New York is estimated to be $11.5 billion. The contribution of direct activity within the industries is estimated at $5.7 billion, and the indirect economic impact (sales of related goods and services) is estimated at $5.9 billion. The employment contribution of these three industries is reported to be 113,300 direct jobs and 64,600 equivalent jobs generated from economic activity within the industries. The Report estimates that commercial fishing alone employs 10,500 in New York state. This Report describes activity and trends in almost all sectors of the commercial and recreational fisheries in New York and provides much additional and useful information about New York's fishing communities.

Demographic Profile of New York

NEW YORK	1990		2000		Percent change
Population (total individuals)	17,990,455		18,976,457		5.5%

	618,903	6.9%	640,108	7.1%	3.4%

Table 673 - Population, education, poverty and unemployment statistics for the state of New York (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in New York increased by 5.5% from 18 million in 1990 to 19 million in 2000 (Table 673). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 4.3% over the course of a decade, from 74.8% in 1990 to 79.1% in 2000. The number of families below the poverty level increased 17.8% from 1989 to 1999 and the unemployment rate increased over the decade, from 6.9% to 7.1% of the civilian labor force, aged 16 years and older.

Table 674 - Population by race in selected New York counties, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

The total population of New York state far exceeds the *combined* population of New England states. In New York, around 68% of the population is white, 16% black/African American, 5.5% Asian, just over 3% of two or more races, 0.4% American Indian/Alaska native, and 7% of other races (Table 674). 15% are Hispanic/Latino of any race. Queens and Kings counties have a greater percentage of non-whites than Nassau and Suffolk counties, the total populations composed of 20-36% black/African American, 8-18% Asian, 4-6% of two or more races, less than 1% American Indian/Alaska native and Hawaiian, and 10-12%

other races. 20-25% of the populations in Queens and Kings counties are Hispanic/Latino of any race. Nassau and Suffolk counties have very similar racial distributions within the total populations, which are 79.3% and 84.6% white, respectively. Blacks/African Americans, Asians, and individuals of two or more races make up the next largest proportions of the total. Each county's population is made up of approximately 10% Hispanic/Latino of any race.

9.4.5.11.1 Eastern Long Island, NY

Eastern Long Island, NY has been identified as a primary multispecies port group. This group includes the ports of Montauk, Hampton Bays (Shinnecock), and Greenport.

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of Montauk, Hampton Bays, and Greenport, along with information about many other smaller ports in Eastern Long Island. These profiles should be referenced for social and demographic data not contained in this document.

Due to funding constraints, McCay and Cieri Report is not a complete analysis of the dependence of these communities on fishery resources, but it can provide guidance about how vulnerable these communities are to regulatory change. There are many other smaller ports in eastern Long Island that were discussed in the McCay and Cieri Report, but only the communities specified in this group are discussed below.

Greenport is the largest port on the North Fork of Long Island with five large offshore vessels, one medium-sized dragger, two small 40' draggers, 3 trap vessels, 4 lobstermen, 4 or 5 conch potters, 4 or 5 gillnetters, and 25 or so baymen. The fishermen from this area have adapted over time and taken advantage of different gears and specie s. McCay and Cieri found that despite local support, the commercial fleet in Greenport has decreased significantly in the last 20 years. Many fishermen in this area offload in a variety of ports in the area, and do not always land primarily in Greenport. There are several charter and party boats in the area.

Montauk is located at the tip of the South Fork on Long Island, and is the largest fishing port in New York. McCay and Cieri found that otter trawls and longlines are the principle gear types, and loligo squid and silver hake were the two most important finfish species in 1998. Furthermore, Montauk is the leading U.S. port for tilefish landings, which amounted to 21% of total revenues for Montauk in 1998. The majority of fish landed in Montauk is sold on consignment in the Fulton Fish Market in New York City. When researching the number of crew employed in the area, one individual told McCay and Cieri that there are about three longliners who employ eight per boat (double crew), he employs ten on his two boats, the two largest vessels each employ ten crew members, and there are about 20-30 lobstermen.

Hampton Bays/Shinnecock is the second largest port in New York after Montauk. McCay and Cieri determined that this port is primarily a dragger fishing port, and loligo squid and whiting made up 70% of total revenues in 1998. There is a Municipal Dock on the west side of the Shinnecock Inlet, a commercial fish dock, the local fisherman's cooperative, and a marina. One respondent in this report estimated that there are 30 boats working out of Shinnecock, and fewer are owner-operated than in the past. Even though fishermen are landing less, prices have been good, so fishermen appear to be sustaining themselves pretty well in this area. The town of South Hampton is generally supportive of the commercial fishing industry, but some fishermen feel that the regulators are trying to "squeeze them out."

Social Impact Informational Meetings – Council staff conducted a social impact informational meeting in Riverhead, New York on November 21, 2000. Residents from Montauk, Greenport, and Hampton Bays attended and submitted comments about the impacts of groundfish regulations since Amendment 5. The summary from this meeting can be found in Appendix I.

Based on comments received at the Social Impact Informational Meetings, the most important social impact issues for residents of Eastern Long Island relate to a loss of morale from regulatory discarding (not groundfish), problems finding and keeping crew, and a general loss of faith in the federal fisheries management process. Meeting participants feel that regulations in other fisheries have produced the most significant social impacts in the past six years. They cited Groundfish DAS as offering flexibility, stability, and opportunity when other fisheries close due to quotas. For these communities, groundfish has become a more important alternative fishery as restrictions in other fisheries increase. Please see the complete meeting report for additional discussion of these and other important social impact issues.

Suffolk County	**1990**		**2000**		**Percent change**
Population (total individuals)	1,321,864		1,419,369		7.4%

Table 675 - Population, education, poverty and unemployment statistics for Suffolk County, NY (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Suffolk County increased 7.4% from 1990 and 2000 (Table 675). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 82.2% in 1990 to 86.2% in 2000, a rise of 4 percentage points over the period. The number of families living in poverty increased 26%, while the number of unemployed decreased over 16% from 1990 to 2000. The unemployment rate increased from 4.8% of the labor force in 1990 to 3.9% in 2001.

Fishing Industry Employment in Eastern Long Island

Suffolk County

The number of fishing establishments in Suffolk County increased from 1997 to 1998, decreasing in the following two years (Table 676). The average payroll for fishing establishments was $33,874 in 2000. Fish and seafood wholesale establishments decreased from 53 in 1998 to 44 in 2000 and remained stable in 2001. Fish and seafood markets were relatively stable, averaging 33 over the time period. One establishment was reported from 1998 to 2001 for the seafood product preparation and packaging and fresh and frozen seafood processing sectors. No seafood canning establishments were reported in Suffolk County.

Fishing Activity in Eastern Long Island, NY

By Port of Landing

The number of active multispecies vessels increased from 100 in 1994 to 173 in 2000, decreasing to 149 in 2001 (Table 677). The number of vessels landing groundfish increased from 1994 to 1998, decreasing afterwards. Total landings and revenues rose from 1994 to 1998, decreasing in the following years. Groundfish landings generally rose, with peaks of over 1 million pounds in 1998 and 2000. Small mesh multispecies landings composed the majority of total landings in this region, with a four-fold increase from 1994 to 1998 followed by a 49% decrease from 1998 to 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 677 - Landings and Revenues from Multispecies Permit Holders in Eastern Long Island, NY (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The total number of permitted multispecies vessels generally declined, with a 15% decrease from 1994 to 2001 (Table 678). The number of active vessels increased over the period, as did the number of vessels landing groundfish, peaking at 104 in 1998. Total landings fluctuated between 1994 and 2001, with an overall positive trend across the period. Groundfish landings generally increased as well. Dependence on groundfish averaged just over 10% across the period.

9.4.5.11.2 Other Long Island, NY

The Other Long Island, NY group is a secondary multispecies port group that includes Mattituck, Islip, Freeport, Brooklyn, Other Nassau County, and Other Suffolk County.

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of Mattituck, Islip, Freeport, Brooklyn, Other Nassau County, and Other Suffolk County communities. It also includes a general profile of the Long Island, New York sub-region. These profiles should be referenced for social and demographic data not contained in this document.

Nassau County	1990		2000		Percent change
Population (total individuals)	1,287,348		1,334,544		3.7%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	84.2%		86.7%		Difference = 4.0%
Poverty* (Number of families)	8,650		12,207		41.1%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	28,580	4.1%	24,175	3.7%	-15.4%

Table 679 - Population, education, poverty and unemployment statistics for Nassau County, NY (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Nassau County increased 3.7% from 1990 and 2000 (Table 679). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 84.2% in 1990 to 86.7% in 2000, a rise of 4 percentage points over the period. The number of families living in poverty increased 41%, while the number of unemployed decreased just over 15% from 1990 to 2000. The unemployment rate increased from 4.1% of the labor force in 1990 to 3.7% in 2001.

Queens County	**1990**		**2000**		**Percent change**
Population (total individuals)	1,951,598		2,229,379		14.2%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	71.1%		74.4%		Difference = 3.3%

Table 680 - Population, education, poverty and unemployment statistics for Queens County, NY (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Queens County increased 14.2% from 1990 and 2000 (Table 680). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 71.1% in 1990 to 74.4% in 2000, a rise of 3.3 percentage points over the period. The number of families living in poverty increased substantially (56.7%), and the number of unemployed increased just over 4% from 1990 to 2000. The unemployment rate increased from 7.6% of the labor force in 1990 to 7.7% in 2001.

Kings County	**1990**		**2000**		**Percent change**
Population (total individuals)	2,300,664		2,465,326		7.2%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	63.7%		68.8%		Difference = 5.1%
Poverty* (Number of families)	109,811		129,694		18.1%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	106,664	10.3%	111,528	10.7%	4.6%

Table 681 - Population, education, poverty and unemployment statistics for Kings County, NY (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Kings County increased 7.2% from 1990 and 2000 (Table 681). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from

63.7% in 1990 to 68.8% in 2000, a rise of 5.1 percentage points over the period. Relative to other counties examined in this document, this educational attainment level is quite low. The number of families living in poverty increased 18%, and the number of unemployed increased 4.6% from 1990 to 2000. The unemployment rate increased from 10.3% of the labor force in 1990 to 10.7% in 2001.

Fishing Industry Employment in Other Long Island

Nassau County

The number of total fishing establishments increased from 124 in 1997 to 154 in 1999, decreasing slightly in 2000 (Table 682). The average payroll for fishing establishments was $41,993 in 2000. The number of fish and seafood wholesale establishments averaged 36 from 1998 to 2001, while fish and seafood markets averaged 34 during this period. There were two seafood product preparation and packaging and fresh and frozen seafood processing establishments in each year from 1998 to 2001.

NAICS Code and Description		1997	1998	1999	2000	2001

Queens County

The number of fishing establishments increased from 25 in 1997 to 31 in 2000, with an average payroll of $19,645 in 2000 (Table 683). Fish and seafood wholesale and fish and seafood markets remained fairly stable from 1998 to 2001, averaging 37 and 31, respectively. There were between 1 and 2 establishments reported in the seafood product preparation and packaging and fresh and frozen seafood processing sectors from 1998 to 2001 and no establishments reported in seafood canning.

Kings County

Fishing establishments remained stable from 1997 to 2000, with a peak of 42 in 1999 (Table 684). The average payroll for participants in the fishing sector was $31,811 in 2000. The number of fish and seafood markets (avg. 64) exceeded the number of fish and seafood wholesale establishments (avg. 47); both sectors remained relatively stable over the period from 1998 to 2001. All other establishments were reported in low numbers, declining slightly across the time period.

Fishing Activity in Other Long Island

By Port of Landing

The number of active multispecies vessels landing fish in Other Long Island peaked at 84 in 1996 and declined afterwards (Table 685). Vessels landing groundfish declined by over 50% from 1994 to 2001. Total landings and revenues generally declined across the time period, averaging a 5% decline in landings each year. Groundfish landings increased from 1994 to 1997, dropping during the late-1990s and peaking in 2000 at 248,000 pounds. Small mesh non-multispecies made up the highest proportion of total landings of all species groups, fluctuating over the period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 685 - Landings and Revenues from Multispecies Permit Holders in Other Long Island, NY (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The total number of permitted multispecies vessels declined by over 50% from 1994 to 2001 (Table 686). A small percentage of these vessels were active during this time period, decreasing from 23 in 1994 to 15 in 2001. Vessels landing groundfish declined from 1994 to 1996 and remained stable for the remainder of the period at around 9 vessels. Total landings fluctuated, and landings in 2001 were lower than 1994 landings. Groundfish landings increased at an average annual rise of nearly 30%. Groundfish dependence increased on average but exhibited a large decline from 32.2% in 2000 to 16.6% in 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

9.4.5.11.3 Other New York

All Other New York Counties
The number of fishing establishments increased from 1997 to 2000, reaching almost 400 by the last year in this period (Table 687). The average payroll for participants in the fishing sector was $19,645 in 2000. The number of fish and seafood wholesale establishments declined while fish and seafood markets increased from 1998 to 2001; in general, these sectors reported similar numbers of establishments during this period. Seafood product preparation and packaging establishments increased from 9 in 1998 to 14 in 2001. The fresh and frozen seafood processing sector was stable from 1998 to 2000, increasing to 9 establishments in 2001. The seafood canning sector reported between 4 and 5 establishments during these years.

Fishing Activity in Other New York

By Port of Landing

The number of active multispecies vessels increased almost 54% from 1994 to 2001, while the number of vessels landing groundfish remained relatively stable over the period, averaging 53 (Table 688). Total landings increased from 3.5 million pounds in 1994 to 12 million pounds in 1998, decreasing afterwards to 8.5 million pounds in 2001. Groundfish landings generally increased from 1994 to 2001, with some fluctuation throughout this period. Landings of small mesh non-multispecies, which comprised a greater proportion of total landings than other species groups, fluctuated from 1994 to 2001 with a generally increasing trend.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 688 - Landings and Revenues from Multispecies Permit Holders in Other NY (Dealer Activity)
Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

Permitted multispecies vessels declined in number from 1994 to 2001 while the number of active vessels including those landing groundfish remained relatively stable (Table 689). The percentage of active vessels out of the total number of permitted vessels was low throughout the period. Total landings generally declined, with a peak of 5.1 million pounds in 1997. Groundfish landings rose from 1994 to 1995, dropped in 1996 and rose again to 309,000 pounds in 2000. From 2000 to 2001 landings declined 60.4%. Dependence on groundfish fluctuated but remained low throughout the time period, peaking at 11.3% in 1996.

Table 690 - Population, education, poverty and unemployment statistics for the state of New Jersey (1990 and 2000)

** data shown for 1989 and 1999*

Data source: U.S. Census Bureau

The total population in New York increased by 8.9% from 7.7 million in 1990 to 8.4 million in 2000 (Table 690). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 5.4% over the course of a decade, from 76.7% in 1990 to 82.1% in 2000. The number of families below the poverty level increased about 19% from 1989 to 1999 and the unemployment rate increased over the decade, from 5.7% to 5.8% of the civilian labor force, aged 16 years and older.

Table 691 - Population by race in selected New Jersey counties, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

In 2000, the total population of New Jersey was 72.6% white, 13.6% black/African American, 5.7% Asian, 2.5% of two or more races, and over 5% other races (Table 691). Hispanics/Latinos of any race made up 13.3% of the population. Monmouth and Ocean counties, which make up the Northern Coastal NJ port group, each had populations of over 500,000. Monmouth County was 84.4% white, over 8% black/African American, 4% Asian, and each of the other racial groups comprising under 2% of the total. Ocean County is less racially diverse, with 93% whites, 3% blacks/African Americans, and all other racial groups combined making up less than 4% of the total. Atlantic and Cape May counties form the Southern Coastal NJ port group and have smaller populations than counties in the Northern group. Atlantic and Cape May counties are very different in the racial composition of their populations. Atlantic County is 68.4% white, 17.6% black/African American, over 5% Asian, and over 6% of other races, while Cape May County is almost 92% white, just over 5% black/African American, and under 1.5% of each of the other racial groups.

9.4.5.12.1 Northern Coastal NJ

The Northern Coastal NJ group is a secondary multispecies port group that includes Point Pleasant, Belford, Long Beach/Barnegat Light, Barnegat, Highlands, Belmar, Sea Bright, and Manasquan. These communities are located in Monmouth and Ocean counties.

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of Point Pleasant, Belford, Long Branch/Barnegat Light, Barnegat, Highlands, Belmar, Sea Bright, and Manasquan. It also includes a general profile of the Northern Coastal NJ sub-region. These profiles should be referenced for social and demographic data not contained in this document.

Monmouth County	1990		2000		Percent change
Population (total individuals)	553,124		615,301		11.2%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	82.8%		87.9%		Difference = 5.1%

Table 692 - Population, education, poverty and unemployment statistics for Monmouth County, NJ (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Monmouth County increased 11.2% from 1990 and 2000 (Table 692). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 82.8% in 1990 to 87.9% in 2000, a rise of 5.1 percentage points over the period. The number of families living in poverty increased 44.6%, while the number of unemployed decreased almost 6% from 1990 to 2000. The unemployment rate decreased from 5.2% of the labor force in 1990 to 4.6% in 2001.

Ocean County	1990		2000		Percent change
Population (total individuals)	433,203		510,916		17.9%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	74.9%		83.0%		Difference = 8.1%
Poverty* (Number of families)	5,170		6,631		28.3%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	11,344	5.9%	11,615	5.2%	2.4%

Table 693 - Population, education, poverty and unemployment statistics for Ocean County, NJ (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Ocean County increased 17.9% from 1990 and 2000 (Table 693). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 74.9% in 1990 to 83% in 2000, a rise of 8.1 percentage points over the period. The number of families living in poverty increased 28.3% over the period. Although the number of unemployed increased 2.4% from 1990 to 2000, the unemployment rate decreased, from 5.9% of the labor force in 1990 to 5.2% in 2001.

Fishing Industry Employment in Monmouth County

Monmouth County

The number of total fishing establishments in Monmouth County remained relatively stable from 1997 to 2000, except for a peak of 172 in 1998 (Table 694). The average payroll for fishing sector participants was $53,127 in 2000. Fish and seafood wholesale and fish and seafood markets sectors remained relatively constant from 1998 to 2001, averaging 9 and 11, respectively. No establishments were reported for the fresh and frozen seafood processing, seafood product preparation and packaging and seafood canning sectors.

Ocean County

The number of fishing establishments declined from 1997 to 2000 but was greater in Ocean County than in Monmouth County in every year of the period (Table 695). The average payroll for fishing sector participants was $69,882 in 2000. Fish and seafood wholesale sector reported an average of 7 establishments from 1998 to 2001, while fish and seafood markets numbered 9 on average. Two establishments were reported for seafood product preparation and packaging and fresh and frozen seafood processing sectors in each year from 1998 to 2001. No seafood canning establishments were reported during this period.

Fishing Activity in Northern Coastal NJ

By Port of Landing

The number of active multispecies vessels was relatively stable from 1994 to 2001, with some decline towards the end of the period (Table 696). The number of vessels reporting groundfish landings declined from 26 in 1994 to 15 in 2001. Total landings decreased 65.5%, from 10.3 million pounds in 1994 to 3.6 million pounds in 2001. Groundfish landings were stable from 1994 to 1995, declining in the following two years and increasing to a maximum of 470,000 pounds in 2000. Landings of other species composed the greatest percentage of the total from 1994 to 2001 but declined over the period.

Table 696 - Landings and Revenues from Multispecies Permit Holders in Nothern Coastal NJ (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bl uefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels declined through the late-1990s, increasing afterwards to a peak of 176 vessels in 2001 (Table 697). The number of active vessels increased from 78 in 1994 to 86 in 1996, stabilizing at 84 in 1997-1998, and increasing to 104 from 1999-2001. Vessels reporting landings of groundfish declined from 55 in 1994 to 39 in 2001. Total landings increased about 32% from 1994 to 1997, declining 38% from 1997 to 2001. Groundfish landings fluctuated across the period, with a low of 215,000 pounds in 1997 and a high of 836,000 pounds in 1996. Groundfish dependence was low throughout the period, averaging 3.8%.

9.4.5.12.2 Southern Coastal NJ

The Southern Coastal NJ group is a secondary multispecies port group that includes Cape May, Wildwood, Burleigh, Sea Isle City, Ocean City, Stone Harbor, and Avalon. These communities are located in Atlantic and Cape May counties.

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of Cape May, Wildwood, Burleigh, Sea Isle City, Ocean City, Stone Harbor, and Avalon. It also includes a general profile of the Southern Coastal NJ sub-region. These profiles should be referenced for social and demographic data not contained in this document.

Atlantic County	1990		2000		Percent change
Population (total individuals)	224,327		252,552		12.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	72.9%		78.2%		Difference = 5.3%
Poverty* (Number of families)	3,686		4,810		30.5%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	6,672	5.5%	9,405	7.5%	41.0%

Table 698 - Population, education, poverty and unemployment statistics for Atlantic County, NJ (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Atlantic County increased 12.6% from 1990 and 2000 (Table 698). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 72.9% in 1990 to 78.2% in 2000, a rise of 5.3 percentage points over the period. The number of families living in poverty increased 30.5%, and the number of unemployed increased 41% from 1990 to 2000. The unemployment rate increased from 5.5% of the labor force in 1990 to 7.5% in 2001.

Cape May County	**1990**		**2000**		**Percent change**
Population (total individuals)	95,089		102,326		7.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	74.0%		81.9%		Difference = 7.9%
Poverty* (Number of families)	1,528		1,747		14.3%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	3,328	7.5%	3,979	8.2%	19.6%

Table 699 - Population, education, poverty and unemployment statistics for Cape May County, NJ (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Cape May County increased 7.6% from 1990 and 2000 (Table 699). The percent of individuals ages 25 and older who graduated from high school or a higher secondary school increased from 74% in 1990 to 81.9% in 2000, a rise of 7.9 percentage points over the period. The number of families living in poverty increased 14.3%, and the number of unemployed increased 19.6% from 1990 to 2000. The unemployment rate increased from 7.5% of the labor force in 1990 to 8.2% in 2001.

Atlantic County
The number of fishing establishments increased from 99 in 1997 to 115 in 1998, falling to 108 in 1999 and remaining stable in the following year (Table 700). The average payroll for participants in the fishing sector was $42,972 in 2000. The number of fish and seafood wholesale establishments averaged 6 from 1998 to 2001, while the number of fish and seafood markets remained stable, at around 2 establishments in each year throughout the period. No establishments were reported in the fresh and frozen seafood processing, seafood product preparation and packaging and seafood canning sectors.

NAICS Code and Description		1997	1998	1999	2000	2001

Cape May County

The number of fishing establishments generally declined from 1997 to 2000, this number higher than that in Atlantic County (Table 701). All other establishments were represented in low numbers but remained very stable from 1998 to 2001.

Fishing Activity in Southern Coastal NJ

By Port of Landing

The number of active multispecies vessels in Southern Coastal NJ generally declined from 1994 to 2001, with some fluctuation throughout the period (Table 702). Vessels landing groundfish declined 68% from 1994 to 2001. Total landings fluctuated from 1994 to 2001, averaging 6.2 million pounds over the period with a peak of 81.2 million pounds in 1998 and a low point of 49.8 million pounds in 1999. Small mesh non-multispecies and other species comprised the overwhelming majority of total landings, while groundfish made up the smallest percentage. Groundfish landings decreased, from 15,800 pounds in 1994 to 4,800 pounds in 2001.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 702 - Landings and Revenues from Multispecies Permit Holders in Southern Coastal NJ (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C (“confidential”) **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

Data source: NMFS Permit and Dealer databases

By Homeport

The number of permitted multispecies vessels decreased through the late-1990s, increasing in 2000 and 2001 to levels comparable to those in the first years of the time period (Table 703). The number of active multispecies vessels remained relatively stable over the time period, with a peak of 79 vessels in 2000. Vessels landing groundfish declined in number, dropping nearly 52% across the period. Dependence on groundfish was the lowest of any other port group in New England and the mid-Atlantic states, averaging less than 1% from 1994 to 2001.

9.4.5.12.3 Other New Jersey

All Other Counties
The number of fishing establishments in other NJ counties remained relatively stable from 1997 to 2000, with an average payroll of $28,142 in 2000 (Table 704). The number of fish and seafood wholesale establishments and fish and seafood markets increased slightly from 1998 to 2001, averaging 80 and 88, respectively. The seafood product preparation and packaging sector reported from 10 to 14 establishments in each year, while the seafood canning and fresh and frozen seafood processing sectors reported 5 to 8 establishments during this period.

NAICS Code and Description		1997	1998	1999	2000	2001

Fishing Activity in Other New Jersey

By Port of Landing

The number of active multispecies vessels increased from 130 in 1994 to 163 in 2000, decreasing to some extent in 2001 (Table 705). Vessels landing groundfish also declined, and a smaller pecentage of active vessels landed groundfish in 2000 than in 1994. Total landings declined 42% from 1994 to 1996, increasing 20% from 1996 to 2001. Other species accounted for the bulk of total landings. Groundfish landings fluctuated across the period, composing a small percentage of total landings in each year.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

By Homeport

The number of permitted vessels homeported in Other NJ declined from 180 in 1994 to 105 in 1998, increasing slightly afterwards (Table 706). The number of active groundfish vessels remained relatively consistent across the period, with those landing groundfish making up a small fraction of total permitted vessels. Vessels landing groundfish declined in number from 1994 to 2001 as well. Total landings declined an average of around 14% each year throughout the period. Groundfish landings increased approximately 5% from 1994 to 2001 but remained very low throughout the period.

9.4.5.13 Delaware

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of fishing ports in the state of Delaware. This includes the ports of Lewes, Indian River, Port Mahon, Bowers Beach and Mispillion. These profiles should be referenced for social and demographic data not contained in this document.

Detailed data at the trip and individual-vessel level for DE ports are not available for use in this draft amendment. In turn, the assessment of fishing activity and multispecies fishery dependence for communities in DE is not available at this time. Council staff will provide this information for the final Amendment 13 document if it can be made available. For this document, state-level and homeport state data for DE are presented in the section describing the commercial harvesting sector.

DELAWARE	1990		2000		Percent change
Population (total individuals)	666,168		783,600		17.6%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	77.5%		82.6%		Difference = 5.1%

	13,945	4.0%	20,549	5.2%	47.4%

Table 707 - Population, education, poverty and unemployment statistics for the state of Delaware (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Delaware increased by 17.6% from 1990 to 2000 (Table 707). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 5.1 percentage points over the course of a decade, from 77.5% in 1990 to 82.6% in 2000. The number of families below the poverty level increased nearly 23% from 1989 to 1999 and the unemployment rate increased over the decade, from 4% to 5.2% of the civilian labor force, aged 16 years and older.

Geographic area	Total population	Race								
		One race							Two or more races	Hispanic or Latino(of any race)
		Total	White	Black or African American	American Indian and Alaska Native	Asian	Native Hawaiian and Other Pacific Islander	Some other race		
DELAWARE	783,600	770,567	584,773	150,666	2,731	16,259	283	15,855	13,033	37,277

Table 708 - Population by race in Delaware, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

In 2000, the total population of Delaware was 74.6% white, 19.2% black/African American, 2.1% Asian, 1.7% of two or more races, 2% other races, and 4.8% Hispanic/Latino of any race (Table 708).

Fishing Industry Employment in Delaware

The number of total establishments increased slightly from 1997 to 2000, remaining relatively stable during the latter three years of this period (Table 709). The average payroll for participants in the fishing sector was $44,253 in 2000. Fish and seafood markets averaged 12 in number from 1998 to 2001. Seven fish and seafood wholesale establishments were reported in 1998, this number dropping to 5 in 2001. The seafood product preparation and packaging and seafood canning sectors reported one establishment in every year from 1998 to 2001.

9.4.5.14 Maryland

McCAY AND CIERI – The McCay and Cieri Report provides detailed profiles of fishing ports in the state of Maryland. This includes the ports of Ocean City in Worcester County and Crisfield in Somerset County. These profiles should be referenced for social and demographic data not contained in this document.

MARYLAND	1990		2000		Percent change
Population (total individuals)	4,781,468		5,296,486		10.8%
Educational attainment (percent persons 25 yrs and over, high school graduate or higher)	78.4%		83.8%		Difference = 5.4%
Poverty* (Number of families)	75,313		83,232		10.5%
Unemployment (Pop. 16 yrs and over)	Unemployed	Percent of civilian labor force	Unemployed	Percent of civilian labor force	
	111,536	4.3%	128,902	4.7%	15.6%

Table 710 - Population, education, poverty and unemployment statistics for the state of Maryland (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Maryland increased by 10.8% from 1990 to 2000 (Table 710). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 5.4 percentage points over the course of a decade, from 78.4% in 1990 to 83.8% in 2000. The number of families below the poverty level increased 10.5% from 1989 to 1999 and the unemployment rate increased over the decade, from 4.3% to 4.7% of the civilian labor force, aged 16 years and older.

Table 711 - Population by race in Maryland, 2000
Counties examined in Fishing Communities section of AHE in bold type.
Data source: U.S. Census Bureau

In 2000, the total population of Maryland was 64% white, 27.9% black/African American, 4% Asian, 2% of two or more races, 1.8% other races, and 4.3% Hispanic/Latino of any race (Table 711).

Fishing Industry Employment in Maryland

The number of fishing establishments in Maryland remained relatively stable from 1997 to 2001, averaging 2,059 during this period (Table 712). The annual payroll for fishing sector participants averaged $25,289 in

2000. Other sectors also remained very stable from 1998 to 2001, with an average of 93 establishments in the fish and seafood wholesale sector, 70 fish and seafood markets, 27 establishments in seafood product preparation and packaging, 24 fresh and frozen seafood processing establishments, and 3 seafood canning establishments.

Fishing Activity in Maryland

By Port of Landing

The number of active multispecies declined approximately 60% from 1994 to 2001, as did the number of multispecies vessels landing groundfish (Table 713). Multispecies vessels reporting groundfish landings were few in number during each year of the time period, with a maximum of 36 vessels in 1995 and minimum of 7 in 1999-2001. Total landings increased 87% from 1994 to 1995, declining afterwards to a low of 2.3 million pounds in 2001. Groundfish landings composed the smallest percentage of total landings and declined from 1,400 pounds in 1994 to only 200 pounds in 2001. Landings of other species made up the majority of total landings.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001

Table 713 - Landings and Revenues from Multispecies Permit Holders in Maryland (Dealer Activity)
Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.
Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.
Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.
Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.
Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.
High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.
C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**
Data source: NMFS Permit and Dealer databases

By Homeport

The number of multispecies vessels permitted in Maryland increased from 8 in 1994 to 27 in 2001 (Table 714). Active vessels and those landing groundfish also increased but reported low numbers of vessels throughout the time period. Total landings more than quadrupled from 1994 to 1997, declining over 43% from 1997 to 2001. Groundfish landings were very low from 1994 to 2001 and fluctuated, with a small increase during the later years of the time period. As a percentage of total revenues, groundfish revenues in Maryland are almost insignificant, below 0.5% in all years.

Table 715 - Population, education, poverty and unemployment statistics for the state of Virginia (1990 and 2000)
** data shown for 1989 and 1999*
Data source: U.S. Census Bureau

The total population in Virginia increased by 14.4% from 1990 to 2000 (Table 715). The percentage of individuals 25 years and older who graduated from high school or higher secondary school increased by 6.3 percentage points over the course of a decade, from 75.2% in 1990 to 81.5% in 2000. The number of families below the poverty level increased 2.4% from 1989 to 1999. While the number of unemployed increased 6.4% over the decade, the unemployment rate decreased, from 4.5% to 4.2% of the civilian labor force, aged 16 years and older.

Table 716 - Population by race in Virginia, 2000

Counties examined in Fishing Communities section of AHE in bold type.

Data source: U.S. Census Bureau

In 2000, the total population of Virginia was 72.3% white, 19.6% black/African American, 3.7% Asian, 2% of two or more races, 2% other races, and 4.7% Hispanic/Latino of any race (Table 716).

Fishing Industry Employment in Virginia

The number of fishing establishments in Virginia declined from 1997 to 2000, with an average payroll of $39,260 in 2000 (Table 717). The second greatest number of establishments was reported in the fish and seafood wholesale sector, which declined from 108 in 1998 to 100 in 2001. The number of fish and seafood markets increased slightly from 1998 to 2001, while fresh and frozen seafood processing and seafood product preparation and packaging establishments declined in number over this period. Seafood canning establishments remained stable over the period, ranging from 3 to 4.

Fishing Activity in Virginia

By Port of Landing

The number of active multispecies vessels declined from 183 in 1994 to 122 in 1997, increasing in the following years to 157 in 2000 (Table 718). The number of multispecies vessels landing groundfish declined 79% from 1994 to 2001. Total landings declined slightly through the mid-1990s and increased afterwards, reaching a maximum of 16.5 million pounds in 2001. Groundfish landings declined throughout the period, with a 94% drop from 1994 to 2001. Landings of other species and high value species composed the bulk of total landings. While other species landings remained stable throughout the period, high value species landings more than doubled between 1994 and 2001.

By Homeport

Total permitted multispecies vessels increased in number over the period, while number of active vessels remained stable (Table 719). Vessels landing groundfish declined from 1994 to 2001, numbering only 9 in 2001. Total landings were relatively consistent from 1994 to 1997, generally increasing in the following years. Groundfish landings increased substantially (23-fold), though remained low relative to total landings throughout the period. Dependence on groundfish remained low, increasing only slightly in the final two years of the time period.

In 2000, the total population of North Carolina was 72.1% white, 21.6% black/African American, 1.4% Asian, 1.3% of two or more races, 2.3% other races, and 4.7% Hispanic/Latino of any race (Table 721).

Fishing Industry Employment in North Carolina

North Carolina reported more fishing establishments than Delaware, Virginia, or Maryland. This number increased slightly over the period, from 3,367 in 1997 to 3,574 in 2001 (Table 722). The average payroll for participants in the fishing sector was $32,960 in 2000. The fish and seafood wholesale sector, which reported the second greatest number of establishments after the fishing sector, decreased from 97 establishments to 84. Fish and seafood markets increased over the period, while seafood product preparation and packaging establishments fluctuated, fresh and frozen seafood processing establishments declined, and seafood canning establishments remained stable.

NAICS Code and Description		1997	1998	1999	2000	2001

Fishing Activity in North Carolina

By Port of Landing

The number of active multispecies vessels landing fish in North Carolina increased from 1996 to 1999, the years for which the only data were available. Vessels landing groundfish fluctuated in number, dropping to zero in 1997 and never exceeding a maximum of 13 in 1998 (Table 723). Total landings increased from around 7 million pounds in 1996 to 11.1 million pounds in 2001. Groundfish landings were very low throughout the period, with maximum reported landings in any year of 2,200 pounds (1998). Landings of other species comprised the majority of total landings in North Carolina.

Table 723 - Landings and Revenues from Multispecies Permit Holders in North Carolina (Dealer Activity)

Landings are in thousands of pounds and revenues are in thousands of 1999 dollars.

Groundfish includes cod, haddock, yellowtail flounder, witch flounder, winter flounder, windowpane flounder, American plaice, pollock, redfish and white hake.

Small Mesh Multispecies includes silver hake, red hake, offshore hake, and ocean pout.

Small Mesh Non-Multispecies includes butterfish, herring, mackerel, scup, shrimp, loligo and illex squid.

Other Species includes monkfish, fluke, dogfish, skates, cusk and all other species.

High Value Species includes bluefin tuna, bigeye tuna, yellowfin tuna, American lobster, and sea scallops.

C ("confidential") **indicates that landings/revenues are for less than three vessels and cannot be reported for confidentiality reasons.**

By Homeport

The number of permitted multispecies vessels homeported in North Carolina far exceeded the number of multispecies landing fish in that state, increasing from 66 in 1994 to 94 in 2001 (Table 724). The number of active vessels nearly doubled during that period, while the number of vessels landing groundfish fluctuated, with a reported 27 vessels in the first and last years of the time series. Total landings nearly tripled from 1994 to 2001, and groundfish landings demonstrated a 19-fold increase, from 66,200 pounds in 1994 to 1.3 million pounds in 2001. Groundfish dependence in North Carolina is higher than in other mid-Atlantic states, averaging 2.8% from 1994 to 2001 with some fluctuation throughout that period.

Fishing Year	1994	1995	1996	1997	1998	1999	2000	2001
