TYPE OF STATEMENT:

( ) DRAFT (X) FINAL

ABSTRACT:

The New England Fishery Management Council and the NOAA Assistant Administrator for Fisheries propose to adopt, approve, and implement Amendment 13 to the Northeast Multispecies Fishery Management Plan (FMP) pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (the Act). The FSEIS presents the details of a management program designed to ensure compliance with the Act. It proposes measures to implement formal rebuilding programs for overfished stocks and to end overfishing on those stocks where it is occurring. Appropriate management measures will be adopted to implement these rebuilding programs. In addition, the Amendment will adopt measures to reduce excess harvesting capacity in the fishery and measures to minimize, to the extent possible, the adverse impacts of fishing on esential fish habitat. Finally, the Amendment includes measures that address a wide range of other management issues.

DATE BY WHICH COMMENTS MUST BE RECEIVED: ____________________

INTENTIONALLY BLANK

EXECUTIVE SUMMARY

Current Status of the Regulations and Need for this Amendment

The Northeast multispecies fishery (Atlantic cod, witch flounder, American plaice, yellowtail flounder, haddock, pollock, winter flounder, windowpane flounder, redfish, white hake, Atlantic halibut, and ocean pout) is currently managed through limitations on the number of days fished (days-at-sea; DAS), closed areas, trip limits, minimum fish sizes, and gear restrictions. The regulations implemented to manage the fishery are governed by the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act; M-S Act). The M-S Act mandates that action be taken if the size of a fish stock declines below a specified level ("overfished"), or if the annual harvest rate is too high ("overfishing"). Although the numbers of fish of many of the 12 groundfish species (20 stocks) have increased substantially in recent years and harvest rates have gradually declined, for many stocks the rate of increase must be accelerated to comply with the law, and for other stocks the harvest rate must be reduced. The stocks needing the largest reduction in fishing mortality are Gulf of Maine cod, Georges Bank cod, Cape Cod/Gulf of Maine yellowtail flounder, Southern New England/Mid-Atlantic yellowtail flounder, Southern New England/Mid Atlantic winter flounder, white hake, and American plaice.

In December 2001, as a result of a lawsuit (*Conservation Law Foundation et al. v. Donald Evans et al*) against the National Marine Fisheries Service (NMFS), a Federal Judge ruled that the Northeast Multispecies FMP does not comply with the M-S Act and ordered that Amendment 13 measures be implemented by August 22, 2003. The Judge further ordered that measures agreed to by certain parties in a Settlement Agreement be implemented during the interim. One of the most significant measures implemented during this interim period, beginning August 1, 2002, was a freeze on the number of DAS to the maximum level used during recent years (fishing years 1996-2000) and a 20% DAS reduction from that level. Subsequent to the initial ruling, the judge extended the deadline for implementing new measures to May 1, 2004.

In addition to this lawsuit, Amendment 13 includes alternatives to address the court-ordered remedy in the case of *American Oceans Campaign et al. v Daley et al*. In this case the court ruled in this lawsuit that elements of the amendment adopted to comply with the essential fish habitat provisions of the M-S Act were not in compliance with the National Environmental Policy Act (NEPA). Most of these alternatives were previously published and distributed for public comment as the *Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 to the Northeast Multipsecies Fishery Management Plan*. The proposed alternatives and impact analysis from that document have been incorporated into this SEIS.

The Purpose of this Document

This document provides information to the New England Fishery Management Council (Council), the public, and NMFS in order to select the best method of managing the fishery in accordance with the law. This Supplemental Environmental Impact Statement (SEIS) provides detailed information on the proposed action that has been developed by the Council to achieve the objectives of Amendment 13. It also includes information on the alternatives to the proposed action that were considered. The principal objectives of the amendment include rebuilding overfished stocks, ending overfishing, reducing unused effort in the fishery, addressing administrative issues, maintaining flexibility in the fishery, reducing bycatch, and minimizing the impact of the fishery on fish habitat and protected species (such as whales and turtles). In addition, this Amendment responds to the requirements of the court orders in the lawsuits of *Conservation Law Foundation et al. v. Donald Evans et al* and *American Oceans Campaign et al. v Daley et al.* As noted in the previous paragraph, this Amendment incorporates and expands on the *Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 to the Northeast Multispecies Fishery Management Plan.* This document describes and compares the various alternatives and provides analyses of their impacts. There are three major categories of impacts - biological, economic, and social impacts – but impacts on bycatch, habitat, and enforcement are also described. This Executive Summary highlights the major elements of the proposed action and includes a summary table of those measures. It does not list alternatives not adopted. Please see the applicable sections of the amendment for specific details.

Changes from the Draft Amendment and DSEIS

This final amendment and FSEIS differ in several ways from the draft amendment and DSEIS. First, the proposed action is identified. Second, the document has been edited and re-organized to clearly identify the proposed action and alternatives not selected. Finally, additional analyses and discussion have been added to support the proposed actions.

The proposed action are based on the alternatives considered and public comments. One major change resulted from public comments. The Council originally considered choosing one rebuilding strategy for all overfished stocks. The proposed action uses a combination of the phased and adaptive strategies, further modified based on the management measures selected by the Council. This decision to combine rebuilding strategies also resulted in changes to the proposed management measures. These changes are further described in following sections.

With respect to additional analyses, this document includes biological and economic analyses of the combined rebuilding strategies and the management measures implementing those strategies. In addition, in response to public comments, it includes a discussion of the impacts of steaming time and reduced days-at-sea allocations on vessels that claim Maine as a homeport. Some of the habitat analyses have also been revised to incorporate public comments. An initial regulatory flexibility analysis had been included, as well as an evaluation of the adherence of this plan with the M-S Act national standards.

Clarification of Status Determination Criteria

Status determination criteria (overfishing definitions) were previously adopted in Amendment 9. The proposed action will clarify and revise the status determination criteria (overfishing definitions). Criteria for most stocks will be based on fully-recruited fishing mortality and spawning stock biomass. In addition, minimum biomass thresholds are changed to comply with National Standards guidelines. The Amendment also adopts revised numerical estimates of these parameters. The Amendment also requires a review of all status determination criteria in 2008 so that management measures can be adjusted, as necessary, for the 2009 fishing year.

Proposed Rebuilding Periods

For stocks that require a formal rebuilding program, the Council is proposing to rebuild most stocks by 2014. There are exceptions to the proposed date that are explained in the text.

Proposed Rebuilding Programs

In response to comments received from the public, the Council will use a combination of an adpative and phased rebuilding trajectory strategy. The phased fishing mortality reduction strategy would not require as severe reductions in the initial years, but larger reductions in fishing mortality would be needed in later years. The adaptive strategy would fish at F_{MSY} through fishing year 2008, and then adjust mortality in order to rebuild most stocks by 2014. The proposed action combines these two strategies.

Fishery Program Administration

The measures proposed in this section address a wide range of administrative issues concerning groundfish management. Some of the measures also provide mechanisms to mitigate the impacts of the programs designed to rebuild groundfish stocks, such as through special access programs or refined requirements for certified bycath/exempted fisheries.

Periodic Adjustment Process

The proposed action would combine two existing management committees - the Multispecies Monitoring Committee (MSMC) and the Plan Development Team (PDT) - in order to streamline the management process. The amendment also identifies additional measures that can be adjusted through framework action. It also schedules assessments of groundfish stocks in 2005 and 2008 in order to monitor the rebuilding program and provide the information necessary to adjust management measures.

Biennial Adjustment

This action will decrease the frequency of scheduled framework adjustments to existing fishery regulations. Compared with the current annual adjustment, the proposed biennial adjustment (every two years) would provide more time for management measures to take effect and allow more time to evaluate the relevant scientific information on the status of the stocks and the effectiveness of the regulations. If necessary, the Council could choose to initiate an adjustment at other times.

US/Canada Resource Sharing Agreement

This action will incorporate the US/Canada Resource Sharing Agreement into the FMP. The informal agreement specifies an allocation of cod, haddock and yellowtail flounder on eastern Georges Bank for each country. Total catches by U.S. vessels from specific areas may not exceed the designated quota. U.S. vessels fishing in the trans-boundary area would be required to use an approved Vessel Monitoring System, and cannot fish both inside and outside the area on the same trip. There are a range of measures proposed to ensure the U.S. does not exceed its share.

Administration of Certified Bycatch/Exempted Fisheries:

The proposed action allows alterations to the current rules to provide increased flexibility to administer the exempted fisheries program. The Council considered but did not adopt a periodic review of the current exempted fisheries.

Special Access Program

Because management measures are generally applied over a wide geographic area and across many sectors of the fishing industry, access to healthy stocks is sometimes overly restricted. The proposed action implements a system to expedite regulations that allow access to multispecies stocks that are in good condition, or to target non-multispecies stocks that can be harvested without compromising the goals of this amendment.

Four specific special access program are proposed: a program to access GB yellowtail flounder in Closed Area II, a program to allow the landing of small incidental catches of winter flounder in the fluke fishery in Southern New England, a program to allow hook fishing for haddock in Closed Area I, and a program to facilitate catching the U.S. share of eastern GB cod, haddock, and GB yellowtail flounder under the U.S./CA resource sharing udnerstanding.

Closed Area Administration

The Council considered changes to the list of gear allowed access to closed areas. As part of measures to minimize to the extent practicable the adverse impacts of fishing on essential fish habitat, the Council proposes to prohibit hydraulic clamd dredges from groundfish closed areas.

Leasing Days-at-Sea

The proposed action wil implement a DAS leasing program for the fishery in order to enhance economic viability. Under this alternative, DAS can be leased, there is no conservation tax on leased DAS, DAS may be leased for a one-year period, leased DAS must be used during the period of the lease, leasing to more than one vessel is allowed, and only Category A DAS may be leased (see below for a description). Lease agreements must be registered with the NMFS. Additional provisions address administrative and conservation issues related to DAS leasing.

Observer coverage

The proposed action adopts a statement for a desired level of observer coverage.

Vessel Monitoring System Requirements
This measure allows vessels to sign-out of the multispecies fishery and stop VMS messaging for a period of at least 30 days, but they are not allowed to fish during that period.

Handgear Permit
The proposed action establishes one limited access permit category and one open access permit category. To be eligible for a limited access permit, a vessel must haveed 500 lbs. of cod, haddock, or pollock in any one fishing year from fishing years 1997 through 2001 when fishing under the handgear category. The trip limits for this new category would be 300 lb trip limit for cod. Open access permits are limited to 75 lbs. of cod.

Reporting Requirements
The Council proposes to adopt daily electronic dealer reporting. Dealer and vessel reports will be linked by a trip identitifier. Electronic vessel reporting may be required in the future.

Sector allocation
This alternative creates a system for approval of voluntary, co-operative sectors within the multispecies fishery. An organized sector would receive a share of the TAC or available DAS, based on prior history in the case of the TAC or current DAS allocations. The sector would form a plan that when approved by NMFS would control fishing by that sector. This may provide a way for sectors to adapt to the management regulations proposed.

One specific sector is proposed – the GB hook sector. This would implement implement a sector allocation for Georges Bank cod to the hook sector sector and allocates a portion of the Georges Bank cod total allowable catch. Other provisions include:

- Participation in the sector is voluntary
- A 'hard' TAC would be allocated to the sector based upon the share of the Georges Bank cod caught by the hook sector members during fishing years 1996 through 2001.
- Vessels in the sector would be required to have a vessel monitoring system and jig and longline vessels would be subject to seasonal trip limits.
- All vessels in the sector would be required to have a vessel monitoring system and there would be mesh restrictions and net limits according to whether a vessel is a Day or Trip vessel and uses stand-up or tie-down nets.

Alternatives to Control Fishing Capacity

Since the implementation of the DAS program under Amendment 5, a large portion of the total number of allocated DAS have not been used. Such unused DAS (also known as 'latent effort') represent potential future fishing effort. Without some type of control on this latent effort, the use of DAS could increase and thus make it more difficult to rebuild stocks. The following actions were designed to reduce unused DAS and provide additional flexibility to the industry by allowing, for example, transfer of DAS.

Days-at-Sea Transfer
This proposal will allow multispecies limited access permit holders to permanently transfer DAS to other multispecies limited access permit holders, with some restrictions. The selling vessel is required to retire from all Federal and state fisheries (limited access and open access). The current restrictions on the allowable maximum size of a replacement vessel would continue to apply (buying vessel cannot be greater than 10% larger in size or tonnage, or have a horsepower greater than 20% of the selling vessel).

Days-at-Sea Reserve

This alternative is built on the concept that a vessel's DAS can be divided into two classes, those that have been used and those that have not been used. Because DAS represent fishing effort, those DAS that have been used are referred to as "effective effort". This alternative first would calculate the amount of used DAS (effective effort) each vessel has had historically. Effective effort is calculated on the basis of DAS use and groundfish landings during the period fishing year 1996 through 2001.

Once effective effort is calculated, DAS would be divided into three categories: Category A: effective DAS available for use; Category B: effective DAS that can only be used to target healthy stocks either through special access programs or other programs developed in a future management action; and Category C: latent (unused) DAS, which is the difference between a vessel's Amendment 7 allocation of DAS, and its number of effective DAS. Upon implementation of Amendment 13, Category A DAS are available to fish for any groundfish species. Category B DAS may be used to fish in special access programs. Future frameworks will consider additional uses for Category B DAS. In the future, the ratio of Category A to Category B DAS may be adjusted, and Category C DAS may be allowed back into the fis hery subject to a conservation tax.

Measures to Address Rebuilding Requirements

Commercial Fishery Measures

- Category A DAS, that can be fished on on stock, are limited to sixty percent of effective effort as defined by the DAS reserve program. Category B DAS are sub-divided into Category B (regular) and Category B (reserve) DAS. Upon implementation of the amendment, Category B DAS can be used to target healthy stocks through special access programs. Future management actions may create additional opportunities to target healthy stocks using Category B (regular) DAS outside of special access programs.
- The Gulf of Maine cod trip limit is increased to 800 lbs-day/4,000 lbs. per trip
- Rolling closures, year-round closures, and min imum fish sizes, implemented August 1, 2002 are continued.
- The Georges Bank cod trip limit is reduced to 1,000 lbs-day/10,000 lbs-trip for trawl and gillnet vessels. A seasonal trip limit is in place for hook gear.
- Cape Cod/Gulf of Maine yellowtail flounder is subject to a seasonal trip limit: 250 lbs (May/June) and 750 llbs-day/3,000 lbs-trip (October/November)
- Southern New England/Mid-Atlantic yellowtail flounder is subject to a to a seasonal trip limit of 250 lbs (March through June) and 750 lbs-day/3,000 lbs-trip (July through February)
- Several gear modifications are adopted, including increased mesh size (compared to that used in fishing year 2001) and additional restrictions on gillnets. These changes are similar to the measures adopted under the Framework 33 settlement agreement.
- In order to implement the phased and adaptive strategies, in fishing year 2006 through 2008, Category A DAS will be limited to fifty-five percent of effective effort as defined by the DAS reserve program. In fishing year 2009, Category A DAS will be limited to forty-five percent of effective effort as defined by the DAS reserve program. These default measures may be adjusted based on stock conditions.
- Beginning in fishing year 2006, vessels fishing in the Southern New England or Mid-Atlantic Regulated Mesh Areas from December through April would be charged DAS at a rate of 1.5 days for each day fished. This default measure may be adjusted based on stock conditions.

Recreational Fishery Measures

The proposed action implement a 10 cod per person per day limit for the private recreational vessel and a 10 cod per person per day limit for the charter/party vessel fishing in the Gulf of Maine. Any trip greater than 15 hours in length and covering 2 calendar days would be considered more than one day. The minimum recreational cod size would be 22 inches, and minimum recreational haddock size would be 19 inches.

Description of Alternatives to Minimize the Adverse Effects of Fishing on Habitat (to the extent practicable)

A broad range of alternatives have been considered to minimize, to the extent practicable, the adverse effects of fishing on habitat. These meaures were previously analyzed and distributed for public comment as the *Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 to the Northeast Multipsecies Fishery Management Plan.* Of the broad range of alternatives, the Council selsected three (3) to satisfy their statutory mandate.

<u>Alternative 2: Benefits to EFH of other Amendment 13 measures</u>
Because management measures that were designed to reduce fishing mortality may also provide benefits to fish habitat, such management measures should be explicitly considered as part of a formal strategy to reduce impacts on habitat.

<u>Additions or modifications to closed areas (Alterantive 10 (option b): CompromiseHabitat Closure Areas</u>
Closed areas that are modifications of existing mortality closures and other proposed closed habitat closures

<u>Expand list of prohibited gears in closed areas (Alternative 7)</u>
This proposal will expand the of types of fishing gears prohibited in closed areas to include clam dredges.

Other Issues

<u>Northern Shrimp Fishery Exemption Area</u>
This action removes the multispecies plan restriction on the area available to the Northern Shrimp Fishery.

<u>Tuna Purse Seine Access to Closed Areas</u>
This action will allow tuna purse seine vessels access to all groundfish closed areas.

<u>Southern New England General Category Scallop Exemption Program</u>
Subject to any restrictions in the scallop FMP, this action will allow access to an exemption area in southern New England to fish for scallops for vessesl allowed to fish as general category scallop vessels. Vessels would be allowed to fish in this area while not under a multispecies day-at-sea as long as they comply with several restrictions.

Biological Impacts of Alternatives

<u>Fishery Program Administration</u>
The following measures are not expect to have any impact on fishing mortality: changing the periodic adjustment process, modifying the administration of the certified bycatch/exempted fisheries, eliminating the Flexible Area Action System (FAAS), observer coverage requirements, VMS requirements, reporting requirements, sector allocation mechanism, including creation of two specific sectors. Special Access Programs are not expected to increase fishing mortality on stocks of concern, but may increase mortality on healthy stocks.

<u>Rebuilding Strategies</u>
The proposed action will rebuild most overfished stocks by 2014. The three exceptions are CC/GOM yellowtail flounder (2023), GB cod (2026), and redfish (2051).

<u>Measures to Address Rebuilding Requirements</u>
The proposed commercial and recreational fishing measures are expected to reduce fishing mortality to rates necessary to achieve rebuilding and end overfishing. The inclusion of Category B DAS is not expected to adversely impact the rebuilding strategy on managed species. The use of these DAS will be limited to programs designed to have minimal impact on stocks for which fishing mortality must be

reduced. The impacts of eliminating the area restriction for the Northern Shrimp Fishery is difficult to estimate, but is expected to be minimal. Providing unrestricted access for tuna purse seine vessels to closed areas may increase bycatch of groundfish in those areas, but the increase is likely to be small, and the SNE General Category Scallop Exemption Area should have little effect on rebuilding of groundfish stocks in this area.

Habitat Impacts of Commercial Rebuilding Alternatives and Recreational Measures
All the rebuilding alternatives increase the level of habitat protection compared to No Action, but the proposed rebuilding alternative and Alternatives 1 and 2 would have greater habitat benefits due to the increased level of effort (DAS) reduction and the gear restrictions that they include. Reductions in fishing effort, including DAS reductions, are one mechanism known to minimize the adverse impacts on habitat associated with fishing, by reducing the frequency and intensity of fishing gear use. The benefits of closures to habitat are dependent upon the types of habitat within the closed area, the length of the closure, and the types of gear permitted inside them. Recreational fishing, primarily through hook and line, has no significant impact on habitat.

Measures to Minimize the Adverse Affects of Fishing on Habitat
This document includes a detailed gear effects evaluation, determination of adverse effects, and practicability analysis for all habitat alternatives. The potential impacts of the various year-round closed area scenarios have been evaluated from a habitat perspective by analyzing sediment composition, the biomass of selected groups of species within each closed area alternative, and the amount of area designated as EFH for 23 species with benthic life stages that were determined to have EFH that is vulnerable to the effects of mobile, bottom-tending gear. Another factor that was considered was the size of each proposed closed area and the extent to which each one overlaps with portions of the existing groundfish closed areas that have either remained closed to groundfish gear and scallop dredges since these closures were established in 1995 and 1998, versus portions that were opened temporarily to scallop dredging in 1999 and 2000.

Measures to Control Capacity and Increase Flexibility
The proposed action will reduce the possibility of latent effort re-entering the fishery in an uncontrolled manner.

Impacts on Protected Species
Conservation and management measures in Amendment 13 minimize bycatch and bycatch mortality of unavoidable discards to the extent practicable. Amendment 13 is likely to decrease effort among all gear components of the fishery. For this reason, the Amendment will not increase sink gillnet effort in the region and will not affect the ability of the Harbor Porpoise Take Reduction Plan to maintain serious injuries and mortalities below allowable levels. The existing FMP measures in combination with other measures adopted to protect these species will affect, but are not likely to jeopardize the continued existence of large whales, turtles, or other protected species.

Impacts of Alternatives on Bycatch
Many of the measures included in the proposed action will have a direct impact on bycatch and/or bycatch mortality, although it is difficult to quantitatively evaluate these impacts. The adopted rebuilding strategy will require significant reductions in catch in the initial years of the program. Coupled with strict controls on fishing effort, the proposed action should reduce overall bycatch levels of groundfish, skates, monkfish, and dogfish.

The proposed action contain DAS reductions that are likely to significantly reduce discards and discard mortality of all bycatch species by reducing time fishing and by reducing total catch. Some measures, such as increased mesh and higher trip limits for some stocks, may also reduce the rate of discards. Although reduced trip limits may increase bycatch if fishermen are unable to avoid catching the limited species, an increasing daily trip limit reduces the discard to kept ratio. The proposed Georges Bank access program for yellowtail flounder is likely to result in the discarding of several species, including non-groundfish species, however discard rates appear to be minimal based on available data. The proposed US/CA Resource Sharing Understanding Special Access Program may also increase discards, but the adoptiong of a hard TAC for cod, haddock, and yellowtail flounder will control any increases. The SNE/MA Winter Flounder Incidental Catch Special Access Program may reduce discards since vessels will be allowed to land small amounts of winter flounder that now must be discarded to comply with the regulations.

Economic Impacts of Alternatives

The economic effects of the proposed action are evaluated from both a short term and long term perspective.

Rebuilding Periods

Rebuilding most stocks by 2014 will result in an additional discounted economic benefits compared to rebuilding most stocks by 2009.

Rebuilding Strategies

The economic benefits of rebuilding strategies were compared assuming perfect implementation – that is, all target fishing mortality rates are achieved. The rebuilding strategy associated with the Proposed Action, however, is based in part on the fishing mortality rates that are expected toresult from the proposed management measures. The economic impacts of the pproposed measures thus are more likely to reflect future realized economic impacts. The purpose of the analysis, however, is primarily to compare strategies and not to predict specific revenue or net benefit levels.

In general, the net benefit of a rebuilding program, regardless of strategy chosen, would be greater than the net benefit of taking no action, but this is dependent on the time period for evaluation. The proposed action will yield positive economic benefits by 2019, while the adaptive strategy (not selected) would yield positive economic benefits by 2018, the constant fishing mortality strategy (not selected) by 2018, and the phased reduction strategy (not selected) by 2021. Because projected landings streams are subject to uncertainty, it is useful to examine the probability that rebuilding benefits will exceed the no action alternative. There is only a five percent changes that positive benefits will accrue under the proposed action by 2014, while there is at least an 80 percent probability that any of the rebuilding strategies will return positive benefits by 2026. The adaptive fishing mortality rebuilding strategy provides the highest present value, but is only slightly greater than the constant fishing mortality strategy. The difference in present value between the No Action Alternative and rebuilding (any strategy) is less than $300 million over 23 years.

Mean total landings for the regulated groundfish species, projected to be about 127 million lbs in 2003, were projected to be 289 million lb. in 2026 (when all stocks are rebuilt) for the "No Action" alternative. This compares to landings of 146 million pounds under the proposed action in 2004, and 320 million pounds by 2026. Nominal revenues under no action are expect to increase to $344 million in 2026, but will increase to $360 million under the proposed action. Net benefits would increase to $280 million under no action, but will increase to $310 million under the proposed action. The projected revenue streams suggest that over the long term much of the economic losses predicted will be offset by gains in harvest levels. The proposed action yields higher groundfish landings than any of the other rebuilding strategies considered for the period 2004 through 2007, and the second highest landings in 2008. From 2009 through 2014, the proposed action yields lower landings than other rebuilding strategies.

Measures to Address Rebuilding Requirements

While the comparison of rebuilding strategies assumes all target fishing mortality rates are achieved, the evaluation of the distributive impacts of the proposed action uses a model that estimates the actual exploitation rates that could result from the major elements of the alternatives. These impacts are short-term in nature. These revenue impacts are reported for different categories of groundfish vessels. In general, the analysis shows that those vessels or communities that are most dependent on groundfish will be most affected by the proposed action. Twenty-five percent of the vessels that claim Maine, New Hampshire, or Massachusetts as a homeport will lose at least one-third of gross revenues. The ports of Boston, Chatham/Harwichport, New Bedford, Portland, and Upper Mid-Coast Maine will be most affected. Median revenue losses for gillnet and hook gear are expected to be lower than for trawl gear. For those vessels that rely on groundfish for seventy-five percent or more of their fishing revenue, the median revenue loss is thirty-five percent. These impacts do not include any revenues that may be earned while fishing on Category B DAS or in special access programs.

An input/output model was constructed to evaluate the imapcts of rebuilding alternatives on coastal economies. This is also a short-term analysis that does not estimate the impacts of increased future landings as a result of stock rebuilding. The total combined impact on the New England economy, in terms of sales, is estimated to be a loss of $135.5 million. About nineteen hundred jobs will be affected, primarily in the fishing industry, while the proposed action will reduce personal incomes by $55.4 million.

With regard to the recreational measures, the economic impacts are small, relative to the beneficial biological impacts of those measures.

Measures to Minimize the Adverse Affects of Fishing on Habitat

The practicability analysis synthesizes all the conclusions from the habitat alternative analysis, including the socio-economic impacts, biological and ecological impacts, other identified impacts, as well as issues such as compliance with National Standards. Economic impacts of additional habitat closed areas were analyzed by examining recent revenues from those areas different species or species groups. The amount of revenues that would have been displaced if no fishing gear was allowed in those areas was calculated. Generally the more area closed, the more revenues are displaced. Much of the revenues displaced under all habitat closure alternatives is a result of a decrease in lobster landings. The level of habitat closure – that is, what gear is excluded from an area – affects the ranking of the habitat closure alternatives. Habitat closure alternative 5a has the most revenue impacts if all gear is excluded, but Alternative 5b has the most impact if only mobile gear is excluded.

Impacts of habitat alternatives on coastal economies were also estimated. These impacts cannot be added to those expected to result from the rebuilding alternatives, as different methods are used.

Measures to Control Capacity

Each of the capacity proposals is designed to provide greater economic opportunity and flexibility in all fisheries while maintaining the character of the existing fleet, and to achieve some long-term reduction in the number of vessels permitted to fish in the Northeast fisheries. The DAS transfer alternative requires that with the transfer of its DAS, a selling vessel must retire from fishing in state or Federal open and limited access fisheries. While this expands economic opportunities for some vessels, it eliminates participation of others in the groundfish and other fisheries. This may reduce voluntary participation in the capacity reduction programs. The measure which defines effective effort may have widely varied impacts on permit holders depending on their history in the groundfish fishery, benefiting some and severely limiting others.

Social and Community Impacts of Alternatives

Social impacts of DAS reductions tend to be more far-reaching and long-term in nature than social impacts from other management measures like trip limits, gear restrictions, and seasonal area closures. DAS reductions tend to significantly disrupt daily living, limit occupational opportunities, and alter community infrastructure. The majority of vessels that have multispecies Limited Access Individual DAS permits, use more of their allocated DAS, and will be most impacted by the large reductions in DAS proposed are homeported in Portland, Boston, and New Bedford. Trip limits are most likely to affect regulatory discarding and attitudes towards management. If Georges Bank trip limits are set too low, disproportionate impacts are likely to be experienced by the hook sector in Chatham/Harwichport, but the approval of the hok sector may mitigate these impacts to some extent. The nature of impacts of the gear restrictions under consideration will depend on the cost of the new gear, the current availability of the new gear, and vessel's choices as to whether or not to fish in the areas where the new gear is required. Set-asides for bycatch fisheries will reduce negative social impacts. Sector allocation and area management could provide for development of management measures that are more consistent with fishing activity and resource conditions in a particular area, encourage a greater sense of stewardship, and ensure that fishing activity in one sector does not adversely affect fishing activity in another sector.

Cumulative Impacts

Long-term effects of each of these rebuilding alternatives on the multispecies stocks are clear: stocks will rebuild as a result of the accumulated effects of measures applied over time and in response to these specific measures in Amendment 13 targeted at stock rebuilding. Effects of these alternatives in the long term are less clear or quantifiable from a social and economic perspective.

Fishery program administration measures will have generally small or negligible cumulative effects on fishing communities, groundfish stocks and habitat. The capacity reduction measures, which are designed to provide increased flexibility and economic opportunity, may have positive cumulative effects on fishery participants while reducing effort over the long term. In the short term, however, they will limit the opportunity of some permit holders to participate in the fishery. Alternatives to reduce the impacts of fishing on habitat will have limited positive cumulative effects on fishery resources. Cumulative effects of these alternatives on EFH may be positive, and will vary among alternatives. Measures to achieve stock rebuilding will all have strong positive effects on the resource through large reductions in fishing effort. These alternatives will have negative cumulative effects on fishing communities, particularly over the short term, but are intended to ensure that a sustainable fishery is attained in the long term. Some effects of these measures on fishing communities may be irreversible, such as losses in shoreside infrastructure and gentrification of the waterfront in response to reductions in the fishing fleet. As a result, the benefits that will utimately accrue from the rebuilding program may not be realized by current participants in the fishery. The proposed action attempts to mitigate these impacts by allowing higher landings in the 2004 – 2008 period than other alternatives, which should help some fishermen remain in business as stocks rebuild. In general, measures which reduce fishing effort will have a negative cumulative effect on fishery participants while producing a positive effect on the resource and habitat.

Fishery Program Administration Measures

Alternative Name	Description
Periodic Adjustment Process	
Modified Periodic Adjustment Process	revision of PDT to include MSMC SAFE report prepared each year but adjustment process occurs biennially (every 2 years) addition of new frameworkable items
US/CA Resource Sharing Understanding	specifies an allocation of GB cod, haddock and yellowtail flounder for ea. country (allocation based on a formula which includes distribution of the historical catch between the nations and present resource distribution) if a species allocation is reached during course of FY in U.S., TAC for following year is reduced by the same amount
Administration of Certified Bycatch/Exempted Fisheries	as in A-7, incidental catch of regulated multispecies must be less than 5% of total catch by weight (this standard may be changed through Council action) other impacts of fishery must be considered during review bycatch/exempted fishery may be authorized on case-by-case basis to retain and land regulated multispecies
Special Access Programs (SAP)	provides access to limited, specific regulated multispecies fisheries or other non-groundfish fisheries that do not undermine objectives of the multispecies FMP but would otherwise be prohibited requires submission and approval of a management action by the Council demonstrating that SAP will not adversely impact stocks of concern, analyzing impacts of the proposal and demonstrating compliance with applicable law requires submission, review and approval by Council and/or Regional Administrator
Specific SAPs	
Georges Bank Yellowtail Flounder Special Access Program	June-December—fishing vessels may make 2 trips/month into area opened for scallop CAII access program for yellowtail flounder vessels limited to 30,000 lbs yellowtail per trip all vessels required to use VMS no DAS charged for transit to CAII/statistical areas 561 and 562 may not fish until after entering open area and starting DAS clock DAS clock stops exiting area vessels limited to 1/5 of daily GB cod trip limit Maximum of 320 trips, but RA may change # of authorized trips
Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program	a vessel fishing for fluke west of 72-30' W using mesh authorized by fluke plan and not on a groundfish DAS may retain and land up to 200 lbs. of winter flounder vessel must possess valid fluke permit vessel must have fluke on board vessel operator must sign into program for minimum of 30 days and have LOA from RA on board cannot fish on a groundfish DAS when in the program fishing must take place west of 72-30'W possession and/or landing of other groundfish is prohibited
U.S./CAN Resource Sharing Understanding SAP	vessels fishing in 5Zjm given DAS credit for steaming time: time spent steaming to **and** from area will not be charged access provided to CAII to facilitate catching haddock and yellowtail for period of 10 mos. (not March and April) (may be adjusted by RA) measures may be adjusted by RA other incentives possibel in future
CA I Hook Gear SAP	Allows limited hook fishign to target haddock in CA I Observer coverage on all trips

Closed Area Administration	
Rationale for Closed Areas	When closures are adopted, Council will define intent and specific purpose of closures and explicitly describe duration of closure and who can/cannot fish there
Flexible Area Action System (FAAS)	the FAAS will be eliminated
Leasing of DAS	DAS may be leased from one fishing vessel to another, subject to a number of restrictions
Conservation Equivalency Alternatives	lessor may not lease DAS to any vessel with a horsepower that is over 20% more than that of the lessee or a LOA, GRT and NT that is over 10% more than that of the lessee DAS cannot be sub-leased
Limitations on Number of DAS Leased	a vessel may lease the number of DAS equal to its allocation for FY2001 (not including carry-over DAS)
Permit History Provisions	history of DAS use remains with permit that "owns" the DAS landings associated with leased DAS remain with the permit that lands fish if a vessel does not use all allocated and leased DAS, DAS will be considered used first
Expiration of Leasing Program	leasing automatically expires after 2 years unless extended by Council action
Observer Coverage	10% observer coverage requested; NMFS will determine by 2006 w hether this level is appropriate
VMS Requirements	vessel using VMS can withdraw from program for min. of one calendar month and can not during this period or transit in the EEZ with gear capable of catching groundfish unless it is properly stowed
Reporting Requirements	
Dealer Reporting Options	
Daily electronic reporting	Daily electronic dealer reporting where the dealer reports a trip identifier and type of catch; Reports due to NMFS within 24 hours of the transaction Trip identifier generated and reported by the vessel or the dealer(s)
Vessel Reporting Options	
Trip Identifier	Current VTR requirement maintained for all vessels with the addition of the trip identifier and possibel future adoption of electronic vessel reporting
Hand-Gear Only Permit Alternatives	
Category A – Limited Access	vessel in the open access handline/rod and reel category must have landed 500 lbs. of cod, haddock or pollock in at least one FY from 1997-2001 permits may be transferred trip limit is 300 lbs. cod for all other species trip limits same as for limited access vessels cod trip limit adjusted proportionally to that for DAS vessels same yr-round and seasonal closures as for limited access vessels
Category B – Open Access	trip limit is 75 lbs. cod for all other species trip limits same as for limited access vessels cod trip limit adjusted proportionally to that for DAS vessels
Sector Allocation (general)	
Formation of a Sector	participation voluntary (non-participants in common pool) must submit legally binding plan of operations
Sector Review and Approval	
Periodic Adjustment Process	sector will submit operations plan to Council at least one year before planning to start operations Council will implement plan during course of periodic adjustment process
Movement Between Sectors	
Option 3	allow for each sector to set their own rules on movement

Allocation of Resources	allocated based on documented catch allocated TACs for entire sector based on accumulated catch histories over previous five years of participants specific years defined for determining catch history
Mortality/Conservation Controls	hard annual TACs by species allocated to the sector as a whole
Enforcement of Sector Provisions/VMS Requirements	responsibility of each sector to enforce provisions adopted through plan no VMS requirements unless adopted in A-13
Interaction of Sector with Common Pool Vessels	a sector will not pay consequences if TACs exceeded by other sectors or common pool vessels if a sector exceeds TAC, quota will be reduced by same amt. as overage in following year sectors may be subject to same closed areas, min. fish sizes, permitting restrictions, gear restrictions, and reporting requirements as common pool vessels
Georges Bank Hook Sector Allocation	sector created: hook sector for harvesting Georges Bank cod participation voluntary allocation depends on history of participating permit holders
Georges Bank Cod Hook Sector	hard TAC for GB cod allocated to sector (quota determined by calculating share of GB cod harvest by sector participnts with hook gear 1996-2001) when TAC reached, fishing ceases for commercial hook sector longline vessels limited to max. of 3,600 12/0 circle hooks per trip measures to be defined in operations plan

Capacity Reduction Alternatives

Alternative Name	Reduction in DAS?	Affected Groups, general	Additional Restrictions	Details
DAS Transfer	yes 40% active; 90% inactive	multispecies limited access permit holders	LOA or tonnage of buying vessel not more than 10% greater than LOA or tonnage of selling vessel hp of buying vessel not more than 20% greater than hp of selling vessel seller retires from fishing	DAS may be used in entirety any time following transaction (subjec to any limits based on category of DAS)
DAS Reserve	no	multispecies permit holders	Category A DAS may be used to target any groundfish species when A-13 implemented Category B DAS can be used in special access programs, and as defined in future Category C days frozen in reserve account	Based on DAS use FY 1996 through 2001, in years when 5,000 pounds of groundfish landed Three categories of DAS defined (A, B, C)

Management Alternatives to Address Rebuilding Requirements

Alternative Name	Area Closures (yr-round)	Seasonal/Rolling Closures	Possession Limits	Effort Controls	Gear Restrictions	Minimum Fish Sizes	VMS Requirements	Additional Restrictions	Details
Proposed Action	current closures maintained (CA I & II, NLS, CL, WGOM)	**Gulf of Maine** March 121, 122, 123 April 121-125, 129-133 May 124-125, 129-133, 136-140 June 132-133, 139-140, 141-147, 152 October 124, 125 November 124, 125 **Georges Bank** May 80-81, 98-99, 109-114, 118-120 south of 42°20'N	GOM cod- 800 lb/day, 4,000 lb/trip GB cod- 1,000 lb/day, 10,000 lb/trip or seasonal limt for hooks, CC/GOM yellowtail- Apr-1-May 31, Oct 1-Nov 30 250 lb. possession lim.; Rest of year 750 lbs/DAS, 3,000 lbs/trip possession lim. SNE/MA yellowtail- March 1-Jun 30 250 lb. possession lim.; Jun 1-Feb 28 750 lbs/DAS, 3,000 lbs/trip possession lim. RA may adjust haddock trip limit prior to or during FY to prevent exceeding target TAC or allow harvesting up to 75% of target TAC	Based on DAS reserve Baseline FY 2004-2005 Cat A: 60% Cat B (reg): 20% Cat B (res): 20% FY 2006 - 2009 Cat A: 55% Cat B (reg): 25% Cat B (res): 20% In SNE/RMA mesh area, DAS count 1.5:1 FY 2009 Cat A: 45% Cat B (reg): 35% Cat B (res): 20% Cat B DAS can only be used in a Special Access Program until requirements for use of Cat B (reg) DAS specified in a future framework	**Day Gillnet**- • GOM: 6.5" roundfish, 50 net max.; 6.5" flatfish, 100 net max. • GB: 6.5" all nets, 50 net max. • SNE: 6.5" all nets, 75 net max. • MA: 6.5" roundfish, 75 net max.; 6.5" flatfish, 75 net max. **Trip Gillnet**- • GOM: 6.5" all nets, 150 net max. • GB: 6.5" all nets, 150 net max. • SNE: 6.5" all nets, 75 net max. • MA: 6.5" all nets, 75 net max. Monkfish- • 10", 150 net max. **Trawl**- • GOM/GB: 6.5" diamond/sq. cod end, raised footrope trawl (two options on area), 8.5" diamond/sq. large mesh entire net • SNE: 7" diamond/6.5" sq. cod end, 8.5" diamond/sq. large mesh entire net • MA: 6.5" diamond/sq. cod end, 7.5" diamond/8" sq. large mesh entire net **Hook gear** - • GOM: 2000 hooks • GB: 3600 hooks • SNE: 2000 hooks • MA: 4500 hooks • at least 6" between fairlead rollers, all areas; min. size 12/0 circle hooks for longline (except in MA)	Cod 22" Haddock 19" Pollock 19" Witch flounder 14" Yellowtail flounder 13" Atlantic halibut 36" American plaice 14" Winter flounder 12" Redfish 9"	none	management measures adopted by the negotiated settlement agreement (August 1, 2002) are maintained unless sepcifically changed	

Recreational Fishing Measures				
Alternative Name	**Minimum Fish Sizes**	**Possession Limits**	**Closed Seasons**	**Other**
Proposed Action	Cod - 22" haddock- 19"	**Private**- 10 cod/person/day no haddock limit **Party/Charter**- 10 cod/person/day no haddock limit any trip in excess of 15 hrs **and** covering 2 consecutive calendar days is considered >1 day	none	all other measures in place during FY2001 will continue to apply

Alternatives to Minimize the Adverse Effects of Fishing on Habitat			
Alternative Name	**Gear Restrictions**	**Area Closures (see note below on Closure Levels*)**	**Additional Restrictions and Details**
Alternative 2 – Complementary benefits of other Amendment 13 Alternatives	see Details	see Details	measures chosen in Amendment 13 will be relied on to provide habitat protection
Alternative 7 - Expand list of gears prohibited in closed areas	list of fishing gear prohibited from use in habitat closed areas expanded to include clam dredges	no additional closures	none
Alternative 10 - Habitat Closed Areas that are modifications of existing mortality closures and other proposed habitat closures	none	• habitat designated closed areas within existing yr-round closures • extension on NLCA new closures • Modified mortality closed areas and other proposed habitat closures including the *original* Cod HAPC in Closed Area II	Level 3 – The area will be closed indefinitely on a year-round basis to all bottom tending mobile gear.

Other Issues		
Alternative	Description	Other Requirements/Restrictions
Northern Shrimp Fishery Exemption Area	No multispecies FMP restrictions on the area authorized for the Northern Shrimp Fishery	Nordmore grate requirement maintained
Tuna Purse Seine Vessel Access to Groundfish Closed Areas	Tuna purse seine vessels allowed into all groundfish closed areas	Fishing for, landing or retaining multispecies (including small-mesh multispecies) prohibited May not have on board gear capable of catching groundfish Vessels may not fish in CA II HAPC RA can alter access if necessary to protect habitat or groundfish stocks
SNE General Category Scallop Vessel Exemption Program	Exemption program created	Subject to restrictions in the Scallop FMP May not fish for, possess on board, or land any species other than scallops Combined dredge width on board shall not exceed 10.5 feet Eight inch minimum twine top Does not apply to NLCA unless specifically authorized through multispecies FMP

1.0 Introduction

This Amendment 13 to the Northeast Multispecies Fishery Management Plan (FMP) proposes changes to the management program for this fishery. It is prepared by the New England Fishery Management Council (NEFMC, Council) in partnership with the National Marine Fisheries Service (NMFS). It is developed in accordance with the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA, M-S Act), the primary domestic legislation governing fishery management of the nation's marine fisheries and resources. In 1996, Congress passed the Sustainable Fisheries Act (SFA), which amended and re-authorized the M-S Act and introduced new emphasis on rebuilding overfished fisheries, ending overfishing, minimizing bycatch and bycatch mortality, and minimizing to the extent practicable the adverse impacts of fishing activity on essential fish habitat (EFH).

Although this FMP has been prepared primarily in response to the requirements of the M-S Act, it also addresses the requirements of the Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA). However, these are not the only laws and administrative orders that the Council must consider in developing an FMP. In preparing a Fishery Management Plan, the Council must comply with the requirements of the National Environmental Policy Act (NEPA), and Regulatory Flexibility Act (RFA), the Administrative Procedures Act (APA), the Paperwork Reduction Act (PRA), the Coastal Zone Management Act (CZMA), the Data Quality Act (P.L. 106-554), and Executive Orders 12612 (Federalism), 12630 (Property Rights), 12866 (Regulatory Planning), 12898 (Environmental Justice), and 13158 (Marine Protected Areas). These other applicable laws and administrative orders help ensure that in developing an FMP, the Council considers the full range of alternatives and their expected impacts on the marine environment, living marine resources, and the affected human environment. This integrated Supplemental Environmental Impact Statement (SEIS), which is required by NEPA, addresses these requirements.

This document is organized into four volumes:

Volume I:	Introductory material Proposed action and other alternatives considered Impacts of the proposed action and other alternatives considered
Volume II:	Affected environment
Volume III:	Appendices
Volume IV:	Public comments

INTENTIONALLY BLANK

2.0 Background and Purpose

2.1 Brief History of Prior Management Actions

The Northeast Multispecies FMP was adopted in 1986 to manage key groundfish stocks from Maine to Cape Hatteras. Management actions under this FMP were summarized in Amendment 5, adopted in 1994. The key actions leading to this action since Amendment 5 are summarized below.

Sustainable Fisheries Act

Despite the efforts taken in Amendment 5 and the cutbacks made by the industry during the following years, new legislation in 1996 set the standards for effective management even higher. The Magnuson-Stevens Act was amended with the adoption of the Sustainable Fisheries Act (SFA) in 1996. The SFA placed new demands on fishery management plans to reduce bycatch, identify and protect Essential Fish Habitat, and minimize adverse effects of fishing on EFH to the extent practicable. It also initiated new National Standards in the MSFCMA that emphasized minimizing impacts to fishing communities, improving safety at sea, significantly reducing bycatch and improving the collection and use of fishery and biological data.

Amendment 7

Amendment 7, implemented in 1996, sought to address the requirements of the SFA and newly amended MSFCMA. The amendment accelerated the DAS effort reduction program established in Amendment 5, eliminated significant exemptions from the current effort control program, provided incentives to fish exclusively with mesh larger than the minimum required, broadened the area closures to protect juvenile and spawning fish, and increased the haddock possession limit to 1,000 pounds. It established a rebuilding program for Georges Bank (GB) and Southern New England (SNE) yellowtail flounder, GB and GOM cod, and GB haddock based primarily on days-at-sea (DAS) controls, area closures, and minimum mesh size. Additionally, the amendment changed existing permit categories and initiated several new ones, including an open access multispecies permit for limited access sea scallop vessels. Amendment 7 also created a program for reviewing the management measures annually and making changes to the regulations through the framework adjustment process to insure that plan goals would be met. Of all the major changes to the Northeast Multispecies Plan, Amendments 5 and 7 had the greatest impact on the fishery, both for stock rebuilding and in shaping the socio-economic conditions of the industry and fishing communities.

Amendment 9 and Essential Fish Habitat

Amendment 9 (1999) also had a significant impact on the fishery, establishing new status determination criteria (overfishing definitions) and setting the Optimum Yield (OY) for twelve groundfish species to bring the plan into complete compliance with the SFA. However, according to a 2000 ruling in *American Oceans Campaign et al. v. Daley et al.* [Civil Action No. 99-982(GK)], EFH considerations continued to be inadequate in fishery management plans. The prosecution contested the adequacy of evaluations of fishing gear impacts on EFH and challenged NMFS approval of amendments and management plans which did not fully address the impacts of fishing on habitat. The U.S. District Court for the District of Columbia found that the agency's decisions on the subject EFH amendments were in accordance with the Magnuson-Stevens Act, but found that the EAs for the Councils' amendments were inadequate and in violation of NEPA. The court determined that the EAs prepared for the EFH provisions of the fishery management plans did not fully consider all relevant alternatives. The court specifically criticized several of the EAs for evaluating only two options for the EFH amendments: either approval of the amendment or status quo. Additionally, the decision noted that the descriptions and analyses of the environmental impacts of the proposed actions and alternatives were vague or not fully explained. The court ordered NMFS to complete a new and thorough NEPA analysis for each EFH amendment named in the suit. Amendments 11 and 12 addressed the SFA requirements for designating EFH for all managed species and for managing whiting (silver hake), red hake and offshore hake through a separate small-mesh multispecies management plan implemented in 2000.

Framework Adjustments and Interim Rule

The Northeast Multispecies FMP has been subject to many additional changes since its inception. Besides the 11 amendments implemented prior to development of Amendment 13, the multispecies plan has been altered through framework adjustments 30 times since 1994.

The Council has held four annual reviews and made eight adjustments to the FMP to address Amendment 7 rebuilding needs (Frameworks 20, 24, 25, 26, 27, 30 and 33). In 1999, the Council submitted Framework 27 as the primary annual adjustment framework. At the final framework meeting on January 27-28, the Council focused on the finalizing the severe restrictions necessary to achieve the plan objectives for GOM cod and was unable to complete development of the measures needed for GB cod. It followed immediately with the development of Framework 30 to address GB cod, which was submitted to NMFS on April 30.

Both Frameworks 27 and 30 contained trip limits for GOM and GB cod. In both cases, the Regional Administrator was authorized to reduce the trip limit when 75 percent of the target TAC for each stock was reached. On May 28, 1999, the Regional Administrator reduced the GOM cod limit implemented on May 1, 1999 of 200 pounds per day to 30 pounds per day, just three weeks into the fishing year. However, even before the trip limit was reduced, fishermen reported excessive discards of cod as seasonal closures ended.

On May 28, 1999, responding to widespread reports from the industry about the levels of cod discards in the western Gulf of Maine, the Council requested that the Secretary of Commerce increase the trip limit under the emergency action authority provided in §305 of the Magnuson-Stevens Act. On August 3, NMFS published an interim rule that increased the trip limit from 30 pounds per day to 100 pounds per day, with a maximum possession limit of 500 pounds and modifications to the running clock. The interim rule expired on January 30, 2000.

NMFS announced on July 29, 1999 that it disapproved the 30-day closure on Georges Bank proposed in Framework 30, but it approved the trip limit, which took effect on August 15. Framework 30 established a GB cod trip limit of 2,000 pounds per day/20,000 pounds maximum possession limit that the Regional Administrator may reduce when 75 percent of the target TAC is landed.

To address potential discarding in the GOM cod fishery upon expiration of the interim rule, and to prevent repeating on Georges Bank the discarding situation that occurred in the Gulf of Maine when the trip limit was reduced, the Council submitted Framework 31 on October 14, 1999. NMFS approved the increased GOM cod trip limit on January 5, 2000, but it disapproved the change to the GB cod trip limit program that would have eliminated the authority of the Regional Administrator to make mid-season adjustments to the trip limit when 75 percent of the target TAC is reached.

Framework 33 was implemented on June 1, 2000 to reduce or maintain fishing mortality rates for the five critical stocks below fishing mortality rebuilding targets established by Amendment 7. This framework continued the status quo seasonal closures for Gulf of Maine cod, but incorporated a "trigger" for additional closures: if 50 per cent of the target TAC was landed by July 31, the Cashes Ledge Closed Area would be closed in November and Blocks 124 and 125 would be closed in January. The WGOM closure was extended for an additional year, to April 30, 2002. GOM cod trip limits were held at 400 pounds per day with a maximum possession limit of ten times the daily limit. Party and charter vessels were required to obtain a letter of authorization to fish in any of the GOM closed areas, and a limited access vessel in this program was prohibited from fishing on a DAS while in possession of the letter. A GB cod trip limit of 2,000 pounds per day, not to exceed 20,000 pounds per tip, was also adopted. In addition, a closure of Blocks 109-114, 98, and 99 during May was implemented. The Council also proposed changes to the large mesh permit category, but these were not approved by NMFS.

The Multispecies Monitoring Committee (MSMC) reviewed stock status in November, 2000, and concluded that Amendment 7 fishing mortality targets were likely being met for GB cod, GB haddock, GB yellowtail flounder, and SNE yellowtail flounder. The fishing mortality of GOM cod could not be determined with precision because of extensive discards that were believed to have occurred in 1999 because of the low trip limit. The MSMC recommended that an annual adjustment not be made until the status of GOM cod could be determined.

GB cod was assessed in June 2001 and fishing mortality was reported to be slightly above the Amendment 7 target; subsequent assessments have shown this report to be in error. GOM cod was assessed in June 2001, and fishing mortality was found to be significantly above the F_{MAX} target for this stock. After receiving the information on GOM cod at the July, 2001 Council meeting, the Council renewed efforts to develop Framework 36. The initial plan was to determine final management measures at the September Council meeting. Just prior to this meeting, however, the National Marine Fisheries Service advised the Council that an Environmental Impact Statement (EIS) was required for this action. Scoping was immediately initiated and it was decided to incorporate the annual adjustment into this action. Framework 36 was completed by December 2001, but the Council did not adopt the framework and it was not submitted.

Frameworks 37 and 38 instituted changes to management of the whiting fishery.

Conservation Law Foundation et al. v. Evans et al.

In December 2001, Conservation Law Foundation and other organizations successfully filed suit against NMFS alleging that the rebuilding plans the NMFS implemented were not consistent with Amendment 9 overfishing definitions (*Conservation Law Foundation et al. v. Evans et al.*). Additionally, they charged that there had been a consistent failure in management plans to assess bycatch reporting and establish measures to minimize bycatch and bycatch mortality (when bycatch is unavoidable). After a long series of negotiations among various parties, interim measures were adopted by the court and NMFS was instructed to submit a management plan to comply with the law. The response to this is Amendment 13, which will address stock rebuilding issues, greatly reduce fishing effort and capacity in the multispecies fishery and implement additional measures to specifically address habitat protection.

Trawl Survey Issues and Amendment 13 Development

During the period of Amendment 13 development, the relationship between the multispecies fishing industry and the scientific community has also undergone important changes. In September 2002, a Cape Cod fisherman convinced federal scientists that the trawl warps used to tow the groundfish survey gear used by the Northeast Fisheries Science Center were of different lengths, a fact that was confirmed. A series of workshops took place to assess how the warp length discrepancy and confounding structural problems with the otter trawl doors and footrope may have affected data quality. Issues surrounding the trawl warps, reference point estimates, and a trawl survey experiment were evaluated by Payne et al. (2003) and the general conclusion was that the information available was suitable for management. Payne et al. (2003) also provided numerous recommendations for further investigation of the issues raised. It is likely that in the future, greater emphasis will be placed on collaborative efforts in fisheries research in order to improve communication and understanding among fishermen and scientists, and collect more comprehensive and complete data for management of the fishery. The problems with the survey trawls emerged at a critical time in the development of this amendment and have resulted in a series of setbacks to implementation of the plan. The court granted NMFS an eight-month extension in the date of implementation of the amendment to May 1, 2004 in order to reevaluate the biological data used in establishing biological reference points for the stocks.

Demonstrating abounding variety in its multitude of fishery participants, fishing communities, stocks and species, and individuals and organizations involved in management, the Northeast multispecies fishery is one of the most complex and colorful in this country. This diversity, which is implicit in the uniqueness of New England's fishing heritage, also creates challenges to equitability and simplicity in management. The evolution of groundfish management in New England has served to shape and transform all elements of the fishery.

2.2 Purpose and Need for Action

This amendment is designed to meet all the requirements of the M-S Act for the Northeast Multispecies Fishery. This amendment is prepared by the New England Fishery Management Council (NEFMC; Council). After the proposed action is reviewed, the Amendment will be approved and implemented by the National Marine Fisheries Service (NMFS). Stocks managed in this fishery are described in Amendments 5, 7 and 9. Specific alternatives are identified to:

- Rebuild overfished fisheries
- End overfishing where it occurs
- Minimize, to the extent practicable, the adverse effects of fishing on essential fish habitat to comply with section 303(a)(7) of the Magnuson-Stevens Act. More specifically, the purpose is to identify and describe adverse effects of fishing on EFH and to minimize to the extent practicable these adverse effects. This Environmental Impact Statement (EIS) responds, in part (see above), to the court's directive to NMFS to complete new NEPA analyses for the Northeast Multispecies Fishery Management Plan. Although the plaintiffs' complaint focused on whether NMFS had adequately evaluated the effects of fishing on EFH, NMFS decided to complete new EIS's to evaluate all of the EFH components of the applicable fishery management plans. Accordingly, this SEIS reevaluates the impacts of amending the Northeast Multispecies fishery management plans to include the EFH provisions required by the Magnuson-Stevens Act. The SEIS analyzes alternatives for the EFH FMP amendments, including the alternative that was adopted by the Council and approved by NMFS in 1999 and other alternatives.
- Minimize bycatch and minimize mortality of bycatch that cannot be avoided
- Provide options for reducing harvesting capacity
- Address numerous issues with respect to the administration of the fishery
- Implement management measures for tuna purse seine vessel access to groundfish closed areas, an expansion of the northern shrimp fishery exemption area, and an exemption for general category scallop vessels in southern New England.

Twelve groundfish stocks are either overfished, or have been declared overfished in the past and are currently rebuilding under programs that do not meet the requirements of the M-S Act. In addition to these stocks, two additional stocks are experiencing overfishing. Failure to reduce fishing mortality in order to rebuild these stocks and/or end overfishing will result in the loss of net benefits valued at $200 million or less (at a cumulative probability of 90 percent) over a 23 year period. While many stocks will continue to increase under current fishing mortality rates – indeed, some will increase to levels not observed in the last thirty years – most stocks will not achieve levels that will support maximum sustainable yields.

In the 1996 reauthorization of the Magnuson-Stevens Act, Congress recognized that one of the greatest long-term threats to the viability of commercial and recreational fisheries is the continuing loss of marine, estuarine, and other aquatic habitats. To ensure habitat considerations receive increased attention for the conservation and management of fishery resources, the amended Magnuson-Stevens Act included new EFH requirements, and each fishery management plan must now include specific EFH provisions. Section 303(a)(7) of the Magnuson-Stevens Act requires that each FMP describe and identify EFH for the fishery based on the guidelines established by the Secretary (50 CFR part 600, Subpart J), minimize to the extent practicable adverse effects on EFH caused by fishing, and identify other actions to encourage the conservation and enhancement of EFH. The description an identification of EFH is applied as included in Amendment 11 to the Northeast Multispecies FMP of 1998.

2.2.1 The NEPA Analysis and Fishery Management Plan Actions

NEPA provides a mechanism for identifying and evaluating the full spectrum of environmental issues associated with Federal actions, and for considering a reasonable range of alternatives to avoid or minimize adverse environmental impacts. In addition to considering alternatives to end overfishing and rebuild overfished stocks, NMFS and the New England Fishery Management Council considered a wide range of alternatives designed to minimize, to the extent practicable, the adverse effects of fishing on essential fish habitat (EFH). As noted in the court's decision in *AOC v. Daley*, the alternatives NMFS must consider under NEPA are not restricted to the options originally presented in the fishery management plan amendments submitted by the Council. Additional alternatives were developed during the process, and analyzed in this document.

Amendment 13 is a complex action, and the measures that ultimately will be implemented are expected to have significant implications on the conduct of the fishery in the future. Therefore, the Council considered it critically important that the alternatives be well developed and thoroughly analyzed. The Council and NMFS are subject to a court-ordered deadline of May 1, 2004 to implement Amendment 13. In order to allow the Council staff and the Plan Development Team as much time as possible to complete the final analyses of all of the management measures, and because the stipulation requires that a 90-day public comment period be provided for the designation of the EFH alternatives, the Council, in consultation with NMFS, chose to provide to the public the analysis of the EFH alternatives for Amendment 13 as early as possible. The Council voted to submit the EFH DEIS (stand alone) for public comment at its March 2003 meeting. The NOA for the EFH EIS was published on April 4, 2003 (FR 03). The public comment period was ninety days from April 4 through July 2, 2003. Although the EFH DEIS did not contain the complete analysis for all of the management measures under consideration for Amendment 13, it did consider the impacts of the measures under consideration by the Council on EFH. The analyses for the remaining measures of Amendment 13 were completed for the Amendment 13 DSEIS in preparation for the July 2003 Council meeting, at which the Council adopted the DSEIS for Amendment 13 in its entirety. The DSEIS thus constituted another draft of the EFH DEIS. The public had a 45-day period to comment on the DSEIS, including the EFH alternatives included in the DSEIS, prior to the Council taking final action on Amendment 13 in November 2003. Thus, the public was afforded 135 days to comment on the EFH alternatives in Amendment 13. All comments received on the EFH DEIS and the full Amendment 13 DSEIS were considered by the Council in making its final decisions on the measures to be submitted in Amendment 13, and are summarized in Appendix XVII of this SEIS.

2.2.2 Notice of Intent and Scoping Process

NMFS published a Notice of Intent (NOI) to prepare a supplemental EIS for an amendment to the Northeast Multispecies FMP on February 23, 1999 (*Federal Register*, 64 FR 8788). Scoping comments were solicited by the Council through May 10, 1999. The NOI highlighted that Amendment 13 was being developed to rebuild overfished stocks, but also would address other issues raised during scoping. The primary issues raised during scoping, organized under major themes, were:

- General problems
  - Management plan is to complex, with too many rules and frequent changes
  - Cumulative socio-economic impacts of successive framework actions not analyzed
  - No mechanism in the FMP to expand/upgrade groundfish observer coverage
  - Uncertainty over stock delineation
  - Different perceptions over the role of target TACs

- Stock rebuilding:
  - Need to address M-S Act requirements for rebuilding programs
  - Management cycle not coordinated with stock assessment cycle
  - Management measures to rebuild weak stocks often preclude fishing for stronger stocks, resulting in excessive economic dislocation

- Fishing Effort and Capacity
  - Allocated DAS cannot be increased without jeopardizing rebuilding
  - Only 1/3 of allocated DAS used in 1998; unused allocations could be reactivated, countering rebuilding efforts
  - Difficult to resolve treatment of recent vs. historic participation in the fishery
  - DAS are not being used as the primary management tool
  - Inequities associated with DAS allocations and usage
  - Frontloading and running of the DAS clock decrease ability to estimate true fishing effort

- Allocation and Equity Issues
  - Equal application of regulations often results in unequal impacts
  - Application of different regulations to different fleet sectors often viewed as unfair
  - Measures often tied to specific gear sectors, yet harvest allocations are not assigned to gear sectors
  - Perceptions of inequity with regard to recreational vessel access to closed areas

- Closed Area Management
  - Difficult to spread conservation burden evenly across fleet sectors using closed areas
  - Closed areas force vessels to concentrate effort and fish less efficiently, intensifying competition and gear conflicts

- Trip Limits
  - Often result in excessive discards
  - Species-specific trip limits in a multispecies fishery often result in discarding
  - Difficult to design a trip limit for both large and small vessels
  - Difficult to enforce
  - Create incentives for derby style fishing if used as a "backstop"

- Experimental and Exempted Fisheries
  - Five percent bycatch standard will become increasingly difficult to meet as groundfish stocks recover
  - Process for obtaining an experimental permit is difficult and time-consuming
  - Difficulty of process discourages conservation engineering

- Fishing Gear and Selectivity
  - FMP does not provide incentives for fishermen to use more selective, less destructive gear
  - NO mechanism to increase accountability for bycatch
  - Difficult to match minimum fish sizes with appropriate minimum mesh size
  - Lack of adequate gear/selectivity information for all multispecies stocks/fisheries

NMFS published a NOI to prepare a supplemental EIS for the EFH components of the Northeast Multispecies and Atlantic Sea Scallop Fishery Management Plans on February 1, 2001 (66 FR 8568). The public comment period was open until April 4, 2001. NMFS (and/or the Council) solicited public comment to identify a range of alternatives for identifying and describing EFH and HAPCs and requested information on adverse effects of fishing activities on EFH and HAPCs. NMFS (and/or the Council) solicited public comment on appropriate management measures and alternatives to minimize, to the extent practicable, any adverse effects of fishing on EFH. NMFS (and/or the Council) held one public scoping meeting. The meeting occurred in Gloucester, MA on February 22, 2001. A summary of the public comments and primary issues raised during the meetings is in the Scoping Report (Appendix 9).

2.2.3 Overview of the EFH Elements of the DSEIS

Based in part on the issues identified during scoping, the DSEIS included an evaluation of the effects of fishing on EFH and an analysis of alternatives to minimize to the extent practicable the adverse effects on EFH from fishing. It incorporated and expanded on the information contained in the supplemental EIS for the EFH components of the Northeast Multispecies Fishery Management Plans. The DSEIS considered and evaluated alternatives to minimize adverse effects to the extent practicable and included consideration of measures such as closed areas, effort reductions and gear modifications. It constituted another draft of the EFH DEIS.

The analysis considers the proposed action, along with a range of other reasonable alternatives. Information from the 1998 EA (included in Amendment 11 to the Multispecies FMP) is reflected in this analysis. However, additional information and the selection of alternatives come from a review of the best scientific information available, including new information made available since the fishery management plan amendments were originally completed.

Sections 9.1 and 9.2 of the SEIS describes the affected biological and physical environment. This includes a discussion of the areas and habitat types in the area that EFH is designated. The section's description of the affected environment details the physical and biological resources affected by the alternatives, including a description of the Atlantic Coast shelf ecosystem, benthic habitat, fishery activity and relevant biological resources with an emphasis on benthic organisms.

Section 9.3.1.2 includes an evaluation of gear effects on EFH. Specifically, the section describes the gears used, distribution and use of the different gears, the types of gear effects, the vulnerability of the EFH to the gear type and a determination of the adverse effects of gears on EFH.

Section 3.7 of the SEIS describes the alternatives for minimizing the adverse effects of fishing on EFH. The section discusses significant issues associated with each alternative including those identified during scoping. The discussion of each alternative for minimizing the effects of fishing on EFH describes the associated fishery management measures. This section concludes with a discussion and explanation of alternatives that were considered but not carried forward for further analysis. The description of alternatives provides a broad summary and comparison of each alternative. Section 5.3.8 details the environmental consequences of each alternative for minimizing the effects of fishing on EFH. For each alternative to minimizing adverse effects of fishing on EFH, the chapter describes the practicability of the associated fishery management measures and evaluates the environmental consequences in relation to effects on EFH, the fishery, other fisheries, and protected resources. The discussion of potential impacts resulting from each alternative is presented in comparative form that clearly distinguishes the environmental consequences of each alternative. The discussion in Section 5.0 includes a description of the conservation benefits and the adverse impacts of the alternatives.

In Sections 5.3 and 9.3.1.8, the document also includes material to satisfy the requirements of the NMFS guidelines at 50 CFR part 600, Subpart J for mandatory requirements of an FMP to:

(1) Identify any fishing activities that are not managed under the MSA that may adversely affect EFH.

(2) Identify activities other than fishing that may adversely affect EFH. For each activity, the FMP should describe known and potential adverse effects to EFH.

(3) Identify actions to encourage the conservation and enhancement of EFH, including recommended options to avoid, minimize, or compensate for the adverse effects, especially in HAPCs.

(4) List the major prey species for the species in the fishery management unit and discuss the location of prey species' habitat. Consider adverse effects on prey species and their habitats that may result from actions that reduce their availability, either through direct harm or capture, or through adverse effects to prey species' habitats.

(5) Recommendations, in priority order, for research effects necessary to improve upon the description and identification of EFH, the identification of threats to EFH from fishing and other activities ad the development of conservation and enhancement measures for EFH.

(6) Conduct a cumulative impact analysis that describes impacts on an ecosystem or watershed scale (Cumulative effects of multiple gear types in included in the Gear Effects Evaluation Section)

Appendix 17 includes a summary of comments received on the EFH DEIS and preliminary responses to those comments.

2.3 Goals and Objectives

The goals and objectives of this amendment are:

Goal 1: Consistent with the National Standards and other required provisions of the Magnuson-Stevens Fishery Conservation and Management Act and other applicable law, manage the northeast multispecies complex at sustainable levels.

Goal 2: Create a management system so that fleet capacity will be commensurate with resource status so as to achieve goals of economic efficiency and biological conservation and that encourages diversity within the fishery.

Goal 3: Maintain a directed commercial and recreational fishery for northeast multispecies.

Goal 4: Minimize, to the extent practicable, adverse impacts on fishing communities and shoreside infrastructure.

Goal 5: Provide reasonable and regulated access to the groundfish species covered in this plan to all members of the public of the Untied States for seafood consumption and recreational purposes during the stock rebuilding period without compromising the Amendment 13 objectives or timetable. If necessary, management measures could be modified in the future to insure that the overall plan objectives are met.

Goal 6: To promote stewardship within the fishery.

Objective 1: Achieve, on a continuing basis, optimum yield (OY) for the U.S. fishing industry.

Objective 2: Clarify the status determination criteria (biological reference points and control rules) for groundfish stocks so they are consistent with the National Standard guidelines and applicable law.

Objective 3: Adopt fishery management measures that constrain fishing mortality to levels that are compliant with the Sustainable Fisheries Act.

Objective 4: Implement rebuilding schedules for overfished stocks, and prevent overfishing.

Objective 5: Adopt measures as appropriate to support international transboundary management of resources.

Objective 6: Promote research and improve the collection of information to better understand groundfish population dynamics, biology and ecology, and to improve assessment procedures in cooperation with the industry.

Objective 7: To the extent possible, maintain a diverse groundfish fishery, including different gear types, vessel sizes, geographic locations, and levels of participation.

Objective 8: Develop biological, economic and social measures of success for the groundfish fishery and resource that insure accountability in achieving fishery management objectives.

Objective 9: Adopt measures consistent with the habitat provisions of the M-S Act, including identification of EFH and minimizing impacts on habitat to the extent practicable.

Objective 10: Identify and minimize bycatch, which include regulatory discards, to the extent practicable, and to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

2.4 Changes from the Draft Amendment and DSEIS

This final amendment and FSEIS differ from the draft amendment and DSEIS in several ways. First, the proposed action is identified. Second, the document has been edited and re-organized to clearly identify the proposed action and alternatives not selected. Finally, additional analyses and discussion have been added to support the proposed actions. These changes are a result both of public comments and actions taken by the Council.

A large number of comments were received on the draft amendment and DSEIS. Most of these comments were in support of a particular alternative or proposed measure; those comments were noted. Additional comments were received questioning the analysis or the tools used to analyze the impacts of various alternatives. The volume of comments prevented an individual response, so the comments were summarized and addressed in Appendix XVII.

For the most part, the proposed actions have been selected from the alternatives described in the draft amendment. A major difference, however, is in the choice of rebuilding trajectories (or strategies) and the management measures for the commercial fishery designed to achieve those objectives. The draft amendment proposed selecting one rebuilding trajectory and applying it to all overfished stocks. Public comments suggested combining the adaptive and phased rebuilding trajectories by applying each only to specific stocks. Comments also were received suggesting appropriate management measures to achieve the mortality rates consistent with the combined trajectories. The Council considered these comments and is proposing a rebuilding approach based in large measure on these suggestions. Both a phased and adaptive trajectory have been adopted, applied to specific stocks. In addition, the trajectories have been modified somewhat to take into account the mortality reductions expected from the proposed measures and to incorporate new information on the observed fishing mortality rates in calendar year 2002. The phased trajectory has been modified into a stepped approach, addressing the practical difficulty of continuously reducing fishing mortality by a small amount each year on a number of stocks. The proposed management measures also differ from those suggested during the comment period. Based in large measure on the Alternative 1 rebuilding measures, they have been modified to include the necessary measures to reduce fishing mortality in future years as called for by the adaptive and phased trajectories. The proposed action also includes an innovative use of a limited number of DAS to target healthy stocks, an idea generated during the comment period. There are minor revisions to other management measures as well, both as a result of public comments and additional Council consideration of these issues. For example, specific details of the various special access programs have been clarified, as have the elements of the Georges Bank hook sector.

The document has been re-organized to clearly identify the proposed action and non-selected alternatives. The proposed action is described first. Non-selected alternatives are grouped into two categories: those that were not selected, and those that were considered and rejected. Generally, non-selected alternatives were analyzed in the draft amendment document and that analysis is included in this FSEIS. Alternatives that were considered and rejected were not analyzed in the DSEIS, but the reason for their rejection is briefly described. With respect to analyses, major elements of the biologic and economic analysis have been separated for the proposed action and non-selected alternatives. For less substantive issues, the analyses have not been separated but which measures are proposed or not selected have been identified in the discussion.

Additional biologic and economic analyses have been incorporated for the combined rebuilding strategies and the proposed commercial fishing management measures. These impacts are also compared to the impacts of the other management alternatives that were not selected. Additional analyses have been added to address the comment that the impact analysis did not consider impacts on Maine should vessels relocate to other ports. The social impacts of the DAS allocations and the use of DAS to target healthy stocks are also addressed. The bycatch analysis has been updated for the proposed action, and data on dogfish bycatch from a recent assessment has been added to the summary of bycatch information. Additional habitat analyses have been added for the proposed action, and corrections have been made to some of the habitat information based on a review of the public comments.

2.5 Stock Status

Through the course of development of this amendment, there has been considerable public comment that the scientific advice used as the basis for the amendment did not reflect the observations of fishermen. This concern was elevated when, in September 2002, NMFS notified the Council that the trawl warps used in the trawl survey were not accurately marked. This amendment is based on the estimates for stock status provided Groundfish Assessment Review Meeting (GARM) report (NEFSC 2002b). The GARM compared recent trawl survey results to previous years and did not detect noticeable differences. Issues surrounding the trawl warps, reference point estimates, and a trawl survey experiment were evaluated by Payne et al. (2003) and the conclusion was that the scientific information available was suitable for management. Payne et al. (2003) also provided numerous recommendations for further investigation of the issues raised. While not all these recommendations have been completed, because of the conclusions of Payne et al. (2003) this document is based on stock status as described in NEFSC 2002b and as updated by subsequent assessments. Stock status is discussed in detail in section 9.2.1.1.

The type of action required depends in part on the status of the stocks when compared to status determination criteria. Formal rebuilding programs are only required for stocks that are overfished - that is, less than the threshold biomass – or stocks that were previously declared overfished. While the Council considered three alternatives for determining threshold biomass, the proposed action is based on the estimates of B_{MSY} recommended by NEFSC (2002a).

2.6 The Future – Habitat Omnibus Amendment Components

In 2004, the Council will initiate a Habitat Omnibus Amendment that will be considered Amendment 14 to the Multispecies FMP. It will also amend the Sea Scallop (Amendment 11), Monkfish (Amendment 3), Herring (Amendment 2), Skate (Amendment 1), Red Crab (Amendment 1) and Atlantic Salmon (Amendment 2) FMPs. This Omnibus Amendment will be completed by the deadline specified in the AOC vs. Daley settlement agreement and, tentatively, will contain the following components:

- **Description and identification of EFH**

  Consideration of a range of alternatives for EFH designations
  Update all NMFS Source Documents for Species Reports

- **Non-Magnuson-Stevens Act fishing activities that may adversely effect EFH**

  Update current section on identifying any fishing activities that are not managed under the MSA that may adversely affect EFH.

- **Non-fishing related activities that may adversely effect EFH**

  Update current section on identifying activities other than fishing that may adversely affect EFH. For each activity, the FMP should describe known and potential adverse effects to EFH.

- **Conservation and enhancement**

Update current section on identifying actions to encourage the conservation and enhancement of EFH, including recommended options to avoid, minimize, or compensate for the adverse effects, especially in HAPCs.

- **Prey Species**

Review and update the current list the major prey species for the species in the fishery management unit and discuss the location of prey species' habitat. Consider adverse effects on prey species and their habitats that may result from actions that reduce their availability, either through direct harm or capture, or through adverse effects to prey species' habitats.

- **Research and Information Needs**

Review and update the current recommendations, in priority order, for research effects necessary to improve upon the description and identification of EFH, the identification of threats to EFH from fishing and other activities ad the development of conservation and enhancement measures for EFH.

- **Development and adoption of a habitat susceptibility and recovery index for the Northeastern US**

- **Identification of habitat areas of particular concern (HAPCs)**

This will be done through the HAPC process approved by the Council and included in a formal RFP. The RFP will be initiated in NOI for the Omnibus Amendment 2 and terminated 6 months later.

- **Consideration and identification of Dedicated Habitat Research Areas**

May consider using the same type of process as the HAPC process and work closely with the Research Steering Committee on this effort.

- **Integrate alternatives to minimize the adverse effects of fishing on EFH, to the extent practicable, across all NEFMC FMPs.**

3.0 Proposed Action

The Council intends to address a wide range of management issues through this amendment. In order to organize the measures proposed to address these issues, they are discussed in five broad categories:

- Clarification of status determination criteria and adoption of formal rebuilding programs for overfished stocks: The rebuilding programs in this section are the basis for development of management measures to rebuild overfished fisheries and end overfishing.
- Fishery program administration: measures developed to address issues that are primarily administrative in nature, though some may have biological, social, or economic impacts.
- Measures to reduce capacity: measures developed by the Council to control fishing capacity.
- Measures to achieve stock rebuilding: measures designed to comply with M-S Act requirements to rebuild overfished fisheries, and end overfishing where it is occurring.
- Measures that minimize, to the extent practicable, adverse effects of fishing on habitat
- Other issues: measures developed to alter restrictions on two exempted fisheries and one exempted gear.

3.1 Clarification of Stock Status, Status Determination Criteria and MSY Control Rules

This section establishes the underlying basis for the other management measures that are being considered. The criteria used to determine stock status and the target fishing mortality rates that result from the control rules and rebuilding strategies are used to define the biological objectives. Management measures - restrictions on fishing activity - are then designed to achieve those biological objectives. The stock biomass goals and maximum fishing mortality targets ultimately bound the catches that can be taken.

3.1.1 Reasons Clarification Is Necessary

Amendment 9 adopted overfishing definitions for the stocks managed by the Northeast Multispecies Fishery Management Plan (FMP) to bring the FMP into compliance with the requirements of the M-S Act. There has been considerable confusion, however, on the interpretation of the overfishing definitions adopted through Amendment 9. This confusion complicates the determination of stock status.

In brief, the Sustainable Fisheries Act amended the Magnuson-Stevens Act in 1996 to require that fishery management plans specify objective and measurable criteria for when the fishery to which the plan applies is overfished. The Council convened an Overfishing Definition Review Panel (Panel) in 1997 to provide the Council guidance on this requirement. The Panel reviewed existing overfishing definitions and concluded that many did not meet the new legal requirements, so revised overfishing definitions were recommended. The Panel's Overfishing Definition Report (OFD) was provided to the Council in June 1998 (Applegate et al. 1998) and the Council subsequently considered these recommendations for its management plans. The Council's adoption of new overfishing definitions was accomplished through the adoption of new FMPs or amendments to existing FMPs, and not merely by acceptance of the Panel's report. Amendment 9 to the Northeast Multispecies Fishery subsequently adopted overfishing definitions to meet SFA requirements that are based on the report of the Panel.

At the same time that the Panel was meeting, the National Marine Fisheries Service (NMFS) was updating its guidance on the National Standards Guidelines (NSGs) to reflect the changes in the SFA. Proposed guidelines were published on August 4, 1997, and the final guidelines were published on May 1, 1998. As a result of this timing, the Panel was only able to review the final guidelines at its last meeting. As a result, there are differences in terminology and approach between the final NSGs and the OFD. The OFD briefly discussed some of these differences, and also commented on the substance of the guidelines.

As a result of the differences among the first three documents, there has been considerable confusion on the interpretation of the Amendment 9 overfishing definitions and their use to determine stock status. Much of this confusion is because the three documents do not use the same terms, or use them in different ways. The following table lists the major differences.

OFD	Amendment 9
• Does not define when a stock is "overfished" • Does not define "overfishing" as when fishing mortality exceeds the threshold defined by the relevant control law • Use of "rebuilding period" differs from "rebuilding program" in NSG1 • "Minimum biomass threshold" is different than NSG1 "minimum stock size threshold" • Incorrectly interprets NSG1 guidance for stocks that cannot rebuild in ten years	• According to a court ruling, defines "overfished" as when biomass is less than the target biomass • Does not define biomass threshold • Uses term "control laws" from OFD rather than "MSY control rules" as used in NSG1 • Does not state when numerical estimates of parameters will be updated • Does not define how index-based proxies are calculated • Maximum rebuilding period for halibut and redfish is not consistent with NSG1

Table 1 – Summary of inconsistencies between Applegate et al (1997), Amendment 9, and NSG1

Further complicating the situation was the application of different analytic techniques in March, 2002 to estimate status determination criteria parameters (NEFSC 2002a). These techniques resulted in suggestions to change both the parameters and numerical estimates of those parameters for all groundfish stocks. In some cases, the revised biomass targets were outside the range of stocks sizes observed during the assessment time horizon (generally since the 1960s). Consternation over these new targets, as well as other concerns over the science underpinning the amendment, led to a formal peer review of the biomass targets, stock assessments, and trawl surveys in February 2003. A formal independent peer review of revised biological reference points, stock assessments, and trawl surveys was conducted in February 2003.The report of that peer review is subject to differing interpretations.

The immediate issues that should be addressed are:

(1) One sentence in a discussion paragraph in Amendment 9 states that a stock is overfished if the biomass is less than the biomass necessary to produce maximum sustainable yield (B_{MSY}). Since "overfished" is not defined in the report of the Panel, this apparently is an extension of the approach taken by the Panel that suggests fishing mortality should be reduced in order to increase stock size when the stock is at a biomass less than B_{MSY} (Applegate et al. 1998). This definition differs with the definition established by NMFS and published in the NSGs, which defines a stock as overfished when the biomass is less than the minimum biomass threshold.

(2) Amendment 9 defines threshold fishing mortality as less than or equal to the fishing mortality rate that can produce maximum sustainable yield and that varies with stock size. In the text and in Table 2 of Amendment 9, it states that overfishing occurs when the fishing mortality exceeds the threshold fishing mortality for a given stock size. Table 2 thus defines overfishing in terms of a control rule that takes into account the current stock biomass and the propensity of the stock to recover to MSY conditions within a specified time frame. Table 1 identifies the relevant biomass and fishing mortality targets and thresholds that define the key points on the control rules identified in Table 2. Table 1 includes a "threshold" fishing mortality, which is the maximum fishing mortality for a rebuilt stock and is not to be exceeded under any conditions. NMFS interprets the threshold fishing mortality in Table 1 as defining a maximum fishing mortality rate that does not vary with stock size, and uses that criteria to determine if overfishing is occurring.

(3) Amendment 9 defined stock reference points as parameters (such as "1/2 B_{MSY}" or "F_{MSY}") and listed current numerical estimates of these parameters. The amendment is not clear on when the numerical estimates of the parameters will be re-estimated. Numerical estimates of the parameters are typically re-evaluated during the Stock Assessment Workshops (SAW), and reviewed by the Stock Assessment Review Committee (SARC). There has been confusion over whether these re-estimates replace the values in Amendment 9.

(4) Some of the overfishing definitions in Amendment 9 are index-based proxies. The Council's Overfishing Definition Review Panel (Applegate et al 1998) recommended the use of a three year moving average when estimating stock status using index proxies, however, the Amendment is not clear on how those proxies are calculated – that is, are they based on an average or a one year value.

(5) The maximum rebuilding period for halibut and redfish should be corrected to reflect the NSG guidance for stocks that cannot rebuild in ten years or less in the absence of any fishing pressure.

(6) The *Final report of the Working Group on Re-Evaluation of Biological Reference Points for New England Groundfish* (NEFSC 2002a) applied different methods for evaluating status determination criteria, recommended changes to those criteria, and provided numerical estimates. This information needs to be incorporated into the management plan in some fashion.

In order to minimize confusion, the Council establishes the following status determination criteria and MSY control rules for the Northeast Multispecies Fishery.

3.1.2 When is a stock overfished?

A stock is "overfished" when the actual size of the stock or stock complex in a given year falls below the minimum stock size threshold or reasonable proxy thereof. This is consistent with current guidance in NSG1. If this definition is not consistent with future revisions in NSG1, the Council will make necessary changes through a framework action.

<u>Rationale</u>: This statement clarifies when a stock is overfished and is consistent with current NMFS guidance.

3.1.3 When is overfishing occurring?

"Overfishing" occurs when the fishing mortality rate exceeds the maximum fishing mortality threshold for a period of one year. These maximum fishing mortality thresholds are shown in Table 2. Requirements for Council action are specified in NSG1. If this definition is not consistent with future revisions to NSG1, the Council will make necessary changes through a framework action.

Rationale: Under the proposed definition, overfishing occurs when the fishing mortality rate exceeds the maximum fishing mortality threshold for a period of one year. This value remains constant over the range of possible stock sizes. From a management standpoint, the proposed action is easy to administer, since the point at which overfishing occurs remains constant. In addition, it is consistent with the current NS1 guidelines.

3.1.4 Optimum Yield

No changes are being made to the definition of optimum yield as justified in Amendment 9 and approved by NMFS with approval of that document. Optimum yield for a stock is achieved when fishing at the target fishing mortality for a given stock size.

3.1.5 Maximum Sustainable Yield

Maximum sustainable yield (MSY) is defined by the National Standards Guidelines (NSGs) (50 CFR 600.310) as the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions. If possible, MSY must be defined for each stock. The current estimates of MSY shown in Table 4 for groundfish stocks are based on the *Final Report of the Working Group on Re-Evaluation of Biological Reference Points for New England Groundfish* (NEFSC 2002a). These MSY estimates will only be possible if stocks rebuild to the target biomass recommended in the report.

3.1.6 Status Determination Criteria

Discussion: Status determination criteria define appropriate biomass and fishing mortality levels for the stock to insure sustainable harvests. The NSGs (50 CFR 600.310) require specification of two criteria: a minimum stock size threshold (or a proxy), and the maximum fishing mortality threshold (or a proxy). Minimum stock size thresholds are often specified as some fraction of the biomass level that will produce MSY (B_{MSY}). B_{MSY} is commonly referred to as the *biomass target*, though this term is not used or defined in the NSGs and at present there is no explicit requirement to specify this value. According to the NSGs, the minimum stock size threshold should be equal to the greater of the following: one-half the MSY stock size, or the minimum stock size at which rebuilding to the MSY level would be expected to occur within ten years if the stock or stock complex were exploited at the maximum fishing mortality threshold specified. The maximum fishing mortality threshold is frequently based on the fishing mortality rate (F) that produces MSY (F_{MSY}).

These criteria were first defined in Amendment 9 to the Northeast Multispecies FMP. For most stocks, Amendment 9 defined criteria such as BMSY and FMSY based on the results of surplus production models, as developed and explained in Applegate et al (1998). Since adoption of these criteria, a number of technical limitations have emerged that are detailed in the *Final Report of the Working Group on Re-Evaluation of Biological Reference Points for New England Groundfish* (NEFSC 2002a). To briefly summarize the major issues:

- A need to make the reference points as consistent as possible with the age-based assessments used for many groundfish stocks. Reference points based on surplus production models could not be used for stocks with age-based assessments.

- Estimates of Bmsy generated by surplus production methods tend to be limited to the range of observed values. For fisheries such as groundfish that have been heavily exploited for a considerable period of time, this may under-estimate the true potential of the stock.
- Several authors have suggested that when estimating management parameters, a wide range of candidate models and approaches should be evaluated.
- Since the adoption of the original status determination criteria, a more thorough understanding of the NSGs has evolved.

Action: As a result of these issues, the Council proposes to amend status determination criteria for multispecies stocks. Status determination criteria are defined as parameters that identify a specific biological element of a stock. The defined parameter should not be confused with the numerical estimate of that parameter. For most stocks with age-based assessments, the parameters are based on spawning stock biomass at MSY (SSB_{MSY}) as a proxy for B_{MSY}, and fully-recruited fishing mortality that produces MSY (F_{MSY}). Estimates for F_{MSY} may be based on proxy fishing mortality rates (such as F40% or F50%). For those stocks without an age-based assessment, trawl survey indices and exploitation indices (landings divided by trawl survey index) are used as proxies for B_{MSY} and F_{MSY}. The proxy for stock size usually uses a three-year average of the survey index; for halibut, a five-year moving average is used. Relative fishing mortality rates are calculated based on the catch divided by the stock size estimate. The calculation of the three-year (or other time period) moving average will be documented in the baseline assessment performed by a SARC. That method will be used until an alternate is approved through a peer reviewed process (SARC or other peer review).

The third element of the status determination criteria is the minimum biomass threshold. Amendment 9 included minimum biomass thresholds that were less than ½ B_{MSY}, the recommended lower limit specified in the National Standards Guidelines (NSGs). Applegate et al. (1998) concluded that this was justified because of the rebuilding potential of many groundfish stocks, but also recommended that if a stock falls below this level, fishing mortality be reduced to as close to zero as possible. Minimum biomass thresholds of less than ½ B_{MSY} are not consistent with the NSGs.

The status determination criteria parameters for groundfish stocks are as shown in Table 2. This table reflects changes to the parameters and increases all minimum biomass thresholds to at least half the target biomass.

3.1.6.1 Revisions to status determination criteria

Section 303(a)(10) of the M-S Act assigns the drafter of a fishery management plan the responsibility for specifying the objective and measurable criteria (e.g. status determination criteria) for determining when a fishery is overfished:

> *"Any fishery management plan which is prepared by any Council, or by the Secretary, with respect to any fishery, shall—*
>
> ** * **
> *(10) specify objective and measurable criteria for identifying when the fishery to which the plan applies is overfished (with an analysis of how the criteria were determined and the relationship of the criteria to the reproductive potential of stocks of fish in that fishery)…"*

Some confusion has resulted from a failure to adhere to the principle that it is a Council responsibility to establish the criteria for determining stock status. Amendment 9 implemented status determination criteria for groundfish stocks, generally using the parameters of B_{MSY} and biomass-weighted F_{MSY}. Since approval of Amendment 9, various scientific panels have recommended the use of different parameters such as SSB_{MSY}, fully-recruited fishing mortality, or an index-based proxy. While the Council has never formally adopted any of these other parameters, the NMFS has used the scientific recommendation as the basis for determining stock status. As a result, status determinations have been based on criteria that have not been reviewed, subject to public comment, implemented, or even formally approved by the NMFS. This creates considerable uncertainty over exactly what criteria is being used to evaluate performance of the management plan.

Action: Over time, development of new analytic techniques or additional data may result in scientific advice recommending changes to the status determination criteria parameters. In order to comply with M-S Act requirements that status determination criteria be determined by the Council, a Council action is necessary to change the status determination criteria parameters. The types of changes that will require a Council action include:

- Changing the parameter (such as using B_{MSY} instead of SSB_{MSY}, or biomass weighted F instead of fully recruited F, or an index-based measure rather than a B_{MSY} or SSB_{MSY}, or an index based on a different part of the stock)
- Substituting a biomass ratio (such as an ASPIC production output ratio of B/BMSY) rather than using units defined in the parameter (such as metric tons of SSB or total biomass)

If a report is received suggesting a change in the parameters (such as a SARC Advisory Report or other document), the change will be submitted to the Council for review and adoption through a framework or other management action. Determinations of stock status will be based only on approved and implemented criteria – that is, changes suggested by the SARC Advisory Report or other document will not be used to determine stock status until adopted through a Council amendment or framework action. As noted in earlier paragraphs, the parameter should not be confused with its numerical estimate.

This is not a change from the current system as understood by the Council and required by law. It is merely a clear statement on how changes to parameters will be adopted.Changes to the fundamental parameters should not be confused with changes in the numerical estimates of those parameters. In essence, changes to Table 2 require a Council action, but changes to the numerical estimates in Table 4 do not. The exception to the latter will be any changes that result from the 2008 review of status determination criteria (described in section 3.1.7).

Stock	Biomass Target	Minimum Biomass Threshold	Maximum Fishing Mortality Threshold	Fishing Mortality Target
GOM Cod	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GB Cod	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GB Haddock	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GOM Haddock	B_{MSY} Proxy/Fall Trawl Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
GB Yellowtail Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
Cape Cod/GOM Yellowtail Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
SNE/MA yellowtail flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
American Plaice	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
Witch Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
Gulf of Maine Winter Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GB Winter Flounder	B_{MSY}	½ Btarget	F_{MSY} (1)	75% of F_{MSY}
SNE/MA Winter Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
Acadian Redfish	SSB_{MSY}	½ Btarget	$F_{50\%}$ proxy for F_{MSY}	75% of F_{MSY}
White Hake	B_{MSY} Proxy/Fall Survey Index (> 60 cm fish)	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index (> 60 cm fish)	75% of F_{MSY}
Pollock	B_{MSY} Proxy/ Fall Survey Index	½ Btarget	F_{MSY} Proxy/ Relative Exploitation Index	75% of F_{MSY}
Windowpane Flounder (North)	B_{MSY} Proxy/Fall Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Windowpane Flounder (South)	B_{MSY} Proxy/Fall Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Ocean Pout	B_{MSY} Proxy/Fall Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Atlantic Halibut	B_{MSY}	½ Btarget	F_{MSY} (1)	75% of F_{MSY}

Table 2 – Proposed status determination criteria parameters for groundfish stocks.
Fully recruited fishing mortality unless otherwise noted. See text for calculation of B_{MSY} proxy based on trawl survey index, and F_{MSY} proxy based on exploitation index.

3.1.6.2 Numerical Estimates of Status Determination Criteria

3.1.6.2.1 Overview

In order to provide an objective basis for measurement, numerical values of the status determination parameters must be estimated. In addition to suggesting that parameters for most stocks should be based on SSB_{MSY} or fully-recruited fishing mortality, NEFSC 2002a reviewed the technical basis for the status determination criteria and developed point estimates for nineteen of twenty groundfish stocks. There are significant differences in the point estimates for both target biomass and fishing mortality thresholds between NEFSC 2002a and the approach used by Applegate et al. 1997 (as updated). For many stocks, the target biomass increased and the fishing mortality threshold decreased.

With respect to target biomass levels, NEFSC 2002a notes that the new estimates rely on recruitment distributions that are either near the long-term mean or that are correlated with increases in projected spawning stock biomasses. NEFSC 2002a also reported:

> "For many of the stocks the proposed biomass reference points are in *terra incognita* – chronic growth overfishing has limited stock biomasses to well below their estimated potential. Given the lack of experience in observing these populations at high biomass, we can only model the expected behavior of the system under varying assumptions. The NEFMC is advised that an adaptive approach to biomass management is a prudent tactic to explore the implications of higher biomasses and to find the point of diminishing returns to yields as a function of increased stock density. The adaptive approach recommended is to build the spawning stock biomasses by reducing fishing mortality (or in some cases maintaining current rates) such that the realized recruitments at high spawning stock biomasses are observed. This will allow direct examination of recruitment associated with maximum sustainable yield and thus the appropriateness of recruitment levels used to set biomass reference points.
>
> Given the histories of most of these stocks, there is likely substantial biomass growth and commensurate increases in catch, before these points are reached. Continued monitoring of vital population rates - including growth, sexual maturity at age, feeding habits to reveal predation and competition among populations, and distribution patterns in relation to abundance – will indicate when biomass production becomes limited by density-dependent factors…Thus, the panel recommends that the NEFSC adopt the revised biological reference points recommended herein, and evaluate the rebuilding process at periodic intervals."

The Council referred NEFSC 2002a to its Science and Statistical Committee (SSC) for review and advice on how to incorporate the reports recommendations into groundfish management. Noting the extensive amount of scientific work represented in the report, the SSC concluded it was the most comprehensive treatment of the subject of overfishing and rebuilding reference points yet produced. The SSC went on to say:

> "In general, we believe this report provides useful information for management decision making. Additional work is needed specifically to explore the implications of uncertainty in the stock recruitment relationship."

In February 2003, the proposed reference points were reviewed by a panel of scientists. This panel did not prepare a consensus summary – instead, each panelist prepared an individual report and the chair summarized the key elements in an executive summary (Payne et al 2003). Some common themes concerning the status determination criteria in most of the individual reports include the following:

- The analytic methods used in NEFSC 2002a are generally sound, though some could be improved or were misapplied in specific situations.
- There is considerable uncertainty over the reference points recommended in NEFSC 2002a – particularly biomass targets – partly as a result of available data.
- The current management system places great reliance on accurate biomass targets. The Council should carefully consider the risks of adopting high biomass targets.
- Because of these risks, an adaptive approach should be considered.

The reports are not clear on what is meant by an "adaptive" approach, with at least two different descriptions used by the reviewers. One form suggested is to establish a biomass target that moves towards those suggested by NEFSC 2002a but that lies within, or just above, the range of observed biomass. Another form suggested is to monitor stock increases through identified waypoints and evaluate the accuracy of the biomass targets based on progress through those waypoints.

3.1.6.2.2 Revised Estimates

Discussion: In order to provide an objective basis for measurement, numerical values of the status determination parameters must be estimated. NEFSC 2002a reviewed the technical basis for the status determination criteria and developed recommended point estimates for nineteen of twenty groundfish stocks. There are significant differences in the point estimates for both target biomass and fishing mortality thresholds between NEFSC 2002a and the approach used by Applegate et al. 1997 (as updated). For many stocks, the target biomass increased and the fishing mortality threshold decreased.

Action: The Council will adopt the numerical estimates of the status determination criteria that were determined by NEFSC 2002a. For GOM winter flounder, the criteria were determined by SAW 36, and for white hake, the GARM (NEFSC 2002b) provided additional information. These values are shown in Table 4.

Stock	Biomass Target (B_{MSY} or proxy)		Fishing Mortality Threshold (Fmsy)		Basis for Reference Points
	Amend-ment 9	NEFSC 2002A/ Proposed	Amend-ment 9	NEFSC 2002A/ Proposed	
Gulf of Maine Cod	22,100[1]	82,800	0.27[4]	0.23	Parametric S-R
Georges Bank Cod	83,500[1]	216,800	0.32[4]	0.18	Parametric S-R
Georges Bank Haddock	105,000	250,300	0.26	0.26 (F40%)	Empirical Non-parametric

Table 4 - Numerical estimates of status determination criteria for the Multispecies FMP.

These estimates will be periodically updated through the assessment process and adopted through Council action. Option. Refer to Table 3 to determine units.

1) Biomass level based on total biomass
2) > 60 cm fish
3) Survey based equivalents from GARM 2002

3.1.7 Review of Status Determination Criteria

Discussion: Regardless which biomass targets are selected, there is a need to plan for review of the targets. Any adaptive approach to the determination of biomass targets for rebuilding stocks requires periodic review of the performance of stock status and changes in vital rates that may influence the attainment of biomass goals. This option sets forth a process to monitor and review the pace of stock rebuilding of overfished resources and some population attributes to be considered in such reviews.

NEFSC 2002a proposed that an adaptive approach be used to periodically evaluate the ability of the stock to attain the target biomass for stocks whose biomass targets are set at levels higher than that observed in the time series of abundance indices. Specifically, information on the following population parameters is available for many of the important groundfish species:

- length and weight at age
- condition factor (weight in relation to length)
- maturity-at-age
- stomach contents
- relative abundance
- recruitment
- spawning biomass
- environmental conditions (temperature, salinity)
- geographic distribution
- ecosystem interactions as a condition of status determinations
- simultaneous achievement of all stocks to the B_{MSY} level

Changes in one or more of these parameters may influence the ability of the stock to reach target spawning biomasses, and the time frame necessary to reach the target. Considerations in conducting such reviews are the ability to discern trends in parameters from normal year-to-year variation (due to sampling variability), and the development of a process to conduct and peer review such analyses. The critical technical issue is the ability to discern if and when density dependence in growth, maturity and natural mortality is occurring, and the implications of density dependence for biomass targets. Likewise, if long-term environmental conditions influence resource productivity, they may also influence target biomasses.

Action: Based on the above considerations, a four to five year review cycle will be used for re-evaluation of biomass reference points for these stocks. This would allow a "mid course" evaluation in 2008, with respect to the 2014 rebuilding time frames for most of the groundfish stocks. If the review is undertaken in 2008, there will be five additional observations of year class strength, and associated population and environmental data (e.g. through 2007). The review of these references points should be synchronized to the schedule for "benchmark" assessments if possible, so that adequate technical review is afforded to the assessment basis for evaluating reference points.

The structure of such analyses and peer review can take many forms – a working group with integrated external peer review (similar to the structure used for the 2002 re-evaluation), or a two part analyses and peer review process. Because (presumably) there will not the complicating factors of timing with regards to court orders, the latter process is considered preferable. The working group will include a wide cross section of technical experts, including representatives from the NEFMC and MAFMC staffs and state agencies. The proposed working group could include a wide cross section of experts. A peer review of the WG report could be conducted by NMFS headquarters (Office of Science and Technology), the CIE, or other appropriate scientific entity. Composition of the working group and formation of the peer review must be approved by the Council and NMFS. For this review, any updated numerical estimates will be adopted through a Council management action (amendment or framework adjustment).

As noted in section 3.4.2.2 below, an assessment update of the groundfish complex will be conducted in 2005 for potential management action in 2006. This assessment will include a full and independent review of an age-structured production model developed by Dr. Doug Butterworth. This assessment update will not update the numerical estimates of status determination criteria unless the review of Dr. Butterworth's work justifies reconsideration. Benchmark assessments, including a review of the status determination criteria, will be conducted in 2008 for implementation in 2009. Both the update assessments in 2005 and the benchmark assessments in 2008 will be subject to peer review by independent scientists.

3.1.8 MSY Control Rules

"MSY control rules" required by the NSGs provide advice to the Council on fishing mortality rates that are likely to achieve MSY in the long-term. During the development of management alternatives, the Council will use these MSY control rules as guidance for determining biological goals for management actions. Management measures, however, will be developed only after consideration of all biological, economic, and social goals of the management plan and consistent with all National Standards. The MSY control rules proposed in this amendment are based on the control rules promulgated in Amendment 9 because development of new MSY control rules were not included in the Terms of Reference for NEFSC 2002a. They will become effective on implementation of the Amendment. The Council will review these control rules in the future and may revise them if necessary through a future management action.

The Council will use the fishing mortality rates in Table 5 as a guide for management actions and will strive to achieve the mortality targets associated with these control rules. At a minimum, the Council will design management measures to lower fishing mortality to less than the fishing mortality defined by the MSY control rule, and will strive to achieve the fishing mortality target specified in Table 2 as applied to the MSY control rule mortality for the current stock biomass. There is no time line associated with achieving the fishing mortality rates associated with these control rules. The Council does not intend that exceeding these thresholds or targets will be classified as overfishing (unless the fishing mortality rate also exceeds the maximum fishing mortality threshold listed in Table 2, consistent with when overfishing occurs). Optimum yield is defined in Amendment 9 as fishing at the target fishing mortality for the current biomass. Fishing mortality rates that exceed the thresholds defined in Table 5 over the long-term will not be consistent with the management plan and will require Council action because optimum yield is not being achieved. For overfished stocks, the Council may implement a mortality reduction and rebuilding plan that differs from the MSY control rule but that achieves the rebuilding objectives of the FMP. This rebuilding plan will be developed in a framework or amendment to achieve biological, economic, and social objectives. Such a plan will rebuild overfished stocks or stock complexes consistent with legal requirements.

Discussion: This measure clarifies the parameters used for status determination criteria, consistent with the definitions that define overfishing and when a stock is overfished. Table 5 treats all groundfish stocks on a consistent basis with respect to MSY control rules, as opposed to Amendment 9, which applied different rebuilding trajectories for stocks that are not overfished.

3.1.9 Maximum Rebuilding Period

Consistent with the NSGs, the maximum rebuilding period for any stock that cannot rebuild in ten years or less in the absence of any fishing mortality will be the time it will take to rebuild in the absence of fishing mortality, plus one mean generation. If necessary to comply with future revisions to the NSGs, this definition will be modified through a future Council action.

Rationale: This change makes the multispecies management plan consistent with the National Standards guidelines.

SPECIES	STOCK	MSY CONTROL RULE
COD	GB	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
	GOM	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
HADDOCK	GB	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
	GOM	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
YELLOWTAIL FLOUNDER	GB	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{msy}
	SNE	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{msy}
	MID-Atl.	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
	Cape Cod	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
AMERICAN PLAICE		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
WITCH FLOUNDER		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
WINTER FLOUNDER	GB	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
	GOM	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{msy}
	SNE/MA	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{msy}
REDFISH		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
WHITE HAKE		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{msy}
POLLOCK		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
WINDOWPANE FLOUNDER	North	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
	South	F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
OCEAN POUT		F calculated to rebuild to B_{msy} in 10 years when ½ B_{msy} < B < B_{target}
ATLANTIC HALIBUT		F=0 until stock is rebuilt (provisional control law)

Table 5 - MSY control rules

For all stocks, when stock size is less than the threshold biomass the F will be as established by the formal rebuilding program.

3.2 Proposed Rebuilding Programs for Overfished Stocks

The M-S Act and NSGs require the Council to define formal rebuilding programs or plans for stocks that are below the minimum biomass threshold (overfished). These programs define how the Council will rebuild those stocks to the target biomass within the statutory time frame. The Council has approached this issue in two steps. The first step, described in this section, is to identify the fishing mortality strategy that the Council will use as the basis for management measures that will rebuild the stock. The second step is to adopt management measures to achieve these strategies. The formal rebuilding program consists of both elements – they should not be viewed independently. Once a stock is defined as overfished, a rebuilding program must be continued until the stock reaches the target biomass. During the rebuilding programs, adjustments can be made through the annual adjustment process based on the condition of the stock and consistent with this Amendment, as long as statutory requirements are met.

When possible, long-term projections were used to estimate future stock size and landings. Long-term projections are sensitive to the assumptions used in their development and should not be viewed as precise predictions of future stock conditions. Actual future recruitment and the fishing mortality that occurs before implementation of Amendment 13 could result in future stock conditions that differ from the projection results.

3.2.1 Formal Rebuilding Programs

Summaries of stock status for groundfish stocks are in section 9.2.1.1. The M-S Act requires a formal rebuilding program for stocks that are overfished. The determination of whether a stock is overfished - stock size is less than the minimum biomass threshold – depends on the numerical estimate of B_{MSY} and the criteria chosen for the minimum biomass threshold. Another criteria to be considered is whether the stock was previously declared overfished. If a stock was previously declared overfished, <u>and</u> has not rebuilt to the proposed target biomass, a formal rebuilding program is necessary even if the stock is not currently overfished.

The following table (Table 6) identifies those stocks for which formal rebuilding programs are required. This table is based on the GARM (NEFSC 2002b). In two cases there are differences between the information in this table and that contained in the 2002 Report to Congress on Status of Stocks. The Report to Congress did not use assessment information for determining stock status, relying on information in the Report of the Working Group on Biological Reference Points (NEFSC 2002a). This Report said that plaice was <u>not</u> overfished and that pollock <u>was</u> overfished. The GARM, on the other hand, was an assessment meeting that was specifically charged to make status determinations. GARM 2002 concluded that in 2001 plaice was overfished and pollock was not. The following tables reflect the information from the GARM. Because the conclusions of the GARM rely on more current available scientific information, it is being used to make status determinations used in this amendment rather than the Report to Congress, which is based on less current data and assessments.

For each stock, if there is a "yes" in either column, a formal rebuilding program is required. Both columns are shown so it is clear which criteria led to the determination that a formal rebuilding program is required. GB yellowtail flounder is unusual, in that it was previously declared overfished but was rebuilt to the then-current estimate of B_{MSY} in 2001 (TRAC 2001, MSMC 2001). Since the stock was rebuilt prior to the re-estimation of reference points, and is greater than the minimum biomass threshold, a formal rebuilding program is not required for this stock.

Summarizing Table 6, the stocks that require a formal rebuilding program are:

GOM cod, GB cod, GOM haddock, GB haddock, CC/GOM yellowtail flounder, SNE/MA yellowtail flounder, American plaice, white hake, SNE/MA winter flounder, redfish, windowpane flounder (south), ocean pout, Atlantic halibut

The lack of a defined formal rebuilding program for stocks that are not overfished should not be construed as meaning that the Council is ignoring these stocks. The Council will insure fishing mortality remains below the fishing mortality threshold for these stocks. In all cases, these thresholds are defined as F_{MSY} or a suitable proxy for F_{MSY}. As noted by Restrepo et al (1998), "F_{MSY} is the fishing mortality rate that maximizes long-term yield under a constant-F policy, and B_{MSY} is the equilibrium biomass expected when fishing constantly at F_{MSY}." Controlling fishing mortality below the threshold should result in stock size fluctuating around the estimate of B_{MSY} over the long term. This is clearly shown in the age-based projections for stocks that are not under formal rebuilding programs (see section 5.2.3). This is approach is consistent with both the M-S Act and the National Standard 1 Guidelines.

Because of a lack of information, it is not possible to develop a formal rebuilding program for Atlantic halibut. The Council has adopted a provisional control rule that reduces fishing mortality on Atlantic halibut to as close to 0 as possible.

SPECIES	STOCK	Was Stock Overfished in 2001?	Was stock previously declared overfished and has not reached proposed biomass target?
Cod	GB	***Yes***	***No***
	GOM	***Yes***	***No***
Haddock	GB	***Yes***	***Yes***
	GOM	***Yes***	***Yes***
Yellowtail Flounder	GB	No	No*
	SNE/MA	***Yes***	***Yes***
	CC/GOM	***Yes***	***No***
American Plaice		***Yes***	***No***
Witch Flounder		No	No
Winter Flounder	GB	No	No
	GOM	No	N/A
	SNE/MA	***Yes***	***No***
Redfish		***No***	***Yes***
White Hake		***Yes***	***No***
Pollock		No	No
Windowpane Flounder	North	No	No
	South	***Yes***	***Yes***
Ocean Pout		***Yes***	***Yes***
Atlantic Halibut		***Yes***	***Yes***

Table 6 – Required formal rebuilding programs, based on minimum biomass threshold Option 2 (1/2 Btarget for all stocks). Formal rebuilding program required for stocks that have a "yes" in either column under a specific biomass target option.

3.2.2 Rebuilding Timelines

The M-S Act requires that for a fishery that is overfished, any fishery management plan, amendment, or proposed regulations shall:

> "…specify a time period for ending overfishing and rebuilding the fishery that shall…be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem."

Action: Rebuilding programs will be developed to rebuild most overfished stocks with a median (50 percent) probability by 2014. There are three exceptions to the 2014 end date: Georges Bank cod, Cape Cod/GOM yellowtail flounder, and Acadian redfish. These stocks will have longer rebuilding periods.

Rationale: The guidelines to National Standard 1 clearly state that rebuilding programs for overfished stocks begin when the regulations adopting those programs are implemented (50 CFR 600.310(e)(4)(ii)(C)). This action is consistent with that guidance. This action is planned for implementation on May 1, 2004. In addition, there are practical reasons to use this starting date for rebuilding. Initial M-S Act overfishing definitions were adopted under Amendment 9 and implemented in November, 1999. Amendment 9 did not include measures to achieve these rebuilding targets. Indeed, the *CLF vs. Evans et al.* lawsuit argued that the lack of measures to implement the Amendment 9 definitions did not comply with the M-S Act. This lawsuit was not resolved until May, 2002. There has also been extensive further scientific work on the status determination criteria that have considerably changed the understanding of the biology of the groundfish complex. For example, the target biomass for several stocks – GOM cod, GB cod, and GB haddock – doubled or tripled when re-estimated by NEFSC 2002b from previous values. This created considerable uncertainty over the appropriate biomass targets and delayed implementation as those issues were addressed through a peer review process.

The M-S Act and the NSGs require that any time period for ending overfishing and rebuilding the fishery shall be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem. This option recognizes that the shortest possible rebuilding period, taking into account the needs of fishing communities, is ten years. Analysis of different rebuilding periods showed that net economic benefits increase by $40 million if rebuilding periods are extended until 2014 vice 2009 (see section 5.4.3). Additional analyses showed that all of the proposed alternatives will reduce gross revenues, resulting in negative impacts on fishing communities. As a result, the Council believes it appropriate to extend the rebuilding period to mitigate, in part, the economic impacts of the rebuilding programs. Using a ten year rebuilding period results in an ending date of 2014 for most stocks that require a formal rebuilding program.

Another reason to extend the rebuilding programs is the change in numerical estimates of B_{MSY}. Under most alternatives for biomass targets, there are significant increases. This change in the understanding of the biology of the stocks warrants extending rebuilding programs to the maximum length allowed by the M-S Act.

Rebuilding periods for GB cod, CC/GOM yellowtail flounder, and Acadian redfish are extended consistent with the M-S Act and NSG1 as explained below.

> Georges Bank cod: Projections show that this stock can only be rebuilt by 2014 at very low levels of fishing mortality (similar to 0.05). Because this is a trans-boundary stock and is fished by Canada, this fishing mortality may only be achieved if all U.S. fishing on this stock is eliminated and Canadian fishing is kept at very low levels. Effectively, this is a fishing mortality of 0 for U.S. fishermen. This triggers the exception in NSG1 which allows the period to be extended to the length of time it takes to rebuild in the absence of fishing plus one mean generation. This is calculated to be 2026.
>
> CC/GOM yellowtail flounder: Projections show this stock can only be rebuilt by 2014 at very low levels of fishing mortality (similar to 0.08). Because of the small size of the stock, this limits fishing to several hundred metric tons. This could only be achieved if all fishing – including fishing for non-groundfish species such as scallops – is stopped in the CC/GOM yellowtail stock area. This rebuilding mortality is thus effectively 0. This triggers the extended rebuilding period authorized by the NSGs. The rebuilding period is calculated to end in 2023.
>
> Acadian redfish: Because of the slow growth of this stock, it cannot rebuild by 2014 even if all fishing mortality is eliminated. The rebuilding period is determined as the time necessary to rebuild in the absence of any fishing mortality, plus one mean generation. The end of the period is calculated to be 2051.

3.2.3 Rebuilding Trajectories for Overfished Stocks

There are an infinite variety of ways to alter fishing mortality so that a stock will rebuild within the legally required time frame. The Council considered three variations:

- Constant fishing mortality rate: Fishing mortality is held to the level that is projected to achieve the target biomass in the desired time period. If the stock increases as projected, catch will increase over time. Correctly designed management measures should remain relatively constant over the time period.
- Phased fishing mortality reduction: Fishing mortality is reduced over time so that the target biomass is achieved in the desired time period. Management measures will become progressively more stringent over the early years in the rebuilding period.
- Adaptive rebuilding strategy approach: Fishing mortality is held at F_{MSY} through 2008 for all stocks that require formal rebuilding programs. After an evaluation of the rebuilding program in 2008, mortality is adjusted to an Frebuild that will achieve biomass targets in the time required by the M-S Act.

A fourth option – constant catch rate – was considered and rejected (see section 4.2.1).

In order to calculate a rebuilding trajectory, the target biomass and time necessary to rebuild must be defined. The Council based rebuilding trajectories on the biomass targets recommended in NEFSC 2000a. The Council considered analyzing rebuilding trajectories with greater than a median (50 percent) probability of achieving the biomass targets recommended by the Reference Point Working Group. This was considered unreasonable and the Council rejected this approach for the following reasons. First and foremost, for many stocks, the rebuilding fishing mortalities at the median level require large reductions in fishing mortality – in excess of 50 percent from current fishing mortality. In order to achieve a higher probability of achieving the target, even greater reductions would be necessary. The social and economic implications of the rebuilding programs are already substantial, and larger reductions in mortality would threaten the continued existence of the groundfish fishery. As discussed later in this document, the present value of the economic net benefits of rebuilding are already marginal and might be negative if more severe mortality reductions are adopted. Given the multispecies nature of the fishery, further reductions in fishing mortality for stocks such as GB cod or GOM cod would result in further reducing catches for stocks that do not need reductions (e.g. GB haddock, GOM haddock, GB yellowtail flounder). Given that the goal of the M-S Act remains achieving OY, the Council believes its selection of rebuilding trajectories is more consistent with this goal. Second, the projection methodology used to generate the strategies is subject to uncertainty, and how well the projections perform with respect to actual stock response is not well understood. While in some cases the projections may be optimistic and overstate rebuilding potential, in other cases they may be pessimistic. These variations are likely to occur from stock to stock. Absent an understanding of how the projection models perform on a stock-by–stock basis, it is not possible to determine the appropriate probability that should be selected. Payne et al. (2003), while concluding that the projection methodology was generally sound, also noted projections should be validated against historical observations of stock dynamics since the projections are based in large measure on the stock recruit relationship observed at MSY rather than during the rebuilding phase. In another comment, Payne et al (2003) noted that a key issue yet to be resolved is the number of years into the future that the projection approach can be deemed to give reliable results. Third, in the case of some stocks, choosing a higher probability of rebuilding success may actually delay rebuilding and/or relax the rebuilding program. For stocks in a depressed condition (such as SNE/MA yellowtail flounder), it may not be possible to rebuild by 2014 with a high probability of success. This would then trigger an extension to the allowed rebuilding period.

The biological success of the rebuilding programs will be measured using two criteria:

- The rebuilding fishing mortality rate must be achieved. This criterion is necessary for two reasons. First, for some stocks, fishing mortality must be reduced below the maximum fishing mortality threshold to end overfishing. Second, only if this target fishing mortality is achieved will the Council be able to make valid judgments concerning the appropriateness of the biomass targets recommended by NEFSC 2002a.
- The target biomass is achieved within the appropriate time period.

3.2.3.1 Combined Rebuilding Trajectories

In public comments received on the draft Amendment 13 DSEIS, the suggestion was made that the Council should use a combination of rebuilding trajectories, rather than use one form of trajectory for every stock. In response to these comments, the Council has decided to use a combination of the phased and adaptive trajectories as described in the following sections. Section 3.2.3.1.1 describes the theoretical basis for the phased fishing mortality reduction. Section 3.2.3.1.2 describes the theoretical basis for the adaptive strategy. Section 3.2.3.1.3 describes the Council's proposed action, which is based on the theory behind the phased and adaptive strategies but adapts those strategies to reflect the expected impacts of the proposed management measures in section 3.6.1.

3.2.3.1.1 Phased fishing mortality reduction

This strategy steadily reduces fishing mortality during the rebuilding period in order to achieve the target biomass with a median probability. When the stock achieves its target biomass, the formal rebuilding program adopted because the stock was overfished will be completed. Once the stock achieves the target biomass, fishing mortality targets will be based on the status determination criteria and MSY control rule. The fishing mortality for the rebuilding program may be adjusted if there are <u>substantial</u> changes in stock status and recruitment from those used in the long-term projections used to estimate this fishing mortality. Stock condition should be evaluated over at least a two-year period to smooth fluctuations that are the result of variability rather than true trends. A wide variety of variables will be considered to determine stock condition: fishing mortality and biomass (including the uncertainty around the estimates), recruitment patterns, environmental conditions, etc.

Current estimates of the mortality rates necessary to rebuild groundfish stocks are shown in Table 7. The formula used can be described in algebraic terms as:

$$F_{2003} = a * F_{2002}$$

$$F_{2004} = a * F_{2003}$$

$$F_{year} = F_{2004} * e^{\left[-l\,(year-2004)+m(year-2004)^2\right]}$$

Values for l and m were selected for each stock to ensure that the median spawning biomass trajectory reached its target value in the last year of the rebuilding program.

In concept, the phased reduction approach can be extended to index-based stocks that require formal rebuilding programs. For ocean pout and southern windowpane flounder, the current landings, landings at the biomass target, and the landings needed to rebuild are so low that this becomes little more than an academic exercise. In the case of GOM haddock, the current exploitation ratio is less than that necessary to rebuild by 2009 or 2014; fishing mortality can increase under the proposed rebuilding program, and there is no benefit to a phased reduction approach.

The phase reduction strategy will be used for the following stocks:

- GB cod
- American plaice
- CC/GOM yellowtail flounder
- SNE/MA yellowtail flounder
- White hake

The fishing mortality rates for the phased rebuilding strategy that were included in the draft amendment document are shown in Table 7. One difficulty with using a phased rebuilding strategy is that the reduction in mortality that is needed each year differs from stock to stock. This makes it difficult to develop effort controls that will precisely achieve the desired reductions. As a result, the measures designed to achieve the phased reduction strategy can only approximate the calculated reductions over time. In the draft amendment document, Alternative 1 included options for implementing a phased strategy that reduced used DAS over four consecutive years to approximate the phased strategy. Comments were received that this approach was very different from that suggested by Table 7, and it was questioned whether these measures could be considered implementing that strategy. As a result of these comments and the practical difficulties of implementing a phased strategy, the Council is not following the trajectories shown in Table 7.

3.2.3.1.2 Adaptive Rebuilding Strategy

NEFSC 2002a provided estimates of B_{MSY} that are beyond the observed range of stock biomasses. Although these estimates of B_{MSY} are based on demonstrated recruitment and current growth and fishery selection parameters, there remains uncertainty in the direction of these critical population rates under stock rebuilding, and thus in the ability of the stocks to attain the calculated B_{MSY} values. The calculated B_{MSY} values may be too high or too low, depending on how dynamic rates of recruitment, growth and natural mortality are as the stock complex is rebuilt. NEFSC 2002a recognized these uncertainties and suggested an adaptive approach be adopted. Similarly, the Peer Review (Payne et al. 2003) reiterated the uncertainty of high targets and also suggested an adaptive approach.

By definition, fishing a stock at or below F_{MSY} will eventually result in the attainment of B_{MSY}, with the stock thereafter fluctuating at or around that value, depending on rates of recruitment and fishing mortality. By allowing the stock to equilibrate when fished at these rates, more information regarding the actual biomasses associated with F_{MSY} will follow. Based on NEFSC 2002a and the recent *Peer Review of Groundfish Science* (Payne et al. 2003), estimates and proxies for F_{MSY} (Table 4) are robust to uncertainty in B_{MSY} and are appropriate thresholds for management. Therefore, attaining fishing mortalities at or below these rates is the cornerstone of this option. The extension of the stock rebuilding time frames (e.g., to ending dates of 2014 for most stocks) allows for fishing plans that are consistent with an overall strategy of initially fishing the stocks at or below F_{MSY}, and adjusting either the fishing rates or the biomass reference points, consistent with the pace of rebuilding relative to the nominal targets. If a 2014 time frame is assumed for all stocks (e.g., 2004-2014 rebuilding period) except GB cod (2004-2026), redfish (2004-2051), and CC/GOM yellowtail flounder (2004-2023), then the strategy of fishing at or below F_{MSY} for a significant portion of the rebuilding period becomes more viable as a strategy, thereby minimizing the influence (and reliance) on a particular value of B_{MSY}.

The proposed strategy outlined in Table 8 and Table 9 below and Figure 1 and Figure 2 implements the following fishing scenario:

(1) Fishing mortality rates for all stocks are maintained at or below F_{MSY} for the first 5 years of the plan (2004-2008). In 2009-2014, the fishing mortality rates are adjusted to those required to meet B_{MSY} targets initially estimated for the stocks (Table 8) with a 50% probability by the end of the rebuilding period. The Frebuild adopted in 2009 will be estimated in 2003 and will be the default value adopted unless the 2008 evaluation suggests a different value (lower or higher) is appropriate. This strategy will, on average, result in the attainment of B_{MSY} by 2014 for most stocks with a 50% probability, all things being equal (e.g. recruitment growth, natural mortality). The rebuilding program will be judged successful if biomass at the end of the rebuilding period lies within the inter-quartile range (range between the 25^{th} and 75^{th} percentiles of biomass) of the projected 2014 biomass.

(2) As shown in Figure 1 and Figure 2 and Table 8, there is a median rebuilding path that is described by the results of stochastic population projections under the various fishing scenarios. This path is essentially a series of "way-points" upon which the pace of stock rebuilding can be judged. The values of "SSB_{2008}" represent, then, an interim biomass target along the path to stock rebuilding that can be used as an appropriate benchmark to evaluate the efficacy of the rebuilding program. Analyses of progress towards achieving the final B_{MSY} targets by the end of the rebuilding period wall be based on management measures adopted to achieve the median estimate of biomass at the 5—year waypoint, not the upper or lower quartile of those way-point estimates.

(3) In early calendar year 2008 progress towards rebuilding the stocks is formally assessed. Based on the findings of that review, one of three determinations can be made:

(a) the stocks are “on track” to rebuilding -that is, the point estimate of 2008 stock biomass lies within the inter-quartile range (range between the 25th and 75th percentiles of biomass in 2008) of the *projected* 2008 biomass (estimated in 2003), consistent with the proposed rebuilding trajectory,
(b) the stock is above the projected strategy, or
(c) the stock is below the proposed rebuilding trajectory.

One key assumption for this strategy is that overfished stocks are not required to be rebuilt prior to 2014.

Depending on the actual stock biomass in 2008, there are a number of default management and scientific actions that are prescribed (Figure 1 and Figure 2). One of the critical elements to be assessed is whether the management program has been successful in achieving F_{MSY} or below for individual stocks. This is important since the condition of the stock and the specific management actions are dependent on the causal factors contributing to the observed stock biomasses. For example, if the stock size in 2008 is judged to be significantly below the projected path, the critical question is why? If fishing mortality rates were consistently and significantly above F_{MSY}, the question to be assessed is if F_{MSYs} *were* attained, would the stock condition intersect the rebuilding path? Alternatively, is there evidence in population dynamics data (recruitment, growth, natural mortality) that show no significant improvement in the stock could have occurred, due to these stock conditions, even though the stock was overfished. The management and scientific responses in these cases may be different.

A brief set of potential factors associated with all nine possibilities for stock and fishing mortality rate conditions during 2008 are given in Figure 1. The intent of this figure is to depict some of the obvious factors that might be influencing the stock, depending on fishery or natural phenomena. These factors would be examined in detail in developing appropriate adaptive management advice pertaining to the second half of the rebuilding period (e.g. 2009-2014). Figure 2 provides pre-defined (default) management and/or scientific review actions that are proposed as a key element of the adaptive approach. These defaults are intended to be illustrative, rather than restricting management response to only the listed actions. These outcomes are conditional on the status of the stock biomass relative to the interim (2008) waypoints, and the 2002-2008 fishing mortality rates relative to F_{MSY}. The nine possible situations (cells of Figure 2) are reviewed briefly below. These responses are not intended to pre-empt the planned review of reference points described in section 3.1.7.

$F_{2004\text{-}2008} > F_{MSY}$ and $B_{2008} > B_{waypoint}$

In this situation the fishing mortality rates for 2002-2008 have exceeded the F_{MSY} values, but the stock is judged to be above the median rebuilding path (way point). This condition may arise due to exceptional recruitment or other biological factors that offset the continued overfishing of the stock. In this case, the management action would be to reduce F to F_{MSY}. More analysis would be required to see if the fishing mortality on the stock should be reduced further to the rebuild value originally projected for the stock (Table 8). Also, it is possible that F_{MSY} or B_{MSY} may have originally been set too low, and re-consideration of the evidence should be done before fishing rates are reduced (e.g. for 2009-2014).

$F_{2004\text{-}2008} > F_{MSY}$ and $B_{2008} = B_{waypoint}$

In this case, F exceeds F_{MSY} but the stock is on the rebuilding trajectory. The default management advice is to reduce F to the F rebuild value, or, if it can be demonstrated to be appropriate, to the F_{MSY} value, <u>whichever is higher</u>. In this situation, stock conditions are apparently offsetting the continued overfishing. This would most likely be due to greater than expected recruitment. While there may be some justification to revise B_{MSY} and F_{MSY} values, they are not likely to be different from those currently in place. The exception may be F_{MSY}, which may need to be re-evaluated if the partial recruitment pattern (gear selectivity-at-age) changes due to additional gear restrictions.

$F_{2004-2008} > F_{MSY}$ and $B_{2008} < B_{waypoint}$

The condition of excessive fishing mortality and biomass below the projected rebuilding path would require, at a minimum, reduction of F to the original F rebuild value. In this case, there may be appropriate analyses to evaluate if the stock would have been on the rebuilding path had overfishing not been occurring. This could be accomplished by simulating the combined impacts of the observed recruitment stream and the F_{MSY} values. If the stock would have been near the path had the stock not been overfished, the managers may consider the feasibility of additional F reductions (below the original Frebuild values) to allow the stock to regain the rebuilding path.

$F_{2004-2008} = F_{MSY}$ and $B_{2008} > B_{waypoint}$

If the fishing mortality rate is held at F_{MSY} for 2002-2008 and the stock is above the rebuilding path, the managers should consider suspending the default reduction in F to Frebuild. Simulations could determine if stock rebuilding to B_{MSY} would be impeded by such a strategy. This scenario is likely to occur due to one or more exceptional year classes spawned, and may, or may not indicate that revisions in B_{MSY} (upward) are warranted (although they would not apply to the 2014 rebuilding program).

$F_{2004-2008} = F_{MSY}$ and $B_{2008} = B_{waypoint}$

In this condition, F targets have been achieved and stock rebuilding is on track. The prescriptive advice would be to reduce F to F rebuild, but new F rebuilds should be considered if the stock can be fished at a higher rate (than the original F rebuild) and still attain the target.

$F_{2004-2008} = F_{MSY}$ and $B_{2008} < B_{waypoint}$

If fishing mortality rate targets are met and the stock lags below the rebuilding trajectory, the nominal management advice is to reduce F to the original F rebuild value. Specific conditions in the stock should be re-evaluated to determine why stock biomass has not responded. Three potential causal factors are (1) continued below-average recruitment due to poor environmental conditions (e.g., regime change), (2) multispecies effects such as increased predation on juveniles or (3) competition with other species for food, resulting in reduced growth rates, or other population dynamics factors. In this case, scientists should re-consider biomass and fishing mortality rate targets in light of prevailing hypotheses for poor stock performance.

$F_{2004-2008} < F_{MSY}$ and $B_{2008} > B_{waypoint}$

If fishing mortality is below F_{MSY} and the stock biomass exceeds the rebuilding waypoint, then the appropriate management advice is to maintain F at or below F_{MSY}. In this situation it is unlikely that F needs to be reduced to F rebuild to meet the 2014 time frame for rebuilt stocks. Revision (upwards) of biomass and especially F targets should be considered, but if biomass targets are revised upwards, they would not apply to the 2014 end point of the original rebuilding program.

$F_{2004-2008} < F_{MSY}$ and $B_{2008} = B_{waypoint}$

If the fishing mortality rate is below the F_{MSY} value but above Frebuild, and the stock is on track, then a re-evaluation of the need to reduce F to F rebuild should be undertaken. If the stock can be rebuilt to the original B_{MSY} fishing at $F_{2002-2008}$, then these rates should be maintained.

$F_{2004-2008} <$ Fmsy and $B_{2008} < B_{waypoint}$

In this condition, there are significant problems with the near-term productivity of the stock likely unrelated to current fishing effects (although there may be ongoing depensatory effects due to historical stock depletion). The lack of recovery of stock biomass may be due to continued below-average recruitment (e.g., due to environmentally-caused regime change) or other single- or multispecies influences on growth, natural mortality, and maturity. In this case, scientists should re-consider biomass and fishing mortality rate targets in light of prevailing hypotheses for poor stock performance.

The adaptive rebuilding trajectory will be used for the following stocks:

GOM cod
GOM haddock
GB haddock
Redfish
SNE/MA winter flounder
Windowpane flounder (south)
Ocean pout

Figure 2 – Adaptive management action table

3.2.3.1.3 Proposed action

The Council proposes to use a combination of phased and adaptive rebuilding strategies as described below.

The phased reduction strategy will be used for the following stocks:

- GB cod
- American plaice
- CC/GOM yellowtail flounder
- SNE/MA yellowtail flounder
- White hake

As noted in section 3.2.3.1.1, it is difficult to design a management program that precisely mirrors the changes in fishing mortality that are shown in Table 7. In most cases, the proposed measures in section 3.6.1 achieve more of a reduction than is necessary to comply with the phased reduction strategy in the early years of the rebuilding program. In essence, the proposed management measures "jump start" the phased reduction strategy for GB cod and for CC/GOM yellowtail flounder. This was not inadvertent – the Council made a conscious decision to select these measures in order to lower mortality more rapidly than would be required through strict adherence to the phased reduction strategy schedule. For these stocks, the realized fishing mortality rates that the Council plans to achieve are more restrictive than those shown in the phased strategy. For this reason, the Council modified the phased strategy from the theoretical values shown in Table 7 to take into account the impacts of the proposed management measures, the schedule for assessment updates, and the practical difficulties of making constant adjustments to management measures.

An adaptive rebuilding strategy (as described in section 3.2.3.1.2) will be used for the following stocks:

- GOM cod
- GOM haddock
- GB haddock
- Redfish
- SNE/MA winter flounder
- Windowpane flounder (south)
- Ocean pout

The fishing mortality rate schedule that will result from combining these two approaches is shown in Table 10 below. This table will be used to evaluate the success of the formal rebuilding programs, and to guide future management decisions (unless changed by a later action). It should be noted that this table has been updated to reflect current estimates of the fishing mortality in 2002 and 2003 (developed October, 2003 by the NEFSC). These rates are slightly different than those used to develop the rebuilding trajectories in the draft amendment (as shown in Table 7 and Table 8). In addition to the fishing mortality rates, for each stock the target TACs are shown for calendar years 2004, 2005, and 2006 in Table 11. Projection models calculate catch or landings based on calendar years, not fishing years. If stocks are changing in size, this difference can lead to a misinterpretation of landings information. If a stock is declining, using a TAC based on a calendar year will over-estimate the TAC for the fishing year. The opposite is true if a stock is growing. One way to adjust for this is to use the average target TAC for two calendar years as the target TAC for the fishing year. These averages can be calculated from the information shown. These target TACs do not include any recommendations resulting from implementation of the US/CA Resource Sharing Understanding.

For ocean pout, the target mortality from 2004 through 2008 will be significantly less than F_{MSY}, but is still three times higher than the estimated exploitation in calendar year 2002. The analytic techniques used to estimate the rebuilding trajectory for this stock are not the same as the techniques used to estimate F_{MSY}. NEFSC 2002a attempted to re-estimate the F_{MSY} value for ocean pout using index based techniques, but found the results uninformative.

Adjustments to management measures will be needed to ensure that rebuilding program fishing mortality rates are met. An adjustment may be needed in fishing year 2006 to reduce mortality on plaice and SNE/MA yellowtail flounder, and a second adjustment may be needed in 2009 to reduce mortality on several stocks. Finally, additional measures may be needed after 2010 to reduce mortality for CC/GOM yellowtail flounder. An update assessment is planned for 2005, which will provide information necessary to adjust the measures for 2006. A benchmark assessment of the complex, including a review of status determination criteria, will be conducted in 2008. Default measures are included in section 3.6.1 that are designed to meet the appropriate fishing mortality rates through 2009.

3.3 Ending Overfishing

The M-S Act also requires the Council to submit a management plan that will end overfishing where it is occurring. The measures in this amendment that are designed to rebuild overfished stocks are also designed to end overfishing. Some stocks are both overfished and overfishing is occurring – formal rebuilding programs for these stocks will also end overfishing. Based on stock status as described in section 9.2.1.1, the following table lists those stocks where overfishing is occurring whether or not they are overfished. This table uses the definition of overfishing applied by NMFS and proposed by the Council – that is, a fishing mortality rate that exceeds the maximum fishing mortality threshold. Fishing mortality in 2001 is compared to the F_{MSY} shown earlier to make this determination. Projected fishing mortality in calendar year 2002 is also shown.

Stock	F2001	F2002 (Projected)	FMSY
Gulf of Maine Cod	0.47	0.33	0.23
Georges Bank Cod	0.38	0.43	0.18
Cape Cod/GOM Yellowtail Flounder	0.75	0.68	0.17
Southern New England/Mid-Atlantic Yellowtail Flounder	0.91	0.85	0.26
Southern New England/Mid-Atlantic Winter Flounder	0.51	0.44	0.32
American Plaice	0.43	0.27	0.17 (F40%)
Witch Flounder	0.76 (SAW 37)	0.41 (SAW 37)	0.23 (F40%)
White Hake	1.36 (C/I)	0.91 (C/I)	0.55 (C/I)
Atlantic Halibut	unknown	unknown	0.06

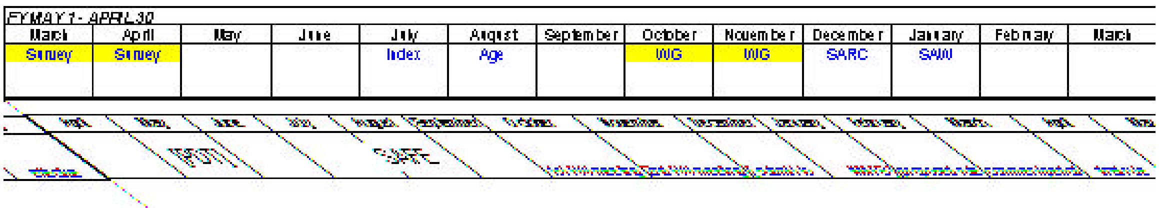
Table 12 – Stocks where overfishing is occurring. (Source: GARM 2002. Projected 2002 F estimates provided by NEFSC, unpublished data, except for witch flounder)

3.4 Fishery Program Administration

Since Amendment 7, a number of issues surfaced that primarily relate to the administration of the groundfish fishery, though some of these issues may also have biological, social, or economic impacts.

3.4.1 Fishing Year

There is no change to the groundfish fishing year, which will continue to be defined as the period May1 – April 30.



Rationale: The current start of the fishing year is May 1. The Council is retaining this date since it has been used since Amendment 5, is familiar to the fishery, and any chance would cause additional disruption to an industry that will be subject to a drastic change in regulations through this amendment. Retaining the current fishing year will not create an administrative burden or require any additional alterations to the incorporation of scientific and fishery data into management analyses. All annual adjustments would continue to be implemented on May 1. However, a recent legal action dictated that proposed rulemaking may be required as a part of the framework adjustment process. This extends the time from submission of the Council-approved framework to its implementation by approximately 2.5 months. As a result, the previous schedule for incorporation of current scientific information into management which was based on a May 1 fishing year will not longer be applicable to the process when a proposed and final rule must be published.

The schedule outlined above demonstrates one disadvantage to maintaining a May 1-April 30 fishing year. Proposed rulemaking extends the gap from availability of data required for development of the framework to implementation of the framework. With this schedule, there are 25 months between the last month of the spring survey and the start of the fishing year, when framework measures take effect.

3.4.2 Periodic Adjustment Process

3.4.2.1 Revision of the Multispecies Monitoring Committee/Plan Development Team

The Multispecies Monitoring Committee (MSMC) will be folded into the Plan Development Team (PDT) and cease to exist as a separate committee. As a result, PDT membership will be revised to include technical staff from the New England Fishery Management Council, the NMFS Northeast Regional Office, the Northeast Fisheries Science Center (biologists, social scientists, and economists), technical personnel from state management agencies or qualified researchers, a representative from the United States Coast Guard, the chair of the groundfish advisory panel, and another interested party designated by the Council chair. The PDT will continue to provide technical support to the groundfish committee in the development of fishery management plans and amendments. In addition, it will monitor the current plan and develop options for framework adjustments through a periodic adjustment process, described below.

Rationale: There are several reasons for consolidating the PDT and MSMC into a single group. First, there is already significant overlap in the current membership of the groups. Nearly all PDT members also participate on the MSMC. Additionally, reducing the number of separate committees may simplify and streamline the adjustment process. In general, the current management system would benefit from a simplified approach. One disadvantage to consolidating these groups is that the MSMC is currently perceived as a more external, objective body than the PDT.

3.4.2.2 Biennial adjustment (every two years)

The PDT will prepare a SAFE report each year. The annual adjustment process implemented by Amendment 7, however, will be revised to a biennial adjustment, with the PDT performing a review and submitting management recommendations to the Council every two years. This annual review should be completed by the PDT based on the most current scientific information provided primarily by the Northeast Fisheries Science Center. The PDT may also consider data provided by the states, ASMFC, the USCG and other sources. This proposed schedule does not prevent the Council from taking action at another time.

The biennial adjustment process may be modified during the initial years after the amendment. An updated groundfish assessment is scheduled for 2005, which will facilitate a biennial adjustment (if necessary) that would take effect in the 2006 fishing year. This matches the proposed biennial adjustment. Benchmark assessments, including a review of status determination criteria, are planned for 2008. This will facilitate an adjustment that will take effect in fishing year 2009, one year later than the normal biennial adjustment process.

The schedule outlined in section 3.4.1 (Fishing Year) and repeated below describes the framework adjustment process for the proposed action in Amendment 13. The schedule, as shown, provides enough time for a framework action that requires a proposed and final rule. If the action proposed is narrow enough in scope and impacts to not require a final rule, than the framework meetings can be held at a later date. According to current regulations, if the Council fails to submit measures by February 1, the Regional Administrator is authorized to choose any PDT alternatives not specifically rejected by the Council.

By September 1 of the adjustment year the PDT will report new measures to the Council for their consideration that would appropriately address current management needs in the multispecies plan (within the scope of a framework). The PDT will review the most current data pertaining to landings, stock status and fishing mortality rates, enforcement issues, DAS use, social and economic impacts, and any other relevant information. The Council should hold its first framework meeting in September to review the PDT options. The second framework meeting will be held in October or November. This schedule is necessary if the action must go to a proposed rule; if it is of a limited scope that does not require a proposed rule, the submission could be slightly delayed.

Between November 1 and December 1, the Council will submit recommendations to the Regional Administrator. The Regional Administrator will review the Council's recommendations, including the supporting analysis, and publish the appropriate proposed or final rule within 30 days of the Council's submission.

FY MAY 1 - APRIL 30

March	April	May	June	July	August	September	October	November	December	January	February	March
Survey	Survey			Index	Age		WG	WG	SARC	SAW		

April	May	June	July	August	September	October	November	December	January	February	March	April	May
	[PDT]			SAFE		1st FW meeting	2nd FW meeting	[submit to	NMFS]	proposed rule	comment period	final rule	effective

Discussion: The resource must be allowed some time to respond biologically to changes in management. Extending the duration of time between each periodic review and adjustment of the multispecies FMP would allow such measures to take effect on the stock, enabling the PDT to more accurately evaluate their performance in helping to achieve mortality and biomass targets for the managed stocks.

In addition, more time between each review of the plan means that there will be more current scientific information available upon which to base the evaluation. Furthermore, changing the review and adjustment schedule from an annual to a biennial process will free time and resources for managers, administrators and other participants. Performing an annual adjustment would place a significant burden on technical and administrative staff of the NEFMC, NMFS and NEFSC. The biennial adjustment process is more feasible and allows more flexibility in the utilization of time and resources of individuals and administrations.

3.4.2.3 List of Frameworkable Items

Many management measures can be adjusted through a framework action. In addition to those measures that are currently identified in the regulations, the following measures can be adjusted in the future:

- Revisions to status determination criteria, including, but not limited to, changes in the target fishing mortality, minimum biomass threshold, numerical estimates of parameter values, use of a proxy for biomass, etc.
- DAS allocations (such as the category of DAS under the DAS reserve program, etc.), DAS "baselines", etc.
- Additional uses for Category B DAS (including uses not part of a Special Access Program), and future uses for Category C DAS
- Modifications to capacity alternatives, such as changes to any conservation taxes, changes to any DAS leasing provisions, or DAS transfer provisions, etc.
- Area management boundaries, calculation of area management TACs, or other details of the area management program, including adoption of area-specific management measures
- Sector allocation requirements and specifications, including establishment of a new sector, adopting the GB cod gillnet sector, or changing the allowable maximum TAC available to a sector through the sector allocation program
- Measures to implement the US/CA resource sharing understanding, including any specified TACs (hard or target)
- Changes to administrative measures
- Changes to reporting requirements
- Changes to the handgear only permit category
- Gear requirements or gear changes in order to improve selectivity, reduce bycatch, and reduce impacts on essential fish habitat
- Gulf of Maine Inshore Conservation and Management Stewardship Plan
- Adjustments for steaming time
- Changes to special access programs, including the implementation of additional Special Access Programs
- Other management measures adopted through this management plan

3.4.3 United States/Canada Resource Sharing Understanding

Several stocks on Georges Bank are transboundary and require coordinated actions between the US and Canada to effectively manage these resources. Since 1984 when the international maritime boundary line between the United States and Canadian federal waters was drawn, the two countries have worked together more effectively to manage and enforce fishery management programs. In 1998 the Transboundary Resource Assessment Committee (TRAC) was formed to coordinate stock evaluations of transboundary resources, and to combine all available scientific information between the two nations. Soon after, the Transboundary Management Guidance Committee (TMGC) was created to develop a management advisory process. After several meetings, in December 2001 the TMGC agreed to a final compromise for how several transboundary stocks should be allocated between the two nations. This resource sharing understanding does *not* connote a formal international agreement or memorandum of understanding. However, it is expected that groundfish regulations in both nations will satisfy the terms specified in this informal agreement.

The NEFMC reviewed this understanding and voted to incorporate the US/Canada Sharing Agreement into Amendment 13 at the July 2002 Council meeting. Canada incorporated the agreement into its management of Georges Bank stocks for 2003. Management of Georges Bank cod, haddock and yellowtail flounder will be subject to the terms set forth in the United States/Canada resource sharing agreement. The actual agreement text is included in Appendix III. Primary provisions of this agreement are:

- The agreement specifies an allocation of Georges Bank cod, haddock, and yellowtail flounder for each country. This allocation is based on a formula, which includes historical catch percentage and present resource distribution. (The specific formula is described in detail in the sharing agreement in Appendix III. For GB cod and haddock, only the portions of the stock in statistical areas 5Zjm/561 and 562 are subject to the agreement. The entire stock area for GB yellowtail flounder is covered by the understanding. The U.S. portions of these stock areas are shown in Figure 3).
- Catches by U.S. vessels from these management units will not exceed the appropriate allocation. If a species allocation is reached during the course of the fishing year in the United States, the TAC for the following year will be reduced by the same amount.

This section describes measures proposed to implement the understanding.

3.4.3.1 Management Bodies

In addition to the Council, there are two other organizations involved in administering the understanding:

U.S./Canada Steering Committee: NMFS and Canadian DFO committee that has overall responsibility for the understanding.

Trans-Boundary Management Guidance Committee (TMGC): U.S. and Canadian committee that provides non-binding guidance to the Steering Committee. Each country's delegation consists of six members: one manager, one scientist, and four industry representatives. The U.S. delegation is appointed by the NERO RA after consultation with the Council. The TMGC is not a Council committee and does not hold public meetings or provide public notice of its meetings.

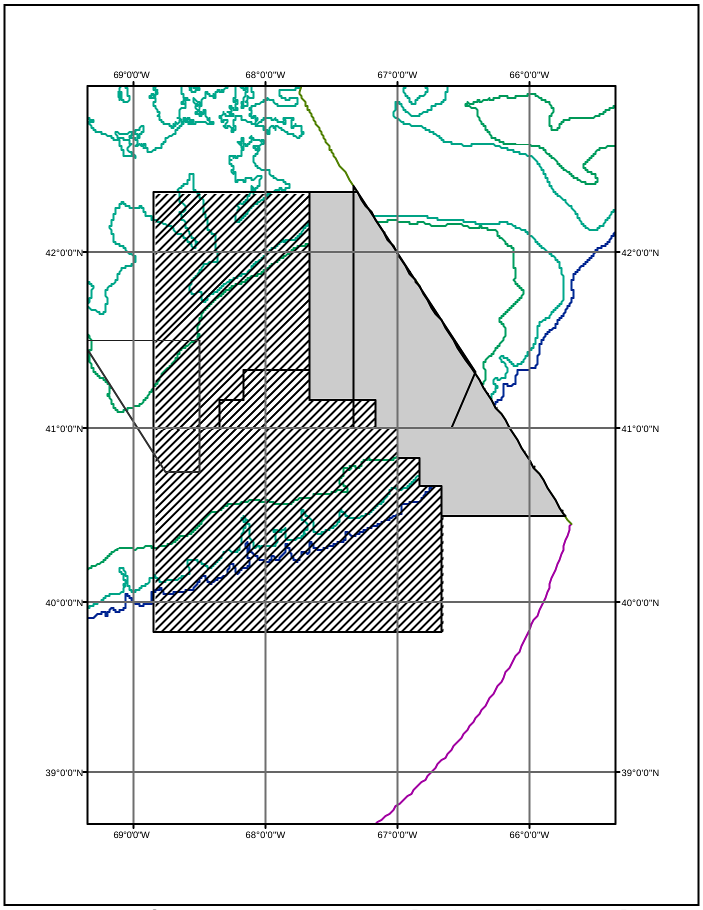


Figure 3 – Area for US/CA Resources Sharing Understanding. Shaded area applies for eastern GB cod and haddock, shaded and cross-hatched area applies for GB yellowtail flounder.

3.4.3.2 Determining and Implementing Annual Harvest Levels

Annual harvest levels and recommended management measures for the management units are determined by a process that involves the Council, the TMGC, and the Steering Committee. See the following flowchart (Figure 4) for an outline of the process to set harvest levels and adopt management measures. Specific details for determining harvest shares are described in Appendices II and III. Note that for the U.S. fishery, all harvest levels and any measures must be approved and submitted by the Council before implementation. This provides opportunity for public comment. If the Council or GOMAC disagree with TMGC recommendations, they will be referred back to the TMGC for further refinement.

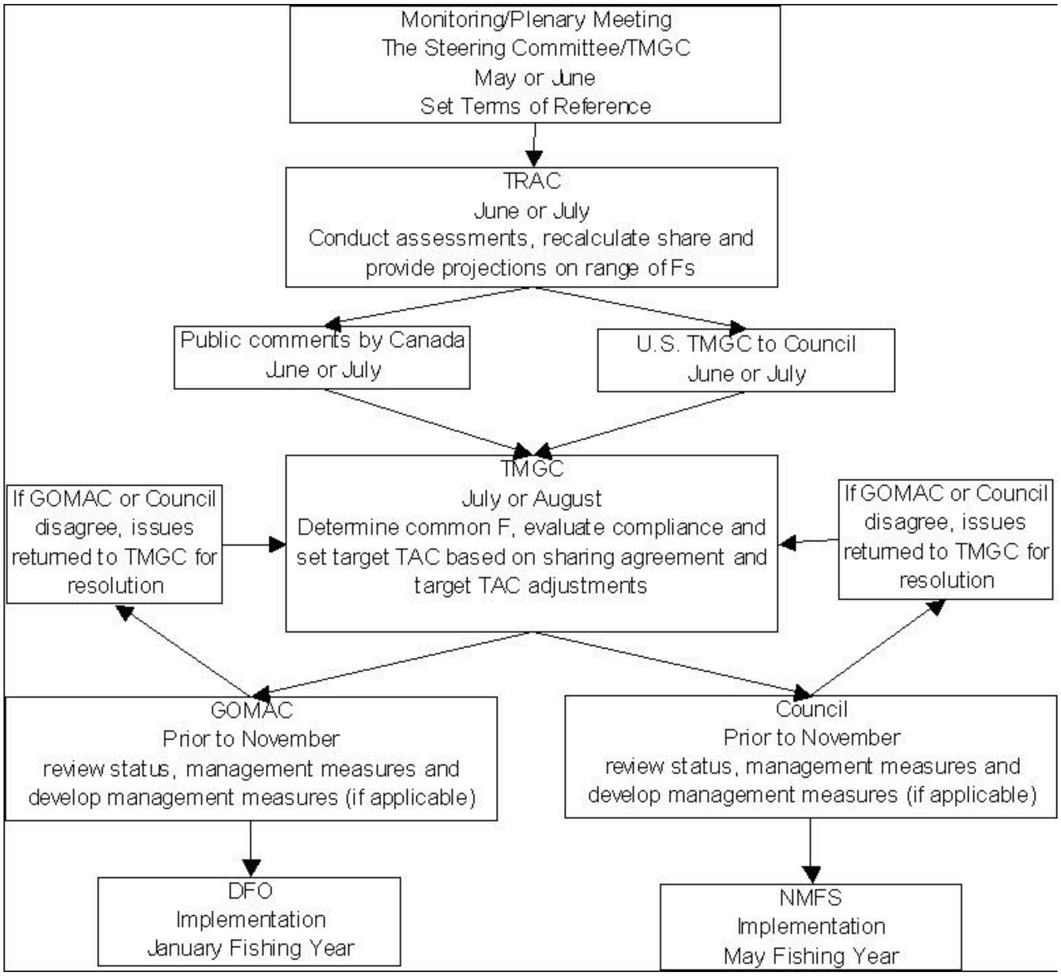

Figure 4– Process for adopting TACs and measures implementing US/CA resource sharing understanding.

3.4.3.3 Proposed Measures

The proposed measures apply to fisheries that impact cod or haddock in statistical areas 551, 552, 561 and 562 (Canadian unit areas 5Zj and 5Zm) and yellowtail flounder in statistical areas 551, 552, 561, 562, 522 and 525 (Canadian unit area 5Zh, 5Zj, 5Zm, 5Zn) and are hereafter referred to as the agreement management units. The management objective for the shared cod, haddock and yellowtail flounder resource is to achieve but not exceed the US allocation fraction as allocated through the US/CA Sharing Agreement.

3.4.3.3.1 Generic Measures

3.4.3.3.1.1 Other fisheries

The understanding does not affect other (non-groundfish) fisheries, but the catch of cod, haddock, and yellowtail flounder in the agreement management units are counted against the TAC regardless of gear type. Existing exempted/certified bycatch fishery and exempted gear provisions continue. A partial list of exempted fisheries/gear that may take place in this area:

- Lobster pots
- Herring (trawl and purse seine)
- Red Crab
- Pelagic longline

- Tuna purse seine and other pelagic tuna gear
- Hagfish
- Swordfish harpoon
- (Scallop gear, while technically not exempted gear or an exempted fishery, is authorized in the area subject to other regulations)
- (Recreational groundfish fishing, while technically not exempted gear or an exempted fishery, is authorized in the area subject to other regulations)

3.4.3.3.1.2 Identification of participants:

Vessels fishing on a groundfish DAS in the agreement area (statistical areas 551, 552, 561, 562, 522 and 525) must use VMS. A vessel must declare (using VMS code) at the start of a trip. On a given trip, a vessel can only fish either inside the US/CA area, or outside the US/CA area (no combined trips).

3.4.3.3.1.3 Reporting requirements:

Vessels making trips in the area required to report using Interactive Voice Reporting (IVR) system at the end of each trip in the area, unless or until a catch reporting system is available through VMS.

3.4.3.3.1.4 Observer coverage

The same level of observer coverage as implemented elsewhere (e.g. if coverage of 10% of total DAS is implemented, 10% of DAS in this area must have observer coverage) will be required in the agreement area. The observer coverage must also meet or exceed the TMGC specified targets.

3.4.3.3.1.5 Dockside scientific sampling

Catch sampling by NMFS port agents must be adequate to characterize catch-at-age from this area.

3.4.3.3.1.6 Industry input on revisions to measures

Industry input on revisions to management measures in the area will be solicited through the Groundfish Advisory panel (supplemented if necessary with additional personnel) and the Groundfish Oversight Committee.

3.4.3.3.1.7 Gear requirements

May be modified to achieve but not exceed the statistical area 561 and 562 (5Zjm) haddock and cod stocks and the GB yellowtail flounder TACs.

3.4.3.3.1.8 Incentives

It is important for the U.S. to harvest available cod, haddock, and yellowtail from the management units. Because of other restrictions contemplated for this action, there may be a need for incentives to fish on these offshore stocks. One specific incentive program is described as a Special Access Program in section 3.4.5.3.3. Possible additional incentives to fish in the 5Zjm area:

- DAS adjustments
- Credits for steaming time (implemented on adoption of Amendment 13) to statistical areas 561 and 562 (Canadian areas 5zjm)
- Higher trip limits

Upon implementation of the Amendment, vessels will not be charged for steaming time to and from statistical areas 561 and 562 (Canadian areas 5zjm).

3.4.3.3.1.9 Other restrictions

The Council may consider limiting the number of trips in the area for each vessel, for example to address following concerns:

- Provide opportunities for vessels of all sizes to access area
- Address market concerns
- Extend TAC
- Reduce risk of discards during specific seasons

3.4.3.3.1.10 Special access programs

Can be implemented through process proposed in section 3.4.5.

3.4.3.3.1.11 Changes to Measures

Measures remain in place until altered (i.e. no requirement for annual changes). If changes to measures are warranted, the following may be modified through a notice action published in the Federal Register:

Periodic adjustments: In consultation with the Council, the RA may adjust gear requirements, modify access to fishing areas within the agreement management units, and trip limits to meet established TACs as specific in the sharing agreement.
In season adjustments: At 30% and 60% of the total specified TAC for each species harvested from the agreement management units, the RA may adjust the gear requirements, modify access to the agreement management units, trip limits, and number of trips to meet established TACs as specific in the sharing agreement.

The RA, in consultation with the Council, can withdraw from provisions of understanding if deemed inconsistent with M-S Act or other applicable law, or with goals and objectives of groundfish FMP. After consultation with Council, RA will contact DFO representatives to address time critical issues that arise outside of normal review schedule.

3.4.3.3.2 Harvest Controls

Since the sharing agreement is based on a target catch determined by a common fishing mortality strategy, it is important to note that the choice of mortality reference points for the respective cod, haddock and yellowtail flounder stocks is critical. The US and Canada must set consistent mortality targets. If the US and Canada set mortality targets that are substantially different there will likely be difficulties in agreeing to the initial TACs.

3.4.3.3.2.1 Hard TAC

- Stock specific TACs (561 and 562 (5Zjm) cod and haddock; and 522, 525, 561, 562 (5Zhjmn) yellowtail flounder)
  Implement conservative measures up front to preserve the cod TAC in order to allow a directed haddock and yellowtail flounder fishery:
  - In consultation with the Council, the RA may adjust gear requirements, modify access to fishing areas within the agreement management units, and trip limits to meet established TACs.
  - Special access program rules that allow fishing for yellowtail flounder with no bycatch of cod. These programs may modify or change gear requirements.
  - Flat fish net or separator trawl gear (see definitions below)
  - Cod trip limit of 5% of total catch not to exceed 500 pounds per DAS, 5,000 pounds per trip

- When 70 percent of the target species (cod, haddock, or yellowtail flounder) is projected to be caught and catch rates indicate the TAC will be caught before the end of the year, the following restrictive trip limits go into place:
    - Haddock: 1,500 lbs/day, 15,000 lbs per trip
    - Yellowtail flounder: 1,500 lbs/day, 15,000 lbs per trip
- When 100 percent of the TAC is projected to be caught, the area (statistical areas 5zjm) will be closed to all fishing on a groundfish DAS that may take cod, haddock, or yellowtail flounder, unless an approved special access program allows some fishing in the area to target a specific species. If the GB yellowtail flounder TAC is caught, possession of yellowtail flounder will also be prohibited in statistical areas 522 and 525.

A flounder net is defined as a two-seam low-rise groundfish net.
A haddock separator trawl is defined as a groundfish trawl modified to a vertically-oriented trouser trawl configuration, with two codends arranged one above the other. The bottom cod end is left open. A horizontally oriented large mesh (6 ½ inch square mesh minimum) separating panel is installed between the selvedges joining the upper and lower panels, extending from the front of the trouser junction forwards to the aft section of the first belly behind the fishing circle.
Flounder and haddock separator trawl net specifications may be altered by the Regional Administrator.

3.4.4 Administration of Certified Bycatch/Exempted Fisheries

The standards for certification of a bycatch/exempted fishery that were implemented through Amendment 7 will continue to be used with the following changes.

- The Amendment 7 standard is that fishing only be allowed in a fishery where it can be certified that the incidental catch of regulated multispecies is less than five percent of the total catch, by weight 950 CFR 648.80(a)(8)). This incidental catch standard can be modified by the Council or Regional Administrator in future actions for those stocks that are not in an overfished condition, or if overfishing is not occurring on a stock. When considering modification of the standard, it must be shown that the change will not delay a rebuilding program, nor will it result in an overfished or overfishing condition. The standard can be modified either through a Council action (framework or adjustment) that changes the standard for all fisheries or on a case by case basis. For example, the standard could be revised to say that the incidental catch of regulated species is less than ten percent of the total catch, by weight. Or, to be more specific, the standard could require that the incidental catch of regulated species, not including a rebuilt stock with a low fishing mortality, is less than ten percent of the total catch.
- Other factors will also be considered in the review of a certified bycatch/exempted fishery, such as the impact of the fishery on juvenile fish, sacrifices in yield that will result from that mortality, the ratio of target species to regulated species, status of stock rebuilding, recent recruitment of groundfish species, etc.
- On a case by case basis, a certified bycatch/exempted fishery may be authorized to retain and land regulated multispecies. In making this determination, the Council or the Regional Administrator should consider the status of the stock or stocks caught in the proposed fishery, the risk that allowing this practice will result in a targeted groundfish fishery, the extent of the proposed fishery in terms of time and area, the possibility of expansion in the proposed fishery, the extent of exemption will not be allowed for any bycatch/exempted fishery that takes place in a groundfish closed area, for any stock that is overfished, or if overfishing is occurring on a stock caught by the certified bycatch/exempted fishery. It may be allowed on a stock under a rebuilding program, but only if it can be determined that the catch of the stock in the bycatch/exempted fishery is not likely to result in exceeding the rebuilding mortality rate.

Rationale: These alternatives provide increased flexibility to the Council and NMFS to administer the exempted fisheries program as stocks rebuild.

3.4.5 Special Access Programs

3.4.5.1 Introduction

Because management measures are generally applied over a wide geographic area and a number of sectors of the fishing industry, the management measures designed to reduce fishing mortality on groundfish stocks that are overfished are likely to also reduce mortality or inhibit fishing on groundfish stocks that could support an increase in mortality and landings. In the case of groundfish stocks, this unnecessarily sacrifices yield from these stocks and limits the ability of fishermen to mitigate adverse economic and social impacts of effort reductions by targeting stocks that are in good condition.

Similarly, the multispecies management measures may prevent fishing on stocks in other fisheries. For example, the restrictions associated with the year-round closure areas of the multispecies FMP (closed area I, closed area II, and Nantucket Lightship closed area) prevent access to non-groundfish resources such as Atlantic sea scallops. Such restrictions reduce the management options for other fisheries and may prevent those fisheries from harvesting the optimal level of the resource. For the purposes of the following discussion, the term "stocks of concern" will refer to a regulated multispecies stock that must have fishing mortality reduced, either to comply with a formal rebuilding program, because overfishing is occurring, or to rebuild to the biomass level associated with maximum sustainable yield. Stocks harvested in other fisheries will be referred to as non-groundfish stocks.

In order to facilitate access to groundfish stocks that can support an increase in mortality and to facilitate management of, and access to non-groundfish stocks, the Council proposes to establish a Special Access Program (SAP) process. A Special Access Program is the regulatory mechanism by which fishers could be provided access to limited, specific regulated multispecies or other fisheries that would otherwise be prohibited. The premise for development is that specific fisheries can be developed that do not undermine achievement of the goals of the multispecies FMP. It is important to note that although such a program would have some similarities with the exemption program developed by Amendment 7, it would be fundamentally different. The current exemption regulations as described in 50 CFR 648.80 define a system for approving fisheries that do not target regulated species, and have a limited (less than 5 percent by weight) catch of regulated multispecies. A SAP authorizes fishing for either regulated groundfish or target species in other fisheries, without compromising efforts to rebuild overfished stocks or end overfishing of regulated multispecies. Incentives may be provided to the users of these gear or techniques to encourage participation and move effort off of stocks of concern. A special access program represents a narrowly defined fishery that is prosecuted in such a way as to avoid or minimize impacts on stocks of concern (as well as minimize bycatch and impact on essential fish habitat). Examples of gear or techniques that may be utilized in such a fishery in order to be eligible for a SAP include but not limited to:

- Use of a gear design (net mesh, excluder device, sorting panel, etc.) that avoids or significantly reduces the catch of a stock of concern
- Fishing at a time or season, or in an area, that avoids or significantly reduces the catch of a stock of concern.
- Fishing in an area or with a method that minimizes, to the extent practicable, the adverse effects of fishing on essential fish habitat

This Special Access program alternative is designed to create a process and define minimum criteria that would be utilized in the future to standardize the development and implementation special access programs. A secondary goal of this alternative is to expedite the development of special access programs (through standardization and definition of a process). This management option contains two sub-options, one that defines a process and standards for special access programs for the multispecies fishery and a second sub-option that defines a process and standards for special access programs for other non-groundfish fisheries. Adoption of this program does not change the status of any exempted gears or exempted/certified bycatch fisheries, and does not change or eliminate the exempted fishery process.

3.4.5.2 Special Access Program for Vessels Targeting Groundfish

Under most Amendment 13 alternatives, the primary incentive for a groundfish vessel to enter a SAP will be an adjustment to the DAS. This could be through differential DAS counting (counting DAS at a slower rate) or allocating additional DAS to a vessel. Other incentives may be possible depending on the specific program – for example, allowing regulated access to an area closed to reduce groundfish mortality or protect habitat.

Similar to the exempted fishery program, there are two routes for approval of a SAP. In both cases, the assumption is that there is sufficient information available to support the claim that the SAP will not adversely impact efforts to control mortality on stocks of concern, would, to the extent practicable, minimize bycatch of all non-target species, and to the extent bycatch cannot be avoided, minimize the mortality of such bycatch, and minimize, to the extent practicable, adverse effects on EFH caused by fishing. If that information is not available, the first step in getting authorization will be to demonstrate the feasibility of the SAP through an experimental fishery.

A SAP can be implemented by:

1. Submission and approval of a management action (framework adjustment or plan amendment) by the New England Fishery Management Council. SAPs implemented through this approach will follow the usual rulemaking procedures (including, if applicable, abbreviated rulemaking under a framework action).

2. Submission of a proposed SAP by an industry participant or other member of the public, followed by review and approval by the Regional Administrator (RA), in consultation with the Council. This approach is designed to more rapidly implement a SAP than the formal management action approach. For this to be possible, the impacts of the SAP must fall within the range of the impacts analyzed by the appropriate NEPA analytical document accompanying Amendment 13 or other management action. In order to be approved by the RA, a SAP submitted through this approach must meet the following criteria:

> (a) The SAP must target a groundfish stock or stocks in which the previous year's catch fell short of the target or hard TAC. The proposed SAP application must also demonstrate that it will not catch more than the previous year's shortfall and the SAP will not result in overfishing of any stock, or cause any stock to become overfished. These elements ensure that the biological impacts for the target stock will fall within the range of the biological and economic impacts analyzed in the Amendment (economic impact analyses will include the assumption that all stocks are caught at their target levels). In order to demonstrate consistency with the goals of the FMP, the application shall specify the number of vessels, how such vessels are to be selected, and the estimated catch rate of the target and bycatch species.
> (b) The proposed SAP cannot adjust or change any of the measures that minimize, to the extent practicable, the adverse impacts of fishing activity on habitat. This limitation increases the likelihood that any habitat impacts of the SAP will fall within the range of the impacts analyzed in the FSEIS.
> (c) The proposed SAP must not increase fishing mortality on a stock of concern. This limitation increases the likelihood that the biological impacts of the SAP will fall within the range of the impacts analyzed in the FSEIS for stocks of concern. This can be accomplished in several ways:
>
> > (1) By adoption of a limitation on catch of the stock of concern, for example through a special TAC for the SAP, adequately monitored through sufficient observer coverage. (2) By adopting gear or fishing techniques previously demonstrated to reduce or avoid the catch of stocks of concern. In the case of a reduction, it must be shown that the reduction is sufficient that any increase in time fishing (effort) (through additional DAS allocations or differential DAS counting) will not increase the catch of a stock of concern beyond that which would result if the program were not approved.

(3) By a sufficient overall effort (fishing time) reduction or redirection such that there is no net increase in bycatch mortality.

(d) The SAP shall occur within a defined area.
(e) Participation in the SAP cannot be limited to vessels from a particular state or political subdivision. This reduces the likelihood the SAP will be considered an allocation of resources to a particular community.
(f) To the extent practicable, the SAP must reduce discards and/or discard mortality of all species.
(g) The proposed SAP shall not have significant impacts (as defined by NEPA), or, if significant, that these impacts were analyzed in the FSEIS for Amendment 13 or later management action.
(h) The proposed SAP shall specify the type of data reporting to be utilized to monitor the status of harvest and should include a realistic plan of implementation.
(i) The RA must make a finding that adherence to the prescribed conditions can be assured in light of available enforcement resources and in light of the enforcement record of vessel owners and operators of the vessels.

If a SAP request is submitted to the RA for approval in the process described in (2), the RA will:

- Perform an initial cursory review to insure the required elements are present.
- If all required elements are present, notify the Council of receipt of the SAP proposal within 21 days of receipt of the application.
- Publish a notice in the Federal Register requesting comment on the SAP proposal within a 30-day comment period.
- After considering comments from the Council and the public, make a determination on the proposed SAP and issue a permit authorization or regulations, as appropriate, within 60 days of the end of the comment period.

3.4.5.3 Special Access Program for Vessels Targeting Other Fisheries

There are two routes for approval of a SAP. In both cases, the assumption is that there is sufficient information available to support the claim that the SAP will not adversely impact efforts to control fishing mortality on stocks of concern, would, to the extent practicable, minimize bycatch of all non-target species, and to the extent bycatch cannot be avoided, minimize the mortality of such bycatch, and minimize, to the extent practicable, adverse effects on EFH caused by fishing. If that information is not available, the first step in getting authorization will be to demonstrate the feasibility of the SAP through an experimental fishery.

A SAP can be implemented by:

1. Submission and approval of a management action (framework adjustment or plan amendment) under the FMP that manages the target species by the New England Fishery Management Council. In this instance, documents submitted by the Council will ~~clearly~~ demonstrate the SAP will not adversely impact stocks of concern and will not result in identifying any groundfish stock as overfished or subject to overfishing. The action will also analyze the impacts of the proposal and demonstrate compliance with all applicable law. SAPs implemented through this approach will follow the usual rulemaking procedures (including, if applicable, abbreviated rulemaking under a framework action).

2. Submission of a proposed SAP by an industry participant or other member of the public, followed by review and approval by the Regional Administrator (RA), in consultation with the Council. This approach is designed to more rapidly implement a SAP than the formal management action approach. For this to be possible, the impacts of the SAP must fall within the range of the impacts analyzed by the appropriate NEPA analytical document accompanying Amendment 13 or other management action. In order to be approved by the RA, a SAP submitted through this approach must meet the following criteria:

(a) In order to demonstrate consistency with the goals of the FMP, the proposed SAP must specify the number of vessels, how such vessels are to be selected, and the estimated catch rate of the target and bycatch species.
(b) The proposed SAP cannot adjust or change any of the measures that minimize, to the extent practicable, the adverse impacts of fishing activity on habitat. This limitation increases the likelihood that any habitat impacts of the SAP will fall within the range of the impacts analyzed in the FSEIS.
(c) The proposed SAP must not increase fishing mortality on a stock of concern. This limitation increases the likelihood that the biological impacts of the SAP will fall within the range of the impacts analyzed in the FSEIS for stocks of concern. This can be accomplished in several ways:

(1) By adoption of a limitation on catch of the stock of concern, for example through a special TAC for the SAP, adequately monitored through sufficient observer coverage.
(2) By adopting gear or fishing techniques previously demonstrated to reduce or avoid the catch of stocks of concern. In the case of a reduction, it must be shown that the reduction is sufficient that any increase in time fishing (effort) (through additional DAS allocations or differential DAS counting) will not increase the catch of a stock of concern beyond that which would result if the program were not approved.
(3) By a sufficient overall effort (fishing time) reduction or redirection such that there is no net increase in bycatch mortality.

(d) The SAP shall occur within a defined area
(e) Participation in the SAP cannot be limited to vessels from a particular state or political subdivision. This reduces the likelihood the SAP will be considered an allocation of resources to a particular community.
(f) To the extent practicable, the SAP must reduce discards and/or discard mortality of all species (consistent with requirements of the M-S Act).
(g) The proposed SAP shall not have significant impacts (as defined by NEPA), or, if significant, that these impacts were analyzed in the SEIS for Amendment 13 or later management action.
(h) The proposed SAP shall specify the type of data reporting to be utilized to monitor the status of harvest and should include a realistic plan of implementation.
(i) The RA shall make a finding that adherence to the prescribed conditions can be assured in light of available enforcement resources and in light of the enforcement record of vessel owners and operators of the vessels.

If a SAP request is submitted to the RA for approval in the process described in (2), the RA will:

- Perform an initial cursory review to insure the required elements are present.
- If all required elements are present, notify the Council of receipt of the SAP proposal within 21 days of receipt of the application.
- Publish a notice in the Federal Register requesting comment on the SAP proposal within a 30-day comment period.
- After considering comments from the Council and the public, make a determination on the proposed SAP and issue a permit authorization or regulations, as appropriate, within 60 days of the end of the comment period.

3.4.5.3.1 Georges Bank Yellowtail Flounder Special Access Program

From June through December, fishing vessels can make two trips per month into the area of Closed Area II south of 41-30 N (area opened for the scallop Closed Area II access program to target yellowtail flounder, see the following chart). Additional requirements for participation in this program include:

- Vessels are limited to 30,000 pounds of yellowtail flounder per trip.
- All vessels are required to use VMS.
- The DAS clock starts when entering statistical areas 561/562 (5zjm) (or that part of Closed Area II that lies outside statistical areas 561/562 (5zjm))
- The DAS clock stops when the vessel leaves statistical area 561/562 (5zjm) (or that part of Closed Area II that lies outside statistical areas 561/562 (5zjm))
- A vessel cannot fish outside statistical areas 561/562 (5zjm) (or that part of Closed Area II that lies outside of statistical areas 561/562 (5zjm))
- A vessel can fish inside Closed Area II and in statistical areas 561/562 (5zjm) on the same trip. A vessel cannot transit the part of Closed Area II that remains closed in order to fish in other parts of statistical areas 561/562 (5zjm).
- The number of total trips participating in this program is 320. The Regional Administrator may change the number of trips authorized based on projected catch of the GB yellowtail flounder TAC.
- Vessels will be limited to one-fifth of the daily GB cod trip limit specified for the US/CA Resource Sharing Understanding (e.g. 100 lbs. if the trip limit is 500 lbs./day) for the entire trip

Measures adopted to implement the US/CA resource sharing understanding may impose additional restrictions on this access program. The more restrictive measures will apply. For example, while fishing outside of CA II south of 41-30N, vessels must comply with the requirement to use a haddock seperator or flounder net.

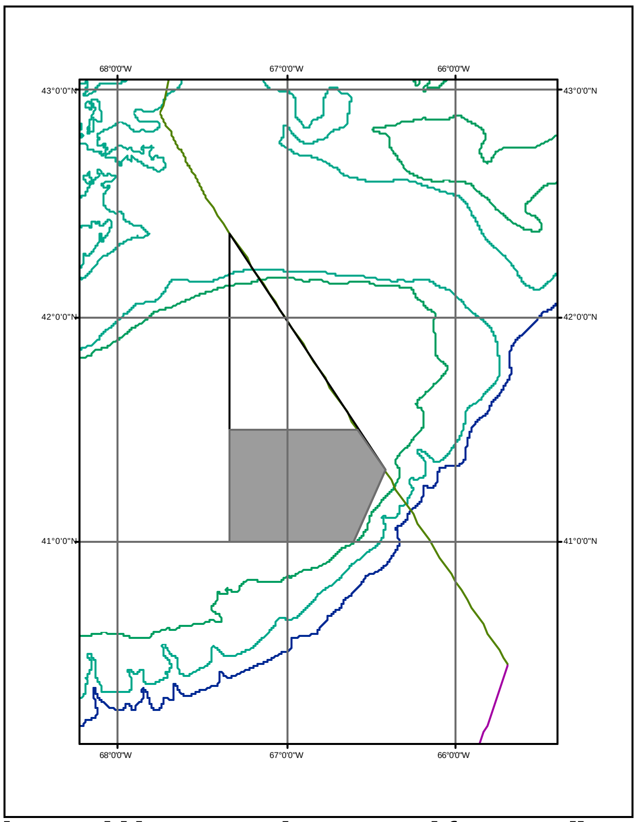

Figure 5 – Area in CAII that would be open under proposed for GB yellowtail flounder special access program

3.4.5.3.2 Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program

A vessel fishing for fluke west of 72-30W, using mesh authorized by the fluke plan and not on a groundfish DAS, is allowed to retain and land up to 200 lbs. of winter flounder subject to the following restrictions:

- Vessel must possess a valid federal fluke permit
- Winter flounder cannot exceed the amount of fluke on board
- The vessel operator must sign into this program for a minimum of thirty days and must have a letter of authorization from the Regional Administrator on board
- While in the program, a vessel cannot fish on a groundfish DAS
- All fishing must take place west of 72-30W
- Possession and/or landing of other groundfish is prohibited

Rationale: Vessels fishing for fluke occasionally catch small amounts of winter flounder. This program reduces regulatory discards by allowing landing of these small quantities, and it increases opportunities to land winter flounder. Analysis shows that many of the alternatives will reduce SNE/MA winter flounder catches more than necessary – this measure helps to mitigate those impacts.

3.4.5.3.3 US/CA Resource Sharing Understanding Special Access Program

These measures are proposed to facilitate taking of the U.S. share of cod, haddock, and yellowtail flounder as allocated under the U.S./Canada Resource Sharing Understanding (see section 3.4.5.3.3). These measures apply to statistical areas 5Zjm (see Figure 6). Only vessels with limited access permits will be allowed to participate in this program.

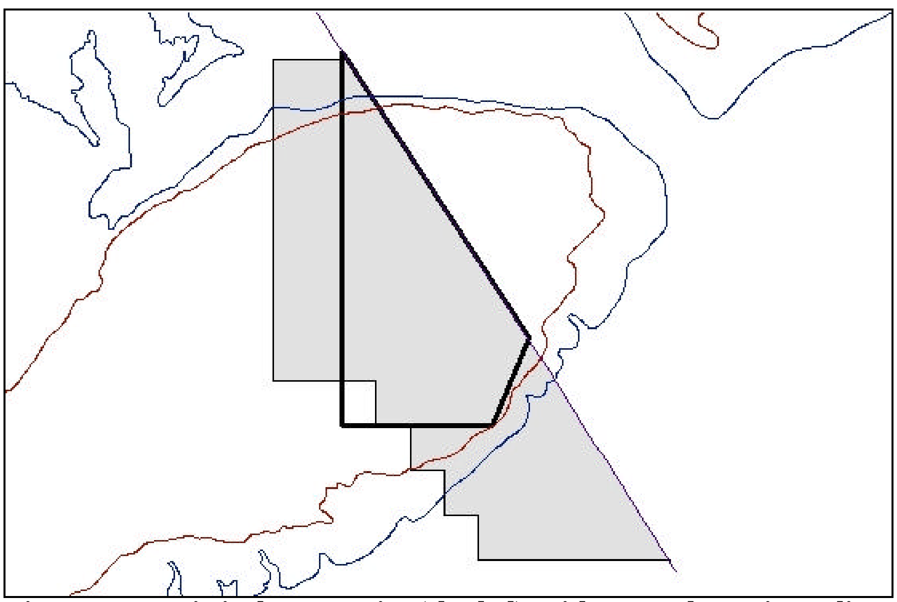

Figure 6 – Statistical areas 5zjm (shaded), with CAII shown in outline.

3.4.5.3.3.1 DAS Adjustment

Vessels fishing in the area may be charged DAS at a differential rate. The rate will range from 1:1 to not counting DAS all for vessels fishing in the area. These rates will be specified in a future action.

3.4.5.3.3.2 Gear

Vessels trawling in the area will be allowed to use different mesh size in their cod ends. Mesh can be adjusted downward from the U.S. regulations to the size used by Canadian vessels on eastern Georges Bank. Any gear changes may be specified in a future action.

3.4.5.3.3.3 Access to Closed Area II

Access will be provided to Closed Area II to facilitate catching haddock and yellowtail flounder. Access to the area north of the habitat area of particular concern and deeper than 100 fathoms will be provided for a period of ten months of the year. This area is bounded by the following points:

42-12.0N	67-11.0W	(intersection of 42-12.0N with the U.S. – Canada Maritime Boundary)
42-11.0N	67-20.0W	
42-22.0N	67-20.0W	(the U.S.-Canada Maritime Boundary)

Access will not be allowed during March and April in order to protect spawning haddock. At any time, the Regional Administrator can adjust the months the area is open in order to achieve and not exceed the US/CA TACs. Part of the area south of 41-30N will be open for yellowtail flounder fishermen; details of this program are in section 3.4.5.3.1. A vessel will be allowed to fish in Closed Area II, both north and south of 41-30N on the same trip if both areas are open, but cannot transit closed areas when transiting between the two programs.

Rationale: The area subject to the US/CA understanding is well offshore. DAS reductions proposed in this amendment may discourage U.S. fishermen from transiting to this area. A possible result is that U.S. fishermen would not harvest their share of haddock and yellowtail flounder (there are likely to be very low limits on GB cod catches due to the need to rebuild that stock). This program will provide incentives for U.S. fishermen to transit to the area and target haddock and yellowtail flounder, while protecting cod stocks. Limits on where fishermen can fish on these trips are intended to prevent confusion attributing catches to a particular stock. Allowing fishing in the northern part of CAII is designed to provide access to haddock. The requirement to use either a haddock separator trawl or a flounder net will reduce cod bycatch. In any case, the US/CA understanding includes a hard TAC on GB cod taken in this area, so participation in this SAP will not harm cod rebuilding as long as catches (both landings and discards) can be adequately monitored.

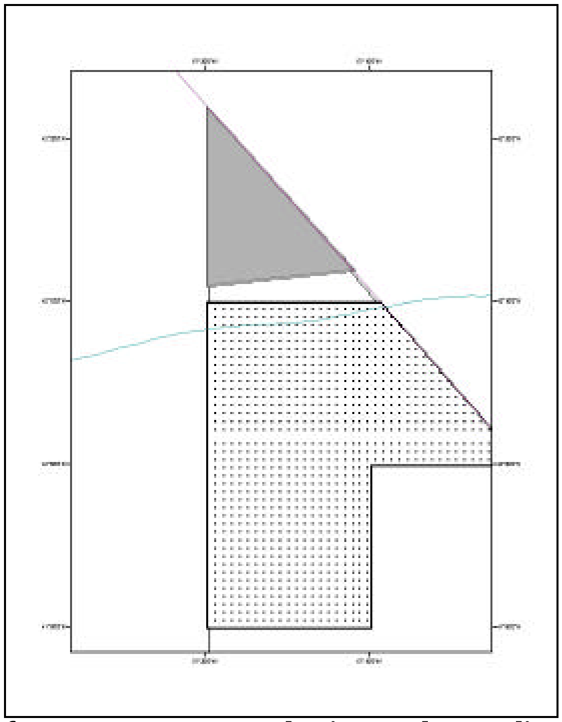

Figure 7 – Area authorized for US/CA Resource Sharing Understanding SAP. (Shaded area is area authorized, stippled area is cod HAPC)

3.4.5.3.3.4 Adjustments

Any of these measures can be adjusted by the Regional Administrator in order to achieve, or not exceed, the appropriate TAC as established by the US/CA resource sharing understanding.

3.4.5.3.4 Hook Gear Closed Area I Special Access Program

Vessels using hook gear may participate in a program to access haddock in Closed Area I.

Area

Participants may fish in the area defined by the following coordinates (loran coordinates shown for information only):

41–24.5N 069-18.5 W (43800/13700)
41-25.5N 069-14.5W (43800/13675)
41-08.0N 068-59.5W (43680/13675)
41-07.0N 069-04.0W (43680/13700)

Season

Hook: September 16 through December 31

Incidental Catch Limits

Hook: 35 mt incidental catch of cod., 400 lbs/trip. Access program closes when cod limit is projected to be caught.

Gear Restrictions

Hook: Maximum of 3,600 circle hooks, 12/0.

Administrative Requirements

Vessels must declared into the access program in advance of sailing. No fishing is allowed outside the area boundaries on a dedicated closed area access trip.

Observer Coverage
Observers are required on all trips.

VMS
All vessels must be equipped with an approved VMS.

Rationale: Proposed measures are likely to reduce fishing mortality on GB haddock well below the level called for in the rebuilding program. This SAP will provide an opportunity for hook gear to target that resource, mitigating some of the impacts of other measures on that sector and helping the plan to achieve OY for that stock. The strict limits on cod bycatch are intended to prevent the program from harming cod rebuilding, and to act as an incentive for more selective fishing practices. With all trips covered by observers, the catches can be closely monitored and the program can be closed if necessary.

3.4.6 Closed Area Administration

3.4.6.1 Clarification of closed area rationale

Year round closed areas have both direct and indirect benefits. Direct benefits are related to the species managed by the management plan, and include reductions in fishing mortality (that may remove need for other management measures), protection of spawning fish, etc. Indirect benefits can be protection provided to stocks not included the FMP (including reduced fishing mortality or spawning protection), habitat, etc. When closures are adopted, the Council will:

- Define the intent and specific purpose for the closure;
- Explicitly describe the duration of the closure, who can fish in the closed area, and who cannot fish in the closed area.

Rationale: Many of the existing closed areas have been adopted at different times – in some cases, the closed areas have existed in some form for over thirty years. This statement of intent clarifies the reasons for closed areas and can be used to evaluate changes to the areas in the future.

3.4.6.2 Flexible Area Action System

The FAAS system will be eliminated and not replaced.

Rationale: because the regulatory requirements necessary to implement a closure were too cumbersome to react quickly to changing resource conditions. Given the analysis requirements of NEPA and the M-S Act, it is not likely that the system will ever respond quickly enough to a short-term resource condition to implement a closure. Removing this measure will simplify the regulations.

3.4.7 DAS Leasing Program

Rationale: The DAS leasing program that follows is intended to provide flexibility for fishermen to adapt to the proposed measures in this amendment. Significant DAS reductions may make some vessels unprofitable. The leasing program allows for the transfer of DAS so that vessels that decide not to fish for groundfish can earn some revenue from their DAS by transferring them, on a short term basis, to other vessels who will fish them. Because of concerns over how these transfers may change the character of the fishery, transfers between vessels of different sizes are limited to the permit upgrade restrictions. Finally, the impacts of this program are subject to uncertainty, so the program is scheduled to end in two years unless extended by Council action.

3.4.7.1 Basic elements

The following elements form the basis for a leasing program.

- Term of Lease: DAS would be leased for only one fishing year.
- Vessels may lease DAS from more than one other vessel (conversely vessels may lease DAS to more than one vessel) subject to conservation equivalency provisions.
- DAS may be leased on a unit basis where a unit is defined as being 1 DAS or 24 hour increment.
- Leases would not be subject to a "conservation tax."
- Renewal of Lease: Vessels may renew leased DAS on an annual (fishing year) basis.
- Required Use: Leased DAS must be used in the same fishing year they are acquired
- Prohibition on Carry-Over: Leased DAS may not be used as part of any carry-over.
- Limit on Leasing by Category: DAS available for leasing shall be limited to only Category A DAS; DAS that may be immediately available for use.
- Registration of Leases: Lease agreements must be registered with the NMFS Northeast Regional Office (NERO). Administrative process based on two possible approaches 1) internal administration by NERO or 2) external administration by approved "brokers" (for example, permit brokers could be sanctioned by NERO to document exchanges and provide data to NERO for monitoring and enforcement purposes) to be developed.
- Permit History: the lease agreement must clearly state which permit retains the history of the leased DAS

3.4.7.2 Conservation Equivalency

A lessor may not lease DAS to any vessel with a main engine horsepower rating that is 20% more than that of the lessee and may not lease DAS to any vessel that is 10% more than that of the lessee vessel's LOA. These criteria are based on the permit baseline. (Note that these restrictions do allow a larger vessel to lease DAS to a smaller vessel).

Rationale: DAS leasing could result in a net increase in fishing mortality if DAS are transferred across disparate platforms. This measure limits lease agreements to vessels that meet specified vessel size categories. They are consistent with restrictions on upgrading a vessel, with the exception that the tonnage restrictions are not adopted to facilitate administration of the program.

3.4.7.3 Sub-leasing DAS

DAS cannot be sub-leased.

Rationale: This provision is intended to simplify administration of the program.

3.4.7.4 Limitations on Number of DAS Leased

A vessel can lease the number of DAS equal to its allocation for fishing year 2001 (not including carry-over DAS). The total number of Category A DAS available to a vessel under Amendment 13 is thus its Amendment 13 allocation and any leased DAS, with the leased DAS not exceeding the vessel's allocation in FY 2001 (not including carryover DAS).

Rationale: This provision reduces the possibility that a vessel will accumulate excess DAS.

3.4.7.5 Permit History Provisions

To clarify the implications of leasing DAS on permit history, the following policies will be followed:

- The history of DAS use remains with the permit that "owns" the DAS (that is, the lessee retains the DAS history of any DAS leased to another vessel –even after the DAS are leased).
- Any landings associated with leased DAS remain with the permit that lands the fish.
- If a vessel does not use all the DAS that are allocated to it and that it leases, leased DAS are considered used first.

Rationale: These provisions standardize the treatment of DAS and landings history in order to simplify administration of the program. Allowing a vessel that "owns" the DAS retain the history of those DAS will alleviate the concern that leasing out a DAS will affect future decisions, if any, that are based on DAS history. Considering leased DAS as used first reduce the possibility that a lessor will acquire DAS in excess of his ability to use them.

3.4.7.6 Interaction with Monkfish DAS

According to the existing monkfish FMP, vessels that possess a Category C or D monkfish permit must use a multispecies DAS when using a monkfish DAS. A multispecies permit holder that leases DAS to another vessel should be aware that if the number of multispecies DAS retained (not leased) is less than the number of monkfish DAS allocated, the permit holder may not be able to use all his monkfish DAS while fishing with a Category C or D monkfish permit. This may not be a concern if a future monkfish amendment separates groundfish and monkfish DAS use.

Example: Original DAS allocation: 40 multispecies/40 monkfish
DAS after leasing: 20 multispecies/40 monkfish
Monkfish DAS that can be used: 20 monkfish

Rationale: This section clarifies the interaction between leasing of multispecies DAS and the use of monkfish DAS.

3.4.7.7 Expiration of Leasing Program

The DAS leasing program will automatically expire after two years unless extended by a future Council action. There is no implicit or explicit guarantee that the DAS leasing program will be renewed.

Rationale: This sunset provision means that the program will be reviewed after two years and any necessary modifications can be made at that time, or the program can be terminated. Vessel owners entering into lease agreements should recognize that absent a future Council action, the DAS leasing program will be in place only for fishing years 2004 and 2005. A future action could terminate the DAS leasing program before FY 2005, or could extend it past that date.

3.4.7.8 Confirmation of Permit History

Any permit in the permit history category cannot lease DAS to an active permit.

Rationale: This provision slows the re-activation of effort that is frozen in the permit history category.

3.4.8 Recreational Fishing Permit

Four options were considered for requiring a recreational fishing permit. The proposed action is the No Action alternative – no recreational permit is required.

Rationale: The administrative problems and costs of a recreational permit were seen as obstacles to this program unless improved reporting could be adopted as well.

3.4.9 "Running clock" alternatives

The "modified running clock" will remain in effect as described in current regulations. Under this regulation, a vessel fishing for less than a full 24 hour block of time can land a daily possession limit for the last day as long as the operator does not call out of the DAS program until the final 24 hours have elapsed. This requirement starts on the second day of a trip. No other changes are being made to the running clock by this amendment.

Rationale: No changes are made to the current running clock because of enforcement and administrative concerns.

3.4.10 Observer Coverage

The Council desires 10 percent observer coverage of all gear sectors. No later than 2006, NMFS will determine if this level of observer coverage is sufficient to monitor catches and discards in the groundfish fishery with an acceptable level of precision and accuracy. The level of desired observer coverage will be adjusted (increased or decreased) consistent with that analysis.

Rationale: The Council does not manage the observer program. Nevertheless, this measure is intended to reflect the Council's recognition that adequate observer coverage will foster improved information that can be used to manage the groundfish fishery. In April 2003, NMFS advised a federal court that 5 percent observer coverage provides an acceptable level of precision.

3.4.11 Modified VMS Operation Requirements

A vessel using a VMS can opt out of the program for a minimum period of one calendar month by notifying the Regional Administrator (RA). Notification must include the date a vessel will resume transmitting VMS reports. A vessel cannot resume fishing (for any species) prior to that date. After receiving confirmation from the RA, the vessel operator can stop sending VMS reports. During the period out of the program, the vessel cannot participate in the following activities:

- Engage in any fishery
- Operate (meaning transit) in the Exclusive Economic Zone with gear capable of catching groundfish, unless that gear is properly stowed below decks.

While this provision facilitates cost savings for vessels that exit the fishery for an extended period of time, it does not authorize a vessel required (because of participation in a SAP, fishing in the US/CA Understanding area, etc.) or voluntarily using a VMS, to switch back and forth between the VMS and call-in programs.

Rationale: Current regulations require a vessel equipped with a VMS to send position reports for the entire year (unless hauled out). This requirement results in unnecessary costs to vessels since they have a limited number of DAS available. In many instances, these costs include not just the communication costs charged by the vendor, but the costs of running a generator to provide electrical power to the unit. This measure provides an opportunity to reduce costs since a vessel operator can choose to turn his vessel's VMS off if exiting the fishery for an extended period. In order to address enforcement concerns, strict limitations are placed on the vessel's activity during this period. The requirement that gear capable of catching groundfish be stowed below decks is more strict than the normal stowage requirements for transiting closed areas.

3.4.12 Day Gillnet Block Out of the Fishery

There will not be any changes to existing requirements for day gillnet vessels to take blocks of time out of the fishery (the No Action alternative).

Rationale: This requirement limits the ability of day gillnet vessels to compensate for reduced DAS by extending soak time.

3.4.13 DAS Counting

No changes will be made to the method used to count DAS. DAS will be counted based on hours and minutes for all vessels (the No Action alternative). Day gillnet vessels will continue to be charged a minimum of 15 hours for trips over three hours in length.

Rationale: Changes to the way DAS are counted would be an administrative burden with few benefits. All of the DAS analyses and allocations used in the amendment would have to be recalculated. Changing the way DAS are counted could also result in unsafe fishing practices, as small vessels could react by choosing to fish a full twenty-four hours without adequate crew size.

3.4.14 Reporting Requirements

The proposed action requires a closer link between vessel, dealer, and DAS reporting. Timely information on area fished is required to know which measures apply to the vessel, and to monitor landings accurately. Programs such as the proposed Special Access Programs and the US/CA Resource Sharing Understanding require timely landings information so that targeted catch levels are not exceeded.

3.4.14.1 Dealer Reporting Options

Dealers will be required to use daily electronic reporting where the dealer records the vessel's trip identification number and disposition of catch (e.g., human consumption, bait, animal food, reduction, etc.) along with the current set of data elements for all vessel purchases. Reports are due to NMFS within twenty-four hours of the transaction. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction. Electronic reporting systems would replace the current paper based dealer reporting as well as the IVR reporting for cod and haddock and other species under various FMPs. Until such time as an electronic reporting system is in operation, existing reporting requirements remain in effect.

Rationale: Daily electronic reporting will improve the timeliness of information on groundfish landings. Delaer landings, however, do not have any information on catch location. The reporting of a trip identifier will create a link between the location (statistical area) information reported in VTRs and the landings reported by dealers. This will improve estimates of catches by stock area and enable more timely monitoring of removals by stock.

3.4.14.2 Vessel Reporting Requirements

The vessel owner/operator will be required to report a vessel trip identification number to the dealer where the vessel is offloading its trip. This may be generated by the vessel using such current information as the VTR serial number, days-at-sea call-in number or a number generated by VMS, and reported to the dealer for submission to NMFS. Alternatively, the dealer may generate the number such as an invoice number for the fish received and provide the number to the vessel, which would submit it to NMFS along with the remaining trip information. The vessel trip identifier would link the dealer and vessel information for each trip. This would improve the utilization of both data sets and allow for the identification of the stock area that was fished. This is essential to monitoring of catch allocations by stock area.

Once an approved, viable electronic system becomes available, it will replace the current VTR. Under this option, vessels would report all of the information currently required by the VTR, as well as the following information: a) password; b) trip identifier; and c) landings information by NMFS statistical area. Reports would be submitted at least at the current statistical area level of reporting. As a means of reporting, vessels would have the option of using any approved, viable electronic means possible to report this information.

The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

Rationale: As noted in the previous section, the use of a trip identifier will create a closer link between dealer and vessel reporting. The current paper reporting system for VTRs is time –consuming, slow, and costly. Electronic vessel reporting will speed the collection of catch information from vessels.

3.4.15 Hand Gear-Only Permit Alternatives

3.4.15.1 Permits

The current open access handgear permit will be changed to include two different categories of permit. Handgear permits will include the use of hand-hauled tub trawls limited to 250 hooks.

> Category A - To be eligible, a vessel in the NE Multispecies Open Access Handline/Rod and Reel category must have landed 500 pounds of cod, haddock or pollock in at least one of the fishing years from 1997 to 2002. Category A hand gear only permits can be transferred from one vessel to a replacement vessel.
>
> Category B - Open access

Rationale: Only a small fraction of category H permit holders have either reported landings of regulated groundfish in either the dealer or VTRs these permit holders do depend on regulated groundfish for at least a portion of their fishing income. Nevertheless, the large number of permit holders represents a potential latent effort problem that is better addressed through management action in Amendment 13 rather than ignored. This measure limits the number of hand-gear permits that can fish to those that were active during the period 1997 through 2002. At the same time, it creates a second hand gear category that allows a small open access fishery to continue.

3.4.15.2 Management Measures

The management measures will differ for the two permit categories.

Category A – Trip limit will be 300 pounds of cod, trip limits for all other species shall be the same as for limited access (DAS) vessels. Cod trip limit to be adjusted proportionally to DAS vessels; i.e. if GOM cod trip limit doubles then the Category A trip limit would double and vice versa. Category A vessels will be subject to the same year-round and seasonal rolling closures as DAS vessels.

Category B - Trip limit will be 75 pounds of cod, trip limits for all other species shall be the same as for limited access (DAS) vessels. Cod trip limit to be adjusted proportionally to DAS vessels; i.e. if GOM cod trip limit doubles then the Category B trip limit would double and vice versa. Category B vessels will be subject to the same year-round and seasonal rolling closures as DAS vessels.

Rationale: By creating a limited access and open access handgear permit, the Council is able to manage the hand gear fishery in a way that mitigates adverse economic impacts for the current hand-gear participants while preventing any adverse biological effects should the open access hand-gear permits become more active. While the low trip limit associated with the open access category will discourage significant participation, that trip limit could be increased in the future as stocks rebuild.

3.4.16 Sector Allocation Alternatives

3.4.16.1 Sector Allocation

This option is not proposed as a stand-alone option for a system of management to be implemented by Amendment 13. Rather it is envisioned as an option that might be adopted in addition to and independent of the principal management option chosen for Amendment 13 (e.g., hard TACs, DAS management, Area management, etc.).

A sector allocation system would apportion part or all of groundfish fishery resources (denominated in terms of catch) to various industry sectors. While vessels might be assigned to sectors based on factors such as gear used, permit category, vessel size, homeport, area fished, etc., this measure allows vessels to form sectors of their own choosing. Such self-selected sectors might be based on common fishing practices, vessel characteristics, community organization, or marketing arrangements, but this would not be required. Since self-selection of sector membership would not necessarily be based on any common vessel or gear characteristics this alternative offers a great deal of flexibility in the formation of sectors. A group of permit holders would simply agree to form a sector and submit a binding plan for management of that sector's allocation of catch or effort. Allocations to each sector may be based on catch (hard TACs) or effort (DAS) with target TACs specified for each sector. Vessels within the sector would be allowed to pool harvesting resources and consolidate operations in fewer vessels if they desired. One of the major benefits of self selecting sectors is that they provide incentives to self-govern, therefore, reducing the need for Council-mandated measures. They also provide a mechanism for capacity reduction through consolidation.

3.4.16.1.1 Formation of a Sector

Participation in a self-selecting sector would be voluntary. Vessels that did not decide to join would remain in a common pool which would fish under the constraints impose by the Council. Individuals that wished to form a sector and receive an allocation of catch or effort would be required to submit a proposal for formation of a sector and a legally binding plan of operations which would require approval from the Regional Administrator. These would be agreed upon and signed by all members of the sector.

The motivation to form or join a sector could be for several reasons: a desire of its members to consolidate operations in fewer vessels (reducing the cost of operations and possibly facilitating the profitable exit of some individual vessel owners from the fishery); assurance that the members of the sector would not face reductions of catch or effort as a result of the actions of vessels outside the sector (e.g., if the other vessels exceed their target TACs), and, potentially, freedom from restrictive regulations not needed to meet conservation objectives if the sector is constrained by a hard TAC (e.g., trip limits and potentially some time-area restrictions).

3.4.16.1.1.1 Preparation of a sector formation proposal and operations plan

The formation proposal and operations plan submitted by a self-selecting sector must have, at a minimum, the following components:

- A list of all participants and a contract signed by all participants indicating their agreement to abide by the operations plan accompanying the proposal.
- An operations plan detailing the following:
  - A list of all vessels that would be part of the sector including an indication for each vessel of whether it would continue to fish;
  - The original distribution of catch history, TACs, or DAS within the sector;
  - A detailed plan for consolidation of TACs or DAS, if any is desired, including a detailing of the quantity and duration of any redistribution of TAC or DAS within the sector;
  - A plan and analysis to show how the sector will avoid exceeding their allocated TACs (or target TACs if the allocation is in terms of DAS). This plan should include provisions for

monitoring and enforcement of the sector regulations, including documentation of both landings and discards;
- o Rules for entry and exit to the sector (see more on this in next section) including procedures for removing or disciplining members of the sector who do not abide by its rules. Rules for entry and exit must also define how catch or DAS history that is developed by vessels participating in a sector is assigned to each vessel;
- o Procedure for notifying the National Marine Fisheries Service if a member is expelled from the sector for violation of sector regulations.

An appropriate NEPA document assessing the impacts of forming the sector must be prepared. This will be written by the sector applicants, and submitted to NMFS through the Council. The contracts drawn up for the whiting and pollock cooperatives on the West Coast and Alaska might serve as a guide for determining the form and content of these plans.

3.4.16.1.1.2 Sector Review and Approval

Once a group organizes and prepares a sector operations plan, the plan must be reviewed and approval given before the sector can operate. A sector will submit its operations plan to the Council no less than one year prior to the date that it plans to begin operations. An exception to this date will be made for the Cape Cod hook sector proposal included in this amendment. The Council will consider this plan in the course of the periodic adjustment process and will implement it through that process.

3.4.16.1.1.3 Movement Between Sectors

Each sector will set its own rules on movement into and out of the sector.

Rationale: By not mandating the commitment time to a sector and allowing the sectors to set their own rules, the sector might be more successful in the long-term. This success will be realized, while working within their allocation (hard TAC or DAS), the group will be largely self-regulating. A code of conduct for all sectors should be developed by the Council or by industry with Council approval.

3.4.16.1.2 Allocation of Resources

Allocation of resources will be based on documented catch. Thus, allocated TACs would be based on the accumulated catch histories over the previous five years of each member of the self-selected sector. For any sectors formed that target GB cod during the period 2004 through 2007, landings will be based on fishing years 1996 through 2001. Note that this accumulated catch history would be allocated to the sector as a whole and not necessarily to individual vessels within the sector. The self-selecting sector would then have to develop its own set of rules to distribute the sector's allocation among its membership.

Allocation of TACs must be consistent with the measures adopted for the remainder of the fishery. If measures designed for the rest of the fishery will reduce mortality of a species well below its target, it may be inappropriate to base the TAC for a sector on the target fishing mortality.

Rationale: The use of a specified period for sectors targeting GB cod is so that allocation of resources will be consistent with the period used for the GB cod hook sector. Documented catch refers to catch that was reported to NMFS through a required reporting system.

3.4.16.1.2.1 Mortality/Conservation Controls

It will be necessary to establish appropriate restrictions on catch or effort for each sector to ensure that they do not exceed their allocation of TAC (through landings or discards). Hard annual TACs by species will be allocated to the sector as a whole. The sector would be required to submit an operating plan for approval by the regional administrator. The plan would detail the allocation of TAC within the group , how the catch of the sector would be monitored, and a plan for operation or cease of operations once the TACs of one or more species were taken. The plan would have to provide assurance that the sector would not exceed the target TACs allocated to it (either through landings or discards).

3.4.16.1.2.2 Enforcement of Sector Provisions

It will be the responsibility of each sector to enforce any provisions adopted through procedures established in the operations plan and agreed to through the sector contract. Ultimately, a sector may desire to expel a member due to repeated violations of sector provisions. Once a vessel enters into a sector, it cannot fish during that fishing year under the regulations that apply to the common pool. In other words, if a vessel is expelled from a sector, it cannot participate in the groundfish fishery during the remainder of that fishing year.

For the purposes of enforcement, a sector is a legal entity that can be subject to NMFS enforcement action for violations of the regulations pertaining to sectors. Vessels operating within a sector are responsible for judgments against the sector.

3.4.16.1.2.3 Interaction of Sector with Common Pool Vessels

As noted above, sectors will be assigned a TAC share (percentage of total TAC) based on some history period. While it is appropriate for changes in stock condition to affect the amount of fish that the share represents, sectors should not suffer if other sectors, or common pool vessels, exceed target or hard TACs and create a need for mortality reductions.

If a sector does not exceed its assigned TAC in a given fishing year, but other sectors or common pool vessels do, the sector's quota [in absolute (not share) terms] in the following years will not be reduced. This does not permanently change the sector's percentage of the total TAC, however. In the extreme case, the total resources available may be less than a sector's absolute quota. In this instance, the sector's share will be temporarily increased by the percentage that other sectors exceeded their quota. As stock conditions improve, the sector will keep this temporary increase in share until its annual quota is the same as it was prior to the stock decline. The sector's permanent share will then revert to its original share.

If a sector exceeds its TAC, the sector's quota will be reduced in the following year and the sector may be subject to enforcement action. If the sector exceeds its TAC repeatedly, the sector's share can be permanently reduced as a penalty or the sector's authorization to operate withdrawn.

If declining stock conditions result in a need to reduce fishing mortality, and all sectors and common pool vessels have operated within target or hard TAC limits, a sector's share will not be changed, but the amount this share represents may be due to reduced overall TACs.

If stock conditions improve, and a sector stays within its quota while other sectors do not, the sector will receive a temporary increase in share equal to the amount that other sectors exceeded their quota.

Some management provisions that apply to common pool vessels will also apply to any vessel in a sector. This list may be modified through a framework adjustment. Measures that are not included in this list may be altered through a sector's operations plan, if approved by NMFS. These are:

If quotas are allocated to a sector:

- Year round closed areas
- Permitting restrictions (vessel upgrades, etc.)
- Gear restrictions designed to minimize habitat impacts (roller gear restrictions, etc.)
- Reporting requirements (not including DAS reporting requirements)

3.4.16.1.3 VMS Requirements

There is no VMS requirement specific to this alternative; however, if other alternatives must be used in conjunction with the sector allocation alternative, then any VMS requirements under those alternatives will be imposed on the sectors. Sectors may establish their own VMS requirements as long as they remain in compliance with any other VMS requirements established by other alternatives adopted in conjunction with sector allocation.

3.4.16.1.4 Possible Modifications

Changes in the necessary mortality reduction will result in changes of the amount of the resource assigned to each self-selecting sector. This will not impact the process of approving and implementing a sector.

3.4.16.2 Georges Bank Hook Sector

This alternative creates a sector for hook fishermen. The sector is designed for vessels that harvest Georges Bank cod. Participation in the sectors is voluntary; permit holders must elect to participate in the sector. The allocation of resources for each sector will depend on the history of the permit holders that choose to participate. This is not a stand-alone alternative, but is intended to be implemented with one of the other alternatives. Provisions for adjusting TACs if a sector or other vessels exceed a TAC will be as described in section 3.4.16.1.2.2.

Participation in this sector is open to vessels that use jigs, demersal longline, or hand gear to harvest GB cod. Permit holders must declare their intention to participate in the sector at least three months in advance of the beginning of the fishing year. Once declared into the sector, the vessel must remain in the sector for the entire fishing year and must abide by the regulations applicable to the sector for the entire year. If a permit is transferred during the fishing year, the new owner must also comply with the sector regulations for the remainder of the fishing year.

TAC

A GB cod quota (hard TAC) will be allocated to the sector. The sector's share of the overall GB cod TAC will be determined by calculating the share of the GB cod harvest taken by hook gear (sector participants) during fishing years 1996 through 2001. When the TAC is reached, the commercial components of the sector will cease fishing for the remainder of the fishing year.

Management Measures

Management measures will be specified in the sector operations plan.

3.5 Alternatives to Control Capacity

There is a concern that excess fishing capacity in the groundfish industry will slow rebuilding efforts and prevent the economic success of those vessels in the fishery. More DAS and permits are available than are active in the fishery, yet at 2001 used DAS levels – a fraction of the allocated effort – fishing mortality is too high. The proposed action addresses these concerns. See section 9.4.2.5 for additional background on capacity concerns.

3.5.1 Policy on Cooperative Research

The proposed action limits the use of DAS allocated to a permit based on the history of DAS use. The Council's policy is that a vessel will not lose DAS because of documented participation in a research project or experimental fishery. These instances will have to be evaluated by the Regional Administrator on a case-by-case basis. If a permit holder believes that allocation of DAS under Amendment 13 has been limited by the vessel's participation in a research project or experimental fishery, the permit holder should provide NMFS documented proof of the time spent participating in the research project that was not considered for its Amendment 13 DAS authorization. NMFS will review the information and consider adjusting the DAS allocation.

3.5.2 Days-At-Sea Transfer

This alternative allows multispecies limited access permit holders to permanently transfer DAS to other multispecies limited access permit holders, with some restrictions. The objectives of this alternative are to provide greater economic opportunity and flexibility in all fisheries, while maintaining the character of the existing fleet and to achieve some long-term reduction in fishing effort by removing active and inactive DAS from the groundfish fishery.

Rationale: This measure provides a limited opportunity for some consolidation in the groundfish fishery. Transfers are constrained by vessel upgrading restrictions in order to prevent increases in fishing effort from occurring rapidly and to help maintain the character of the fishery. By applying a conservation tax on the transfer of DAS, the proposal will reduce not just the number of vessels in the fishery but will reduce allocated DAS. Vessels transferring their groundfish DAS must leave all federal and state fisheries in order to prevent this program from merely transferring excess harvesting capacity into other fisheries.

3.5.2.1 Measures

All transfers of DAS are limited to multispecies limited access vessels. The LOA or gross registered tonnage of the purchasing vessel may not be more than 10% greater and its horsepower may not be more than 20% greater than the baseline of the selling vessel. The selling vessel is required to retire from all state and federal commercial fisheries. Consistent with the DAS leasing proposal, a history permit cannot transfer its DAS to another vessel.

Rationale: Fishing effort may increase if transfers of DAS take place between vessels of disparate size. This restriction reduces those concerns. Requiring the vessel to leave all state and federal fisheries removes the possibility that reducing effort in this fishery will result in a transfer of that effort into other fisheries.

3.5.2.2 Restrictions

Only those vessels with a history of landing groundfish or another species during the period used to define effective effort (fishing years 1996 through 2001, as defined below) may transfer DAS with a reduction in fishing privileges for the recipient. Transferred active DAS (Category A or B DAS) will be reduced by 40% and inactive (Category C) DAS will be reduced by 90%.

Rationale: By limiting transfers of DAS to vessels that have a history of fishing, the possibility that this proposal will result in a re-activation of latent effort is reduced.

3.5.2.3 Reactivation of DAS – (DAS Use by Permit Buyer)

All DAS acquired by a vessel under this alternative may be used immediately following the transaction.

Rationale: The Council considered phasing in the use of these DAS over time in order to reduce the possibility that unused effort would rapidly enter the fishery under this measure. This provision, however, would make this measure unattractive to fishermen and would hinder its use. The combination of the effective effort baseline (see below) and the limit of these transfers to vessels that were actively fishing reduces the possibility that this action will rapidly introduce unused effort into the fishery.,

3.5.3 Days-At-Sea Reserve

3.5.3.1 Measures

DAS allocated to each permit are divided into three categories. First the number of effective DAS (documented DAS that were used during a baseline period, see section 3.5.3.5.-Defining Effective Effort) is defined for each permit. DAS not defined as effective are called Category C DAS. The effective DAS are divided into Category A and Category B DAS.

Category A DAS: The number of effective DAS that are available for use upon implementation of Amendment 13.
Category B DAS: The number of effective DAS that cannot be used at the implementation of Amendment 13 in order to achieve mortality objectives. These DAS will be further subdivided into "B regular" and "B reserve" DAS, with different restrictions on the use of those DAS.
Category C DAS: Latent days that are equal to the difference between a vessel's documented effective DAS and the Amendment 7 allocated DAS.

Example-- Consider a fleet allocation vessel with 88 DAS in fishing year 2000 and assume that this vessel can document a total of 60 DAS in the call-in system during the baseline period. If the rebuilding program required a 30% reduction in effective DAS the total number of DAS in each category for this vessel would be 42 DAS in Category A, 18 DAS in Category B, and 28 DAS in Category C.

3.5.3.2 Reserve DAS

All Category B and C DAS will be placed in a reserve account for each vessel. DAS in the reserve will be frozen at a fixed amount. Upon implementation of Amendment 13, Category A DAS may be used to fish for any stock of groundfish. Category "B regular" DAS can be used to target healthy stocks, subject to conditions defined through Council action, and Category "B reserve" DAS can only be used in an approved Special Access Program. As rebuilding occurs, Category B DAS may be re-activated from the reserve account first, followed by Category C DAS. All Category B DAS will be restored before any Category C DAS may be released from the reserve. Vessels that have documented activity in the groundfish fishery will restore their DAS before vessels that did not fish during the baseline period.

Rationale: The excess number of DAS available to groundfish complicates management efforts. In recent years, as stocks have started to rebuild, these unused DAS have re-entered the fishery, keeping fishing mortality rates higher than desired. Attempts to reduce overall DAS are complicated by these unused DAS as well, since an across the board reduction penalizes active fishermen more than those who are not currently using their DAS. Understandably, however, many fishermen oppose permanently taking DAS away from any permits, since the permit is not as valuable if it cannot be fished. This program reduces the number of DAS that can be fished on any stock (Category A DAS), while keeping the total number of DAS assigned to a permit at a fixed level. Many of those DAS, however, cannot be used until stocks rebuild, slowing their entry back into the fishery.

3.5.3.3 Conservation Tax on Category C DAS

A conservation tax will be applied to reactivated Category C DAS. The tax rate will depend on resource conditions at the time at which Category C days are withdrawn from the reserve.

3.5.3.4 Reactivation of Category B or C DAS

Whether Category B or C DAS are used in the future and the rate at which they return to use depend on the response of stocks to the management program. The Council may decide in the future to allow the initial reactivation of a portion of Category B and the subsequent reactivation of Category C DAS during the FMP annual adjustment process. Reactivation rates will be determined by the following formula:

Number of Category B or C DAS a permit holder may reactivate =

*(No. of B or C DAS Held) * (Cat. B DAS Allowed to Re-enter / Total No. B or C DAS that exist)*

Example: For a permit holder with 20 Category B DAS where 5,000 Category B are allowed back into the fishery and 50,000 B DAS exist,
*(20) * (5,000 / 50,000) = 2 Category B DAS allowed to renter the fishery.*

3.5.3.5 Defining Effective Effort

Effective effort is defined as the maximum DAS used in any single fishing year from FY 1996 through FY 2001. Qualifying years are only those in which a vessel landed 5,000 pounds or more of regulated groundfish (landings must be documented in the NMFS reporting system).

> *Example (1):* A fleet permit used fifty DAS every year from FY 1995 through 2001, but never landed 5,000 pounds of regulated groundfish in any single year.
>
> Effective effort: 0 DAS
> Category C DAS: 88
>
> *Example (2):* A fleet permit used 88 DAS in FY 1996 to land less than 5,000 pounds of regulated groundfish, and used 50 DAS in FY 2001 to land more than 5,000 pounds of regulated groundfish.
>
> Effective effort: 50 DAS
> Category C DAS: 38 DAS

3.6 Management Measures to Address Rebuilding Requirements

The following measures have been designed to achieve specific fishing mortality reductions described in section 3.2. The needed fishing mortality reductions are based on the selected rebuilding trajectory and/or ending overfishing. Statistical area and thirty minute square charts are provided for reference.

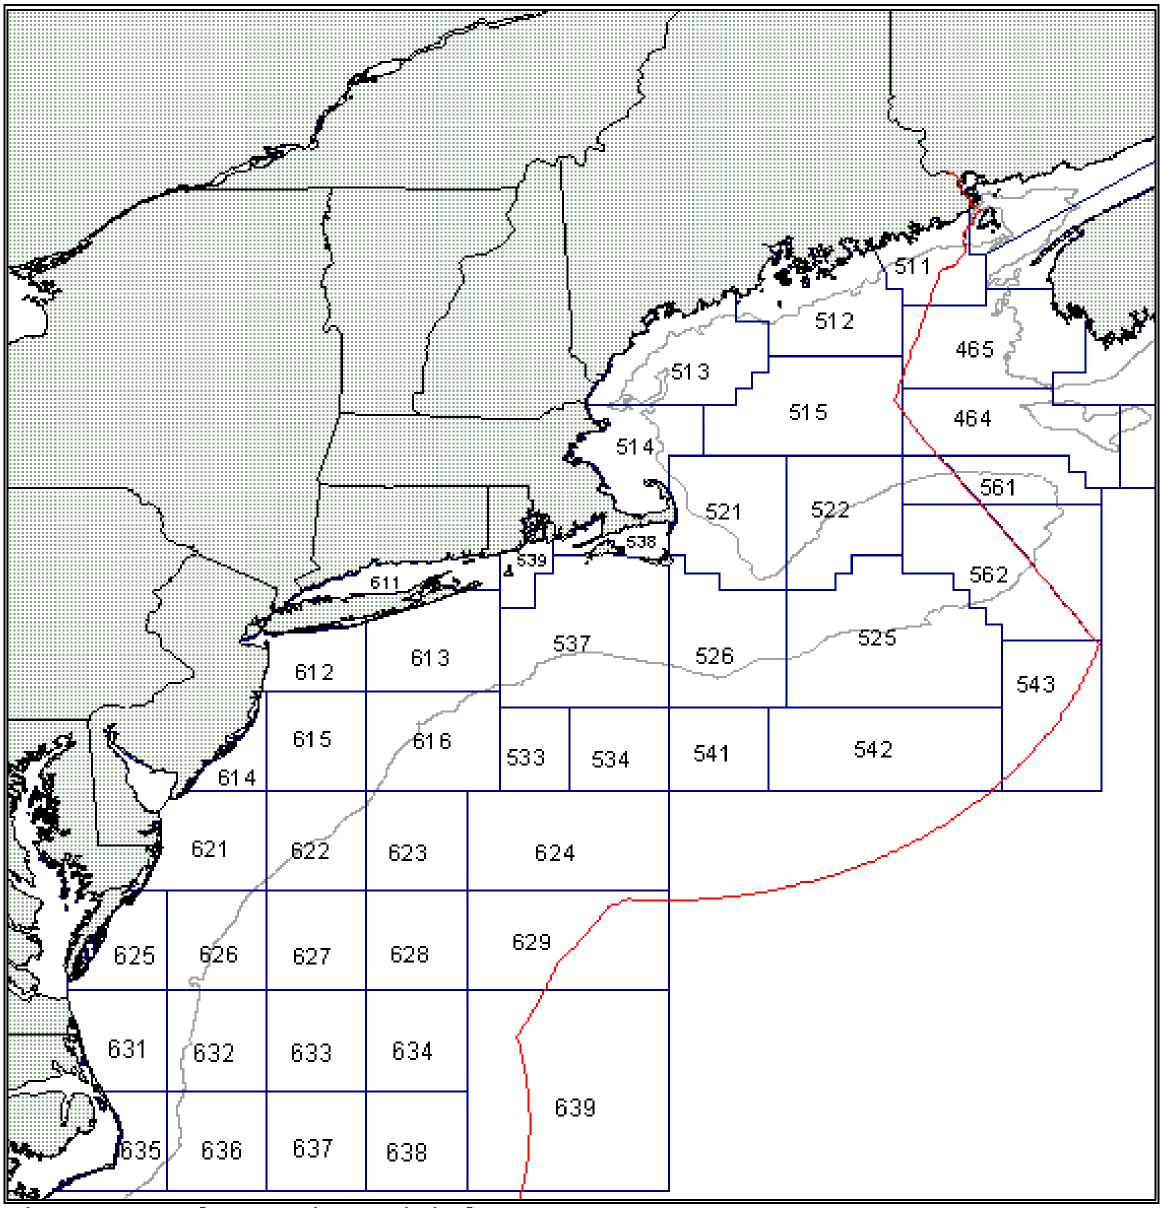

Figure 8 – Northeast region statistical areas

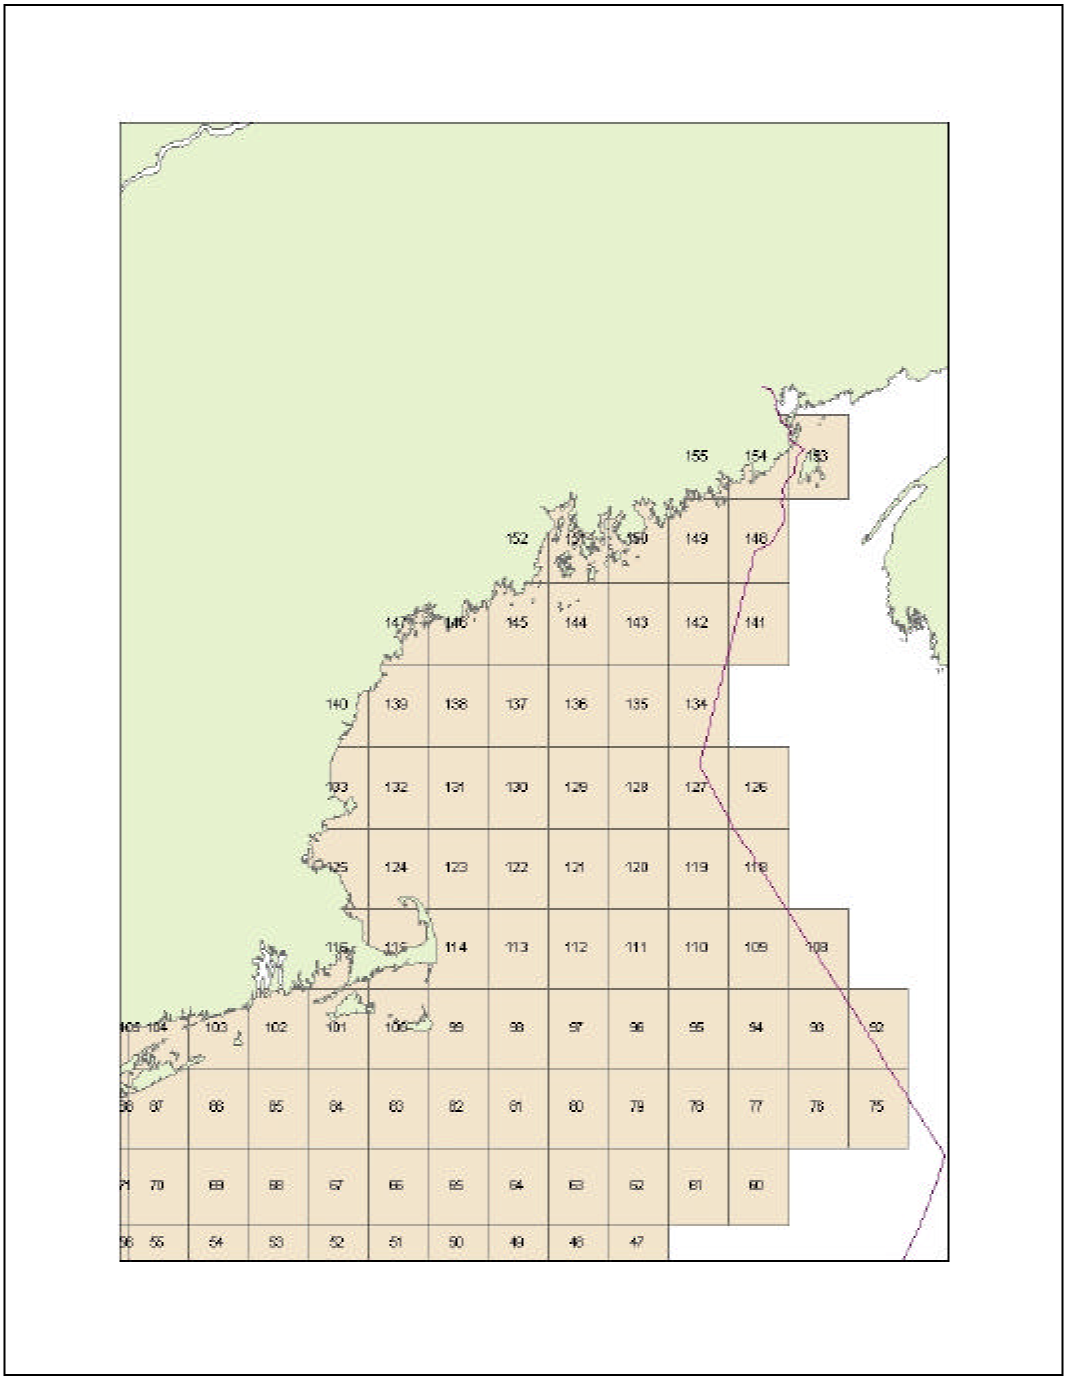

Figure 9 – Thirty minute squares used to describe management areas

3.6.1 Commercial Fishery Management Measures

This proposal adopts management measures to achieve a mix of adaptive and phased reduction rebuilding strategies. In addition, it develops opportunities for fishing on stocks that do not need reductions in fishing mortality. As described in section 3.2, these measures are designed to meet the phased reduction rebuilding strategy for GB cod, CC/GOM yellowtail flounder, SNE/MA yellowtail flounder, American plaice, and white hake. For all other stocks that require a formal rebuilding program, it is designed to achieve the adaptive rebuilding strategy.

The proposed action was developed in response to comments received from the public on the Amendment 13 SEIS, developed through the efforts of the Northeast Seafood Coalition. The action combines several elements contained in the draft:

- The action is designed to achieve a combination of rebuilding trajectories, rather than one trajectory
- The action builds on the categorization of effective effort by defining opportunities for using B DAS
- It addresses a recognized weakness of the initial alternatives - the impact of restrictive measures on catches of stocks in good condition – by creating opportunities to fish on healthy stocks using B DAS.

3.6.1.1 Effort Controls

3.6.1.1.1 DAS Allocations

The DAS reserve program (see section 3.5.3) will be used to categorize DAS into Categories A, B, and C and to define effective effort. The effective effort for each permit will be divided into Category A and Category B DAS according to the following formula:

Category A: 60 percent of effective effort as defined by section 3.5.3
Category B: 40 percent of effective effort as defined by section 3.5.3
Category C: FY 2001 allocation (not including carry-over) less section 3.5.3effective effort

In addition, Category B DAS will be sub-divided:

B(regular) DAS: 20 percent of effective effort as defined by section 3.5.3
B(reserve) DAS: 20 percent of effective effort as defined by section 3.5.3

Example (1): For a fleet DAS permit (88 DAS allocated in FY 2001), that qualifies for 88 days of effective effort under the criteria and qualification period of section 3.5.3:

Option 9 effective effort:		88 DAS
Category A DAS:	60 percent of 88 DAS =	52.8 DAS
Category B (regular) DAS:	20 percent of 88 DAS =	17.6 DAS
Category B (reserve) DAS:	20 percent of 88 DAS =	17.6 DAS
Category C DAS:	88 - 88 =	0 DAS

Example (2): For a fleet DAS permit (88 DAS allocated in FY 2001), that qualifies for 50 days of effective effort under the criteria and qualification period of section 3.5.3:

Option 9 effective effort:		50 DAS
Category A DAS:	60 percent of 50 DAS =	30 DAS
Category B (regular) DAS:	20 percent of 50 DAS =	10 DAS
Category B (reserve) DAS:	20 percent of 50 DAS =	10 DAS
Category C DAS:	88 – 50 =	38 DAS

<u>Rationale</u>: The primary tool for controlling fishing mortality will be through the use of limits on DAS – the time available to be fished. This proposal refines the use of a blunt effort control by limiting the number of DAS that can be fished on any stock, but providing opportunities to use DAS to fish on healthy stocks. The limits on Category A DAS will reduce the number of DAS that are allocate and can be fished on any stock from about 71,000 in fishing year 2003 to about 41,000 in fishing year 2004. Actual DAS use in 2003 is expected to be about 50,000 DAS, and actual use in fishing year 2004 will likely be in the range of 31,000

to 35,000 DAS. This is over a forty percent reduction in fishing effort compared to the fishing year 200/2001 average.

3.6.1.1.2 DAS Use

On implementation of Amendment 13, a vessel can use Category A DAS subject to the management measures listed in following sections. Category A DAS can also be used in an approved Special Access Program.

- Category B DAS can be used to target stocks that do not need a reduction in fishing mortality subject to the following conditions.
  - A vessel must declare its intent to use a Category B DAS at the start of a trip.
  - In addition to restrictions on gear, closed areas, etc. listed below, vessels on a B (regular) day will be subject to stringent trip limits for stocks of concern. These restrictions will be defined in a future management action. Until those restrictions are defined, B (regular) DAS can only be used in an approved Special Access Program.
  - B (reserve) DAS can only be used in an approved Special Access Program
- A vessel can only use a "regular" Category B DAS if it has an equal amount of unused Category A DAS remaining for that fishing year. The number of remaining **regular** Category B DAS eligible for use can not exceed the amount of Category A DAS **remaining** for an individual permit
- If the vessel exceeds the stringent trip limits for a stock of concern, the operator can change the designation of the trip to a Category A DAS trip and retain the possession limit for that species that is authorized under a Category A DAS. This is referred to as "flipping" a DAS. A vessel cannot "flip" a B regular DAS if fishing in an approved Special Access Program.

The following Special Access Programs will be developed:

- Georges Bank Yellowtail Flounder in CA II (see section 3.4.5.3.1)
- Georges Bank Haddock in Closed Area II (see section 3.4.5.3.3)
- Georges Bank Haddock in Closed Area I (see section 3.4.5.3.4)
- Gulf of Maine haddock in the WGOM Closed Area (to be developed)
- Cashes Ledge Closed Area (to be developed)

Rationale: By creating opportunities for the use of Category B DAS, this measure may help direct effort onto healthy stocks. This will help to mitigate the economic impacts of the restrictions on the use of Category A DAS. Once conditions are specified for the use of Category B (regular) DAS,

3.6.1.1.3 Re-classification of DAS

As stocks recover, there may be opportunities to increase the number of available Category A DAS. All Category B DAS will be converted to Category A DAS before any Category C DAS are converted to Category A DAS. If necessary to achieve rebuilding targets, Category A DAS may be changed to Category B (regular) DAS.

Rationale: This measure creates a mechanism to shift effort to stocks that can support additional fishing pressure – either as a result of successful rebuilding efforts, or to facilitate additional rebuilding. The restriction on Category C DAS is to provide active participants the ability to return to fishing at 1996 through 2001 levels before other fishermen are allowed to target groundfish.

3.6.1.2 Management Measures

All management measures adopted by the negotiated settlement agreement among certain parties as implemented August 1, 2003 are maintained unless changed (see following sections) . These measures are not repeated here, but can be found in 50 CFR 648 Subpart F.

3.6.1.3 Closed Areas

3.6.1.3.1 Year Round Closed Areas

The current Closed Area I, Closed Area II, Western Gulf of Maine, Cashes Ledge, and Nantucket Lightship Closed Areas will be continued as year round closed areas. See section 3.7.3 for additional areas that are prohibited to mobile bottom tending gear in order to minimize to the extent practicable the adverse effects of fishing activity on essential fish habitat.

Rationale: The existing year round closed areas have proven beneficial to the rebuilding of several stocks. Parts of these areas also provide important habitat benefits. The year round Cashes Ledge closed area was not in place in fishing year 2001. This closed area should help expand the range of cod in the GOM.

3.6.1.3.2 Seasonal Closed Areas

The seasonal closed areas are:

March:	121, 122, 123
April:	121-125; 129-133;
May:	124- 125; 129-133; 136-140; 80 – 81; 98-99; 109-114; 118-120 south of 42°20'N
June:	132-133; 139-140; 141-147; 152
October:	124-125
November:	124-125

Rationale: This measures reduces the number of months that seasonal closed areas are in effect, while expanding the GB closed area during the month of May. This will provide additional protection to GB cod. Reducing the number of months of closures in the GOM will help provide more opportunities for fishermen to effectively use their limited number of available DAS.

3.6.1.4 Possession Limits

Category A DAS

GOM cod: 800 lbs/DAS / 4,000 lbs/trip.

GB cod: 1,000 lbs/DAS/10,000 lbs/trip for trawl and gillnet vessels

For hook vessels:

- July 1 – September 15: Jig and commercial longline directed cod season. 2,000 lbs limit. No groundfish landings on Friday and Saturday.
- September 16 – December 31: Restricted cod season. 600 lbs/DAS
- January through March: Jig and demersal longline fishing. 2,000 lbs
- April, May, June: no jig or demersal longline groundfish fishing on Georges Bank
- In order to use this seasonal hook gear trip limit, vessels must make an annual declaration for using hook gear.

CC/GOM yellowtail flounder: April/May and October/November : 250 pound possession limit
June 1 – September 30 and December 1 – March 31: 750 lbs. per DAS/3,000 lbs. per trip possession limit

SNE/MA yellowtail flounder: March 1 – June 30: 250 pound possession limit;
June 1 – February 28: 750 lbs. per DAS/ 3,000 lbs per trip possession limit

Category B (regular) DAS
To be developed through a future framework action.

Rationale: The increase in the GOM cod trip limit will reduce regulatory discards of this stock and make each DAS more profitable for fishermen. It may also help reduce fishing effort on plaice, yellowtail flounder, and other flatfish, as fishermen may not harvest those stocks in as large a quantity because of the revenue generated from GOM cod. The GB cod trip limit reduction helps reduce mortality on this stock, and has been selected so as to minimize the possibility that it will increase regulatory discards. The yellowtail flounder trip limits are adopted to reduce mortality on these two stocks. They are seasonal in order to shift effort away from aggregations of flounders.

3.6.1.5 Gear Restrictions

The gear restrictions implemented August 1, 2002 are continued with the following modifications (see Table 27 for details)

- Changes to the number of gillnets that can be used by trip gillnet vessels on Georges Bank
- Changes to the number of gillnets in the SNE/MA area
- Changes in restrictions on the use of gillnets in the GOM

Rationale: This action continues many of the gear restrictions adopted under the FW 33 settlement agreement. Compared to the regulations in place in FY 2001, there is an overall increase in mesh size for both trawl and gillnet gear. This is intended to change the selection pattern of the fishery to target larger fish, providing more opportunities for fish to spawn before being selected by the fishery. The number of gillnets that can be fished are also reduced, both to limit effort/mortality on stocks targeted by these fisheries and to reduce the likelihood that the trip limits will result in discards from this sector. Compared to the FW 33 settlement agreement, the number of trip gillnets allowed in both the GOM and GB are the same, removing what some perceived as an unfair, unwarranted restriction. The minimum hook size and requirement to use a circle hook are intended to both reduce the catch of small fish and improve their survivability in the hook fishery. Limits on the number of hooks are intended to reduce overall effort by the hook fishery.

3.6.1.6 Minimum Fish Sizes

The minimum fish sizes implemented August 1, 2002 are retained (cod minimum size increased to 22 inches) (see below).

Species	Size (Inches, Total Length)
Cod	22 (55.9 cm)
Haddock	19 (48.3 cm)
Pollock	19 (48.3 cm)
Witch flounder (gray sole)	14 (35.6 cm)
Yellowtail flounder	13 (33.0 cm)
American plaice (dab)	14 (35.6 cm)
Atlantic halibut	36 (91.4 cm)
Winter flounder (blackback)	12 (30.5 cm)
Redfish	9 (22.9 cm)

Rationale: Compared to the no action alternative, this proposal will adopt and increased minimum size for cod. This is to provide additional protection to rebuilding cod stocks, particularly on GB.

3.6.1.7 Default Measures

The combined rebuilding strategy proposed requires that fishing mortality for several stocks decline in future years, according to the schedule shown in Table 10. Default measures are defined in order to accomplish these reductions. The default measures are designed to reduce mortality on specific stocks, though in some instances they can be expected to reduce mortality for other stocks as well. Unless they are modified by a future Council action, the default measures shown in the following table (Table 13) will be implemented unless:

(1) The targeted stock(s) is(are) projected to be at the target biomass with at least a median probability in the year the measures are to be implemented and overfishing is not occurring on those stocks, or
(2) Biomass estimates show rebuilding is on track and the best available estimate of the fishing mortality rate for the targeted stock(s) meets the fishing mortality rate for the rebuilding program as specified in Table 10, or
(3) Overfishing is not occurring and the best available estimate of the fishing mortality rate for the targeted stock(s) is projected to rebuild the stock with at least a median probability by the end of the rebuilding period.

In addition to the above three conditions for the stocks targeted by the default measure, all other stocks must meet the fishing mortality rates specified in Table 10 for the default measures to be deferred.

Fishing Year Implemented	Stocks Targeted	Default Measure
2006	American Plaice SNE/MA Yellowtail Flounder	DAS Category A/B ratio: 55/45 Differential DAS counting in the SNE/MA RMA at a rate of 1.5:1
2009	GB Cod GOM Cod CC/GOM Yellowtail Flounder SNE/MA Yellowtail Flounder American Plaice White Hake SNE/MA Winter Flounder	DAS Category A/B Ratio: 45/55

Table 13 – Proposed default measures to meet rebuilding program fishing mortality rates

Rationale: The proposed measures implement a combination of adaptive and phased rebuilding strategies. These strategies call for reductions in fishing mortality in future years. Default measures are included in the amendment that target the necessary reductions. These defaults are based on the use of DAS as the primary mortality control. The change in the categorization of DAS will reduce the number of DAS that can be fished on stocks that need reduced mortality. It may be possible to identify other measures that will be as effective, but these will need to be adopted in a future Council action.

3.6.1.8 VMS Requirements

There is no VMS requirement automatically implemented by this alternative. The current call-in system and voluntary VMS will be maintained. Section 3.4.14.2 describes changes to vessel reporting requirements that will be adopted by this amendment.

	GOM	GB	SNE	Mid-Atl
MINIMUM MESH SIZE RESTRICTIONS FOR GILLNET GEAR				
NE Multispecies Day Gillnet Category*	Roundfish nets 6.5" (16.5 cm) mesh; 50-net allowance	All nets 6.5" (16.5 cm) mesh; 50-net allowance	All nets 6.5" (16.5 cm) mesh; 75-net allowance	Roundfish nets 6.5" (16.5 cm) mesh; 75-net allowance
	Flatfish nets 6.5" (16.5 cm) mesh; 100-net allowance			Flatfish nets 6.5" (16.5 cm) mesh; 75-net allowance
NE Multispecies Trip Gillnet Category*	All nets 6.5" (16.5 cm) mesh; 150-net allowance	All nets 6.5" (16.5 cm) mesh; 150-net allowance	All nets 6.5" (16.5 cm) mesh; 75-net allowance	All gillnet gear 6.5" (16.5 cm) mesh; 75-net allowance
Monkfish Vessels**	10" (25.4 cm) mesh/150-net allowance			
MINIMUM MESH SIZE RESTRICTIONS FOR TRAWL GEAR				
Codend only mesh size*	6.5" (16.5 cm) diamond or square		7.0" (17.8 cm) diamond or 6.5" (16.5 cm) square	6.5" (16.5 cm) diamond or square
Large Mesh Category - entire net	8.5" (21.59 cm) diamond or square			7.5" (19.0 cm) diamond or 8.0" (20.3 cm) square
MAXIUM NUMBER OF HOOKS AND SIZE RESTRICTIONS FOR HOOK-GEAR* **				
Limited access multispecies vessels	2,000 hooks	3,600 hooks	2,000 hooks	4,500 hooks (Hook-gear vessels only)
	No less than 6" (15.2 cm) spacing allowed between the fairlead rollers			
	12/0 circle hooks required for longline gear			N/A

* When fishing under a NE multispecies DAS
** Monkfish Category C and D vessels when fishing under a monkfish DAS
*** When fishing under a NE multispecies DAS or when fishing under the Small-vessel permit

Table 14 – Proposed gear requirements

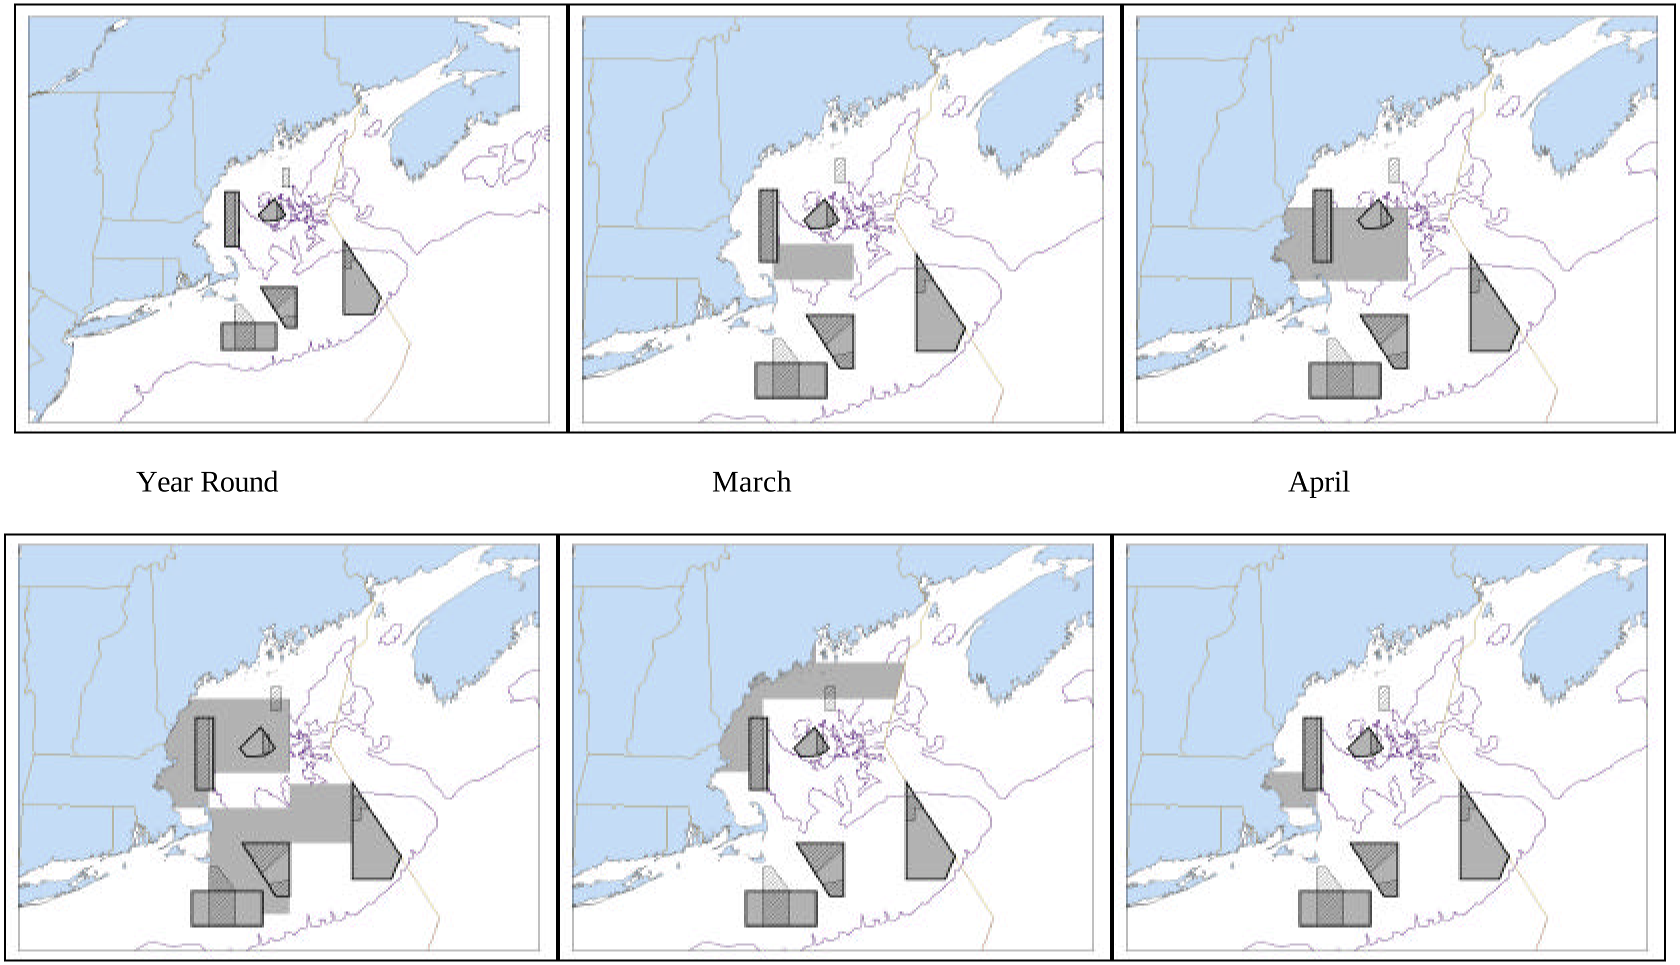

Figure 10 – Proposed action year round and seasonal closed areas. Level 3 habitat areas are cross hatched.

3.6.2 Recreational Fishery Management Measures

Bag limit for all private recreational vessels:	10 cod/person day
Bag limit for party/charter vessels fishing in the Gulf of Maine:	10 cod/person/day

(Note there is no bag limit for haddock).

For the purposes of recreational and party/charter fishing vessels, any trip in excess of 15 hours **and** covering two consecutive calendar days will be considered more than one day. A similar standard will be applied to longer trips (i.e. a trip in excess of thirty-nine hours and covering three consecutive calendar days will be considered more than two days).

Minimum cod size:	22 inches
Minimum haddock size:	19 inches

All other measures in place during fishing year 2001 continue to apply.

Rationale: These proposed measures are designed to reduce recreational harvest of GOM cod by imposing a bag limit on party/charter fishing in the Gulf of Maine. As discussed in section 9.4.3, this sector is a major component of this fishery that under the no action alternative was not subject to any limit on the number of cod caught. By imposing a bag limit, this sector will contribute to rebuilding GOM cod. At the same time, the limit is set at a level which will allow these vessels to attract passengers and remain in business. Recreational fishermen will no longer be subject to a bag limit for haddock. The M-S Act requires that all sectors share in the benefits of stock recovery. The removal of the bag limit for haddock will enable recreational fishing vessels to benefit from the rebuilding of this stock.

3.6.2.1 Possible Modifications

Significant changes in the fishing mortality reduction for GOM cod could result in changes to the recreational fishing measures.

3.7 Alternatives to Minimize the Adverse Effects of Fishing on Essential Fish Habitat

The 1996 Amendments to the MSA require that FMPs minimize, to the extent practicable, adverse effects on EFH caused by fishing (MSA section 303(a)(7)). Additionally, based on the federal court order regarding the National Environmental Policy Act (NEPA) requirements of the Council's Omnibus EFH Amendment (AOC v. Daley, September 14, 2000), the following is a list of proposed habitat-related management measures, which are included in the supplemental environmental impact statement (SEIS) prepared for Amendment 13 to the Multispecies FMP. The actions included in this amendment represent some of those received by NMFS and the Council during scoping for Amendment 13, as well as other alternatives developed in an effort to assist the Council comply with the AOC v. Daley court order.

3.7.1 Benefits to Essential Fish Habitat of Other Amendment 13 Alternatives (Alternative 2)

Some of the non-habitat-related management measures in Amendment 13 are likely to provide benefits to essential fish habitat in the region. This alternative will rely on the habitat benefits of other non-habitat management measures that are implemented in Amendment 13 to meet the EFH provisions of the MSA. Depending on which measures are adopted, those benefits may or may not satisfy the EFH provisions of the MSA. Table 15 summarizes the expected habitat benefits of the proposed non-habitat management measures that are being considered by the Council in Amendment 13.

3.7.2 Expand list of gears prohibited in closed areas (Alternative 7)

This alternative will expand the list of fishing gears prohibited from use in the year-round closed areas to include clam dredges. This gear is allowed in portions of the existing groundfish closed areas and, due to their impacts, excluding their use may better protect essential fish habitat.

Alternative	Overall Habitat Impact	Feature	Description of Habitat Impact
US/Canada Resource Sharing Agreement	Negative Impact (-)	Adoption of understanding with hard TACs for cod, haddock, and yellowtail flounder with incentives for participation	This area is primarily sand and gravelly sand. About half of this relatively small access area is deep undisturbed bottom with a high cover of emergent epifauna (Collie et al., 2000).
Observer Coverage	Indirect benefits (+)	10% requested by 2006 for each gear type	If observers are able to collect data of interest to EFH management, increased coverage could indirectly benefit habitat.
Alternatives to Control Capacity	Positive Impact (+)	DAS can be transferred with restrictions and new measures for "reserve days"	Any measure that is intended to reduce the amount of time fishing by mobile gear will likely have benefits to EFH. These measures reduce amount of latent effort as well.
Management Measures to Address Rebuilding Requirements	Overall Positive Impact (+)	Mix of adaptive and phased reduction strategies. Provides opportunity to fish on stocks that do not need rebuilding	The effort reductions, year-round closed areas, and existing gear modifications are likely to have positive impacts on EFH.
Effort Controls	Positive Impact (+)	A days (60% of effective effort) B days (40% of effective effort) C days (FY01 allocation)	Reducing DAS will likely benefit EFH by reducing the amount of time vessels can fish. There are studies that document the recovery of benthic habitats following the cessation of bottom fishing.
Closed Areas	Positive Impact (+)	Addition of Cashes as a year round closure	Year-round closures provide habitat benefits to the areas within the closures. The addition of Cashes Ledge as a year-round closure will benefit the EFH and rare kelp beds found in that area.

Table 15 – Summary of the potential habitat benefits of non-habitat measures proposed in Amendment 13.
Note: Seasonal (rolling) closures, possession limits, and hard TACs that are included in a number of proposed management measures are not considered to provide any significant habitat benefits. Habitat benefits identified above apply primarily to bottom trawls, not to fixed gear such as hooks and gill nets

3.7.3 Habitat Alternative 10, Option (b) – Compromise Habitat Closure Areas

The Council selected Habitat Alternative 10, Option (b) to implement under Amendment 13 to the Northeast Multispecies FMP to minimize the adverse impacts of fishing as demonstrated in the Adverse Impact Determination section.

This action identifies several areas as habitat closures. These areas are a Level III habitat closure, with one exception, shrimp trawls are allowed in the WGOM closed area (see the description of Levels for habitat closures in Section 3.7.4). This alternative was developed to incorporate areas that would benefit EFH, but not in the most productive fishing grounds currently available to fishermen. Both existing mortality closures and proposed habitat closures were modified to develop one alternative that closes sensitive habitat. It is important to note that these modifications are for habitat closures only; none of the habitat alternatives adjust boundaries of groundfish mortality closed areas. In general, the alternatives suggest changing the eastern boundary of the Western Gulf of Maine closure for habitat purposes, and modifying the Nantucket Lightship closure for habitat purposes. In addition, the access areas used in

Framework 13 for Closed Area I were modified slightly as habitat closed areas. Lastly, the habitat closure proposals for Closed Area II, Jeffrey's, Bank, and Cashes Ledge were included in this alternative, with some modifications.

These modifications were suggested for different reasons. Specifically, the boundaries within Closed Area I for the FW13 access program were modified to protect better spawning grounds for Cod (open area shifted to the South). The proposed habitat closure for the Western Gulf of Maine (in Alternatives 3a, 3b, and 4) was modified to include the complex bottom that is found along the western border of the closure. The areas on Cashes Ledge and Jeffrey's Ledge that have been proposed for habitat closures in Habitat Alternatives 3a, 3b, and 4 were recommended as well, with a modification to the southern boundary of the Cashes habitat closure. This recommendation was primarily for enforcement reasons, and this area is deeper, so does not contain the rare kelp beds that are contained on Cashes Ledge. The modification to the Nantucket Lightship closure was recommended to include more complex bottom and small fish that are found north of the existing boundaries, rather than the areas in the western and eastern portion of the closure. Overall, the main intent of this alternative is to protect EFH through long term closed areas, but at the same time it recognizes that access to primary fishing grounds is important as well.

Detailed justification of each closed area modification:

<u>Closed Area I (CAI)</u> - According to industry, Closed Area I is very beneficial for rebuilding haddock and may be the primary reason haddock are recovering today. However, CAI does not provide much benefit for cod. Much of CAI is sand, however, there are diverse sediment types scattered within the area. The southeastern portion of CAI was contains the much of the complex bottom in the closed area. The northern part of the Framework 13 scallop access area in the middle of CAI has important habitat for cod spawning. As such, the Framework 13 scallop access area was shifted southward so that the cod could gain protection in the north for spawning, and the scallop resource would be accessible in the closed area. Both option (a) and (b) include the modified version of the Closed Area I as a habitat closure.

<u>Closed Area II (CAII)</u> – The habitat closed area was defined as the boundaries of the existing cod HAPC. From Amendment 11 to the Northeast Multispecies FMP, the following justification was provided for the designation of the existing cod HAPC:

"Several sources document the importance of gravel/cobble substrate to the survival of newly settled juvenile cod (Lough et al. 1989; Valentine and Lough 1991; Gotceitas and Brown 1993; Tupper and Boutilier 1995; Valentine and Schmuck 1995). A substrate of gravel or cobble allows sufficient space for newly settled juvenile cod to find shelter and avoid predation (Lough et al. 1989; Valentine and Lough 1991; Gotceitas and Brown 1993; Tupper and Boutilier 1995; Valentine and Schmuck 1995). Particular life history stages or transitions are sometimes considered "ecological bottlenecks" if there are extremely high levels of mortality associated with the life history stage or transition. Extremely high mortality rates attendant to post-settlement juvenile cod are attributed to high levels of predation (Tupper and Boutilier 1995). Increasing the availability of suitable habitat for post-settlement juvenile cod could ease the bottleneck, increasing juvenile survivorship and recruitment into the fishery. For these reasons, areas with a gravel/cobble substrate meet the first criterion for habitat areas of particular concern.

Specific areas on the northern edge of Georges Bank have been extensively studied and identified as important areas for the survival of juvenile cod (Lough et al. 1989; Valentine and Lough 1991; Valentine and Schmuck 1995). These studies provide reliable information on the location of the areas most important to juvenile cod and the type of substrate found in those areas. These areas have also been studied to determine the effects of bottom fishing on the benthic megafauna (Collie et al. 1996; Collie et al. 1997). Gravel/cobble substrates not subject to fishing pressure support thick colonies of emergent epifauna, but bottom fishing, especially scallop dredging, reduces habitat complexity and removes much *of the emergent epifauna (Collie et al. 1996; Collie et al. 1997). Acknowledging that a single tow of a dredge across pristine habitat will have few long-term effects, Collie et al. (1997) focus on the cumulative effects and intensity of trawling and dredging as responsible for potential long-term changes in benthic communities. For these reasons, the identified area on the northern edge of Georges Bank meets the second criterion, as well as the cumulative effects consideration, for designation as a habitat area of particular concern.*

Collie et al. (1997) also describe the relative abundance of several other species such as shrimps, polychaetes, brittle stars, and mussels in the undisturbed sites. These species are found in association with the emergent epifauna (bryozoans, hydroids, worm tubes) prevalent in the undisturbed areas. Several studies of the food habits of juvenile cod identify these associated species as important prey items (Hacunda 1981; Lilly and Parsons 1991; Witman and Sebens 1992; Casas and Paz 1994; NEFSC 1998). These areas provide two important ecological functions for post-settlement juvenile cod relative to other areas: increased survivability and readily available prey. These areas are also particularly vulnerable to adverse impacts from mobile fishing gear."

Western Gulf of Maine Closed Area (WGOM) **-** The new boundaries proposed in some of the habitat alternatives seem hard to enforce, and the industry would not gain much from the areas that would open. Modify the proposed habitat closure for the WGOM by the eastern boundary to come straight down the 70°W line instead of the irregular boundary proposed in habitat alternatives 3a, 3b, and 4. The main rationale behind this modification is that the closed area would be easier to enforce and there are resources in the eastern portion of the closure that should be available to fishermen. Furthermore, the important areas for habitat are along the western boundary. If all the deep areas are closed to fishing then there is no where to go to avoid cod bycatch. It was also pointed out that this area is close to Gloucester, and this port depends on this area heavily. Both option (a) and (b) include the modified version of the WGOM as a habitat closure. The shrimp season has been short in recent years: 1998-1999 (40 DAS), 2000-2001 (61 DAS), 2001-2002 (25 DAS), 2002-2003 (38 DAS). Therefore, the extent and duration of the impact to EFH from shrimp trawling is minimal.

Nantucket Lightship Closed Area (NLCA) **-** Anecdotally, the substrate in the Nantucket Shoals is very complex. As such, this area has diverse sediment types and is important for the protection of small fish. An extension of the area north of the Nantucket Lightship would be closed primarily to protect the habitats on which small fish depend. A benthos map completed roughly in the 1960s showed that most of the concentrations of benthos in this area were contained in the central portion of the Nantucket Lightship area. Although this area is mostly sand, it contains many species. The modifications to include the central portion and an extension to the north contain a diversity of sediments and species. Both option (a) and (b) include the modified version of the NLCA as a habitat closure.

Cashes Ledge Closed Area - the closure should be modified to the 42°45W line. The southern boundary should be moved up, because the deeper area to the south does not contain kelp and should be assessable for fishing. Both option (a) and (b) include the modified version of the Cashes Ledge Closure as a habitat closure.

Jeffreys Ledge Closed Area - Both option (a) and (b) include the version contained in Alternative 3 (a) and (b) of the Jeffrey's Ledge Closed Area as a habitat closure.

Figure 11 Proposed habitat closures (Alternative 10b)

3.7.4 Options for Levels of Habitat Area Closure

Four levels of Habitat Closures were approved by the Council as a basis for determining appropriate gear types for habitat closure areas. These levels apply to the closed area alternatives that follow. It is possible that a closure level could be applied to all closed areas, or that closure levels be assigned specifically to each habitat closed area. Bottom tending mobile gear is defined as the following gears: hydraulic clam dredges, quahog dredge, scallop dredge, otter trawls (shrimp, scallop, fish, crab), beam trawls, sea urchin dredges and Danish/Scottish seines. Bottom tending static gear is defined as the following gears: lobster pots, fish pots, crab pots, sink and stake gillnets, and bottom longlines.

Level 1 Habitat Closure: The area will be closed indefinitely on a year round basis to all fishing gear.

This is the most restrictive option. This level would essentially establish a no-take marine protected area and would prohibit the use of all types of fishing gear in these closures. This level of closure would close the area to all fishing gear, both commercial and recreational.

Level 2 Habitat Closure: The area will be closed indefinitely on a year round basis to all bottom tending gear (static and mobile).

This option is slightly less restrictive than the Level 1 closure because it allows non-bottom-tending gear to operate in the habitat closures. Because is does prohibit all bottom tending gear, it will protect EFH for benthic species and life stages to the same degree as a Level 1 closure. The differences between Level 1 and Level 2 closures are primarily social and economic. Refer to Section **9.3.1.2** for a discussion of the impacts of both mobile and static gear on benthic habitats.

Level 3 Habitat Closure: The area will be closed indefinitely on a year round basis to all bottom tending mobile gear.

This level of closure is less restrictive because it allows static bottom tending gear to operate in these closures, but prohibits bottom tending mobile gears. Although less restrictive than Levels 1 and 2, the effects of this level of closure on benthic habitats do not differ significantly from the effects of Level 1 or 2 closures since static gear is generally considered to have minimal adverse impacts on benthic habitat (see section **9.3.1.2**).

Level 4 Habitat Closure: The area will be open indefinitely on a year round basis only to gear defined as "reduced impact" gear.

Currently there are no reduced impact gear types defined by the Council. The identification of "reduced impact gear" would begin by first defining the ecological function served by the closure, with the advice from the Habitat Technical Team.

The analysis of this option is difficult because it requires knowledge of the individual ecological functions or features that the Council intends to protect. It is feasible that a Level 4 closure could apply to subsets of habitat closures depending on the intention of the closure. The implementation of this option will require a scientific and technical review procedure that includes, at a minimum, the Habitat Committee and the EFH Technical Team. If this level of closure is recommended, a process similar to the Council's HAPC designation process (See the Council's Habitat Annual Review and Report of 2000 for details) is recommended.

Summary of Level of Closures:

Because the effects of fishing on benthic habitats are caused primarily by mobile bottom-tending gears (bottom trawls and dredges), much less so by static bottom-tending gear (*e.g.*, pots, bottom longlines and gill nets), and not at all by pelagic gears (*e.g.*, mid-water trawls), the habitat metric analyses performed in this amendment/DEIS would apply equally well to Level 1 and Level 2 closures and nearly as well to Level 3 closures. Analysis of Level 4 closures would have to be tailored to the effects of specific "reduced impact" gears on specific habitat types. Economic and social impact assessments that were performed as part of the Practicability Analysis (Section 5.6), as well as assessments of enforcement feasibility and cumulative impacts were conducted for Level 1 and Level 3 closures in order to better distinguish between the impacts of these two closure levels.

None of the proposed habitat closures in this amendment specify which gear types would be prohibited. The Council will make those determinations when it decides whether an area closure is needed in order to minimize the adverse impacts of groundfish fishing on EFH. In implementing a habitat closed area alternative, the Council could prohibit the use of mobile, bottom-tending gear types while allowing the use of pelagic gears (Level 2) or pelagic and fixed bottom-tending gear (Level 3) based on practicability issues. If future closure alternatives are proposed for reasons other than the minimization of fishing impacts identified in this document (e.g. research areas, coral protection, etc.), other closure levels may be appropriate.

3.8 Other Issues

3.8.1 Elimination of the Area Restriction for the Northern Shrimp Fishery

The northern shrimp fishery will no longer be restricted to the area shoreward of the small mesh fishery exemption line by the Northeast Multispecies FMP. All other restrictions (for example, the requirement to use a Nordmore grate, restrictions on incidental catch, prohibition on fishing in some year round closed areas, etc.) remain in effect. The small mesh fishery exemption line will be retained in the regulations because it is used for other reasons, but it will no longer apply to the northern shrimp fishery.

Small Mesh Northern Shrimp Fishery Exemption Area

Point	N. Lat.	W. Long.
SM1	41º 35’	70º 00’
SM2	41º 35’	69º 40’
SM3	42º 49.5’	69º 40’
SM4	43º 12’	69º 00’
SM5	43º 41’	68º 00’
G2	43º 58’	67º 22’; (the U.S.-Canada maritime Boundary).
G1	Northward along the irregular U.S.-Canada maritime boundary to the shoreline.	

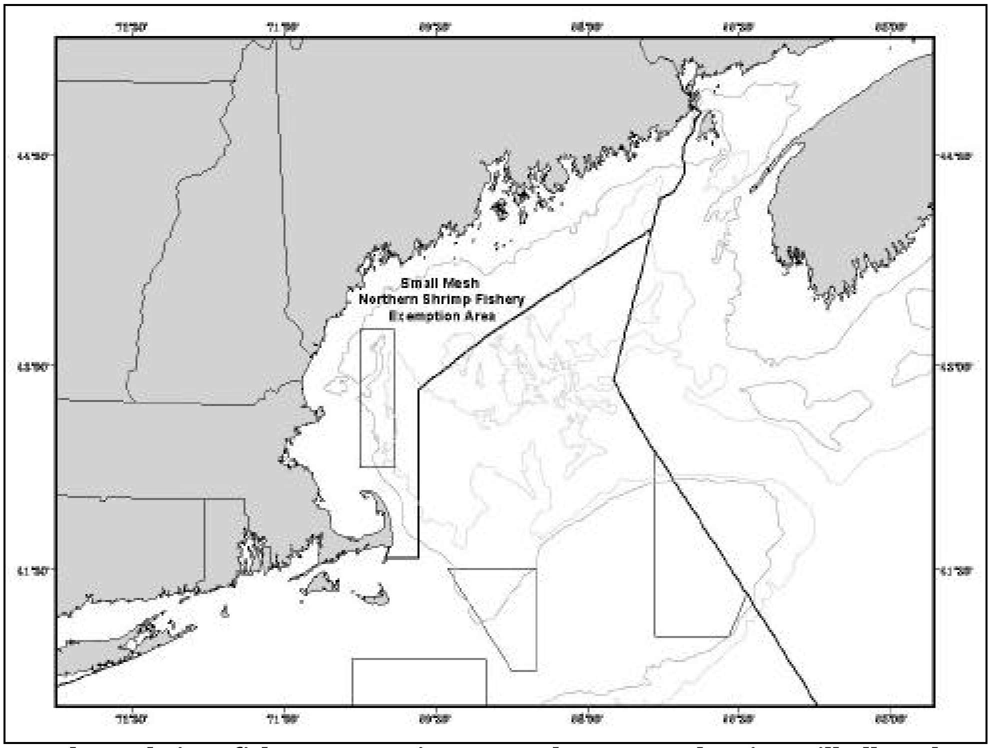

Figure 12 – Northern shrimp fishery exemption area. The proposed action will allow the northern shrimp fishery to take place in all areas.

Discussion: Based on the results of an experimental fishery conducted by the Maine Department of Marine Resources, this option expands the area authorized for the northern shrimp fishery. It provides increased opportunities for shrimp fishermen, while reflecting the results of the experiment that demonstrate that the fishery will not increase the bycatch of regulated groundfish to an unacceptable level. This option removes area restrictions for this fishery that are imposed because of concerns over regulated groundfish bycatch.

3.8.2 Tuna Purse Seine Vessel Access to Groundfish Closed Areas

Tuna purse seine gear is defined as an exempted gear for the purposes of the Northeast Multispecies FMP. Tuna purse seine vessels will be allowed into all groundfish closed areas, subject only to the normal restrictions for using an exempted gear in the area.

- Fishing for, landing or retaining all multispecies (including non-regulated and small mesh multispecies) is prohibited.
- Vessels may not have on board gear capable of catching multispecies.
- Vessels may not fish in the Closed Area II Habitat Area of Particular Concern (HAPC).
- If the Regional Administrator determines that tuna purse seine vessels are adversely affecting habitat or groundfish stocks, individual vessels, or all vessels, may be prohibited from a closed area or areas.

Rationale: This action provides the greatest flexibility to tuna purse seine vessels with minimal restrictions. The Council recognizes that part of a purse seine net uses mesh smaller than the current groundfish regulated mesh size and presumably could retain groundfish, creating an apparent conflict with the prohibition of having gear on board capable of catching multispecies. Purse seine gear, however, is defined as exempted gear under the multispecies regulations and therefore this part of the net is not to be construed as a reason for prohibiting the use of purse seine gear in the closed areas.

3.8.3 SNE General Category Scallop Vessel Exemption Program

Unless otherwise prohibited in §50 CFR 648.81, vessels with a limited access scallop permit that have declared out of the DAS program as specified in §50 CFR 648.10, or that have used up their DAS allocations, and vessels issued a general scallop permit, may fish in the statistical areas 537, 538, 539, and 613 – defined as the Southern New England General Category Scallop Exemption Area - when not under a NE multispecies DAS, providing the vessel complies with the requirements specified below.

- A vessel fishing in the area (defined above) may not fish for, possess on board, or land any species of fish other than Atlantic sea scallops.
- The combined dredge width in use by or in possession on board vessels fishing in the SNE General Category Scallop Vessel Exemption Area shall not exceed 10.5 ft (3.2 m), measured at the widest point in the bail of the dredge.
- Dredges must use a minimum of an eight-inch twine top to minimize groundfish bycatch.
- The exemption does not apply to the Nantucket Lightship Closed Area unless specifically authorized access through the Groundfish FMP.

Rationale: This proposal removes a groundfish plan restriction that prevented general category scallop vessels from fishing in this area because of concerns over groundfish bycatch. This proposed action does not affect any measures adopted in the Scallop FMP to manage this fishery, with the exception of limiting dredge size and twine tops.

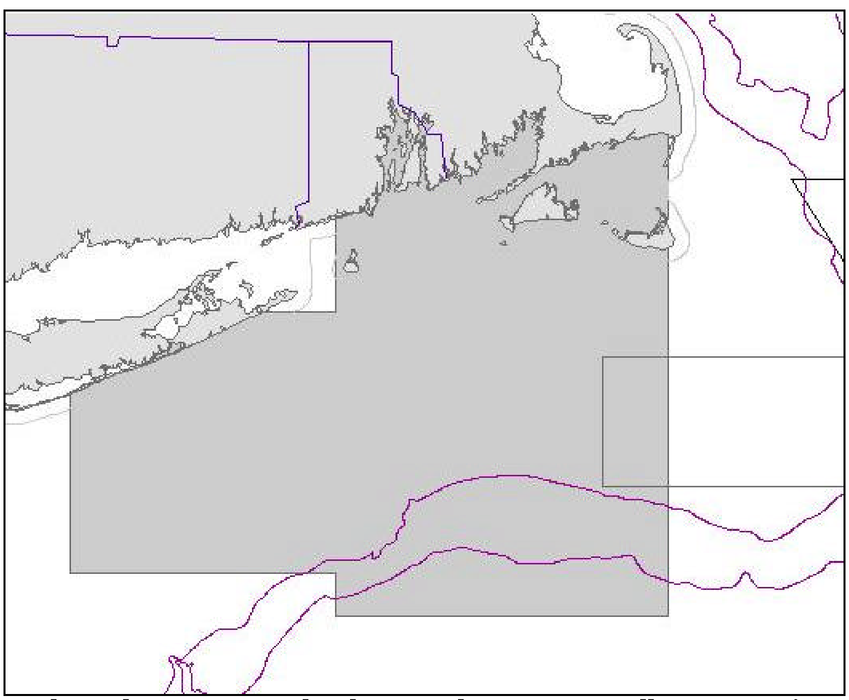

Figure 13 – Proposed Southern New England General Category Scallop Exemption Area

4.0 Alternatives to the Proposed Action

4.1 Alternatives Not Selected

4.1.1 Clarification of Stock Status, Status Determination Criteria, and MSY Control Rules

As described in section 3.1, this amendment will clarify the criteria used to evaluate stock status and the biological targets used to manage the fishery. The Council considered a number of options for these issues. The non-selected alternatives are described below.

4.1.1.1 When is a stock overfished?

The "No Action" alternative defined a stock as "overfished" when it is less than the biomass target., consistent with some interpretations of Amendment 9. This option was not selected because it conflicts with NSG1. In addition, it would be administratively burdensome because it would trigger a requirement for a formal rebuilding program whenever stock size fluctuated below the target.

4.1.1.2 When is overfishing occurring?

The No Action alternative defined "overfishing" consistent with Amendment 9: it occurs when the fishing mortality rate exceeds the threshold fishing mortality that is specified for a given stock biomass. The Council did not select this alternative because it conflicts with NS1

4.1.1.3 Status Determination Criteria

Option 1, the No Action alternative, proposed to retain the status determination criteria specified in Amendment 9. This option would have retained mean biomass targets for most stocks, as well as biomass-weighted fishing mortality for most stocks (see Table 16). In addition, it would have retained minimum biomass thresholds of less than ½ the target biomass for several stocks. The Council did not select this alternative because of the inconsistencies between assessment information and the status determination criteria. In addition, several of the minimum biomass thresholds were not consistent with NSG1.

Stock	Biomass Target	Minimum Biomass Threshold	Fishing Mortality Threshold	Fishing Mortality Target
GOM Cod	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
GB Cod	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
GB Haddock	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GOM Haddock	B_{MSY} Proxy/Fall Trawl Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
GB Yellowtail Flounder	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
Cape Cod/GOM Yellowtail Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
SNE/MA yellowtail flounder	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
American Plaice	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
Witch Flounder	SSB_{MSY}	42% Btarget	F_{MSY}	75% of F_{MSY}
GOM Winter Flounder	SSB_{MSY}	½ Btarget	F_{MSY}	75% of F_{MSY}
GB Winter Flounder	B_{MSY}	½ Btarget	F_{MSY} (1)	75% of F_{MSY}
SNE/MA Winter Flounder	SSB_{MSY}	¼ Btarget	F_{MSY}	75% of F_{MSY}
Acadian Redfish	SSB_{MSY}	½ Btarget	F50% proxy for F_{MSY}	75% of F_{MSY}
White Hake	B_{MSY} Proxy/Fall Survey Index (> 60 cm fish)	¼ Btarget	F_{MSY} Proxy/Relative Exploitation Index (> 60 cm fish)	75% of F_{MSY}
Pollock	B_{MSY} Proxy/ Fall Survey Index	¼ Btarget	F_{MSY} Proxy/ Relative Exploitation Index	75% of F_{MSY}
Windowpane Flounder (North)	B_{MSY} Proxy/Fall Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Windowpane Flounder (South)	B_{MSY} Proxy/Fall Survey Index	¼ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Ocean Pout	B_{MSY} Proxy/Fall Survey Index	½ Btarget	F_{MSY} Proxy/Relative Exploitation Index	75% of F_{MSY}
Atlantic Halibut	B_{MSY}	½ Btarget	F_{MSY} (1)	75% of F_{MSY}

Table 16 - Option 1 for status determination criteria parameters for groundfish stocks.

Fully recruited fishing mortality unless otherwise noted. See text for calculation of B_{MSY} proxy based on trawl survey index, and F_{MSY} proxy based on exploitation index.

(1) Biomass weighted fishing mortality

4.1.1.4 Numerical Estimates

Three alternatives to the proposed action were considered for the numerical estimates of status determination criteria.

No Action

Status determination criteria would have been as defined in Amendment 9. Retaining these estimates would not have been consistent with revising the parameters, and would not have been consistent with recent scientific work on status determination criteria for these stocks.

Option 2 – Step Increase
This alternative, described below, would have increased biomass targets from the Amendment 9 values to the values recommended by NEFSC 2002b in a series of steps. This alternative was not selected for several reasons. First, it was not considered consistent with the M-S Act requirement to use the best available science. Second, the increase was evaluated as arbitrary, with no scientific basis.

In developing this alternative, the Council considered NEFSC 2002A, the advice of the SSC and the peer review. NSGs require the Council use the "best available scientific information available" in crafting management plans. The NSGs do **not** instruct the Council to use the *most recent* scientific information. The NSGs and the M-S Act provide little guidance on the determination of what is the "best available science," but the NSGs do explicitly recognize that the Council may have to judge what information meets this standard: "If there are conflicting facts or opinions relevant to a particular point, a Council may choose among them, but should justify the choice." The Council is faced with conflicting guidance on the biological reference points because the reference points resulting from the methodological approach of Applegate et al. (1997) conflict with those in NEFSC 2002A. Because of this conflict and the NSG guidance, it is reasonable and consistent with the M-S Act and the NSGs for the Council to exercise its judgment in adopting status determination criteria.

With respect to the reference points proposed in NEFSC 2002A, the Council notes the following:

- NEFSC 2002a contains several caveats on the recruitment assumptions that are used to generate the biomass target estimates. For example, the report says: "It is possible that these stocks (e.g. Georges Bank cod) cannot meet long-term targets without recruitment that will rarely occur even if fishing is stopped." For Southern New England Yellowtail Flounder, the authors note: "The largest recruitment in this period (e.g. the past ten years) was 16.4 million fish, which under no fishing would only produce 45,500 mt of spawning biomass in equilibrium."
- The report does not fully explore the ecosystem implications of the high biomass targets. Some information is presented that suggests stocks can co-exist at biomasses higher than current levels. No information is presented, however, that shows stocks can co-exist at the very high B_{MSY} levels presented in the report. Such conditions have not been documented.
- The report estimated MSY for individual stocks rather than on a multispecies basis. It includes only a brief discussion of the ability of the ecosystem to support all stocks at these estimates of MSY at the same time. Some scientists argue that a multispecies MSY will be lower than the combined sum of the MSYs determined on a single species basis (Link 2002; Brown et al. 1976). If this is accurate, it may not be possible for the ecosystem to support all of the single species MSY values for all stocks at the same time
- The report did not provide any guidance on target fishing mortality or MSY control rules. As a result, the Council must rely on either Restrepo et al. (1997) or Applegate et al. (1998) for the technical basis for these parameters. Because NEFSC (2002) did not report the distribution F_{MSY} estimates, the percentile approach of Applegate et al. (1998) is not consistent with F_{MSY} estimates.
- Section 302 of the M-S Act requires that when a Council determines it appropriate to consider new information from a state or federal agency, interested parties shall have a reasonable opportunity to respond to new data or information before the Council takes final action on conservation and management measures. This report was the product of nearly a month of work by nineteen scientists who have devoted careers to population dynamics issues. It is impossible for the public to mount a similar short-term effort in order to develop an informed opinion of the

results. Given the complex technical issues involved in preparing NEFSC 2002a, it is reasonable to allow an extended period for interested parties a chance to review and respond to the report.

- The adaptive approach recommended in NEFSC 2002a would adopt the biomass targets and alter them if future information indicates they are in error. (Note this is not the same adaptive rebuilding strategy approach proposed in section 3.2.3.1.2). While this approach to biomass targets may make sense from a biological standpoint, it does not take into account M-S Act requirements to balance biological, social, and economic objectives. The economic and social analysis in this document (sections 5.4 and 5.6) clearly demonstrate significant impacts on fishermen and coastal ports as a result of management measures designed to achieve the proposed biomass targets. In particular, the short-term impacts show large declines in fishing vessel revenues compared to the No Action alternative can be expected in the initial years of the rebuilding programs. Break-even analysis in section 5.4.5 shows that many vessels will not earn enough groundfish revenues to cover costs. While the choice of rebuilding period and rebuilding strategy can affect these impacts, basing management measures on strategies designed to achieve biomass targets that ultimately prove unattainable may have severe, irreversible impacts on communities and the public that rely on commercial and recreational fishing.
- The Council's SSC, a panel of independent, highly qualified fisheries scientists, did not give the Council a clear statement recommending immediate implementation of the status determination criteria in NEFSC 2002a.
- Some members of the peer review stated unequivocally that "…a pragmatic solution to covering the substantial uncertainty in estimates of B_{MSY}, where for example they fall outside the largest observed value in the historical time series, could be to set them at a value closer to the range of actual observations." (Payne et al 2003)

While these points give the Council some concern for immediately adopting the recommendations of NEFSC 2002a, the advice of the SSC that the report is useful cannot be ignored. Thus, the dilemma facing the Council is that there is no clear understanding that NEFSC 2002a is the "best scientific information available," but the report does provide evidence that groundfish stocks are significantly more productive than previously assumed. Because the methodology of NEFSC 2002a differs from Applegate et al. (1998), the numerical estimates of the new reference points cannot just be viewed as an update of the earlier information. As a result, the Council must use its discretion (authorized by the NSGs) to choose between the conflicting information it has been presented. NOAA Fisheries notified the Council on March 17, 2003, that these biological targets may not be consistent with the National Standard Guidelines.

Action: The Council proposed an adaptive approach to the numerical estimates of the biological reference points recommended by NEFSC 2002a. (It should be noted this approach differs from the form of an adaptive approach suggested in NEFSC 2002a). Consistent with the report's recommendation to reduce fishing mortality, the Council is adopting the recommended numerical estimates of threshold fishing mortality. With respect to the biomass targets, the Council acknowledges that the report indicates that groundfish stocks appear to be more productive than assumed under earlier modeling efforts and there is considerable potential for stock increases and increased catches. If lower biomass targets (based on Applegate et al. 1998) continue to be used to guide management actions, the Council will forfeit an opportunity to increase stock biomass and yields. However, because of the uncertainties previously noted, the Council will not immediately adopt the recommended biomass targets but instead will gradually increase to them in a series of steps. In the absence of any guidance on an appropriate level of increase, the previous reference points will be increased by twenty-five percent. If over time the stock increases to this new reference point, the biomass target will be increased another twenty-five percent. This process will be repeated for each stock until either the new biomass target is reached or updated information suggests a different target. For some stocks, this approach immediately adopts the numerical estimates recommended by NEFSC 2002a. For Georges Bank yellowtail flounder, the stock has already increased to the first interim target so the target is increased to the second step. Minimum biomass thresholds will be based on these target biomasses (see section 3.1.6). The target biomass will be used to determine stock status and compliance with M-S Act rebuilding requirements. The target biomass and fishing mortality thresholds are shown in Table 17.

It should be clear that if the NEFSC 2002a numerical estimates are correct, and management measures successfully control fishing mortality this adaptive approach will result in biomass targets that steadily increase to either the NEFSC 2002a estimates or some value re-estimated in the future. This will, however, be a planned and predictable change. The growth in stock size will be determined by periodic assessments, and interested parties will be able to anticipate when the biomass targets will be shifted.

The Council will adopt the numerical estimates of threshold fishing mortality rates recommended by NEFSC 2002a. For target fishing mortality rates, the Council will adopt the approach of Restrepo et al. (1996). Target fishing mortality rates will be set at 75 percent of the threshold fishing mortality rate. The setting of the target fishing mortality rate is in part a function of the precision of an assessment's fishing mortality estimate. Target mortality rates may be changed on a stock-by-stock basis as recommended by an assessment, and will be incorporated through the periodic adjustment process.

Status determination criteria were not determined for Gulf of Maine winter flounder in NEFSC 2002a because the stock did not have a current assessment. The proposed reference points are those recommended by SAW 36 (NEFSC 2003).

Additional information: NOAA Fisheries notified the Council on March 17, 2003, that these biological targets may not be consistent with the National Standard Guidelines.

Stock	Biomass target (Bmsy or proxy)			Fishing Mortality Threshold (Fmsy)		Basis for Reference Points

2. Total biomass, metric tons
3. Unit is total stock biomass for fish >= 60 cm., mt
4. Unit is biomass weighted F
5. Survey based equivalents from GARM 2002

Option 3 – "High 3" Biomass Targets
For the same reasons described in Option 2, the Council considered a third alternative to the proposed action. This alternative was not selected for several reasons. First, it was not considered consistent with the M-S Act requirement to use the best available science. Second, the use of the highest three observed biomasses, or the value recommended by NEFSC 20021 (whichever is lower) was evaluated as arbitrary, with no scientific basis.

<u>Action</u>: The Council will follow the advice in peer review reports to establish biomass targets set closer to the range of observed values. The biomass target will either be determined by the average of the highest three observed biomasses, or the value recommended by NEFSC 2002a, whichever is lower. Fishing mortality thresholds are established at the level recommended by NEFSC 2002a. Values are shown in Table 18.

Stock	Biomass target (Bmsy or proxy)			Fishing Mortality Threshold (Fmsy)		Basis for Reference Points

4.1.1.5 MSY Control Rules

The Council considered using the threshold fishing mortality rates in Table 19 or Table 20 establish the criteria for determining when "overfishing" occurs. These thresholds change as a function of stock biomass. At a minimum, the Council will design management measures to meet the threshold fishing mortalities established by these control rules. If the fishing mortality for a stock exceeds the threshold for a given stock biomass, overfishing occurs. In this situation, the Council must take action within one year, with the purpose of ending overfishing. While action must be taken within one year, there is no specified time frame for ending overfishing and the Council may consider actions that will end overfishing as quickly as possible within a justifiable time period. To reduce the likelihood that fluctuations in fishing mortality will exceed this threshold and result in "overfishing," the Council will strive to achieve the fishing mortality targets as applied to the threshold for the current stock biomass. Optimum yield is defined in Amendment 9 as fishing at the target fishing mortality for the current biomass. Fishing mortality rates that exceed the thresholds defined in Table 19 or Table 20 over the long-term will not be consistent with the management plan and will require Council action because optimum yield is not being achieved.

This option reflects Amendment 9 language and could be considered the No Action alternative. NMFS, however, has not been applying this standard when making status determinations. It was not selected for this reason, and because it results in a cumbersome approach to overfishing that requires that the standard be continuously re-evaluated.

SPECIES	STOCK	MSY CONTROL RULE *Overfishing occurs when fishing mortality is above*:

4.1.2 Proposed Rebuilding Programs for Overfished Stocks

4.1.2.1 Rebuilding Timelines –Ending Date of 2009 for Most Stocks

In addition to the proposed action, the Council considered developing rebuilding programs to rebuild most overfished stocks with a median (50 percent) probability by 2009. According to NSG1, rebuilding periods begin when regulations are implemented for the rebuilding program. This action is planned for implementation on May 1, 2004. Amendment 9 implementing the original M-S Act overfishing definitions, however, was approved in 1999 and arguably should have included measures necessary to rebuild overfished stocks. Using that date as the starting date for rebuilding, and applying a ten year program, results in an ending date of 2009 for most stocks.

There were five exceptions to the 2014 end date: Georges Bank cod, Cape Cod/GOM yellowtail flounder, Acadian redfish, American plaice, and SNE/MA winter flounder. These stocks will have longer rebuilding periods. For GB cod, Cape Cod/GOM yellowtail flounder, and redfish, these stocks cannot rebuild in the absence of fishing mortality by 2009. This triggers longer rebuilding period for those stocks. Plaice and SNE/MA winter flounder were not overfished according to the Amendment 9 definitions. They will be overfished under the RPWG targets that may be adopted by this Amendment. Rebuilding plans for these stocks will begin May 1, 2004 and end in 2014.

This measure was not selected. It is not consistent with the NSGs, which say that formal rebuilding programs begin when measures are adopted for their implementation. Analysis showed that rebuilding programs ending in 2009 resulted in additional negative impacts on communities and the industry. Finally, the revision of biomass targets in NEFSC 2002b change the understanding of the biology of many groundfish stocks and warranted additional time for rebuilding.

4.1.2.2 Rebuilding Strategies - Constant Fishing Mortality Rate

Under this strategy, the fishing mortality is determined that, if held constant, will rebuild an overfished stock with at least a median probability in the appropriate time frame. When the stock achieves its target biomass, the formal rebuilding program adopted because the stock was overfished will be completed. Once the stock achieves the target biomass, fishing mortality targets will be based on the status determination criteria and MSY control rule. The appropriate fishing mortality will be based on observed stock conditions and recruitment. The fishing mortality for the rebuilding program may be adjusted if there are substantial changes in stock status and recruitment from those used in the long-term projections used to estimate this fishing mortality. Stock condition should be evaluated over at least a two year period to smooth fluctuations that are the result of variability rather than true trends. A wide variety of variables will be considered to determine stock condition: fishing mortality and biomass (including the uncertainty around the estimates), recruitment patterns, environmental conditions, etc.

Current estimates of the constant fishing mortality rate necessary to rebuild groundfish stocks by 2009 or 2014 are shown in Table 21 .

“Index” stocks or species typically lack sufficient age-based information to allow application of standard assessment models. For some species, the information content of the data does not support the estimation of reliable surplus production parameters. The index assessment methodology is described in detail in NEFSC 2002a. Underlying the methodology is a linear model of population growth which characterizes the population response to varying levels of fishing mortality. The model can be used to estimate the level of relative fishing mortality at which the population is likely to be stable. Fishing mortality rates greater than this value lead to population decline, values in excess lead to population increase. The magnitude of positive or negative population growth rates increases proportionately with relative fishing mortality rates below or above the stable value.

The index methodology can be extended to allow population projections under various scenarios. The basic approach can be summed up as follows. The population growth rate can be expressed as a linear function of the relative fishing mortality rate. The product of population growth rate and current population size projects the population to the next time step. Catch is estimated as the product of relative fishing mortality rate and the index population size. This sequence of computations is applied recursively to forecast population sizes up to the target biomass level (expressed in index units, e.g., kg/tow). Once the population attains the target level, relative fishing mortality is set at the level sufficient to keep the population size constant. The predicted catch when the population is at the target level serves as a proxy for the MSY.

This trajectory was not selected, in favor of a combination of the adaptive and phased strategies. In the initial years of rebuilding, the economic benefits of the other strategies are greater, mitigating the impacts of the amendment on fishing communities.

SPECIES	STOCK		Constant Fishing Mortality in order to:	
		Assumed F2002/2003	Rebuild most stocks by 2009	Rebuild most stocks by 2014
Cod	GB	0.45	0.18 (1)	0.18 (2)

4.1.3 Fishery Program Administration

4.1.3.1 Fishing Year

Three additional options were considered for the groundfish fishing year. None were selected because any change would complicate implementation of this amendment. Because the fishing year was not changed, it was not necessary to consider either of the two sub-options for pro-rating DAS. The three options for a different fishing year are described in the following sections.

Calendar-based Fishing Year – January 1-December 31
The fishing year will begin on January 1 and end December 31.

FY JANUARY 1 - DECEMBER 31

March	April	May	June	July	August	September	October	November	December	January	February	March
Survey	Survey			Index	Age		WG	WG	SARC	SAW [	MMC	] →

April	May	June	July	August	September	October	November	December	January
	MMC report	1st FW meeting	2nd FW meeting	[submit to	NMFS]	proposed rule	comment period	final rule	effective

Discussion: This option sets the fishing year to match the calendar year. All annual adjustments would be expected to be implemented on January 1, and landings and fishing effort would be tracked according to the calendar year. Because current stock assessments are based on the calendar year this change would enable closer coordination between fishery (landings) and biological/stock data. Beginning the fishing year on January 1 would also minimize the gap between availability of the best scientific information and the implementation of the framework while maintaining a realistic schedule for administrative purposes. With this schedule, there are 21 months between the last month of the spring survey and the start of the fishing year, when framework measures take effect. A January 1 fishing year may help to more closely coordinate the management of transboundary stocks with Canada and/or other countries, since allocations for that agreement are based on a calendar year.

Starting the fishing year on January 1 may also allow fishermen to more effectively plan the use of their DAS. There will be less pressure early in the fishing year to rapidly use up new DAS, since winter months yield lower fishery productivity and more weather-related challenges. A January 1 start date may reduce the intense derby fishing that currently occurs in the beginning of the fishing year (May 1), with new DAS allocated during the most productive months of the fishery.

This change to the fishing year may create some administrative burden associated with annual permitting/FMP adjustments because it coincides with the start of the fishing year for some other regional fisheries. It may also pose some challenges to administrators in prorating DAS during the transition years. In general, a transition of this magnitude would require careful structure and planning, including a thorough reevaluation of the way in which scientific and fishery data is incorporated into the management process.

A change in the fishing year may also have allocation impacts if a quota or "hard" TAC system is adopted. Depending how the allocation is distributed in time (through the use of target TACs), some vessels may not have access to the allocation during the winter months because of vessel size and poor weather.

Fishing Year Beginning in October – October 1-September 30
The fishing year will begin on October 1 and end on September 30.

FY OCTOBER 1 - SEPTEMBER 30

September	October	November	December	January	February	March	April	May	June	July	August	September
Survey	Survey			Index	Age		WG	WG	SARC	SAW [	MMC	] →

October	November	December	January	February	March	April	May	June	July	August	September	October
	MMC report				1st FW meeting	2nd FW meeting	[submit to	NMFS]	proposed rule	comment period	final rule	effective

Discussion: As with a May 1 start to the fishing year, beginning the fishing year on October 1 extends the gap between availability of best scientific information and implementation of a framework adjustment. With this schedule, there are 24 months between the last month of the fall survey and the start of the fishing year, when framework measures take effect.

Although it may be somewhat arbitrary, this change to the fishing year may alleviate administrative burdens associated with annual permitting/FMP adjustments because it separates the multispecies fishing year from fishing years for other fisheries. In addition, the gap between the most recent available landings data and framework implementation (22 months) is smaller than that for a fishing year beginning May 1 or January 1. Beginning the fishing year in October may reduce the intense derby fishing that currently occurs in the beginning of the fishing year (May 1), with new DAS allocated during the most productive months of the fishery.

Fishing Year Beginning in July – July 1-June 30

The fishing year will begin on July 1 and end on June 30.

FY JULY 1 - JUNE 30

September	October	November	December	January	February	March	April	May	June	July	August	September
Survey	Survey			Index	Age		WG	WG	SARC	SAW [	MMC	] →

October	November	December	January	February	March	April	May	June	July
	MMC report	1st FW meeting	2nd FW meeting	[submit to	NMFS]	proposed rule	comment period	final rule	effective

Discussion: As with a January 1 start date, beginning the fishing year on July 1 would minimize the gap between availability of the best scientific information and the implementation of the framework while maintaining a realistic schedule for administrative purposes. With this schedule, there are 21 months between the last month of the fall survey and the start of the fishing year, when framework measures take effect. A July 1 fishing year may help to more closely coordinate the management of transboundary stocks with Canada and/or other countries, since the Canadian groundfish fishing year begins close to that date (June 1). Beginning the fishing year in July may also help to reduce high fishing pressure during the spring months when spawning of some species is occurring while providing harvesting opportunities during productive summer months. In addition, it eliminates the administrative burden associated with a January 1st start, when the fishing year for some other regional fisheries begins.

DAS Pro-Ration

DAS are allocated based on the fishing year. A change in the fishing year raises the question of how DAS will be prorated. In addition, DAS may need to be prorated if the Amendment measures are implemented at time other than the start of the fishing year. Two options were considered.

DAS Proration Option 1

New DAS allocations are effective at the start of the next fishing year after implementation of the Amendment. The period between adoption of the management measures and the start of the next fishing year is defined as a transition period. During this period, a vessel will be limited to its 2003 allocation [based on the *CLF et al. v. Evans et al.* (Framework 33 lawsuit) court order but including any carry-over

DAS allowed from 2003 into 2004] times the number of months in the transition period, divided by 12. (The number of months will be rounded up to the next whole value: three months and one day will be treated as four months). A vessel can carry over up to ten DAS into the new, revised fishing year.

Transition period DAS = (Number of months/12) X (2003 DAS allocation +2003/2004 carry-over)

Example: Assume the fishing year is changed to begin July 1. The transition period is two months long (May and June). For a vessel with a 2003 allocation of 70 DAS, with 5 DAS left over to carry into 2004, the DAS allowed during the transition period would be:

(2/12) X (70+5) = 12.5 DAS

Ten of these DAS could be carried over from the transition period into the new fishing year beginning July 1. If the vessel receives a 60 DAS allocation under Amendment 13, the vessel could use a total of 72.5 DAS from May 1, 2004 through June 30, 2005.

Discussion: This formula is easy to understand and to apply, but may disadvantage vessels that use a high percentage of their DAS during a specific time of the year. This option could result in a short-term increase in DAS.

DAS Proration Option 2
New DAS allocations are effective when the Amendment is implemented. The period between implementation and the start of the next fishing year is a transition period. A vessel is limited to its new allocation times the number of months in the transition period, divided by 12. Each vessel's allocation for the period May 1, 2003 to the start of the next fishing year will be capped by the sum of the transition period allocation plus the 2003 allocation (including any carry-over DAS allowed from 2003 to 2004) times the number of months between May 1 and implementation of the Amendment divided by 12. (The number of months will be rounded up to the next whole value: three months and one day will be treated as four months). A vessel can carryover up to ten DAS into the new fishing year.

Transition period DAS= (Number of months/12) X (Amendment 13 allocation +2003/2004 carry-over)

Example: Assume the fishing year is changed to begin July 1. The transition period is two months long (May and June). For a vessel with an Amendment 13 allocation of 60 DAS, with 5 DAS left over to carry into 2004, the DAS allowed during the transition period would be:

(2/12) X (60+5) = 10.8 DAS

Ten of these DAS could be carried over from the transition period into the new fishing year beginning July 1. If the vessel receives a 60 DAS allocation under Amendment 13, the vessel could use a total of 70.8 DAS from May 1, 2004 through June 30, 2005.

Discussion: This option may disadvantage those who use a high percentage of their DAS at a specific time of the year. It addresses the concern that Option 1 could result in a short-term increase in DAS by immediately implementing the Amendment 13 allocations.

4.1.3.2 US/CA Resource Sharing Understanding

The Council considered not adopting this understanding (the No Action alternative). If this understanding was not adopted, management of GB cod, haddock and yellowtail flounder would not be coordinated with Canadian fishermen. As a result, the lack of coordinated management could lead aggravate overfishing on cod and lead to overfishing on haddock and yellowtail flounder.

The Council also considered options for specific elements of this agreement:

Identification of Participants

Option 2: Sign-in program: Vessel must enroll in US/CA area for a minimum of a 10-30 day period, must give 7 day notice to exit program, must have RA certificate/authorization on board while fishing in the area. No limitations on signing in and out of the program over the course of the year.

- On a given trip, vessel can only fish either inside the US/CA area, or outside the US/CA area (no combined trips), or
- On a given trip, vessels can fish both inside and outside the area

This provision was not adopted. Successful implementation of the agreement requires the ability to verify vessel fishing locations, which can only be done through the use of VMS.

Reporting Requirements

Option 1: Based on other reporting options in A13. If a hard TAC option is adopted for the entire fishery, and reporting requirements are changed to monitor the hard TAC, these provisions should be sufficient to monitor US/CA landings as long as trips in this area can be identified.

This option was not adopted. To be successful, the understanding requires timely reporting of catches of GB cod, haddock, and yellowtail flounder. As a result, the Council adopted more stringent reporting requirements for vessel's fishing in the understanding area.

Option 3: Vessels making trips in the area are required to report their catch through the VMS unit on a daily basis during the duration of their trip.

This option was not adopted because at present a system is not in place to handle daily VMS reporting of groundfish.

Harvest Controls

While a hard TAC was adopted for this understanding, the Council did not choose Option 1 for managing the TAC:

Option 1: When 70-90 percent of target species is projected to be caught, restrictive trip limit goes into place:

- Haddock: 1,500 lbs/day/15,000 lbs. trip
- Yellowtail: 1,500 lbs day/15,000 lbs. trip
- Cod: Half of daily cod TAC adopted elsewhere
- Trip limits can be adjusted by NMFS to make sure TAC is harvested at any time (including prior to the fishing year)

- Consequences of reaching 100 percent of TAC:
  - Option 1: Possession of that specific species is prohibited

- Alternative TAC Allocation Scheme:
  - Set TAC for a shorter period than one year (for example, quarterly)

These measures were not adopted. The Council determined it was better to implement measures at the beginning of the fishing year to reduce the likelihood that the GB cod TAC would be caught, closing the area to haddock and yellowtail fishing. In addition, prohibiting possession would likely lead to discards. Allocating the TACs for shorter periods of time was viewed as administratively burdensome.

Target TAC

The Council did not choose to use a target TAC because of concerns that this would not meet Canadian expectations for controlling the catch in the area. This option included the following elements:

- Target TACs adopted for each species (5Zjm cod and haddock; and 5Zhjmn yellowtail flounder)
- Two options for target TAC

  Option 1: As target TAC is approached, measures become more restrictive. For example:
  - DAS differential: for instance, at 90% of TAC DAS count 2:1 for trips into the area
  - Gear change: for instance, at 90% of TAC requirement to use haddock separator trawl or larger mesh
  - Area closures: at 90% of cod or haddock TAC, area to west of CA II closes to gear capable of taking groundfish. At 90% of yellowtail flounder TAC, area, south of CAII closes to gear capable of taking groundfish.
  - Trip limit adjustments: for instance, at 90% of TAC, RA authorized to reduce trip limit to level that is projected to prevent TAC from being exceeded. Or limits on what percentage of landings from a trip can be particular species.
  - Seasons: Area closed for a specific season as TAC is approached, or seasonal fishing implemented at beginning of fishing year to prevent TAC from being reached.

  Option 2: Implement conservative measures up front to preserve the cod TAC in order to allow a directed haddock and yellowtail flounder fishery:
  - In consultation with the Council, the RA may adjust gear requirements, modify access to fishing areas within the agreement management units, and trip limits to meet established TACs.
  - Flat fish net or separator trawl gear
  - Low cod trip limit – 5% of total catch not to exceed 500 per day
  - RA monitors the respective TACs - At 30% and 60% of the total specified TAC for each species harvested from the agreement management units, the RA may adjust the gear requirements, modify access to the agreement management units, trip limits, and number of trips to ensure the established TACs are reached, but not exceeded.

- Consequences of reaching 100 percent of TAC:
  - Option 1: Trip limit reduction.
  - Option 2: As a specified TAC approaches 100%, the RA may take appropriate action to ensure the respective TACs are not exceeded. The options for ensuring a TAC is not exceeded include, but are not limited to, complete area closures to all fishing that may take cod, haddock, or yellowtail within the agreement management units.

- Alternative TAC Allocation Scheme:
  - Set TAC for a shorter period than one year (for example, quarterly)

4.1.3.3 Administration of Certified Bycatch/Exempted Fisheries

In addition to the proposed action, the Council considered not making any changes. This alternative was not selected because that would not increase the flexibility of the Council to address the concerns raised by current requirements. In addition, the Council considered an additional option for of this program.

Review of Exempted Gears and Certified Bycatch/Exempted Fisheries
The Council considered reviewing exempted gears and certified bycatch fisheries on a fixed schedule. This was not adopted because of concerns it would prove administratively burdensome. The Council will review exempted gears and bycatch fisheries on an ad hoc basis.

4.1.3.4 Special Access Programs

The Council did not select one proposed special access program.

Gillnet Gear Closed Area I Special Access Program
The Council considered a SAP for gillnet vessels to fish in CA I to target haddock. This measure was not selected because of a lack of information on the possible bycatch that may occur. It could be adopted in the future if this information becomes available. Provisions of this program are described below:

Area
Participants may fish in the area defined by the following coordinates (loran coordinates shown for information only):

41–24.5N 069-18.5 W	(43800/13700)
41-22.5N 069-14.5W	(43800/13675)
41-0.0N 069-04W	(43680/13700)
41-07.75N 068-59.5W	(43680/13675)

Season
Gillnet: July 1 through March 31

Haddock TAC
Gillnet: TBD

Incidental Catch Limits
Gillnet: 100 mt incidental catch of cod, 400 lbs/trip. Access program closes when cod limit is projected to be caught.

Gear Restrictions
Gillnet: Maximum of 50 gillnets with 6.5 inch mesh. All nets must be brought back to port when vessel returns to port (regardless whether DAS clock is stopped).

Administrative Requirements
Vessels must declared into the access program in advance of sailing. No fishing is allowed outside the area boundaries on a dedicated closed area access trip.

Observer Coverage
Observers are required on all trips.

VMS
All vessels must be equipped with an approved VMS.

US/CA Resource Sharing SAP
The Council considered limiting the number of trips allowed into the area for the US/CA Resource Sharing Understanding SAP. This measure was not selected because catches in the area will be controlled by a hard TAC on GB cod, haddock, and yellowtail flounder. Two options were considered:

Option 1: One to three trips per month for each vessel, with a maximum of 20 trips per year
Option 2: One to three trips per quarter for each vessel

4.1.3.5 Closed Area Administration

Access to Closed Areas
Several alternatives were considered with respect to access to closed areas. None of these changes were adopted, as the Council determined that the current restrictions are sufficient.

Option 1
The Council considered the following uniform policy for determining which gear is allowed in a closed area:

> When a year-round or rolling closure is established, all multispecies exempted gear will be allowed in the area except gear specifically identified as prohibited. Access for closed areas will be described as follows: "Multispecies exempted gear is allowed in the area, with the exception of …"

An advantage of this option is that access to all closed areas will be described in a consistent manner. However, it may complicate enforcement and impose an administrative burden to specifically identify gears that are restricted from multispecies closed areas. Additionally, it may weaken the effectiveness of closed areas because of minimal levels of bycatch incurred by exempted gears. This option was not selected.

Option 2
The Council considered allowing all Northeast multispecies exempted gear into Closed Area I and Closed Area II, provided there is no retention of multispecies and no other gear on board capable of catching the species in the Northeast Multispecies FMP. This change would result in the following additional gears allowed into Closed Areas I and II:

Pelagic gillnets
Pots and traps (only lobster and hagfish pots currently allowed)
Purse seines (including tuna and herring purse seines)
Shrimp trawls (with a properly configured grate)
Surf clam and ocean quahog dredges
Spears
Rakes
Diving gear
Cast Nets
Tongs
Harpoons
Weirs
Dipnets
Stop Nets
Pound Nets

(Midwater trawls are currently allowed into Closed Areas I and II).

This option makes access to Closed Areas I and II consistent with access to the WGOM closed area. It also focuses protection of closed areas on targeted species while reducing impacts on other fisheries. Several disadvantages to this option are that is complicates enforcement in closed areas, may impact benthic habitat in closed areas, and reduces the effect of closed areas on habitat and fishing mortality to some degree. This option was not selected.

Option 3
The Council considered allowing all multispecies exempted gear into the Nantucket Lightship Closed Area (NLCA), provided there is no retention of multispecies and no other gear on board capable of catching the species in the Northeast Multispecies FMP. Party/charter and recreational fishing vessels are allowed to fish in the area under the current regulations. Party/charter boat operators are required to have an operator's permit, as is currently the case.

The following additional gears would be allowed into the NLCA:

Pelagic gillnets
Pots and traps (only lobster and hagfish pots currently allowed)
Purse seines (including tuna and herring purse seines)
Shrimp trawls (with a properly configured grate)
Spears
Rakes
Diving gear
Cast Nets
Tongs
Harpoons
Weirs
Dipnets
Stop Nets
Pound Nets

(Surf clam and ocean quahog dredges are currently allowed into the NLCA).

This option makes access to the NLCA consistent with that of the WGOM closed area. It also focuses protection of closed areas on targeted species while reducing impacts on other fisheries. However, it complicates enforcement in closed areas, may impact benthic habitat in closed areas, and reduces the effect of closed areas on habitat and fishing mortality to some degree. In addition, access to the NLCA and WGOM closed areas would still differ from CA I and CA II. This option was not selected.

Option 4
The Council considered allowing all multispecies exempted gears into the Western Gulf of Maine year round closure, provided there is no retention of multispecies and no other gear on board capable of catching the species in the Northeast Multispecies FMP. The following additional gears are allowed into the Western Gulf of Maine closure:

Pelagic gillnet gear

(Other exempted gears are currently allowed into the Western Gulf of Maine closed area).

This option makes access to the Western Gulf of Maine closure consistent with that of other closed areas, but only if all exempted gear is allowed into all closed areas. It also focuses protection of closed areas on targeted species while reducing impacts on other fisheries. However, it complicates enforcement in closed areas, may impact benthic habitat in closed areas, and reduces the effect of closed areas on habitat and fishing mortality to some degree. In particular, pelagic gillnets are difficult to distinguish from sink gillnets unless hauled, and Coast Guard cutters do not currently have the ability to haul gillnets. This option was not selected.

Option 5
For any year round closure, access for harvest purposes by any commercial fishing vessel is prohibited.

This option prevents any access to closed areas, maximizing their effectiveness and simplifying enforcement. It may result in adverse economic impacts on gear currently allowed into the year round closed areas. This option was not selected.

Review of Year Round Closed Areas

Scheduled Review of Closed Areas (Preferred alternative)
The Council considered reviewing year round closed areas periodically to confirm they are in the correct location to contribute to the goals of the FMP. The review may result in changes to (such as increasing or decreasing the size of the area, or moving the boundaries), or elimination of, a closed area or areas. The review will be conducted during the fifth year after a closed area is implemented. The existing year round closed areas will be reviewed according to the following schedule, and then every five years thereafter.

Gulf of Maine (WGOM and Cashes Ledge): 2005
Georges Bank: (CAI and CAII) : 2006
NLCA: 2007

Seasonal or rolling closures will be reviewed during the periodic adjustment process.

The PDT will provide advice on the closed areas during its annual review and preparation of the SAFE report. The PDT's report will include the following information:

- Whether the closed area continues to meet the objectives for which it was implemented
- Whether the area helps achieve other FMP objectives than those for which it was designed
- Whether the closed area should be eliminated or boundaries altered to better meet FMP objectives.
- Whether access programs can be designed to allow limited fishing in the closed area in order to achieve OY.

This schedule does not preclude changes to closed areas at other times if the Council documents the need for a change.

This measure would have established a formal schedule to review closed areas on a regular basis, insuring that they continue to achieve the goals of the FMP. This review would have served as an indicator of whether a particular closed area is serving the purpose for which it was established and if not, determine the nature of its current utility. It was not adopted because of concerns the required review would prove to be an administrative burden with few benefits.

4.1.3.6 Leasing of DAS

The Council considered not implementing a DAS leasing program. This was not selected. A DAS leasing program is expected to mitigate the adverse economic and social impacts that will result from the restrictions on fishing necessary to rebuild stocks.

While the proposed action includes a DAS leasing program, the Council considered a number of options for elements of the program that were not selected.

Conservation Equivalency Options
Option 1: Leasing Within Categories
This option was not selected because it is both very restrictive and administratively burdensome. In addition, with the exception of the limited access hook gear permit category, groundfish vessels are not limited in the gear they can use. The requirement in this option that DAS transfers be limited across gear types could not be implemented.

DAS leasing could result in a net increase in fishing mortality if DAS are transferred across disparate platforms. This alternative would limit the ability to reach lease agreements to vessels that meet specified vessel size and gear categories.

- Provisions for Size: A lessor may not lease DAS to any vessel with a main engine horsepower rating that is more than 20% that of the lessee and may not lease DAS to any vessel that is more then 10% of the lessee's vessel's LOA, GRT, and NT.

- Provisions for Gear: Subject to the size provision above, lease agreements will be restricted by gear as follows:

  - Vessels with hook-only (Category D permits) may lease DAS only from other hook-only permit holders.

  - Trip gillnet vessels may lease DAS only from other trip gillnet vessels where the designation must be from that of FY2001. Leased DAS must be used with gillnet gear.

  - Day boat gillnet vessels may lease DAS only from other dayboat gillnet vessels where the designation must be from that of FY2001. Leased DAS must be used with gillnet gear.

  - Limited Access permits other than Category D using hook gear may lease DAS only from other vessels using hook gear. Leased DAS must be used with hook gear.

  - Limited Access permits other than Category D using mobile gear may lease DAS only from other mobile gear vessels. Leased DAS must be used with mobile gear

<u>Option 2:</u> Calibrated DAS
This option was not selected. NMFS proposed a DAS leasing program that used a similar approach to "calibrate" DAS that are transferred between vessels of different sizes. The calibration table approach was criticized as too liberal and likely to result in increased effort.

Creating a standardized measure to calibrate effective effort (hereafter referred to as a calibration factor) across gear types and vessel sizes would provide broader opportunities to match buyers and sellers of leased DAS.

Calibration of DAS across vessel platforms needs to take into account the potential difference in capacity output of each vessel to assure that DAS trades are capacity neutral. Such capacity output measures were developed as part of the latent permit buyout and provide a basis for developing a calibration factor for leasing DAS. For the latent permit buyout, capacity estimates for inactive vessels were based on the average capacity output per DAS for active vessels for six different vessel horsepower clusters. These average values may then be used to develop a schedule of calibration factors to determine the number of potential DAS that may be exchanged (note that this approach is identical to what had been developed for Amendment 7 to the Scallop FMP).

<u>Option A</u>: With this option, DAS leases would be subject to the calibration factors in Table 22. Since the calibration factors in Tables A and Table 23 were not developed specifically to accommodate a leasing program they should be regarded as preliminary and may be adjusted upon further review by the PDT. The number of horsepower classes may also need to be adjusted.

These calibration factors provide for both upward and downward adjustments to DAS based on the buying and selling vessel's horsepower class. A selling vessel in any given class would be able to lease DAS to a buying vessel in the same class at a 1:1 rate. A selling vessel in any given class would be able to lease DAS to any vessel in a lower class at a higher rate but would be able to lease DAS to any vessel in a higher class at a lower rate. For example, if a vessel in the 251-324 horsepower class had 10 DAS available to lease, that vessel could lease exactly 10 DAS to another vessel in the same class. If the same vessel were to lease to a vessel in the 176-250 horsepower class then the buying vessel would receive 11.4 DAS. From a DAS accounting perspective, the selling vessel would have its DAS reduced by 10 DAS while the buying vessel would have its DAS allocation increased by 11.4 DAS.

		Selling Vessel Horsepower Class					
		0-175	176-250	251-324	325-400	401-650	651+
Buying Vessel Horsepower Class	0-175	1.00	1.25	1.42	1.72	2.05	2.76
	176-250	0.80	1.00	1.14	1.37	1.63	2.20
	251-324	0.70	0.88	1.00	1.21	1.44	1.93
	325-400	0.58	0.73	0.83	1.00	1.19	1.60
	401-650	0.49	0.61	0.70	0.84	1.00	1.35
	651+	0.36	0.45	0.52	0.62	0.74	1.00

Table 22 – Option A for calibration of DAS between vessels

Option B: Allowing upward adjustments places a significant burden on the precision of the estimated capacity output by horsepower class that is used to calculate the calibration factors. A more precautionary approach would be set all DAS calibration factors for DAS leases from a larger vessel to a smaller vessel equal to one. The calibration factors that would be associated with this option are shown in Table 23. Under this option any vessel within one horsepower class that was leasing DAS from a vessel in a higher class would lease DAS at a 1:1 rate. Vessels leasing DAS from any vessel in a lower horsepower class would lease DAS at less than a 1:1 rate. For example, a vessel in the 176-250 horsepower class would lease DAS at a 1:1 rate from any vessel in the same or higher horsepower class. However, if this vessel were to lease DAS from a vessel in the 0-175 horsepower class then the DAS would be leased at a 0.8:1 rate. For an exchange of 10 DAS in this case the selling vessel's DAS allocation would be reduced by 10 DAS and the buying vessel's allocation would be increased by only 8 DAS.

		Selling Vessel Horsepower Class					
		0-175	176-250	251-324	325-400	401-650	651+
Buying Vessel Horsepower Class	0-175	1.00	1.00	1.00	1.00	1.00	1.00
	176-250	0.80	1.00	1.00	1.00	1.00	1.00
	251-324	0.70	0.88	1.00	1.00	1.00	1.00
	325-400	0.58	0.73	0.83	1.00	1.00	1.00
	401-650	0.49	0.61	0.70	0.84	1.00	1.00
	651+	0.36	0.45	0.52	0.62	0.74	1.00

Table 23 – Option B for calibration of DAS between vessels

Discussion: The PDT approach to effort control under Amendment 13 is predicated on assuring a more direct link between DAS controls and rebuilding targets for a given fishing year. Under Amendment 7 there was never any real link between DAS allocations and limits on DAS that could or should be used consistent with resource conditions. The combination of establishment of category A, B, and C DAS and a substantial reduction in category A DAS at the start of Amendment 13 could leave vessels without enough DAS available to remain in business. This problem will be more acute for individuals that consistently used a high proportion of DAS and that have few alternative fisheries or Federal permits on which to rely. By contrast, some vessels will receive more DAS than they may need or want to use because they may have qualified based on past rather than more recent groundfish activity.

A leasing program would allow vessels to temporarily increase the number of DAS they may fish by leasing these days from another vessel that chooses not to fish. Such a leasing program would allow for greater economic efficiency but would require that any exchanges be conservation neutral. The following describes a DAS leasing alternative with two alternate mechanisms to assure that DAS exchanges would not result in a net increase in fishing mortality (i.e. conservation equivalent).

Other programs to reduce the number of allocated DAS (such as the court order in the case of *Conservation Law Foundation et al. v. Evans,* or any across the board reduction in DAS without addressing unused DAS) may have similar impacts. Some vessels may not have enough DAS to be operated profitably, while others may have more DAS available than they intend to use. Leasing programs can be used to address the economic issues that result. Without a clear link between the number of DAS used and the number that can be supported, however, a DAS leasing program may result in increased effort and may compromise biological objectives. For example, if there are no reductions in allocated DAS, a leasing program clearly can lead to a transfer of DAS from vessels that do not fish to vessels that do.

Sub-Leasing of DAS
The Council considered allowing DAS to be sub-leased, but did not select this option because it would complicate the administration of DAS leasing program and could lead to speculative leasing of DAS.

Options for limitations on DAS leased

Options on expiration of leasing program
The Council considered allowing a DAS leasing program to continue indefinitely unless changed by a future Council action. This option was not selected. The DAS leasing program proposed is controversial and the impacts are not known with certainty. Allowing the program to continue indefinitely would complicate the review of the program. In addition, an indefinite program might lead participants to enter long-term agreements in the belief the Council would not change the program. Third, a leasing program is viewed by some as a short-term measure designed to mitigate the impacts of the amendment, rather than a permanent element of the groundfish plan. Finally, a long-term leasing program may discourage participation in the DAS transfer program, hindering that programs utility in reducing excess capacity in the fishery.

4.1.3.7 Recreational Fishing Permit

None of the three options that follow were selected because of concerns they would be difficult to administer and would not improve reporting of recreational catches.

Option 2 (Preferred alternative)
Any recreational vessel possessing regulated multispecies in the Exclusive Economic Zone (EEZ) is required to have a federal permit.

Option 3
Any recreational vessel fishing for regulated multispecies in the Exclusive Economic Zone (EEZ) is required to have a federal permit.

Option 4
Any recreational vessel fishing for and possessing regulated multispecies in the Exclusive Economic Zone (EEZ) is required to have a federal permit.

4.1.3.8 Running Clock Alternatives

Neither of the following changes to the running clock were selected because of concerns they would be difficult and/or costly to administer.

Option 2 - Industry funded weighmaster

A vessel can exceed a daily trip limit, and be charged the appropriate DAS to account for the overage, under the following conditions:

- The vessel agrees to have all commercial landings (not just groundfish) supervised and verified by an industry-funded weighmaster. A vessel must notify NMFS that it will participate in a weighmaster program.
- NMFS will establish standards for certifying and monitoring weighmaster programs. These standards will include procedures to document the overage so that DAS can be adjusted.

Rationale: Use of a "running clock" is often advocated as a way to reduce discards. Enforcement officials oppose the practice because of concerns over their ability to enforce its use. This measure attempts to balance both concerns. One weakness, however, is that the weighmaster program may be expensive to the industry. As a result, communities with large groups of fishermen, or access to auctions, may be better able to support the program. The measure may be viewed as unfair because outlying communities with few fishermen may not be able to take advantage of the program.

Option 3 - Extended Modified Running Clock

A vessel may land an amount of fish equal to the daily trip limit for the number of DAS on the trip, plus an additional 48 hours. When doing so, the DAS time ending the trip will be postdated for the time necessary to equal the amount of cod landed. A vessel cannot leave port on another trip until the amount of time has elapsed necessary to account for the amount of groundfish landed. The vessel will report via a separate call-in number.

Rationale: This option was intended to reduce regulatory discards caused by trip limits. It provides a limited opportunity to allow landing of fish that exceed a trip limit, but does so by charging the appropriate DAS.

4.1.3.9 Observer Coverage

Option 1 - No Action

Requirements for observer coverage remain as they were during fishing year 2001, prior to the settlement agreement which resulted from *CLF et al. v. Evans et al.* There is no specified level of observer coverage, however, if a vessel is requested to take an observer on board it is required to do so. This option was not selected because the Council believed it beneficial to go on record for a stated level of observer coverage.

Option 2 – Observer Coverage Level Specified in Court Order (Preferred Alternative)

As a result of the court order in the case of *CLF et al. v. Evans et al.*, effective May 1, 2003, NMFS shall provide 10 percent observer coverage for all gear sectors unless it can establish by the most reliable and current scientific information that such an increase is not necessary to achieve an acceptable level of precision and accuracy.

4.1.3.10 Vessel Monitoring System Requirements

The Council considered not allowing vessels to opt out of the VMS reporting requirements, but did not select this option because it would not help reduce the burdens of regulations on small businesses.

4.1.3.11 Day Gillnet Blocks Out

The Council considered two options that would have changed or eliminated the requirement for day gillnet vessels to take blocks of time out of the fishery. These options were not selected. These blocks of time out of the fishery ensure that gillnet gear is removed from the water and limit the ability of vessels to extend soak time to make up for DAS reductions. Many view this requirement as an equity issue, since gillnets continue fishing while the vessels are not using a DAS.

Option 2
The requirement for day gillnet vessels to take 21 days out of the fishery between June and September is eliminated.

Rationale: The requirement to take 21 days out of the fishery may not be effective or necessary to reduce reducing mortality from this sector because of additional gear and DAS restrictions contemplated in the amendment.

Option 3
The requirement for day gillnet vessels to take 120 days out of the non-exempt groundfish gillnet fishery each fishing year is eliminated. (Approval of this alternative would also remove the requirement to take 21 days out of the fishery between June and September).

4.1.3.12 DAS Counting

The Council considered two alternatives for changing the way DAS are counted. Neither was selected. Either approach would have required a review of DAS allocations and use, and would have required a complete recalculation of all proposed alternatives to achieve rebuilding requirements. This was viewed as an unnecessary administrative burden with little benefit for managing the fishery. The options are described in the following sections.

Option 2 – 15 hour minimum
DAS for all vessels will be counted as a minimum of 15 hours, for all trips over three hours in length.

Rationale: This option applies the same DAS counting method that is used for day gillnet vessels to all vessels.

Option 3 – 24 hour DAS
DAS for all vessels will be counted based on a 24 hour day for all trips over three hours in length. Adoption of this alternative means there will not be any partial DAS (e.g., a trip of six hours will count as one DAS, a trip of twenty-six hours will count as two DAS).

Rationale: This option charges DAS in whole day increments. This creates a closer connection between days fished and DAS allocations, consistent with the early intent of DAS included in Amendment 5.

4.1.3.13 Reporting Requirements

Dealer Reporting
Three additional options were considered for dealer reporting requirements. Options 1, 2, and 4 were not selected because they would not result in a reporting system that would meet the needs of the management plan.

OPTION 1: *No action*.
The existing dealer reporting requirements will not be changed.

OPTION 2: *Trip identifier reporting*

- Current system of reporting, with the addition of trip identifier and the disposition of the species purchased via paper reporting within 15 days of purchase.
- Trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

- This is not a viable option should a hard TAC alternative be implemented.

OPTION 4: *Daily electronic dealer reporting, with exemption for small dealers*

- Daily electronic dealer reporting as specified in Option 3, unless otherwise exempted,. where the dealer records the vessel's trip identification number and disposition of catch (e.g., human consumption, bait, animal food, reduction, etc.) for all vessels. "Small" dealers would be exempt from the daily electronic reporting requirement and would continue to report under the current reporting system paper based system with the addition of the trip identifier and disposition. A small dealer, for this purpose, would be defined as one that purchases 5,000 lb or less of regulated multispecies per year.
- Trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

Vessel Reporting Options

Six additional options for vessel reporting requirements were considered. Option 1 and 2 were not selected because the existing reporting system is not sufficient to monitor catches in timely manner for parts of the amendment such as the US/CA Resource Sharing Understanding. Option 3 was not adopted because of concerns over cost and operation requirements for existing VMS systems that make them impractical for many vessels. Option 4 was not adopted for similar reasons, though restricting VMS to larger vessels mitigates some of the concerns raised by Option 3. Option 5 severely restricts the ability of fishermen to operate and is not required since an area management alternative was not selected to control the commercial fishery. Option 6 was not selected, though the proposed action is very similar but allows for development of alternative ways that a vessel can report its catch electronically.

OPTION 1: *No Action*

The current reporting requirements as described in 50 CFR 648 Subpart A would not be changed. This is not a viable option if a hard TAC alternative is implemented.

OPTION 2: *Trip identifier reporting*

- No action, with the addition of trip identifier paper reporting within 15 days of end of month of landing for all permitted multispecies vessels.
- The current VTR requirement would be maintained for all vessels with the addition of the trip identifier. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.
- This is not a viable option if a hard TAC alternative is implemented.

OPTION 3: *VMS reporting for limited access multispecies DAS vessels*

- VMS requirement for all limited access multispecies DAS vessels. Vessel captains would be required to report enter landings information (pounds by regulated species) for each NMFS statistical area that the vessel was fishing in or transiting (an entry of zero landings when transiting) when upon exiting a statistical area through the VMS.
- All other multispecies vessels (Small vessel permit category and open access vessels) would report the following information through a call-in number: a) password; b) trip identifier; and c) landings information by NMFS statistical area.
- The current VTR requirement would be maintained for all vessels with the addition of the trip identifier. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

OPTION 4: *VMS reporting for limited access vessels greater than 45 ft.*

- VMS requirement for all limited access multispecies DAS vessels greater than 45 ft in overall length. Vessel captains would be required to report landings information for each NMFS statistical area that the vessel was fishing in or transiting (an entry of zero landings when transiting) when exiting a statistical area through the VMS.

- All other multispecies vessels (DAS vessel less than or equal to 45 feet, small vessel permit category and open access vessels) would report the following information through a call-in number: (a) password; (b) trip identifier; and (c) landings information by NMFS statistical area..
- The current VTR requirement would be maintained for all vessels with the addition of the trip identifier. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

OPTION 5: *Declaration into one fishing area*

- Prior to fishing, all permitted multispecies vessels would be required to declare their intent to fish in a specific area (a NMFS statistical area) for a minimum period of 30 days and would be required to have on board a Letter of Authorization issued by the Regional Administrator. These vessels would report the following additional information through a call-in number: a) password; b) trip identifier.
- Vessels may choose to acquire and operate VMS and be exempt from declaring into one fishing area. Vessel captains would be required to report landings information for each NMFS statistical area that the vessel was fishing in or transiting (an entry of zero landings when transiting) upon exiting a statistical area through the VMS.
- The current VTR requirement would be maintained for all vessels with the addition of the trip identifier. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

OPTION 6: *Call-in system modification*

- Modification to the call-in system that would require all multispecies DAS vessels to report the following additional information when calling-out of the DAS program: a) password; b) trip identifier; and c) landings information by NMFS statistical area. All other multispecies vessels (Small vessel permit category and open access vessels) would report this same information through a separate call-in number.
- The current VTR requirement would be maintained for all vessels with the addition of the trip identifier. The trip identifier may be generated by the vessel or the dealer(s) and will be reported by all parties involved in the transaction.

4.1.3.14 Hand Gear Only Permit Alternatives

The Council considered three additional alternatives for the hand-gear only permit category. Alternative 1 was not selected because it did not leave any opportunity for movement into the sector at a small level of effort. Alternatives 2 and 4 – maintaining the category as open-access –were not selected because they do not address the concern that increases in this sector could jeopardize rebuilding programs.

Alternative 1

Under this alternative, qualification criteria for a hand gear only permit will be the same as those established under the *CLF et al. v. Evans et al.* court order. Hand gear only vessels are limited to 200 pounds of cod. For other species, trip limits are the same as those for limited access vessels. There is no limit on other species at this time, but limits could be adopted in the future if necessary.

Hand gear only permits will include the use of hand-hauled tub trawls limited to between 0 and 500 hooks, with the hook limit to be specified based on comments received during public comment period.

Hand gear only permits can be transferred from one vessel to a replacement vessel, subject to the same restrictions as are applied to limited access permits, including vessel upgrading restrictions.

Alternative 2

Under this alternative, all handgear vessels will remain within the open access permit category. Open access vessels are limited to 300 pounds of cod, haddock, and yellowtail flounder, with no more than 200 pounds of cod. For other species, trip limits are the same as those for limited access vessels. Open access handgear will include the use of hand-hauled tub trawls limited to between 0 and 500 hooks, with the hook limit to be specified based on comments received during public comment period.

Alternative 4 – No Action
The requirements for open access hand-gear vessels will remain as in fishing year 2001, prior to the FW 33 court order. The permit category will remain open access. Vessels will be limited 300 pounds of cod, haddock, and yellowtail flounder per day.
Alternative 3 alternative trip limit

4.1.3.15 Sector Allocation

The Council considered not allowing the creation of voluntary self-selecting sectors. This was not selected because it would have eliminated one way to mitigate the negative impacts of this Amendment on small businesses. In addition, the Council considered a number of different ways to implement self-selecting sectors. These are described below.

Options for submitting proposals
Two options were considered for submission of sector proposals.

1. As part of the Council's periodic adjustment process. This option was not selected because it transfers the burden of organizing a sector to the Council.
2. Written by the sector applicants and reviewed by NMFS. This option was not selected because it removed the Council from the approval process for a sector.

Options for Sector Review
Option 1 – Streamlined Approval Process
The sector will submit its operations plan to the RA. NMFS will conduct a preliminary review of the application, and, if it determines the application is complete, will publish a notice in the *Federal Register* asking for comment on the proposed sector with a 30 day comment period. After reviewing all comments received, NMFS will either approve or reject the application and authorize the sector to operate in accordance with its operations plan. NMFS will advise the Council of any changes in resource allocations that result due to approval of the sector.

This option was not selected because it removed the Council from the approval process for a sector.

Movement Between Sectors
Two options were considered for movement between sectors. These were not selected because they constrained the ability of a sector to define the rules that govern its participants.

<u>Option 1</u>: Allow for open movement between sectors on a fishing year basis. In other words, all selections for the upcoming groundfish fishing year must be made prior to the start of the fishing year but the obligation only holds until the end of that fishing year.

Discussion: At the beginning of this management program, many individuals might be uncomfortable making a long-term commitment to a sector for a variety of reasons. By allowing them to make a short-term commitment, the whole network of sectors will be able to self-organize over the initial years of the program. However, this approach might lead to such instability among and within sectors and compromise their long term success.

<u>Option 2</u>: Require a multi-year commitment for participation within a sector. This can range from 2-10 years depending on the structure of the sector.

Discussion: This requirement will give sectors adequate time to organize their members and develop sector parameters. Mandating a longer-term commitment to a sector will urge members to work together to create a cohesive unit and ensure the success of the group.

Allocation of Resources
The Council considered an option that would allocate resources to a sector in terms of effort (DAS). This was not adopted, as it would make it difficult to control the harvest of a sector.

Option 1: Allocation could be based on current DAS allocations. Note that this option presumes that allocated days would be based on effective days only (i.e. that a program that would eliminate or hold latent effort in reserve). In addition, the sector would be assigned a target TAC for groundfish species based on catch history of the sector participants.

GB Cod Gillnet Sector
The Council considered implementing a GB Cod gillnet sector, but chose not do so because of concerns the proposal was not fully developed. A voluntary sector for this group could be approved in the future. Participation in this sector is open to vessels using day or trip gillnets to harvest GB cod. Permit holders must declare their intention to participate in the sector at least three months in advance of the beginning of the fishing year. Once declared into the sector, the vessel must remain in the sector for the entire fishing year and must abide by the regulations applicable to the sector for the entire year. If a permit is transferred during the fishing year, the new owner must also comply with the sector regulations for the remainder of the fishing year.

TAC
A GB cod quota (hard TAC) will be allocated to the sector. The sector's share of the overall GB cod TAC will be determined by calculating the share of the GB cod harvest taken by gillnet gear during fishing years 1996 through 2001 by the sector participants. Only fish caught using gillnets will be considered.

When the TAC is reached, the commercial components of the sector will cease fishing for the remainder of the fishing year.

Management Measures
Management measures will be specified in the sector operations plan.

4.1.3.16 Gulf of Maine Inshore Conservation and Management Stewardship Plan

This alternative is an approach to area management and was designed specifically to address the stocks in the Gulf of Maine, north of 42°20’N latitude. As such, it does not meet the biological objectives for stocks in other areas and would have to be adopted in concert with another alternative. For example, this alternative could be used as an element of area management.

The details of this proposal are described in the following sections. This proposal was not selected because it did not address, in detail, the measures that would be adopted for areas outside the Gulf of Maine. Comments received during the public comment period addressed this shortfall, but given the limited time available to analyze these suggestions, the Council did not choose to go forward with this concept in Amendment 13. It could be pursued in a future action.

4.1.3.16.1 Management Areas

Three distinct regulatory areas are created in the Gulf of Maine (see Figure 14). A vessel may fish in only one zone. They must declare which zone they will fish in prior to beginning fishing , and must stay in that zone for a minimum of one year. As an alternative, vessels could be allowed a one-time switch during the year subject to a conservation penalty (such as a 2:1 DAS charge).

Inshore Areas:

Area 1: 42°20'N, 69°54'W to the latitude of the Massachusetts/New Hampshire border (43°04.5'N)
Area 2: From the north end of Area 1 north along 69°45'W to 43°15'N, 69°45'W. East along 43°15'N to the 25600 loran line, then northeast to the Hague Line.

Offshore Area: Area north of 42°20'N, east and south of the boundaries for Areas 1, 2, and 3.

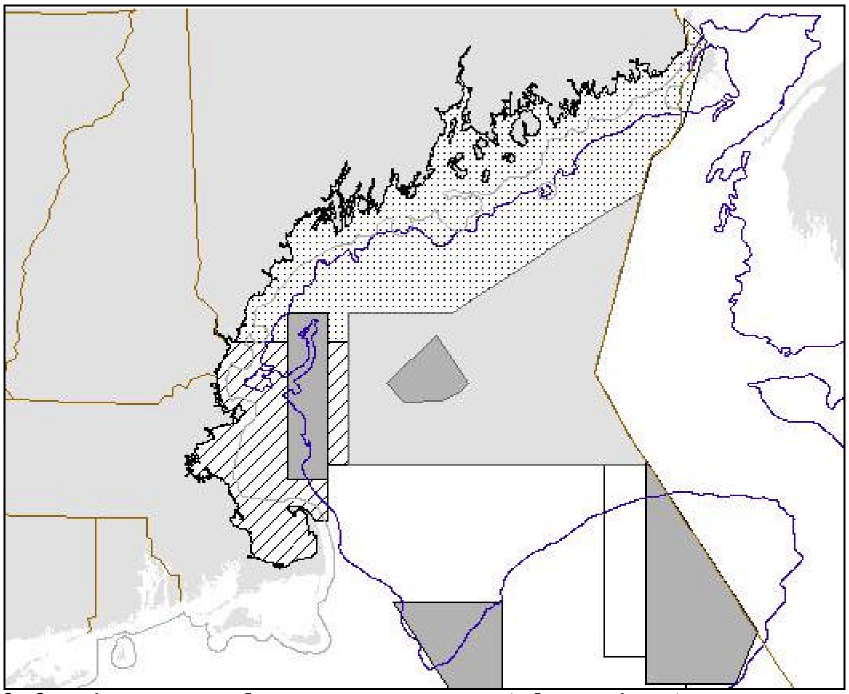

Figure 14 – Gulf of Maine proposed management areas (Alternative 5)

4.1.3.16.2 Fishing Year

The start of the groundfish fishing year is moved to July 1.

Discussion: As described in detail in Appendix XIII, this change moves the start of the fishing year away from when groundfish spawning occurs in the GOM. This may shift some fishing effort off of spawning stocks, as vessel operators will get their new DAS allocations when fish are not aggregated for spawning.

4.1.3.16.3 Possession/Trip Limit

The possession/trip limit for GOM cod is 600 lbs./day with a maximum of 6,000 lbs./trip. Trip limits cannot be changed during a fishing year.

4.1.3.16.4 Effort Controls

Multispecies limited access permits are limited DAS allocations implemented August 1, 2002, with the exception that any permit that qualified for less than 25 DAS will be allocated a minimum of 25 DAS. The difference between the number of DAS that can be used at the implementation of Amendment 13, and the number of DAS allocated in fishing year 2001, is considered "frozen" DAS. Specific criteria will be established that will allow the "thawing" and use of these DAS. Vessels that participated in collaborative research should not lose DAS. Any definition of "latent" DAS will provide protection for vessels engaged in cooperative research.

State management agencies can purchase latent, or unused, permits, and transform them into limited scale Diversification Permits. These permits would be administered or sold by the states to allow commercial fishermen in other fisheries to diversify again and operate at a small scale in the groundfish business. They may also allow for the re-qualification of people who have fished, but not for groundfish, during the last 20 years (since 1983). Diversification Permits would be limited to:

a. One of the three coastal zones
b. Restricted to fish traps, 1,000 hooks, or two jigging machines
c. Allocated with consideration of the long-term (100 years) groundfish yield in each zone.

4.1.3.16.5 Observer Coverage

The desired level of observer coverage is 20 percent of trips on all groundfish boats in all zones.
In addition, all midwater trawl vessels operating in the Gulf of Maine will have 100 percent observer coverage.

4.1.3.16.6 Gear Restrictions

The following management measures apply to the two inshore areas only.

Trawl Gear:

- Maximum of ten-inch roller/rockhopper gear
- Ground cables: maximum of 40 fathoms between doors and wing in the first fishing year after implementation, reduced to 30 fathoms in the second year and 20 fathoms in the third year and each year thereafter.
- Mesh size: 6.5 inch codend. Encourage, where appropriate, composite nets, 6.5 inch square on top, 6.5 inch diamond on bottom
- No night dragging

Gillnets:

- 50 nets maximum for all vessels, for all styles of groundfish gillnets
- Mesh size: 6.5 inch

Hook gear:

- 2,000 hooks per boat for longlining or tub trawling
- 4 jigging machines maximum per boat
- Five hooks per handline or jigging machine, four handlines per boat
- 12/0 circle hooks required for tub trawling or longlining

4.1.3.16.7 Fishing Limitations

Fishing with trawls will not be allowed at night.

4.1.3.16.8 Closed Areas

Seasonal/rolling closures:

March: 121, 122, 123
April: 121-125; 129 - 133
May: 124 - 125; 129-133; 136-140
June: 139-140; 141-147;152
October-November: 124,125; 148, 149, 150, 151, 153, 154, 155

The Herring Committee will consider prohibiting midwater trawl fishing in inshore closed areas I and II and the Western Gulf of Maine closed area

4.1.3.16.9 Changes in Governance Structure

In the future, each zone will have a governance structure that allows the participants declared into that fishery to determine many of the rules for fishing. These Councils will be expected to do the following:

- Change time or gear fished, or locations fished necessary to achieve any area TAC;
- Adjust trip limits to balance requirements for reductions in discards and fishing mortality;
- Change gear technology rules, area, and time fished.

4.1.3.16.10 Recreational Fishing – All Areas

The measures implemented August 1, 2002 will be continued.

Private recreational vessels:

- Minimum cod/haddock size of 23 inches
- 10 cod/haddock per person/per day, except 5 cod limit in GOM December 1 – March 31

Party/Charter Vessels:

- Cod /haddock minimum size of 23 inches for vessels not on a DAS
- 10 cod/haddock creel limit April 1 – November 30
- 5 cod limit GOM December 1 – March 31
- Vessels intending to fish in the GOM closed areas must declare into the charter/party fishery for the duration of the closure or for three months, whichever is greater

4.1.3.16.11 VMS Requirements

There are no VMS requirements for this alternative.

4.1.3.16.12 Possible Modifications

This option relies on a hard TAC in each area to insure biological objectives are met. If stock conditions change, the TAC will result in closure at a different time, but the measures will not be changed until a later Council action. Selection of a different rebuilding program will have the same result.

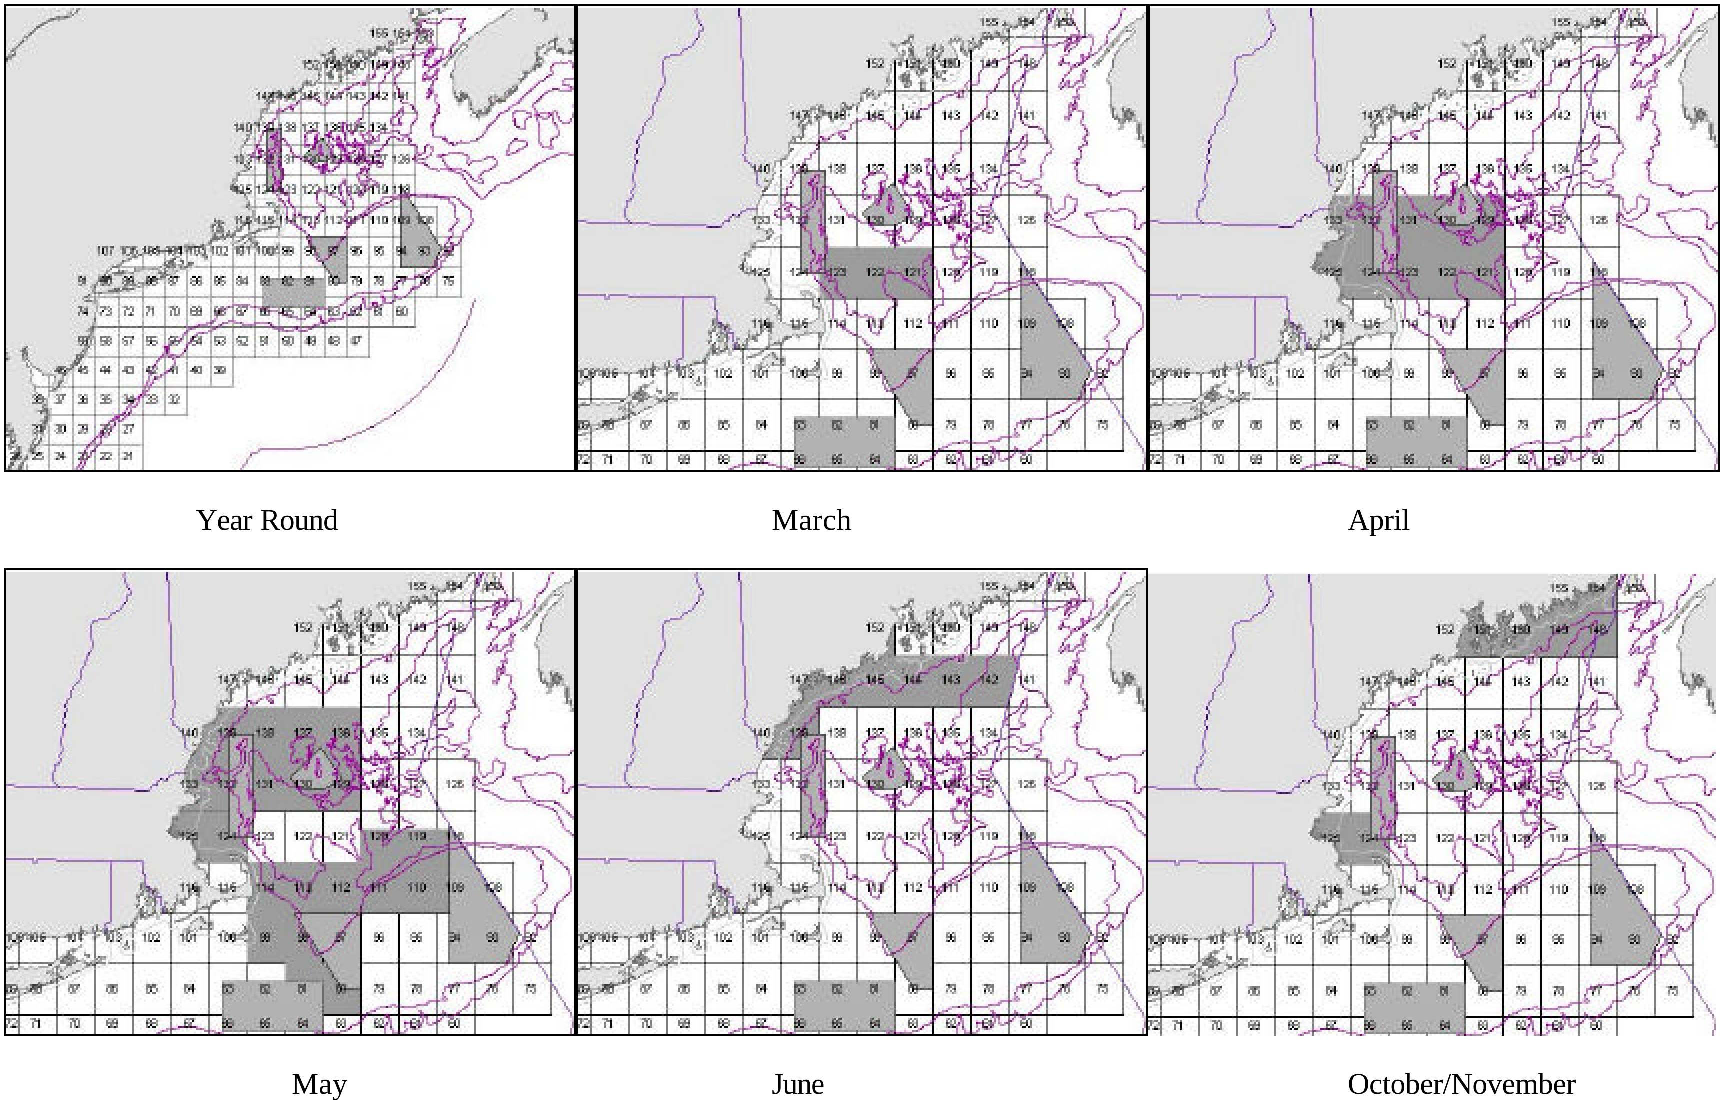

Figure 15 – Gulf of Maine Inshore Conservation and Management Stewardship Plan year round and seasonal closed areas

4.1.4 Measures to Control Capacity

The Council considered several additional alternatives for controlling capacity, described below.

4.1.4.1 No action

Under this alternative, DAS allocations would return to the levels that resulted from the effort reduction schedule of Amendment 7. Absent carry-over DAS or other adjustments (enforcement actions, etc.) vessels will receive the DAS allocations they had during fishing year 2001. No additional measures would be adopted in this amendment to reduce unused DAS, latent effort, or capacity.

This option was not selected because it did not address one of the purposes for the amendment – providing options for reducing harvesting capacity. It does not address the second goal of the amendment – creating a management system so that fleet capacity will be commensurate with resource status.

4.1.4.2 Alternative 1— Permit Absorption

A permit holder can transfer all permits held to another vessel. This alternative would have allowed permit holders to combine scallop and multispecies limited access permits, with some restrictions. It was not selected because it would have required changes to the permitting provisions of other management plans – changes that cannot be implemented solely through a groundfish amendment. The provisions of this alternative are described in the following sections.

Measures

Scallop and multispecies limited access permits may be combined. All permits (for all fisheries) associated with a vessel must be transferred from that vessel to another as a complete package, not distributed separately to a number of vessels. Duplicate permits will expire and the permit history may not be transferred to a third vessel. A multispecies or scallop permit holder may not apply more than one vessel's DAS allocation to a single vessel. The selling vessel is required to retire from fishing and all of its limited access permits must be transferred (sold) to another limited access vessel permit holder. Retirement from fishing means that a vessel may not participate in any other state or federal open or limited access fisheries after its permits are sold. Transfers can only be made between vessels whose characteristics are within the vessel upgrading restrictions.

Restrictions (Conservation Tax)

The recipient of the permits will be subject to some reduction in fishing privileges, imposed by one of the following three options:

Option 1:	No reduction in the number of active or inactive DAS transferred.
Option 2a:	No reduction in the number of active DAS transferred and 20% reduction of inactive DAS.
Option 2b:	10% reduction of the number of active DAS transferred and 20% reduction of inactive DAS.
Option 3:	20% reduction of the number of active DAS transferred and 40% reduction of inactive DAS.
Option 4:	50% reduction of the number of active DAS transferred and 75% reduction of inactive DAS.

For the purpose of this alternative, **active DAS** are determined based on the definition of "effective effort" chosen in Amendment 13. There are nine options for defining effective effort, described in Section 3.5.3.5. If an alternative which defines active DAS is *not* chosen for Amendment 13, active DAS will be defined as the maximum days used (not to exceed current DAS allocations) as determined by the call-in system or days absent computed from the VTR on trips where regulated multispecies were landed, from fishing years 1994 to 1999. **In this document the terms *active DAS* and *effective effort* are used interchangeably.**

Reactivation of DAS – (DAS Use by Permit Buyer)
All DAS acquired by a vessel through a permit transfer and absorption may not be used immediately following the transaction. Instead, they will be made available to the permit recipient according to the following reactivation schedule:

Option 1: 20% of the DAS acquired (after a conservation tax is applied) may be reactivated each year. In other words, a vessel will be allowed to use only 20% of the DAS it bought in the first year, 40% the next year, 60% the next, and so forth.

Option 2: DAS may be used in their entirety at any time following the transaction.

The Council may increase the rate at which the DAS could be activated each year through a framework adjustment.

Discussion
The objectives of this alternative were to provide greater economic opportunity and flexibility in all fisheries, while maintaining the character of the existing fleet and to achieve some long-term reduction in the number of vessels permitted to fish in Northeast fisheries. This long-term reduction will be accomplished through this alternative, since duplicate permits will expire when permits are consolidated.

This alternative relates to fisheries managed by other plans (e.g. Atlantic sea scallop fishery). Measures in other management plans may place limitations on the transfer of permits between groundfish vessels and those in different fisheries. This may reduce participation in the program described in this alternative.

4.1.4.3 Alternative 2—Permit Transfer

This alternative would have allowed limited access permit holders to transfer their multispecies permits to another vessel or vessels, with some restrictions. This alternative was not selected because it would have allowed permit splitting, which is prohibited in other monument plans. As a result, those plans would have required changes. The changes could not be implemented solely through a northeast multispecies plan amendment.

Measures
A vessel may transfer limited access permits that include a multispecies permit, to one or multiple vessels (i.e., the permits may be transferred separately – permit splitting is allowed). The selling vessel is required to retire from fishing and all of its limited access permits must be transferred (sold) to other limited access vessel permit holders or they will expire. Retirement from fishing means that a vessel may not participate in any other state or federal open or limited access fisheries after its permits are sold. Any permits not transferred by the selling vessel will also be retired. Duplicate permits will expire post-transfer. A multispecies permit holder may not apply more than one vessel's DAS allocation to a single vessel. This alternative may be combined with Alternative 4, the freeze alternative. Vessel replacement and upgrading restrictions will apply to these measures.

Restrictions (Conservation Tax)
The recipient of the permits will be subject to some reduction in fishing privileges, imposed by one of the following five options:

Option 1: No reduction in the number of active or inactive DAS transferred.
Option 2a: No reduction in the number of active DAS transferred and 20% reduction of inactive DAS.
Option 2b: 10% reduction of the number of active DAS transferred and 20%

reduction of inactive DAS.

Option 3: 20% reduction of the number of active DAS transferred and 40% reduction of inactive DAS.

Option 4: 50% reduction of the number of active DAS transferred and 75% reduction of inactive DAS.

For the purpose of this alternative, **active DAS** are determined based on the definition of "effective effort" chosen in Amendment 13. There are nine options for defining effective effort, described in Section 3.5.3.5. If an alternative which defines active DAS is *not* chosen for Amendment 13, active DAS will be defined as the maximum days used (not to exceed current DAS allocations) as determined by the call-in system or days absent computed from the VTR on trips where regulated multispecies were landed, from fishing years 1994 to 1999. **In this document the terms *active DAS* and *effective effort* are used interchangeably.**

Reactivation of DAS – (DAS Use by Permit Buyer)
The DAS acquired by a vessel through a permit transfer and consolidation may not be used in their entirety immediately following the transaction. Instead, they will be made available to the permit recipient according to the following reactivation schedule:

Option 1: 20% of the DAS acquired (after the 10 or 20% reduction at time of transfer) may be reactivated each year. In other words, a vessel will be allowed to use only 20% of the DAS it bought in the first year, 40% the next year, 60% the next, and so forth.

Option 2: DAS may be used in their entirety at any time following the transaction.

The Council may change the rate at which the DAS could be activated each year through a framework adjustment.

Discussion
The objectives of this alternative were to provide greater economic opportunity and flexibility in all fisheries, while maintaining the character of the existing fleet and to achieve some long-term reduction in both the number of vessels permitted to fish in Northeast fisheries and the active and inactive DAS in the fishery. This alternative seeks to reduce effort in the fishery without discriminating among vessels based on past performance.

This alternative relates to fisheries managed by other plans (e.g. Atlantic sea scallop fishery). Measures in other management plans may place limitations on the transfer of permits between groundfish vessels and those in different fisheries. This may reduce participation in the program described in this alternative.

DAS Transfer
While the Council adopted the DAS transfer proposal, there were options for its implementation that were not selected.

Restrictions
Option 2 was not selected because the DAS transfer proposal would not have reduced latent effort if this provision was included. In fact, it likely would increase current effort as unused DAS were activated. Option 2 is described below.

Option 2: No reduction in the number of active or inactive DAS transferred.

For the purpose of this alternative, **active DAS** are determined based on the definition of "effective effort" chosen in Amendment 13. There are nine options for defining effective effort, described in Section 3.5.3.5. If an alternative which defines active DAS is *not* chosen for Amendment 13, active DAS will be defined according to one of the following two options:

Option 1: Active DAS are the maximum days used (not to exceed current DAS allocations) as determined by the call-in system or days absent computed from the VTR on trips where regulated multispecies were landed, from fishing years 1994 to 1999.

Option 2: Active DAS are days on which more than 10% of landings by weight (as reported in the VTR) was composed of regulated species from fishing years 1994 to 1999.

Reactivation of DAS
A phase-in of DAS transferred, as described below, was not adopted because it would reduce the incentive for vessels to use the DAS transfer program

Option 1: Phase-In of DAS
20% of the DAS acquired (after a conservation tax is applied) could be reactivated each year. In other words, a vessel would be allowed to use only 20% of the DAS it bought in the first year, 40% the next year, 60% the next, and so forth.

The Council may increase the rate at which the DAS could be activated each year through a framework adjustment.

4.1.4.4 Alternative 4—Freeze on Unused Days-At-Sea

This alternative sought to reduce latent effort in the groundfish fishery by allowing vessels to voluntarily "freeze" their DAS during a specified time period ("freeze period") while incrementally reducing the number of "unfrozen" DAS at an annual rate for the duration of the freeze period.

This alternative was not selected because it is impractical. It would encourage vessels to use all their DAS rather than place DAS in the freeze program. The Groundfish Advisory panel advised that fishermen were unlikely to use this alternative. It would have created an administrative burden with few benefits. The proposed measures are described below.

Measures
Participation is voluntary. Unused DAS of those not participating in the freeze program will be reduced according to one of the following two options:

Option 1: Unused DAS during the freeze period will be reduced 5% annually for permits that do not land groundfish after Amendment 13 is implemented.
Option 2: Unused DAS during the freeze period will be reduced 5% annually for permits that may have landed some groundfish after Amendment 13 but do not use 100% of their DAS.

Once the freeze period expires, permit holders may reenter the fishery with DAS adjusted to reflect the DAS allocated to vessels that remained active in the fishery during the freeze period. The guidelines for use of DAS by those who participate in the freeze program after the freeze period is over will take into account rebuilding that occurred during the freeze and the fleet's remaining active capacity. All vessels, both participants and non-participants in the freeze program, remain subject to additional DAS restrictions implemented in Amendment 13.

There are two options for determining the duration of the freeze:
Option 1: A 5-year freeze
Option 2a: A freeze until 75% B_{MSY} is reached for all stocks combined.
Option 2b: A freeze until 75% B_{MSY} is reached for cod, haddock, and yellowtail stocks combined.

Discussion

The objectives of this alternative are to reduce the level of allocated fishing effort during rebuilding periods without discriminating among vessels based on their past performance.

4.1.4.5 Days-at-Sea Reserve

While the Council adopted the DAS reserve program, there were a number of options considered for defining "effective" effort. This "effective" effort is shown in Table 323, Table 324, and Table 325. These tables include distributive impact data by permit category, length class and homeport state for the options for defining effective effort. In 2002, NMFS completed a latent effort permit buyback program for the multispecies fishery. The vessels that participated in the buyout program were removed from the fishery in Spring 2002. Since these vessels will not participate in the fishery any longer, the fishery impacts from the options for defining effective effort have been calculated without the inclusion of these vessels. In all cases, "landing" refers to the commercial landing of fish for sale, and not to landings by recreational or charter/party fishing vessels.

The higher the number of DAS that are defined as "effective" effort, the greater the percentage of "effective" DAS that will be placed into Category B DAS (that is, they cannot be used at the implementation of Amendment 13) in order to achieve real DAS reductions. The number of DAS that contributed to fishing mortality in fishing year 1999 is 51,500 DAS. Any DAS reductions must reduce the number of DAS used below this level.

***Current allocation* refers to FY 2001 allocation.**

Option 1: Effective effort is defined as the maximum DAS used by a permit in any single fishing year from 1994 to 1999, not limited by current allocation*.
Resulting Effective Effort in DAS: 81,000 of 131,000 (Approximates).

Option 2: Effective effort is defined as the maximum DAS used by a permit from 1994 to 1999 in any single year, not to exceed the current allocation*. For vessels that were not required to use DAS before 1996, only trips that documented one pound of groundfish or more are counted.
Resulting Effective Effort in DAS: 67,000 of 131,000 (Approximates).

Option 3: Effective effort is defined as the maximum DAS used by a permit from 1994 to 1999 in any single year not to exceed the current allocation*. For vessels that were not required to use DAS before 1996, only years in which at least 5,000 pounds of groundfish were landed may be considered when calculating new baseline.
Resulting Effective Effort in DAS: 62,500 of 131,000 (Approximates).

Option 4: Effective effort is defined as the maximum DAS used by a permit from 1994 to 1999 in any single year not to exceed the current allocation*. For vessels that were not required to use DAS before 1996, only trips that documented one pound of groundfish or more are counted. An additional 10 DAS is added to all permit holders not to exceed current allocations*.
Resulting Effective Effort in DAS: 73,500 of 131,000 (Approximates).

Option 5: Effective effort is defined as the maximum DAS used by a permit from 1994 to 1999 in any single year not to exceed the current allocation*. For vessels that were not required to use DAS before 1996, only trips that documented one pound of groundfish or more are counted. An additional 10 DAS is added to all permit holders not limited by current allocations*.
Resulting Effective Effort in DAS: 77,000 of 131,000 (Approximates).

Option 6: Effective effort is defined as the maximum DAS used by a permit in any single year from 1996 to 1999, not to exceed the current allocation*.

Resulting Effective Effort in DAS: 63,500 of 131,000 (Approximates).

Option 7: Effective effort is defined by calculating a DAS utilization percentage (X) for each permit holder based on the fishing year with the highest number of DAS used in fishing years 1996-1999. Only DAS called-in where there is an associated catch (e.g. at least a pound of fish reported would apply) would be considered a "used" DAS. If a permit did not record any commercial fishing revenues since fishing year 1996, no DAS are defined as effective.

Depending on the percentage of DAS used in the best year, a tiered method for defining effective DAS is applied as follows:

0% > X < 25%	=	20% of DAS allocation is effective
25% > X < 50%	=	34% of DAS allocation is effective
50% > X < 75%	=	68% of DAS allocation is effective
75% > X = 100%	=	95% of DAS allocation is effective

Resulting Effective Effort in DAS: 68,000 of 131,000 (Approximates).

Option 8: Effective effort is defined as the allocation of DAS implemented on August 1, 2002 in the interim measures established as a result of the Framework 33 lawsuit (*CLF et al. v. Evans et al.*).

Resulting effective effort in DAS: approximately 58,200 of 131,000. Baseline before 20 percent reduction is about 71,000 DAS.

The Council did not select these other alternatives because it believes that Option 9 (the proposed action) most fairly distributed DAS based on recent groundfish fishing activity.

4.1.4.6 Alternative 6—Mandatory latent effort categorization with voluntary flexibility options

This alternative combines the core elements of Alternative 5 with the tools of permit transfer, permit absorption and days-at-sea transfer in Alternatives 1-3. This alternative illustrated the ability of the Council to adopt more than one of the proposed capacity measures. In essence, the proposed action is a variation of this alternative because the Council adopted both the DAS reserve and the DAS transfer proposals (Option 3 below).

Measures

There is an inherent conflict with the reactivation schedules and transfer taxes in Alternatives 1-3 and the categorization of allocated DAS to A, B, and C days in Alternative 5. To address this problem, the reactivation schedules and transfer taxes are eliminated from this alternative and the vessels will be subject to the reactivation restrictions under Alternative 5. For instance, if a permit is transferred, the buyer will receive a permit with Category A, B and C days as defined under the seller's effort history. If a permit holder wishes to transfer DAS to another permit holder, the buyer will receive DAS in categories A, B, and C as defined for the seller.

Transfers of DAS or permits must occur within upgrade parameters so that that they will remain nearly conservation-neutral. **The Council will place a cap on the number of permits or DAS an individual is allowed to hold.**

Option 1: **Adoption of Alternative 5 first and then Alternative 1**
After DAS are categorized for each permit holder via a selected method for defining effective effort, permit absorption may occur in the fishery within the constraints of the DAS categories.

Option 2: **Adoption of Alternative 5 first and then Alternative 2**
After DAS are categorized for each permit holder via a selected method for defining effective effort, permit transfer may occur in the fishery within the constraints of the DAS categories.

Option 3: **Adoption of Altemative 5 first and then Alternative 3**
After DAS are categorized for each permit holder via a selected method for defining effective effort, days-at-sea transfer may occur in the fishery within the constraints of the DAS categories.

Option 4: **Adoption of Alternative 5 first and then utilize multiple flexibility and consolidation tools**
After DAS are categorized for each permit holder via a selected method for defining effective effort, permit absorption, permit transfer and days-at-sea transfer may occur in the fishery.

Discussion
The objective of this alternative is to develop specific controls on the rate at which latent effort can enter the groundfish fishery through mandatory DAS categorization measures while allowing vessels to remain profitable through flexibility and consolidation options.

4.1.5 Management Alternatives to Address Rebuilding Requirements

The Council considered four broad alternatives to address rebuilding requirements for the commercial fishery, and four options for the recreational fishery. The non-selected alternatives are described below, with brief explanations of the reasons they were not selected.

4.1.5.1 No Action Alternative

Under this alternative, the management measures in place during fishing year 2001 would be maintained. DAS allocations will return to the levels that resulted from the DAS reduction schedule adopted in Amendment 7. These measures have not been achieving the biological objectives of the Amendment. As a result, if the Council selects this alternative, the Secretary of Commerce would most likely prepare an FMP that meets the biological objectives. This alternative was not selected because it did not meet M-S Act requirements to adopt formal rebuilding programs for overfished stocks and to end overfishing. Only brief discussions of the impacts of this alternative are included in this Amendment.

There was considerable public comment that these measures were not the appropriate no action alternative to use as a basis for analysis. These measures were not in place during fishing years 2002 and 2003. Interim measures were implemented consistent with a negotiated settlement agreement in the *CLF et al v. Evans* court case. These interim measures, however, can only be in place for a limited period and are scheduled to expire. It is also unlikely that the no action measures would remain in place absent this amendment, since they do not comply with M-S Act requirements. Either NMFS or the court would implement measures to meet M-S Act requirements. Nevertheless, the Council was directed by NMFS to use the measures in place in fishing year 2001 as the no action alternative because the interim measures have a fixed effective date and it is not certain what measures would replace them if this amendment is not adopted. The Council also chose this as the basis because it would provide a readily understood state that the public could use to understand the impacts of the proposed alternatives.

The following section summarizes the major elements of the no action alternative. It does not identify all management measures. Refer to Amendment 7 and the associated framework adjustments for details of this alternative.

Area closures: Area closures remain the same as in FY 2001. The Western GOM Closed Area will be extended until changed by future Council action. GOM seasonal area closures are shown in Figure 16. The Council will continue the backstop provision that if 50 percent of the GOM cod target TAC (based on the average between the $F_{0.1}$ target TAC and the F_{max} target TAC) is landed by July 31, additional closures result. If the contingency is met and the backstop measures are triggered, Cashes Ledge Closed Area will remain closed for one additional month (November) and Blocks 124 and 125 will close in January (see Figure 16).

Trip Limit: Trip limits remain the same as in Framework 33: 400 lbs./day with a maximum possession limit equal to ten times the daily limit (i.e. 4,000 pounds) for GOM cod. Vessels may land a limited overage of cod as follows:

- Vessels not enrolled in the Gulf of Maine Cod Trip Limit Exemption Program are limited to 400 pounds for each day or part of a day on the trip. On trips under 24 hours a vessel may not land more than 400 pounds of cod, and may not land cod again until 24 hours have elapsed from the start of the trip, although the vessel may call-out of the DAS program before 24 hours have elapsed. On trips longer than 24 hours, a vessel may land 400 pounds of cod for each full day (24 hours) of the trip and 400 pounds for any part of a 24-hour period, provided it does not call out of the DAS program until the remainder of that 24-hour period has elapsed. A vessel on a trip longer than 24 hours and landing up to 400 pounds of cod for any part of a (24-hour) day may not leave port or call out of the DAS program for the remaining part of the 24 hours.
- A vessel may not land more than 4,000 pounds, even if the trip duration exceeds ten days.

Trip limits for GB cod remain the same as implemented through Framework 33: 2,000 pounds per DAS, or part of a DAS, with a maximum possession limit equal to ten times the daily limit (20,000 pounds). There are no trip limits for other key stocks.

Adjustment of the haddock trip limit

The Regional Administrator may adjust the TAC for haddock at any time prior to or during the fishing year to prevent exceeding the target TAC or allow harvesting up to 75% of the target TAC, as described below.

(A) Adjustment to haddock trip limit to prevent exceeding target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that the Regional Administrator determines will prevent exceeding the target TAC. This adjustment may be made if the Regional Administrator projects that the target TAC for haddock will be exceeded, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

(B) Adjustment of the haddock trip limit to allow harvesting up to 75 percent of target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that is determined to be sufficient to allow harvesting of at least 75 percent of the target TAC, but not to exceed the target TAC. This adjustment may be made if the Regional Administrator projects that that less than 75 per cent of the target TAC for haddock will be harvested by the end of the fishing year, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

Effort controls: No revisions to the DAS allocation that resulted from the effort reduction program adopted in Amendment 7.
Gear restrictions: No revisions to gear requirements adopted in Amendment 7 and subsequent frameworks. Vessels in the GOM/GB regulated mesh area must use either 6 inch diamond or 6.5 inch square mesh trawl cod ends, 6 inch or 6.5 inch gillnets. Day gillnet vessels are restricted to 80 stand-up nets or 160 tie-down nets; day gillnet vessels must tag nets. Trip gillnet vessels must bring all nets back at the end of a trip. Trawl vessels are limited to 12-inch roller gear in the inshore GOM.
Recreational restrictions: Recreational vessels are limited to 10 fish per angler, combined cod and haddock. There is no possession limit for other groundfish species. Minimum size for cod is 19 inches.

Minimum Fish Sizes: The minimum sizes for commercially caught groundfish species are:

Cod	19 (48.3 cm)
Haddock	19 (48.3 cm)
Pollock	19 (48.3 cm)
Witch flounder (gray sole)	14 (35.6 cm)
Yellowtail flounder	13 (33.0 cm)
Atlantic halibut	36 (91.4 cm)
American plaice (dab)	14 (35.6 cm)
Winter flounder (blackback)	12 (30.5 cm)
Redfish	9 (22.9 cm)

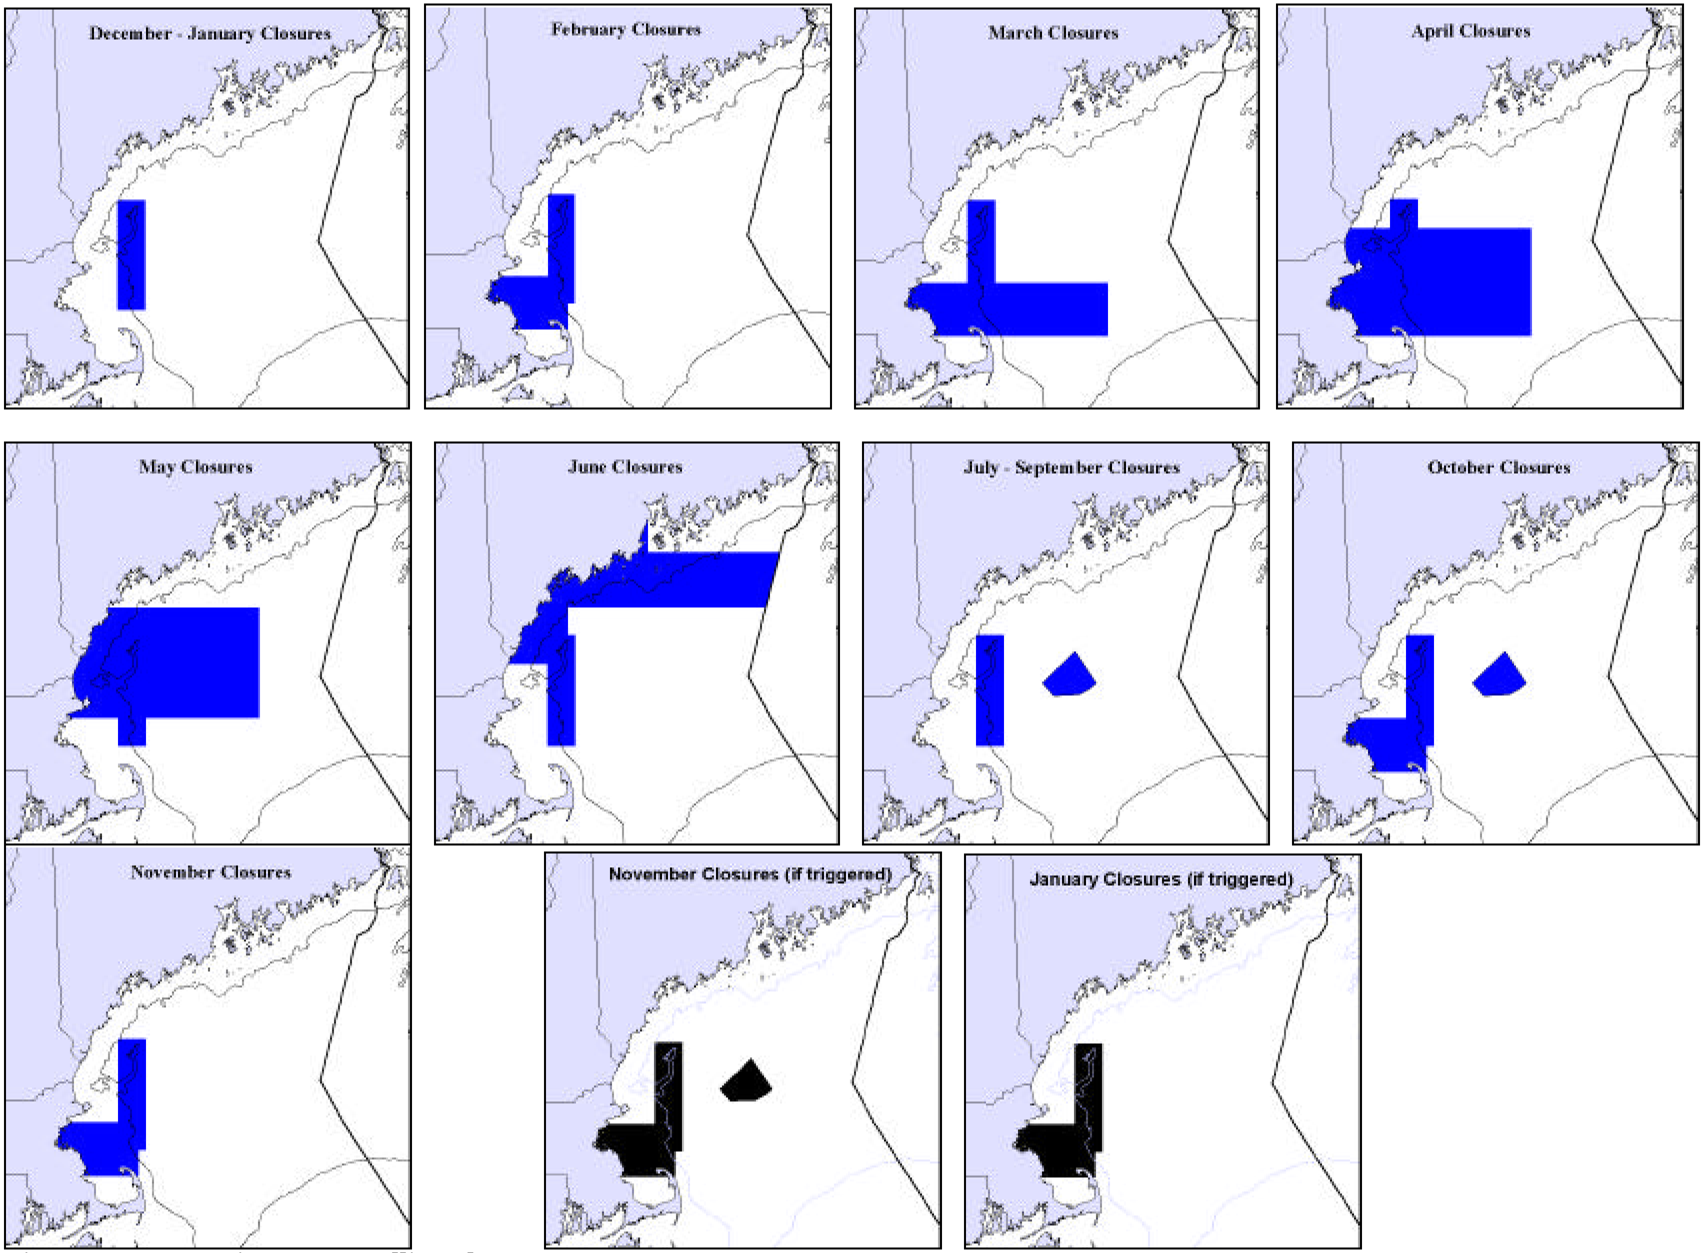

Figure 16 – No action GOM rolling closures

4.1.5.2 Alternative 1 – Up To 65% Reduction in Used DAS

This alternative would adopt all the management measures implemented as a result of a settlement agreement among certain parties in *Conservation Law Foundation et al. v. Evans et al.* Because these management measures are not likely to achieve the biological objectives of Amendment 13, effort controls are imposed to achieve the objectives.

While this specific alternative was not selected, the Council did develop a variant based on comments received during the public comment period. By combining rebuilding trajectories/strategies, the Council was able to mitigate some of the adverse economic impacts caused by the DAS reductions proposed in this alternative.

Effort Controls
The reduction in used DAS depends on the rebuilding strategy selected. Two options are illustrated below.

Option 1: 55 percent reduction in used DAS
This option uses an actual 55% reduction in used DAS as a major element in achieving the mortality reductions in the amendment. It is designed for use with the <u>constant fishing mortality or adaptive rebuilding strategy</u>. The 55% mortality reduction achieves most of the reduction necessary for GOM cod, GB cod, plaice, white hake, and Cape Cod/GOM yellowtail flounder. **An actual 55% reduction in DAS from fishing year 2000 and 2001 levels means that only 28,400 DAS will be fished under this option.** This is 45% of the average DAS used in fishing years 2000 and 2001. *In the analysis of impacts using the Closed Area Model, this is referred to as Alternative 1A when the 2,000 lb-day/20,000 lb–trip GB cod trip limit is used, Alternative 1C when the seasonal hook gear and 1,000 lb-day/10,000 lb-trip GB cod trip limit is used.*

There are a variety of possible ways to achieve the 55 percent DAS reduction in used DAS. As noted earlier, this option assumes that one of the approaches to controlling unused effort suggested by the Capacity Committee or implemented through the FW 33 court order as implemented on August 1, 2002, will be adopted. **The smaller the pool of baseline DAS, the less the additional reduction that must be applied to each permit to reach the targeted 28,400 DAS.**

Section 3.5.3.5 of the capacity reduction alternatives includes alternatives for a variety of ways to calculate "effective" DAS – sometimes referred to as "baseline" or “active” DAS. Table 24 lists some of these alternatives, shows the number of DAS that result, and the additional reduction for each permit in order to achieve the 28,400 DAS target (ignoring any carry-over DAS). The used DAS target may be adjusted as the success of the rebuilding program is evaluated.

Estimation of DAS Allocations to Achieve Target Use for Alternative 1A/1C
The DAS targets in this alternative are based on used DAS, not allocated DAS. Some DAS are not used in every year, suggesting that the allocated DAS can be higher than the targeted used DAS. The difficult question is "how much higher?" Historic use (DAS used/DAS allocated) for each permit category is probably not a good predictor of future DAS use. As allocations become more restrictive, the percentage of DAS used for each permit category is likely to increase from historic levels. Calculating the number of DAS that need to be allocated in order to achieve a target of used DAS is subject to several factors:

> (1) Whether or not leasing or transfers of DAS are authorized by the Amendment. If DAS can be readily transferred, the total number allocated should be equal to the targeted use as it is likely that DAS will be moved from inactive vessels to active vessels.
>
> (2) The option selected for defining "effective effort." If effective effort is defined in such a way that currently active groundfish vessels receive most of the DAS, then the number of DAS allocated should be closer to the targeted number to be used because active groundfish vessels are likely to

continue to use their DAS. On the other hand, if DAS are given to vessels that do not have a recent history of fishing for groundfish, it is not likely that these vessels will start using their DAS under the restrictive measures in Amendment 13. If DAS leasing or other means of transferring these unused DAS are not available, then the number allocated could be higher if it is assumed that these vessels will not use their DAS.

(3) The targeted use level. As the targeted number used declines, a series of interactions could occur that will affect the actual use of allocated DAS. In the absence of DAS leasing or other means to transfer DAS, a low level of used DAS may result in some vessels to choose not to fish at all because they may be unable to remain profitable. A the same time, part-time vessels may recognize an opportunity to fill a market gap and may become more active in the fishery - but only if they have enough DAS to do so, which depends on how effective effort is defined.

(4) Other management restrictions in place. Some measures (for example, area closures or hard TACs) may prevent some vessels from using their allocated DAS.

Estimated reductions in DAS allocations necessary to reach a target DAS level were calculated by applying an assumed use rate by permit category to a given baseline effective DAS definition. Three scenarios were developed for use rates: one assuming DSA leasing or other DAS transfers are authorized and all available DAS will be used, one based on observed 2002 use and another based on a probable increase in use rates. Estimated reductions were also estimated both with and without carry-over DAS. Results are shown in Table 24.

Observed use rates for FY2002 were 90% for individual, 60% for fleet, 69% for combination, 37% for hook-only, and 72% for large mesh permit holders. These use rates seem likely to increase. To account for probable future changes in DAS use the FY2002 the proportion of unused DAS was assumed to decrease by approximately one-half. The resulting use rates that were then applied were as follows: 95% for individual, 80% for fleet, 85% for combination, 70% for hook-only, and 85% for large mesh permit holders.

Based on 2002 use rates, to achieve used DAS of 28,400 days would require a reduction from an effective effort baseline ranging from a low of 32.7% under Option 3 to a high of 48.6% for Option 1 (Table 24). Assuming 2002 use rates continue, the target of 28,400 used DAS could be reached with a 41.4% reduction from the freeze baseline or an additional 21% reduction from FY2002 allocations. Assuming DAS use rates do increase the necessary DAS reduction to keep up with increased effort would have to be greater; about 10 to 13% greater depending on the selected option to define effective. Under Option 8 the DAS reduction would need to be 53.2% from the freeze baseline or an additional reduction of 33% reduction over FY2002 allocations.

Prior to FY2002 only a small proportion of vessels actually used carry-over DAS even though they were available to nearly all vessels. With the proposed DAS reductions under Alternative 1 it seems likely that a much larger number of vessels would take advantage of carry-over DAS from FY2003 which means that the target FY2004 used DAS would probably be exceeded unless carry-over DAS are accounted for. Approximately 11,800 DAS were carried over to FY2002 from FY2001, and to date, 11,400 days were carried over to FY2003 from FY2002. Depending on DAS in FY2003 the number of carry-over days that would be available in FY2004 could be similar to that of FY2002 and FY2003 or may be less if DAS use rates increase.

Assuming carry-over days will be used at the same rate as defined above, the DAS reduction needed to achieve 28,400 used DAS in FY2004 would range from a low of 42.5% to a high of 54.5% under assumed FY2002 use rates and would need to be between 9 and 12% higher if DAS use rates increase (Table 3). Compared to the results reported in Table 1, DAS reduction would need to be increased by between 5 and 10 percent to account for the use of carry-over days. If, as assumed, DAS use rates increase and the number of carry-over days that are used increases, the number of DAS that will be available to carry-over should decline over time. This means that the DAS reduction from an effective effort baseline could be adjusted downward (i.e. a lesser reduction) as available carry-over DAS shrink.

Effective DAS Calculation	DAS Allocated (approximate)	Additional reduction for each permit to achieve 28,400 DAS (assumes all DAS used, no carryover)	Additional reduction for each permit to achieve 28,400 DAS (without leasing/other transfers)			
			Current use, no carryover DAS	Increased use, no carryover DAS	Current use, carryover DAS	Increased use, carryover DAS
None	131,000	78%	63.1%	71.5%	66.3%	74.0%
Capacity Option 1 – Max. DAS used FY 1994 through 1999, not limited by 2001 allocation	81,000	65%	48.6%	58.2%	54.5%	63.3%
Capacity Option 2 - Max. DAS used FY 1994 through 1999, limited by 2001 allocation	67,000	57%	36.7%	49.2%	45.4%	56.6%
Capacity Option 3 – Max DAS used FY 1994 through 1999, with 5,000 pounds rqmnt.	62,500	55%	32.7%	45.7%	42.5%	54.1%
Capacity Option 4 - Max DAS used FY 1994 through 1999, with poundage rqmnt.	73,500	61%	41.5%	53.4%	49.0%	59.7%
Capacity Option 5 - Max DAS used FY 1994 through 1999, with poundage rqmnt., plus 10 DAS	77,000	63%	44.3%	55.6%	51.2%	61.3%
Capacity Option 6 – Max, DAS used 1996 to 1999, limited by 2001 allocation	63,500	55%	33.3%	46.4%	42.9%	54.5%
Capacity Option 7 – Percentage of max DAS used FY 1996 – 1999	68,000	58%	36.8%	49.7%	45.5%	56.9%
Capacity Option 8 - FW 33 Court Order Allocations	71,000	60%	41.4%	53.2%	49.0%	59.5%
Capacity Option 9 – Max DAS used 1996 through 2001, 5,000 pounds reg. Groundfish rqmnt.	68,700	59%	38.8%	50.7%	47.0%	57.7%

Table 24 – Additional DAS reduction necessary to achieve 28,400 DAS under various capacity reduction alternatives. (Note: Option 8 analyzed using baseline (before court ordered 20% reduction) for consistent comparison across alternatives.)

Option 2: Phase-in of 65 percent DAS reduction

This option phases-in over several years a reduction in used DAS that totals 65 percent. It is designed to implement the phased-reduction fishing mortality rebuilding strategy and is not consistent with other rebuilding strategies. Because the fishing mortality in the later years of the program is lower than in the constant mortality strategy, the total reduction in used DAS must also be more in order to achieve the rebuilding obje ctives. *In the analysis of impacts using the Closed Area Model, this is referred to as Alternative 1B when the 2,000 lb -day/20,000 lb – trip GB cod trip limit is used, Alternative 1D when the seasonal hook gear and 1,000 lb-day/10,000 lbd-trip GB cod trip limit is used.*

The used DAS targets for this option are shown in Table 25. These targets may be adjusted by framework action as the success of the rebuilding program is monitored.

Fishing Year	Reduction in Used Das from FY 2000/2001	Used DAS Target
2004	35%	41,050
2005	45%	34,750
2006	55%	28,400
2007	65%	22,100

Table 25 – Planned phase-in of DAS reduction

There are a variety of possible ways to achieve the 55 percent DAS reduction in used DAS. As noted earlier, this option assumes that one of the approaches to controlling unused effort suggested by the Capacity Committee or implemented thr ough the FW 33 court order as implemented on August 1, 2002, will be adopted. **The smaller the pool of baseline DAS, the less the additional reduction that must be applied to each permit to reach the targeted 22,100 DAS.**

Section 3.5.3.5 of the capacity reduction alternatives includes alternatives for a variety of ways to calculate "effective" DAS – sometimes referred to as "baseline" or “active” DAS. Table 26 lists some of these alternatives, shows the number of DAS that result, and the additional reduction for each permit in order to achieve the first year DAS target (ignoring any carry-over DAS). The used DAS target may be adjusted as the success of the rebuilding program is evaluated.

Estimation of DAS Allocations to Achieve Target Use for Alternative 1B/1D

Based on 2002 use rates, to achieve used DAS of 41,050 days for year 1 of the Alternative 1 phased effort reduction would require a reduction as low as 2.7% for effective effort Option 3 or as high as 25.7% for Option 1. Used DAS of 41,050 days could be achieved with a 15.4% reduction from the Option 8 baseline. Note that the estimated reduction for Option 8 is less than the 20% reduction that was actually implemented for FY2002. This is because the observed FY2002 DAS use was less than 41,050 DAS which means that the FY2002 DAS reductions may have been more than necessary to achieve the target DAS use for Alternative 1B. However, this conclusion is contingent on the assumption that DAS use rates will not increase. Should DAS use increase, the needed reduction to keep DAS use to 41,050 days would have to be much greater. For example, the Option 3 reduction would have to be increased to 21.5% while the Option 8 reduction would need to be doubled to 32.4%.

Accounting for carry-over DAS, to achieve a target of 41,050 used DAS for year 1 of Alternative 1B would require a DAS reduction of between 16.8% and 34.2% assuming FY2002 use rates prevail. Should use rates increase, DAS would have to be reduced by an additional 12 to 17 percent depending on the selected effective effort option. These DAS reduction represent an increase of 7 to 14 percent compared to that reported in Table 26.

Effective DAS Calculation	DAS Allocated (approximate)	Additional reduction for each permit to achieve 41,050 DAS (assumes all DAS used, no carry-over)	Additional reduction for each permit to achieve 41,050 DAS (without leasing/other transfers)			
			Current use, no carryover DAS	Increased use, no carryover DAS	Current use, carryover DAS	Increased use, carryover DAS
None	131,000	67%	46.7%	58.8%	51.2%	62.4%
Capacity Option 1 – Max. DAS used FY 1994 through 1999, not limited by 2001 allocation	81,000	49%	25.7%	39.6%	34.2%	47.0%
Capacity Option 2 - Max. DAS used FY 1994 through 1999, limited by 2001 allocation	67,000	39%	8.5%	26.6%	21.1%	37.3%
Capacity Option 3 – Max DAS used FY 1994 through 1999, with 5,000 pounds rqmnt.	62,500	34%	2.7%	21.5%	16.8%	33.6%
Capacity Option 4 - Max DAS used FY 1994 through 1999, with poundage rqmnt.	73,500	44%	15.5%	32.7%	26.4%	41.8%
Capacity Option 5 - Max DAS used FY 1994 through 1999, with poundage rqmnt., plus 10 DAS	77,000	47%	19.5%	35.8%	29.4%	44.1%
Capacity Option 6 – Max, DAS used 1996 to 1999, limited by 2001 allocation	63,500	35%	3.6%	22.5%	17.5%	34.3%
Capacity Option 7 – Percentage of max DAS used FY 1996 – 1999	68,000	40%	8.6%	27.2%	21.2%	37.7%
Capacity Option 8 - FW 33 Court Order Allocations	71,000	42%	15.4%	32.4%	26.3%	41.5%
Capacity Option 9 – Max DAS used 1996 through 2001, 5,000 pounds reg. Groundfish rqmnt.	68,800	40%	11.6%	28.7%	23.4%	38.8%

Table 26 – DAS reduction necessary to achieve 41,050 used DAS under various capacity reduction alternatives. This wouldbe the first year used DAS target under Option 2, phase in of DAS reductions. (Note: Option 8 analyzed using baseline (before court ordered 20% reduction)).

DAS Restrictions
In the SNE and MA regulated mesh areas (see Figure 17), DAS are counted at a differential rate of 1.5:1 during the months of December through April. To facilitate this requirement, a vessel fishing in this area must either:

- Use an approved VMS, or
- Obtain a letter of authorization to fish in the area. A vessel must commit to this program for a minimum of thirty days and cannot fish on a groundfish DAS in any other area during this period.

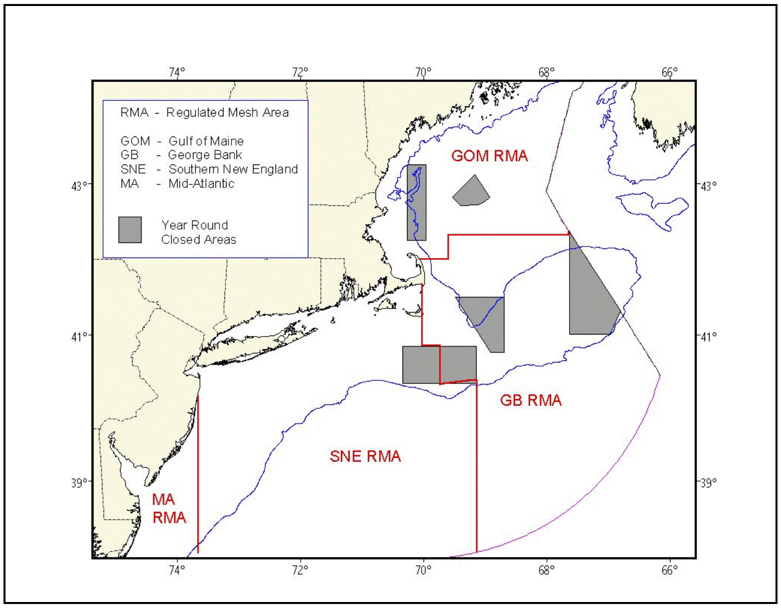

Figure 17 – Regulated mesh areas

Management Measures
All management measures adopted by the negotiated settlement agreement among certain parties as implemented August 1, 2003 are maintained unless changed (see following sections) . These measures are not repeated here, but can be found in 50 CFR 648 Subpart F.

Closed Areas
Year Round Closed Areas
The current Closed Area I, Closed Area II, Western Gulf of Maine, Cashes Ledge, and Nantucket Lightship Closed Areas will be continued as year round closed areas.

Seasonal Closed Areas
The seasonal closed areas are:

March: 121, 122, 123
April: 121-125; 129-133;
May: 124- 125; 129-133; 136-140; 80 – 81; 98-99; 109-114; 118-120 south of 42°20’N
June: 132-133; 139-140; 141-147; 152
October: 124-125
November: 124-125

Possession Limits
GOM cod: 800 lbs/day / 4,000 lbs/trip.
GB cod: Two options:

Option 1A/1B: 2,000 lbs/day /20,000 lbs/trip
Option 1C/1D:
1,000 lbs/day/10,000 lbs/trip for trawl and gillnet vessels
For hook vessels:

- July 1 – September 15: Jig and commercial longline directed cod season. 2,000 lbs./day limit. No groundfish landings on Friday and Saturday.
- September 16 – December 31: Restricted cod season. 600 lbs/day
- January through March: Jig and demersal longline fishing. 2,000 lbs/day
- April, May, June: no jig or demersal longline groundfish fishing on Georges Bank
- In order to use this seasonal hook gear trip limit, vessels must make an annual declaration for using hook gear.

CC/GOM yellowtail flounder: March 1 – May 31: 250 pound possession limit
June 1 – February 28: 750 lbs. per DAS/3,000 lbs. per trip possession limit
SNE/MA yellowtail flounder: March 1 – May 31: 250 pound possession limit;
June 1 – February 28: 750 lbs. per DAS/ 3,000 lbs per trip possession limit

Adjustment of the haddock trip limit
The Regional Administrator may adjust the TAC for haddock at any time prior to or during the fishing year to prevent exceeding the target TAC or allow harvesting up to 75% of the target TAC, as described below.

(A) Adjustment to haddock trip limit to prevent exceeding target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that the Regional Administrator determines will prevent exceeding the target TAC. This adjustment may be made if the Regional Administrator projects that the target TAC for haddock will be exceeded, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

(B) Adjustment of the haddock trip limit to allow harvesting up to 75 percent of target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that is determined to be sufficient to allow harvesting of at least 75 percent of the target TAC, but not to exceed the target TAC. This adjustment may be made if the Regional Administrator projects that that less than 75 per cent of the target TAC for haddock will be harvested by the end of the fishing year, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

Gear Restrictions
The gear restrictions implemented August 1, 2002 are continued with the following modifications (see Table 27 for details)

- Changes to the number of gillnets that can be used by trip gillnet vessels on Georges Bank
- Changes to the number of gillnets in the SNE/MA area
- Changes in restrictions on the use of gillnets in the GOM
- Requirement for a raised footrope trawl in certain areas of the GOM (two options for the area as shown below)

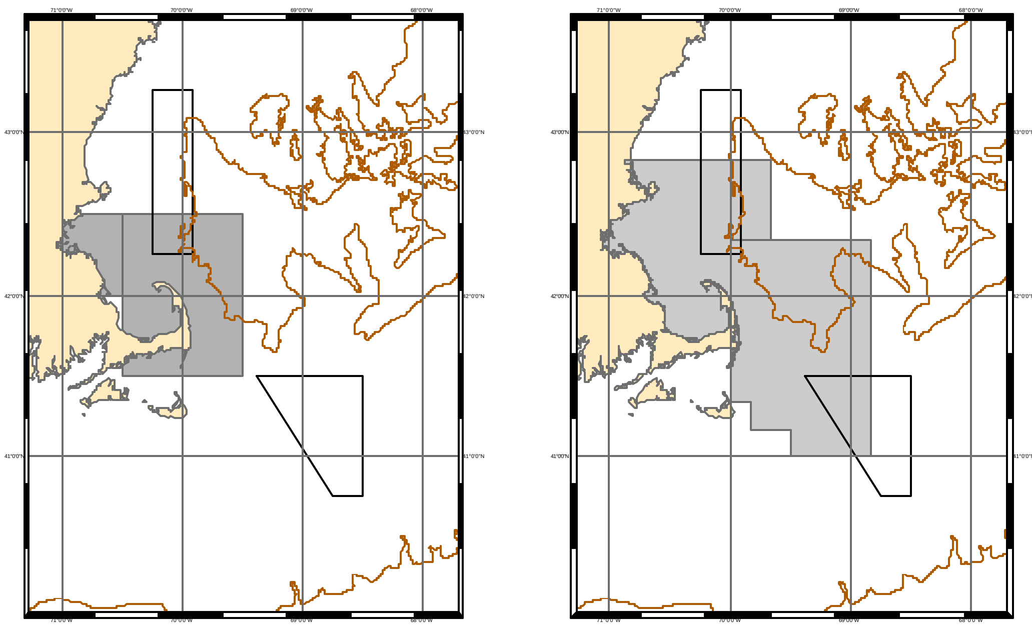

Figure 18 – Two alternatives for the area where use of a raised footrope trawl is required: Option A (left) thirty minute squares 114, 115,123, 124, 124, Option B (right) statistical areas 514 and 521

Table 27 – Alternative 1 gear requirements

Minimum Fish Sizes

The minimum fish sizes implemented August 1, 2002 are retained (cod minimum size increased to 22 inches) (see below).

Species	Size (Inches)
Cod	22 (55.9 cm)
Haddock	19 (48.3 cm)
Pollock	19 (48.3 cm)
Witch flounder (gray sole)	14 (35.6 cm)
Yellowtail flounder	13 (33.0 cm)
American plaice (dab)	14 (35.6 cm)
Atlantic halibut	36 (91.4 cm)
Winter flounder (blackback)	12 (30.5 cm)
Redfish	9 (22.9 cm)

VMS Requirements

There is no VMS requirement automatically implemented by this alternative. The current call-in system and voluntary VMS will be maintained. Section 3.4.14.2 describes possible changes to vessel reporting requirements that may be adopted by this amendment.

Possible Modifications

The exact management measures chosen will depend on the rebuilding strategy selected and the status of the stocks. The precise choices that may be made are difficult to predict because of the interaction of measures on different stocks in a multispecies fishery. This alternative relies on a reduction in effective DAS, closed areas, gear modifications, and, to a lesser extent, trip/possession limits as the primary tools to reduce fishing mortality. The stocks driving the management program are GOM cod, GB cod, Cape Cod/GOM yellowtail flounder, SNE/MA yellowtail flounder, white hake, and, plaice. To illustrate possible changes that might result if the necessary fishing mortality reduction changes (either as a result of the selection of a different rebuilding program or new assessment information):

Constant Fishing Mortality Rate or Adaptive Rebuilding Strategy:

- An increase in the reduction necessary for GOM cod, GB cod, CC/GOM yellowtail , white hake, or plaice will likely result in fewer used DAS. If the increase is confined to one stock area, (GOM or GB), DAS can be counted at a different rate. Generally, if the reduction in mortality needed increases by 10 percent, the DAS will be reduced by an additional 10 percent.
- Minor changes in the reduction needed for all stocks could result in less of a reduction in DAS use. Generally, for every increase of 10 percent in the necessary reduction, DAS used would increase by approximately 10 percent.
- Major changes in the reduction needed for all stocks (such as GOM cod and GB cod needing less than a 40 percent reduction in mortality and similar changes for other stocks) will result in fewer closures and increases in DAS.

Phased Reduction Rebuilding Strategy:

- If the results of the phase-in of DAS are different than expected, the targeted reduction in used DAS may also change.

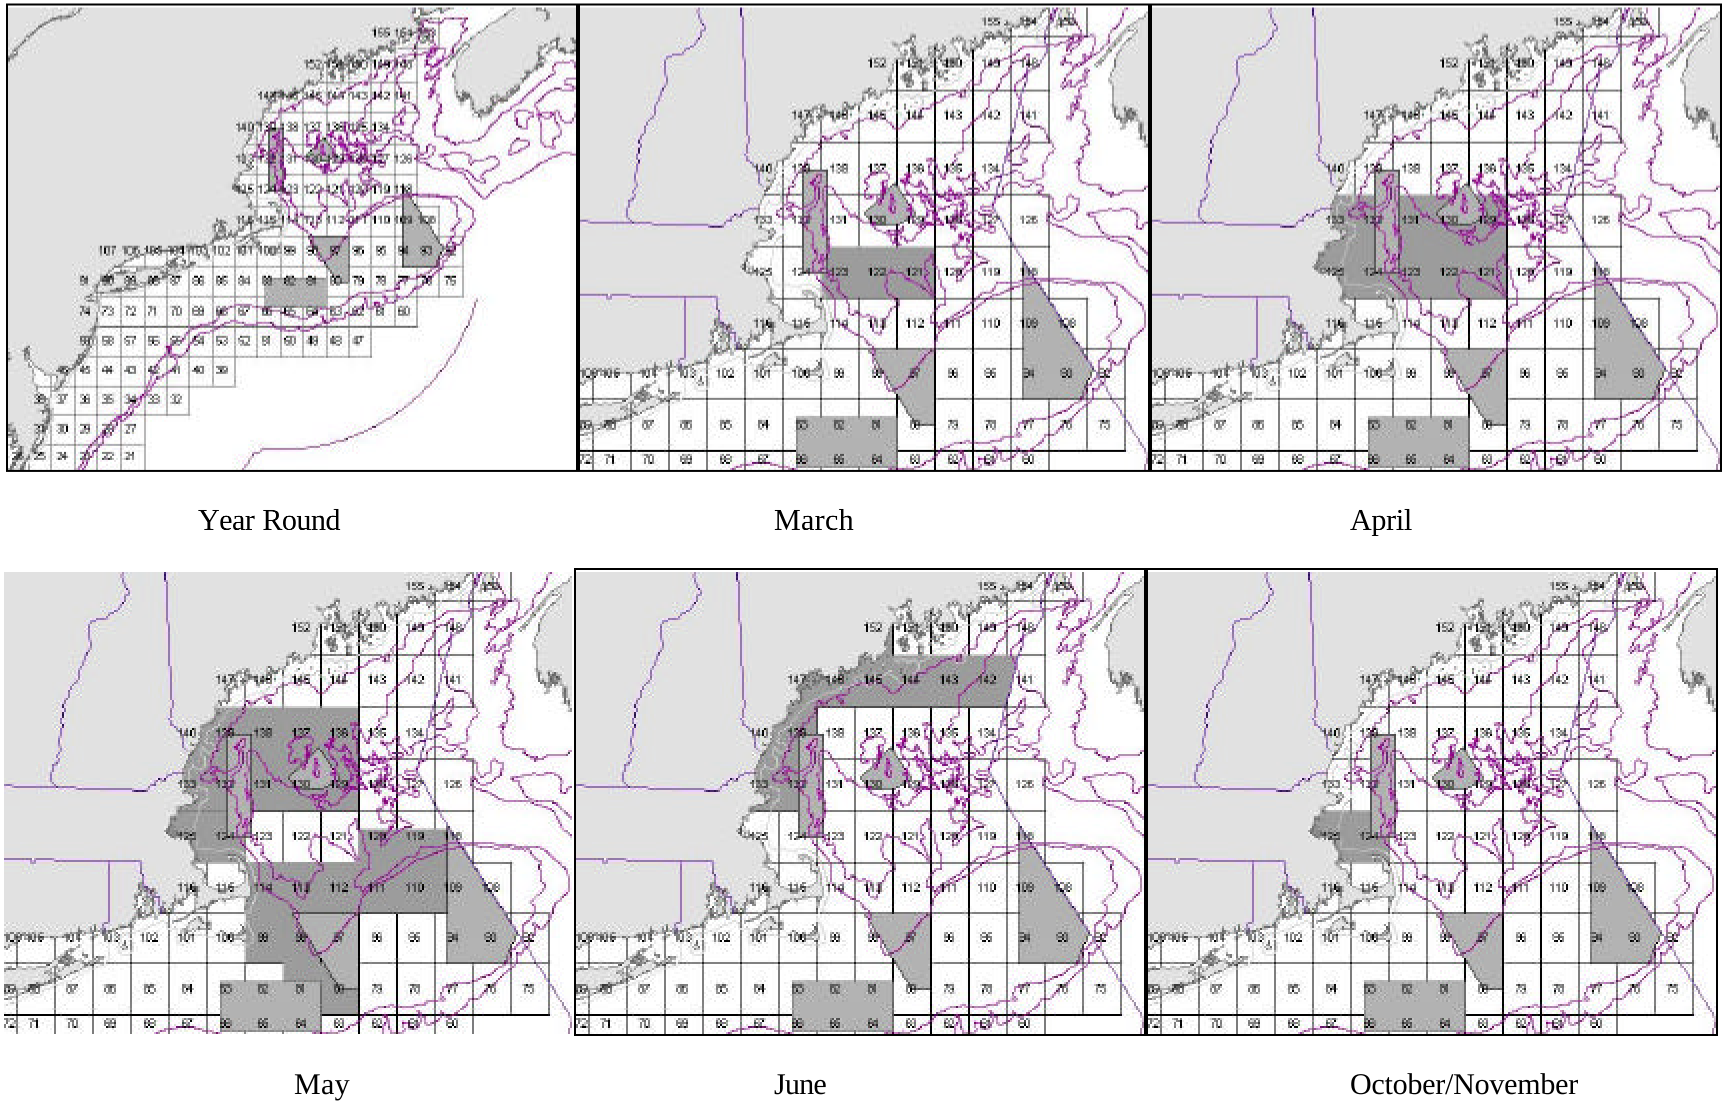

Figure 19 – Alternative 1 year round and seasonal closed areas

4.1.5.3 Alternative 2 – Reduction in Allocated DAS/Gear Modifications

This alternative combined additional gear restrictions and reductions in allocated (not used) DAS. This alternative builds on the management measures implemented as a result of a settlement agreement among certain parties in *Conservation Law Foundation et al. v. Evans et al.* These measures are continued unless changed by the following sections.

This Alternative was not selected. There was uncertainty over the exact impacts of the proposed gear modifications. Analysis suggested that the hard TAC backstop option would be triggered for a number of stocks, leading to excessive discards (if reaching the TAC triggered a prohibition on possession of a species) or a derby fishery and a sacrifice in yield from other stocks (if reaching the TAC triggered a prohibition on all groundfish fishing). The measures that were considered are described below.

Effort Controls

Option 1

Allocated DAS are based on the allocations implemented August 1, 2002 (the baseline established by the court order in the case of *CLF et al v. Evans et al.*, - maximum DAS used over the period 1996 through 2000 - reduced by 20 percent). Vessels wishing to fish in the GOM must sign - in to that area at the beginning of the fishing year. For vessels fishing in the GOM at any during the fishing year, allocated DAS are reduced by 30 percent from the baseline. Vessels fishing in the GOM cannot use more than 25 percent of allocated DAS from May through July. If GOM cod landings are less than 75 percent of the TAC at the end of the third quarter of the fishing year, vessels fishing in the GOM may use up to their full allocation of DAS (August 1, 2002 baseline less 20 percent).

The number of DAS allocated can be changed through future framework actions. At the implementation of the amendment, the DAS allocations are expected to total approximately 58,000 DAS.

Option 2

Allocated DAS are based on the baseline implemented August 1, 2002, reduced by 20 percent. A vessel can only use 70 percent of its baseline DAS in the GOM regulated mesh area. A vessel must declare its intent to fish in the GOM for a minimum of 30 days. All DAS used during that period will be counted against its GOM limit. If GOM cod landings are less than 75 percent of the TAC at the end of the third quarter of the fishing year, vessels fishing in the GOM may use up to their full allocation of DAS (August 1, 2002 baseline less 20 percent) in the GOM. Vessels fishing in the GOM cannot use more than 25 percent of allocated DAS from May through July.

The number of DAS allocated can be changed through future framework actions.

Management Areas

There are no changes to the existing management areas (as revised by the Framework 33 court order).

Closed Areas

Year Round Closed Areas

The current Closed Area I, Closed Area II, Western Gulf of Maine, Cashes Ledge, and Nantucket Lightship Closed Areas will be continued.

Seasonal Closed Areas

In addition to the seasonal closed areas implemented August 1, 2002, the area north of 44N (blocks 148-155) will be closed to vessels fishing for groundfish October and November.

The seasonal closed areas are:

March: 121, 122, 123

April: 121-125;129-133;
May: 124 - 125; 129-133;136-140; 80, 81; 98-99;109-114; 118- 120 (south of 42°20'N)
June: 132-133; 139-140; 141-147; 152
October: 124-125; 148-155
November: 124-125; 148-155

Possession Limits
GOM cod: 500 lbs/day / 4,000 lbs/trip.
GB cod: 500 lbs/day /4,000 lbs/trip. When 75 percent of the GB cod TAC is projected to be taken, the trip limit declines to 100 lbs/day / 1,000 lbs/trip.
CC/GOM yellowtail flounder: 50 lbs/trip in statistical areas 514 and 521 for all gear. No possession of yellowtail flounder when TAC is reached.
SNE/MA yellowtail flounder: March 1 – May 31: 250 pound possession limit;
June 1 – February 28: 750 lbs. day/3,000 lbs. trip possession limit

Adjustment of the haddock trip limit
The Regional Administrator may adjust the TAC for haddock at any time prior to or during the fishing year to prevent exceeding the target TAC or allow harvesting up to 75% of the target TAC, as described below.

(A) Adjustment to haddock trip limit to prevent exceeding target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that the Regional Administrator determines will prevent exceeding the target TAC. This adjustment may be made if the Regional Administrator projects that the target TAC for haddock will be exceeded, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

(B) Adjustment of the haddock trip limit to allow harvesting up to 75 percent of target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that is determined to be sufficient to allow harvesting of at least 75 percent of the target TAC, but not to exceed the target TAC. This adjustment may be made if the Regional Administrator projects that that less than 75 per cent of the target TAC for haddock will be harvested by the end of the fishing year, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

Gear Restrictions
The gear restrictions implemented August 1, 2002 are continued with the following changes. See Table 30. Implementation of gear restrictions that apply to specific areas may be through a sign-in program, similar to the way the GB cod trip limit exemption program is implemented, or as directed by the Regional Administrator.

Georges Bank
Trawl gear: Mandatory use of a haddock separator trawl net and/or a flounder net
Trip gillnet category: 150 nets
Day gillnet category: 50 nets
Hook/longline gear: 1,000 12/0 circle hooks for all multispecies permitted vessels

Gulf of Maine
Trawl Gear: Inshore of 70 W: mandatory use of separator trawl and/or flounder net.
Blocks 114, 115, 123, 124, 125: Raised footrope trawl
Gillnets: Inshore of 70W: 50 nets for both gillnet categories
Blocks 114, 115, 123,, 124, 125: no tie-down gillnets

Hooks/longline gear: 1,000 12/0 circle hooks
Scallop dredge: 10 inch twine top required in blocks 114, 115, 123, 124, 125

A flounder net is defined as a two-seam low-rise groundfish net.
A haddock separator trawl is defined as a groundfish trawl modified to a vertically-oriented trouser trawl configuration, with two codends arranged one above the other. The bottom cod end is left open. A horizontally oriented large mesh (6 ½ inch square mesh minimum) separating panel is installed between the selvedges joining the upper and lower panels, extending from the front of the trouser junction forwards to the aft section of the first belly behind the fishing circle.
Flounder and haddock separator trawl net specifications may be altered by the Regional Administrator.

Minimum Fish Sizes
The minimum fish sizes implemented August 1, 2002 are retained.

Species	Size (Inches)
Cod	22 (55.9 cm)
Haddock	19 (48.3 cm)
Pollock	19 (48.3 cm)
Witch flounder (gray sole)	14 (35.6 cm)
Yellowtail flounder	13 (33.0 cm)
American plaice (dab)	14 (35.6 cm)
Atlantic halibut	36 (91.4 cm)
Winter flounder (blackback)	12 (30.5 cm)
Redfish	9 (22.9 cm

TAC Backstop
There is a risk that reliance on gear modifications and reductions in allocated (rather than used) DAS may not achieve the necessary mortality reductions for all stocks. In order to insure that this option has a high probability of achieving the biological objectives of the amendment, a "hard" TAC, or quota, for each stock will be implemented as a backstop. The TAC or quota will be set to minimize the possibility that it will be exceeded and to allow for incidental catch fisheries to continue as long as possible (see discussion in section 4.1.5.5 for possible ways to administer the backstop TAC). If the DAS reductions and gear are successful, then the hard TAC will not be reached and additional closures will not be triggered.

As per section 4.1.5.5, the Hard TAC/Trip Limit model was applied to this alternative. Specifically, the raised footrope trawl, haddock separator trawl and FY02 used DAS levels were applied to the model. Table 28 and Table 29 show the trip limits that could be implemented at these levels. The trip limit for a particular stock depends on the level of its implementation (that is, at 70% or 90% of the TAC), the selected rebuilding strategy and rebuilding period, whether the TAC is specified on an annual basis or on a trimester basis, and the number of DAS available. The tables provided show the TACs for rebuilding most stocks by 2014 assuming DAS use is similar to FY 2002. These TACs will be recalculated based on the most recent stock status if this alternative is selected, and based on actual DAS allocations. The Regional Administrator may adjust these trip limits as necessary to allow harvesting the TAC.

GOM haddock, GB haddock, Pollock, redfish, GOM winter flounder, GB winter flounder, northern and southern windowpane flounder, GB yellowtail flounder and witch flounder are not predicted to reach the TAC threshold. Landings and threshold in metric tons.

VMS Requirements

VMS is required for all vessels that fish in both the Gulf of Maine and Georges Bank areas over the course of a fishing year.

Possible Modifications
The measures described above are based on a constant fishing mortality rate rebuilding program. The exact management measures chosen will depend on the rebuilding program selected and the status of the stocks. The precise choices that may be made are difficult to predict because of the interaction of measures on different stocks in a multispecies fishery. This alternative relies on a reduction in allocated DAS, closed areas, and gear modifications as the primary tools to reduce fishing mortality. A hard TAC insures biological objectives are met. The stocks driving the management program are GOM cod, GB cod, Cape Cod yellowtail flounder, and, to a lesser extent, white hake, plaice, and Mid-Atlantic yellowtail flounder. To illustrate possible changes that might result if the necessary fishing mortality reduction changes (either as a result of the selection of a different rebuilding program or new assessment information):

Constant Fishing Mortality Rate and Adaptive Rebuilding Strategy:

- Measures will not be modified unless the necessary mortality reduction declines significantly (that is, stocks are in much better shape than assumed during development of the alternative). If that occurs, the number of DAS allocated may be increased. If stock conditions are worse than assumed, the TAC will result in closure earlier in the fishing year, but the measures will not be changed.

Phased Reduction Rebuilding Strategy:

- A schedule for implementation of measures will be developed to achieve declining fishing mortality rates. For example, DAS reductions could be spread over a series of years, or closures could be implemented over successive years rather than implemented the first year.

Table 30 – Alternative 2 gear requirements

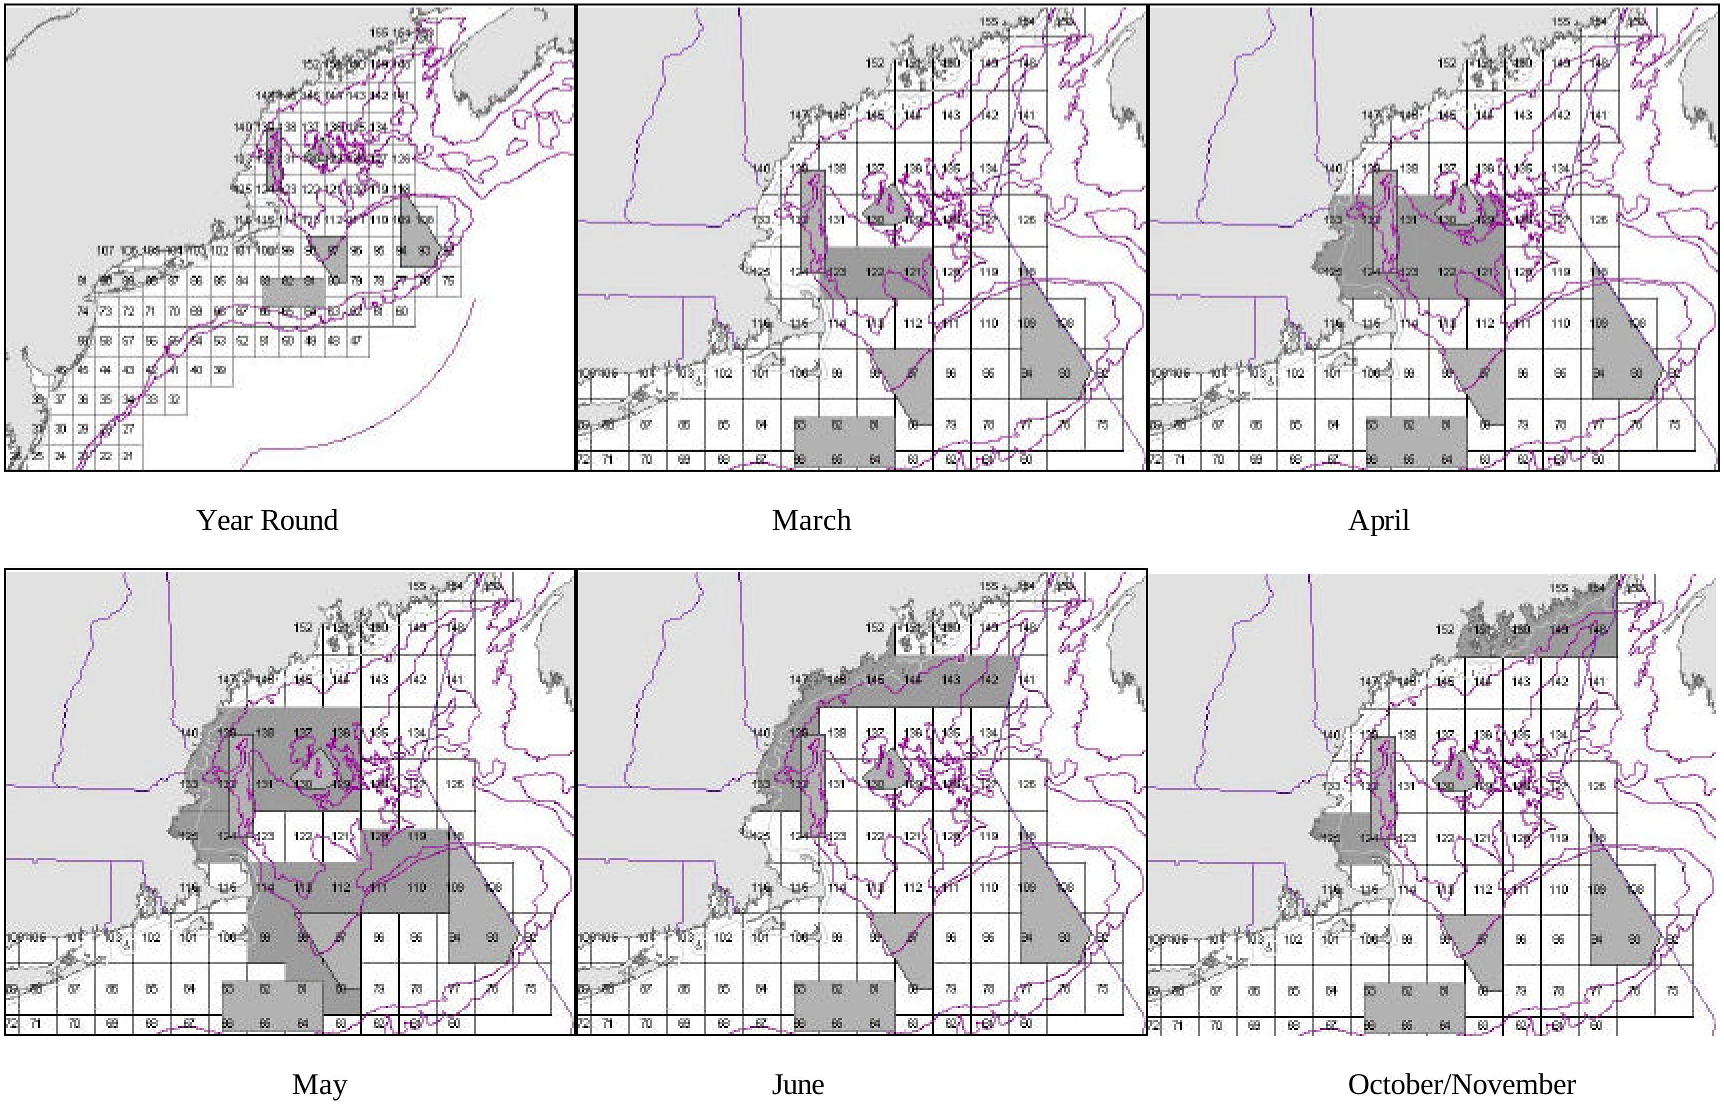

Figure 20 – Alternative 2 year round and seasonal closed areas

4.1.5.4 Alternative 3 - Area Management

The area management alternative is designed for the following reasons:

- Provide for development of management measures that are more consistent with fishing activity and resource conditions in a particular area;
- Encourage a greater sense of stewardship by facilitating the development of management measures by those fishermen that use an area;
- Simplify participation by interested parties in the management process;
- Insure fishing activity in one area does not adversely affect fishing activity in another area

This alternative was not selected because of concerns the complexity of area and species specific TACs would be difficult to implement and administer. In addition, there was concern in the industry that this approach to management would eventually lead to restricting vessels to a particular area, limiting the ability of fishermen to adjust fishing practices based on market or resource conditions.

Definition of Areas

Six options for management areas are proposed as shown in Figure 21 through Figure 26. In general, all of the options have five major areas, with some of the options including a division of the inshore GOM area.

- Area A: Inshore Gulf of Maine, separated into eastern and western sub-areas, defined as A1 and A2, respectively
- Area B: Offshore Gulf of Maine
- Area C: Western Georges Bank
- Area D: Eastern Georges Bank
- Area E: Southern New England/Mid-Atlantic

The following charts illustrate six options for area boundaries. An additional option for areas in the Gulf of Maine is included in the following alternative. All options include a line that identifies statistical areas 5zjm, the area defined for the U.S/Canada resource sharing understanding**.**

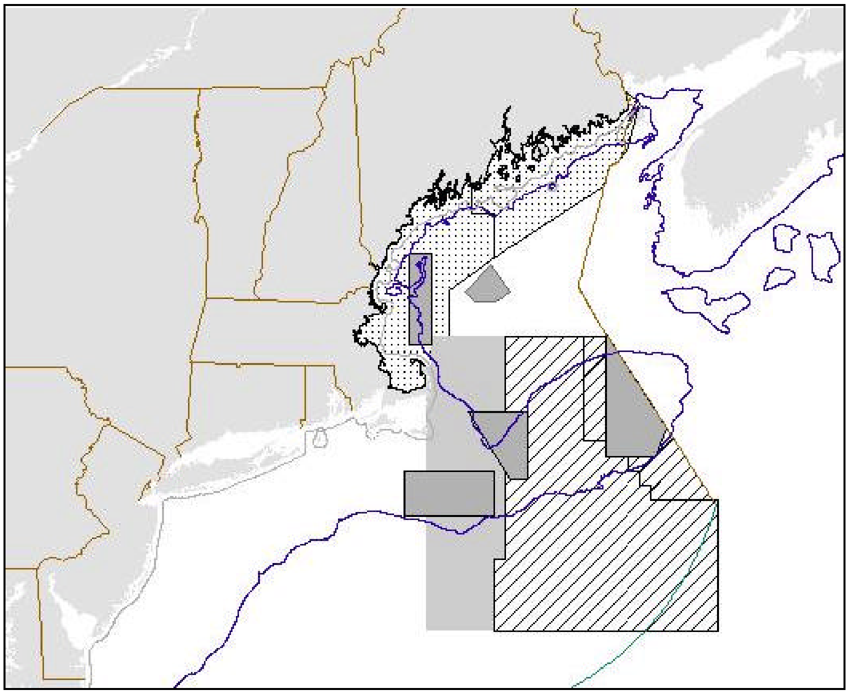

Figure 21 – Option 1 for proposed area management areas

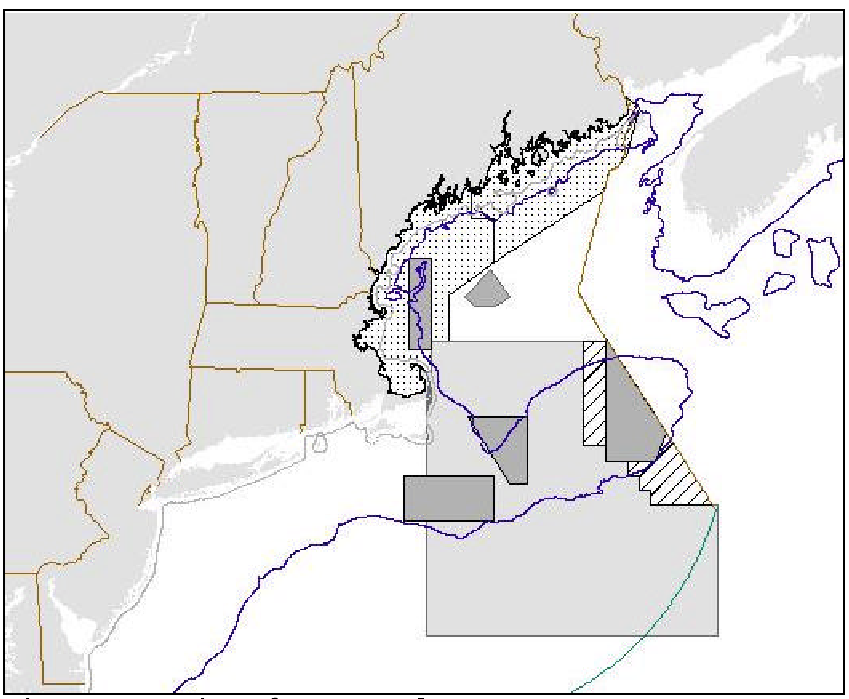

Figure 22– Option 2 for proposed area management areas

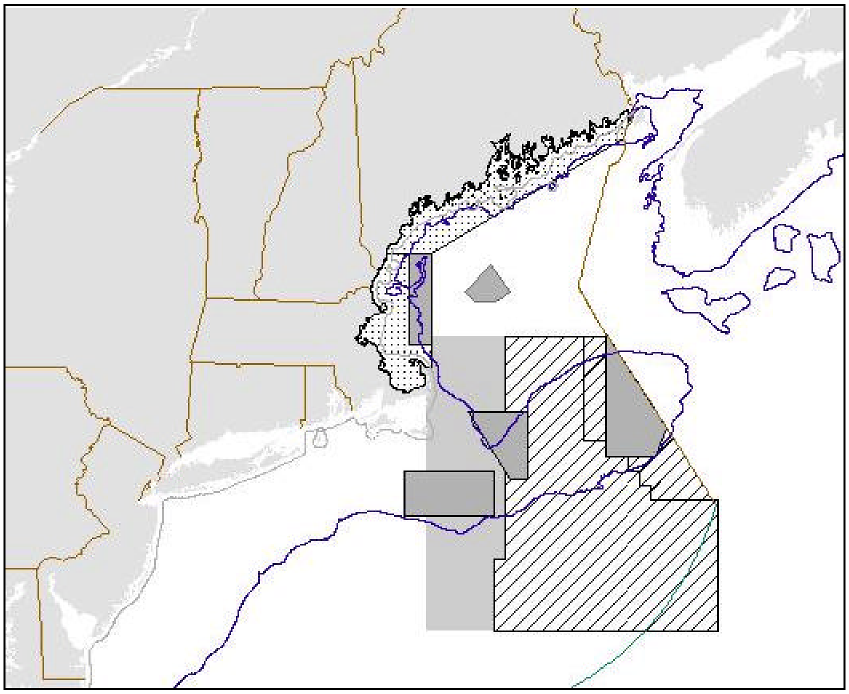

Figure 23– Option 3 for proposed area management areas

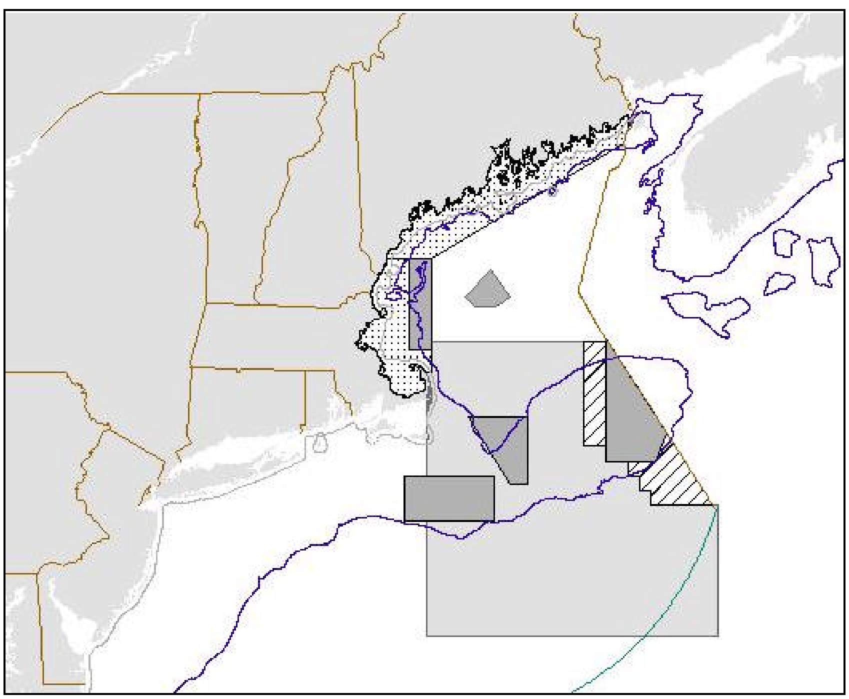

Figure 24– Option 4 for proposed area management areas.

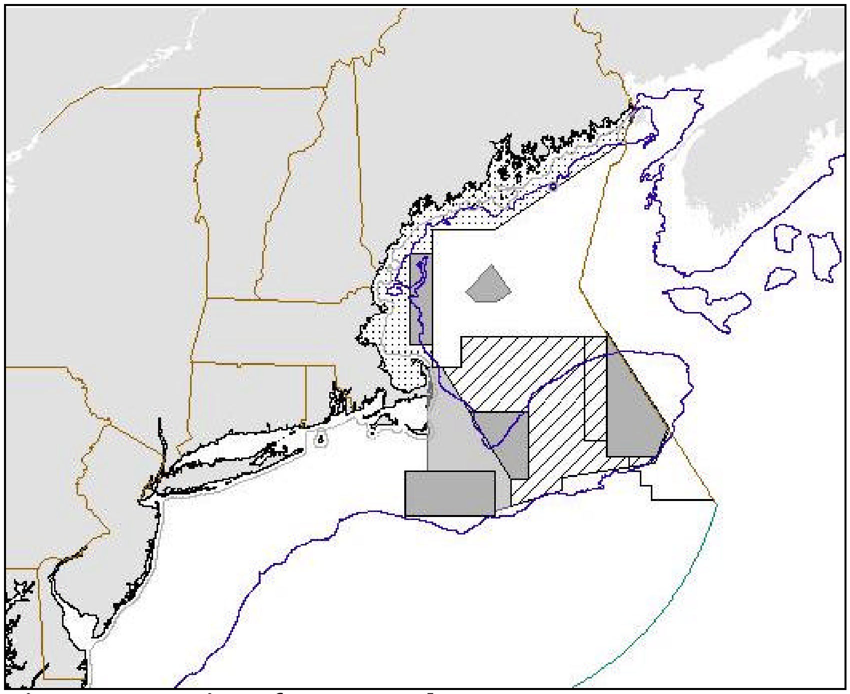

Figure 25 – Option 5 for proposed area management areas

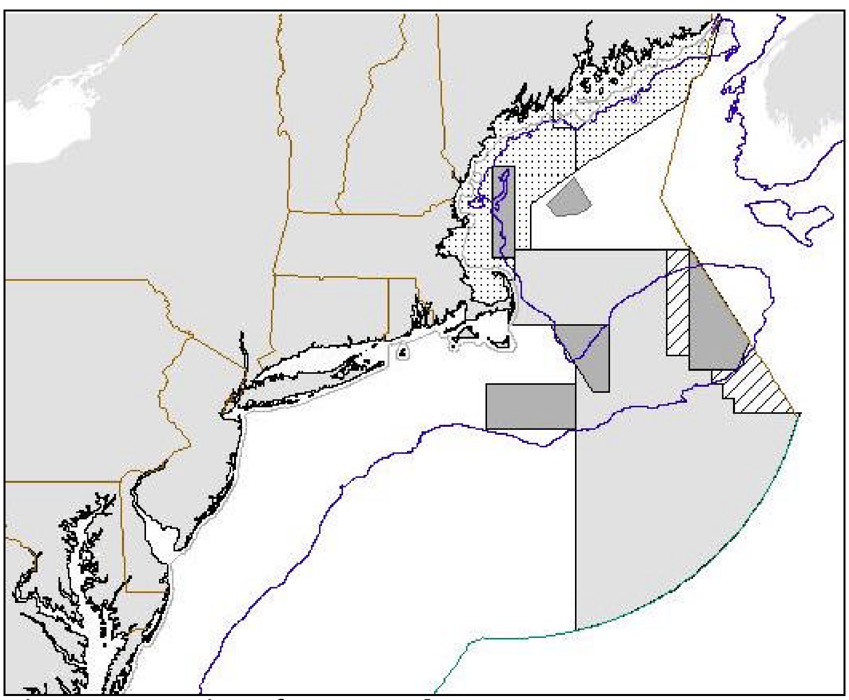

Figure 26 – Option 6 for proposed management areas

Biological Objectives
Species-specific TACs would be defined for each management area. Options for administering the TACs are described in section 4.1.5.5.

Calculation of TACs
In the draft amendment, TACs for each area were illustrated in tables for each area management alternative. These TACs were considered illustrations only and were not the TACs that will be adopted if this alternative is selected. These tables have been deleted since they are no longer pertinent. They are calculated for the major groundfish species only (excluding ocean pout and windowpane flounder). If this alternative is adopted, TACs will be calculated for all regulated groundfish species. If an area management approach is adopted, the TAC will be calculated using the most recent three years of survey data.

Option 1: Species specific TACs for each area will be calculated based on the distribution of each stock. This distribution will be estimated based on survey (spring and fall trawl survey) and vessel trip report information. There are two options for combining survey information with the VTR information. In both instances, the spring and fall surveys are averaged to develop an overall survey distribution.

Option A: Weight the surveys and VTRs equally (50/50)
Option B: Weight the surveys one-fourth as much as the VTRs (20/80)
Option C: Base the TAC on the previous three years survey only (do not include VTR information)

Each of these three options have different strengths and weaknesses. While survey information might be considered more precise and unbiased, the surveys represent stock distribution only during the specific dates of the surveys. The distribution of fish at these two points in time may not accurately reflect the distribution of fish over the course of the year. Incorporating VTR information into the calculation uses information from fishermen to characterize the distribution of fish throughout the fishing year as opposed to just the spring and fall survey periods. The two options for weighting of the survey and VTRs show how sensitive the results are.

There are two options for the period used to determine distribution from the VTRs. This period does not change unless adjusted through a future management action.

Option D: Fishing years 1996 through 1998. This three-year period incorporates when all limited access permits were required to use DAS, but avoids the period when rolling closures may have affected distribution of fishing effort.

Option E: Fishing years 1996 through 2000. This five-year period uses VTRs since adoption of the DAS program for all vessels.

The period used for survey distributions will be the most current three-year period in order to smooth out variations in the annual survey. The dates of the survey will change each year so that the most recent survey information is used.

The distribution for each area will be applied to the stock specific TACs calculated based on the target (not threshold) or rebuilding fishing mortality. TACs will be based on target fishing mortality for two reasons:

- So that management measures are designed to achieve OY

- To reduce the risk of overfishing by providing a buffer between the amount of catch that results in closure of the fishery and the amount of catch that results in overfishing

Option 2: If the resource sharing allocation agreement with Canada is implemented, the same process as is used in Option 1 will be used for all stocks with the exception of Georges Bank cod, haddock, and yellowtail flounder. The U.S. catches of these stocks in statistical areas 5Zjm will not be any higher than that determined by the agreement.

If area options based on the U.S./Canada resource sharing agreement are adopted (Appendix III), the distribution of GB cod, haddock, and yellowtail flounder to the area covered by the agreement will be as determined by the agreement. The allocation of these stocks to Area C will be the remainder of the total TAC. The total amount of cod, haddock, and yellowtail flounder in these two areas will include the appropriate share of the other stocks of cod, haddock, or yellowtail flounder as determined by the stock boundaries.

Discussion: This approach makes the assignment of area specific TACs consistent with any arrangements with Canada.

Consequences for Exceeding TACs

Option 1: If the TAC in an area is exceeded by more than 10 percent, the TAC for the following year will be reduced by the same amount.

Option 2: If the TAC in an area is exceeded by any amount, the TAC for the following year will be reduced by the same amount.

Option 3: TACs in an area are considered target TACs ("soft" TACs). When 80% of the TAC of any species in an area is reached, additional management measures will be put in place to reduce the catch of that species. As much as possible, those measures will be designed to reduce the catch of specific species, but if necessary broad based measures may be applied. Until area-specific "backstop" measures are developed, the Regional Administrator will use differential DAS counting (counting DAS at other than a 1:1 rate) in order to make certain that a the target TAC for a specific species is not exceeded.

Movement Between Areas

There are five options for vessel movement between areas.

Option 1: A vessel may fish in any area at any time. The DAS call-in system and modifications to Vessel Trip Reports (VTRs) will be used to monitor the area specific management measures for those vessels that do not voluntarily participate in the Vessel Monitoring System (VMS). When fishing in more than one area on a trip, the vessel must follow the most restrictive management measures (with the exception of any prohibition on night fishing which would be area specific) regardless of the area currently being fished on a trip.

Option 2: A vessel may fish in any area on a trip, and must follow the management measures for the area currently being fished, with the exception that when fishing in more than one area on a trip, the most restrictive trips limit will apply throughout the trip. The DAS call-in system and modifications to VTRs will be used to monitor the area-specific management measures.

Option 3: A vessel may fish in any area on a trip, but must follow the management measures for the area currently being fished, with the exception that when fishing in more than one area on a trip, the most restrictive trip limit will apply in all areas. If fishing in more than one area during the course of a fishing year, a vessel must be equipped with a VMS.

Option 4: A vessel may fish in only one area on a given trip, and must comply with the management measures that are in effect in that area. When calling in to start a DAS, a vessel must declare what management area it will fish. A vessel fishing in more than one area over the course of a given year must be equipped with an approved Vessel Monitoring System (VMS).

If a vessel wishes to fish in more than one management area over the course of a year, it must declare what percentage of its DAS will be spent in each management area. All time in an area must be considered, not just time fishing. At the end of the fishing year, a vessel must be within +/- ten percent of its time declared in any given area. As an example, if a vessel that uses all its DAS declares that it will spend 50 percent of its time in Area A and 50 percent of its time in Area B, the number of DAS spent in the areas must be within 40 to 60 percent of its DAS allocation and it cannot spend more than 10 percent of its DAS in a third area. If a vessel does not use all its DAS, the number of DAS used in an area cannot exceed by more than 10 percent the number of DAS it declared would be used in an area. If a vessel cannot fish in an area because a TAC was reached, it cannot shift effort into another area.

Option 5: A vessel may fish in only one management area over the course of a fishing year. The vessel must declare to NMFS its choice of management area at least one month prior to its first fishing trip for the year. This declaration of a management area applies to a permit throughout the fishing year, even if the permit's ownership changes mid-year. A vessel/permit is not bound to the area it fished in any previous year, but can only fish in one area in any given year.

Reporting Requirements
In order to monitor the TACs for each management area, timely information is needed on the location of catches by management area. In order to assess stocks, information is needed on catch by statistical area. In most cases, the proposed management areas are not identical to statistical areas, complicating the monitoring of catch, particularly if vessels are allowed to move between areas. Vessel reporting options are described in section 3.4.14.2. If area management is adopted, vessels will be required to report both statistical area and management area for their catch (similar to the current practice in the herring fishery, where vessels must report their catch by management area).

Area-Specific Management Measures
Other than provisions for implementing the area and species-specific TACs, no new management measures are proposed for each area. The measures in effect as a result of the *CLF et al. v. Evans et al.* (Framework 33 lawsuit) court order will be extended until changed in the future through the following process.

Area Management Meetings
The Council's Groundfish Oversight Committee will hold a series of meetings for each management area at the beginning of a fishing year to solicit advice based on the opinions of those who fish in that area and other interested parties. These comments will be forwarded to the Groundfish Advisory Panel for an initial review. Based on these meetings and the advice of the Advisory Panel, the Committee will develop management recommendations for the full Council. In most cases, these measures will be further developed and implemented by the Council through the periodic adjustment process. Upon implementation of the Amendment, however, the Council may choose to follow a different schedule in order to incorporate industry suggestions at an earlier date.

Management Measures Subject to Adjustment
All measures can be revised based on the input of fishermen from each area. It must be recognized, however, that some measures cut across area boundaries. For example, the Council may choose to have requirements for minimum fish sizes, year round closed areas (for both mortality reduction and to reduce

impacts on habitat), and DAS allocations that are consistent in all areas in spite of the recommendations of those fishing in a particular area.

Revisions to Advisory Panel
The Council will revise its Groundfish Advisory Panel to include three representatives that fish in each management area, as well as other interested parties.

Future Developments
One of the reasons for an area management system is to improve a sense of stewardship by establishing closer links between those interested in using and conserving resources in an area and the management system. This may be facilitated by establishing more direct opportunities for interested parties to develop management systems. For example, area governing bodies could be established that work with industry and the public to develop measures that the Council would review for consistency with applicable law and submits to NMFS for implementation. The Council may consider future revisions to its process that delegate authority for some management decisions in an area to other groups, subject to final Council and NMFS approval.

VMS Requirements
VMS is required for all vessels moving between areas within a single trip. This applies to movement between areas in options 1-4 but not areas in option 5.

Possible Modifications
This option relies on a hard TAC in each area to insure biological objectives are met. If stock conditions change, the TAC will result in closure at a different time, but the measures will not be changed until a later Council action. Selection of a different rebuilding program will have the same result.

If trip limits are established as a management measure in any area, the NMFS Regional Administrator has the authority to adjust haddock trip limits during the fishing year, as described below:

Adjustment of the haddock trip limit
The Regional Administrator may adjust the TAC for haddock at any time prior to or during the fishing year to prevent exceeding the target TAC or allow harvesting up to 75% of the target TAC, as described below.

(A) Adjustment to haddock trip limit to prevent exceeding target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that the Regional Administrator determines will prevent exceeding the target TAC. This adjustment may be made if the Regional Administrator projects that the target TAC for haddock will be exceeded, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

(B) Adjustment of the haddock trip limit to allow harvesting up to 75 percent of target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that is determined to be sufficient to allow harvesting of at least 75 percent of the target TAC, but not to exceed the target TAC. This adjustment may be made if the Regional Administrator projects that that less than 75 per cent of the target TAC for haddock will be harvested by the end of the fishing year, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

4.1.5.5 Alternative 4 – "Hard" Total Allowable Catch (TAC)

The Council considered adopting a "hard" TAC management system. This alternative was not selected. The Council is concerned that this alternative would lead to a derby fishery and either excessive discards (if possession of a species is prohibited when a TAC is reached) or a sacrifice in yield from healthy stocks (if groundfish fishing is prohibited when a TAC is reached). In addition, managing twenty stocks, with overlapping geographic ranges, would be administratively difficult. A past Council attempt to manage the fishery with a hard TAC was an abject failure. It id not protect the resource and did not allow for development of a stable industry.

Affected Stocks

TACs will be applied to stocks in the multispecies FMP on a single or multi-stock basis. TACs will be specified and monitored for the commercial fishery. TACs may also be specified for the recreational fishery if the recreational harvest is a significant part of the total catch. If there is a recreational TAC, it will be monitored separately from the commercial TAC. There are two options for applying TACs to the multispecies fishery. In all options, TACs will be set so that incidental catch fisheries are not inadvertently closed as a result of reaching one of the TACs early in the fishing year.

If enough information is available, TACs for a species will be based on total commercial removals which include both commercial landings and discards. This requires sufficient information to adequately estimate and monitor discards. While for some stocks such information is already available and is included in stock assessments, for other stocks it is not. When discards cannot be accurately estimated, then the TAC is specified for and based on landings.

Hard TAC with Input Controls

This alternative combines a hard TAC with additional input controls. Any of the options for administering the TACs described below (sections 0 and 0) may be chosen with this option. The input controls will be based on one of three options:

Option 1: Measures adopted by Alternative 2 (see section 4.1.5.3)
Option 2: Measures implemented by the Framework 33 court order, incorporating any changes and as effective on April 30, 2004
Option 3: The measures in the No Action Alternative (measures in place during FY 2001) with a hard TAC. The No Action Alternative measures are described in section 4.1.5.1 and are not repeated here.

TAC Administration Option 1

Prior to the beginning of the fishing year, the Council and/or the Regional Administrator will set a "hard" TAC for specified stocks and target TACs for all others. One of two options will be used for determining which stocks have a TAC:

Option A: All groundfish stocks will have a hard TAC
Option B: Groundfish stocks that are subject to overfishing, or where fishing mortality is higher than the fishing mortality adopted by a formal rebuilding program will have a hard TAC

For each stock with a hard TAC, more stringent regulations will be implemented as the TAC is approached. These regulations will become effective when projections indicate a certain percentage of the TAC will be reached. This percentage can be adjusted by framework action, as can the regulations that will be implemented. The purpose of the additional regulations is to prevent the TAC from being caught and to encourage fishermen to target other stocks. One example of more stringent regulation is a lower trip limit. The draft amendment included example trip limits that could be implemented at these levels. The trip limit for a particular stock depends on the level of its implementation (that is, at 70% or 90% of the TAC), the selected rebuilding strategy and rebuilding period, whether the TAC is specified on an annual basis or on a trimester basis, and the number of DAS available. The tables provided show the TACs for rebuilding most stocks by 2014 assuming DAS use is similar to FY 2002. These TACs will be recalculated based on the most recent stock status if this alternative is selected, and based on actual DAS allocations. The Regional Administrator may adjust these trip limits as necessary to allow harvesting the TAC.

When the TAC is projected to be reached, either fishing in a stock area or possession of that species in the stock area will be prohibited, as described in the alternatives in section 0. GOM haddock, GB haddock, Pollock, redfish, GOM winter flounder, GB winter flounder, northern and southern windowpane flounder, GB yellowtail flounder and witch flounder are not predicted to reach the TAC threshold. Results are shown based on the constant mortality rebuilding strategy and the phased F rebuilding strategy using both FY 2002 and FY 2001 effort control measures (DAS allocations).

The draft amendment included example trip limits that might be implemented under this alternative. These examples are not repeated here. If this hard TAC alternative were adopted in the future, then the trip limits would have to be recalculated based on current stock conditions, rebuilding strategy selected, and the suite of effort controls (if any) that are in effect. The trip limits from the draft amendment can be found in the analysis of the biological impacts of this alternative, section 5.2.6.6.3.

TAC Administration Option 2
Establish an aggregate TAC for multiple stocks that are not overfished and for which overfishing is not occurring and are not in a current rebuilding program. Establish a separate hard TAC for each of the other stocks managed under the multispecies plan which are in an overfished condition, are rebuilding or for which overfishing is occurring. (An aggregate TAC for multiple stocks will *not* be equal to the sum of individual TACs for those stocks.) The aggregate stock and separate stock TACs will be determined based on the most current stock assessment information as provided by NMFS/NEFSC and adjusted based on the periodic adjustment schedule adopted in Amendment 13.

Discussion: Combined or aggregate TACs may work well for healthy stocks that share similar life history characteristics. For stocks that share similar habitats and/or reproductive behaviors it is difficult to direct fishing on one stock without also catching significant quantities of the other. If separate TACs are applied to such closely associated stocks it will be necessary to establish a bycatch TAC for one of the stocks once the TAC of the other is reached. This approach may address some of the concerns about increased discards and works to simplify management under a hard TAC regime.

A disadvantage of this approach is that there is potential for serial depletion of stocks managed under an aggregate TAC. If the market values for species/stocks managed within an aggregate TAC differ significantly, the more valuable of these species/stocks would be harvested more aggressively than those of lesser value. This may lead to increased discards as stocks managed under an aggregate TAC are targeted unevenly.

United States/Canada Resource Sharing Agreement
If the US/Canada resource sharing agreement is incorporated into Amendment 13, Georges Bank cod, haddock and yellowtail TACs will be based on the formula defined in the agreement.

TAC Management Schedule
Option 1 - Annual TAC
TACs will be established for each fishing year and will be monitored on that basis.

Option 2 – Annual TAC with Target (Trimester) TACs
Hard TACs will be established for each fishing year. The total annual hard TAC will be monitored by trimester target TACs apportioned based on historic catch pattern (to remain sensitive to seasonal and marketing issues).

Each trimester will be four months in duration. For example, if the fishing year extends from January 1 to December 31, the trimesters will be divided as follows:

1st trimester: January 1-April 30
2nd trimester: May 1-August 31
3rd trimester: September 1-December 31

The actual trimesters would be different for a fishing year beginning July 1 or October 1. The target TACs, or percentages of total TAC allocated in each trimester, will be based on average monthly landings for each stock over the period from 1996-2001.

Option 3 – Annual TAC with Hard Trimester TACs (Preferred Alternative)
TACs will be established for each fishing year. The total annual TAC will be monitored by trimester hard TACs apportioned based on historic catch pattern (to remain sensitive to seasonal and marketing issues). The trimester TACs are "hard" TACs in this option – catching the trimester TAC will result in closure of a stock area or prohibition on possession as described in section 0.

The actual trimesters would be different for a fishing year beginning July 1 or October 1. The TACs, or percentages of total TAC allocated in each trimester, will be based on average monthly landings for each stock over the period from 1996-2001.

Setting the TAC and TAC Adjustment
Option 1 – Annual adjustment
The TAC will be reviewed on an annual basis and a new TAC will be applied at the beginning of each fishing year. Even if a biennial review and framework adjustment process is established in Amendment 13, the PDT will update the TAC each year based on the SAFE/MSMC report.

Discussion: One difficulty with this approach is that adjusting the TACs on a yearly basis would require the appropriate NEPA document to be prepared each year.

Option 2 – Biennial adjustment
The TAC will be reviewed on a biennial basis and a new TAC will be applied at the beginning of every other fishing year. The TAC set each year will either be altered from the previous year's TAC based on an (unscheduled) review process or renewed unchanged. If a biennial periodic review process is established in Amendment 13, TACs will be renewed unchanged at the beginning of a non-adjustment fishing year and may be adjusted every other year.

Rationale: Adjusting the TAC every other year would allow additional time to monitor the success of the previous TAC. By understanding how the stock is affected by the specific TAC that was set, more accurate revisions to the TAC will be possible when it is adjusted. Appropriate NEPA documents would only need to be prepared every other year if this alternative is selected.

Monitoring the TAC
In order to effectively monitor usage of the TAC, the following information is needed on a daily basis:

- *catch* composition for each trip (including what species are caught, where they are caught, and an estimation of how much was caught) in addition to landings data
- other information needed to monitor the TAC, as determined by the Regional Administrator

The monitoring schedule should be based on the size of the total TAC and how quickly TACs are being approached. As the total TAC is reduced, the rate of catch monitoring should be increased. For example, monitor the use of the TAC biweekly in the first trimester, weekly in the second trimester and daily in the third trimester. Frequency of reporting should be increased significantly, especially as the TAC is being approached.

Some degree of observer coverage will be required for the purpose of monitoring discards. The NMFS Northeast Regional Office will determine the level of observer coverage (see section 3.4.10).

Reporting System Options
Reporting system options, including requirements for VMS, are specified in section 3.4.14.

Reaching the Total TAC
Option 1 – Closure of Stock Area
When it is projected that 100 percent of the TAC for a stock will be caught, NMFS will close the area where the stock is caught to all gear capable of catching that species. Gear used to catch other species will still be allowed to fish in the area. As an example, if an area is closed to stop the catch of yellowtail flounder, hook gear may still be allowed in the area. If techniques or modifications to gear can be developed that prevent catching a species, that specific employment of a prohibited gear may be allowed. For example, the raised footrope trawl has been repeatedly demonstrated to limit catches of yellowtail flounder and received approval as an exempted/certified bycatch fishery. If an area is closed to trawl gear because the yellowtail flounder TAC is caught, fishing could be allowed using a raised footrope trawl.

The area closed will be based on the area that accounted for ninety percent of the reported (VTR) landings in prior years. Areas that will be closed for each stock are shown in Table 31. These areas are based on statistical areas. The Regional Administrator is authorized to further narrow the areas closed based on additional information. For example, some stocks are found in a narrow depth range and it may be possible to use this information to limit the area that must be closed.

SPECIES	STOCK	Area/Gear Prohibited When TAC is Caught	
		Statistical Areas	**Gear**
Cod	GB	521,522,525,526,561	Trawl, gillnet, longline/hook
	GOM	513,514,515	Trawl, gillnet, longline/hook
Haddock	GB	521,522,561	Trawl, gillnet, longline/hook
	GOM	512,513,514,515	Trawl, gillnet, longline/hook
Yellowtail Flounder	GB	522,525,561,562 (all)	Trawl, gillnet
	SNE/MA	537,539,612,613	Trawl, gillnet
	CC/GOM	514,521	Trawl, gillnet
American Plaice		512,513,514,515,521,522	Trawl
Witch Flounder		512,513,514,515,521,522	Trawl
Winter Flounder	GB	521,522,562	Trawl
	GOM	514	Trawl, gillnet
	SNE/MA	521,526,537,539,612,613	Trawl
Redfish		513,514,515,521,522,561	Trawl
White Hake		511,512,513,514,515,521,522,525,561,613,616	Trawl, gillnet, longline/hook
Pollock		513,514,515,521,522,561	Gillnet, trawl, longline/hook
Windowpane Flounder	North	513,515,521,522,525,562	Trawl
	South	526,537,539,612,613	Trawl
Ocean Pout		*To be developed*	*To be developed*
Atlantic Halibut		*To be developed*	*To be developed*

Table 31– Gears prohibited in specific areas when a TAC is caught. See Figure 8 to reference statistical areas

Rationale: Some stock areas cover broad areas, even though the species may not be caught throughout the area. By limiting closures to areas where most of the stock is caught, the stock is protected while allowing opportunities to fish for other stocks. For example, the GB cod stock area stretches from Georges Bank to New Jersey, but very little cod is caught west of 70W. Other species are caught in narrow depth bands within a stock area. Similarly, there is no reason to restrict gear that does not catch a particular species from an area when the TAC is caught. This may also encourage development of more selective fishing techniques so that fishing can continue when the TAC for one species is caught.

Option 2 – Prohibition on Retention (Preferred Alternative)
When it is projected that 100 percent of a TAC for a stock will be caught, possession of that species will be prohibited in the stock area. Vessels transiting that area with the same species caught from different stock areas must have all gear properly stowed and cannot fish in the area.

Consequences for exceeding target (trimester) TACs and total (yearly) TACs

Exceeding TACs
Overages of the TACs in any trimester (whether a "hard" or target trimester TAC) will result in a deduction from the following year's TAC of the same amount in the same trimester. If the total TAC for the year is exceeded, the overage will be deducted from the following year's TAC.

Action if TAC is not caught
TACs are calculated based on a desired fishing mortality rate. If a TAC is not caught over an annual period, the underage cannot be automatically shifted into the following year. Adding the previous year's underage to a TAC based on a fishing mortality rate could result in overfishing. If the TAC is not caught, the stock will rebuild more quickly and the result will be a higher TAC in later years.

Within a fishing year, if a trimester specific TAC is not caught, the underage will be rolled over into the following trimester.

Adjustment of the haddock trip limit
The Regional Administrator may adjust the TAC for haddock at any time prior to or during the fishing year to prevent exceeding the target TAC or allow harvesting up to 75% of the target TAC, as described below.

(A) Adjustment to haddock trip limit to prevent exceeding target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that the Regional Administrator determines will prevent exceeding the target TAC. This adjustment may be made if the Regional Administrator projects that the target TAC for haddock will be exceeded, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

(B) Adjustment of the haddock trip limit to allow harvesting up to 75 percent of target TAC – At any time prior to or during the fishing year NMFS may adjust, through publication of a notification in the Federal Register, the trip limit per DAS and/or the maximum trip limit to an amount that is determined to be sufficient to allow harvesting of at least 75 percent of the target TAC, but not to exceed the target TAC. This adjustment may be made if the Regional Administrator projects that that less than 75 per cent of the target TAC for haddock will be harvested by the end of the fishing year, based on harvesting rates during previous fishing years (if effort is not expected to change) or, if there is sufficient information to do so, based on harvesting rates during the current fishing year.

Possible Modifications
Changes to the necessary fishing mortality reduction will not have any impacts on the measures in this alternative.

4.1.5.6 Recreational Measures

Option 1 – FW 33 Settlement Agreement
The recreational/party charter measures implemented through the FW 33 settlement agreement (as modified in July 2003) will be extended. These are:

Minimum size: cod 23 inches, haddock 21 inches
Possession limit:
Private recreational vessels: 10 cod/haddock, except 5 cod GOM December 1 – March 31
Party/charter: 10 cod GOM April 1 through November 30; 5 cod creel limit in GOM December 1-March 31

Vessels intending to charter/party fish in the GOM closed areas must declare into charter/party fishery for the duration of the closure of for three months, whichever is greater

All other measures in place during fishing year 2001 continue to apply.

This option was not selected because of concerns it would have negative economic impacts on the party/charter sector.

Option 2
Bag limit for all private recreational vessels: 10 cod per person per day
Bag limit for party/charter vessels in the GOM: 10 cod per person per day
(Note there is no bag limit for haddock.)

Minimum cod size: 23 inches
Minimum haddock size: 19 inches

Closed season: no recreational/party/charter fishing in the GOM, December through March

All other measures in place during fishing year 2001 continue to apply.

This option was not selected because of a concern the closed season in the GOM would have severe economic impacts for party/charter vessels.

4.1.6 Measures to Minimize, to the Extent Practicable, the Adverse Effects of Fishing on Essential Fish Habitat

4.1.6.1 No Action (No additional habitat-related management measures)

This alternative retains the groundfish year-round closed areas that were in effect during fishing year 2001 prior to the settlement agreement *(CLF et al. v. Evans et al.)*. Under this alternative, no new management measures will be implemented as part of Amendment 13 that are specifically intended to protect essential fish habitat or reduce impacts associated with fishing.

The existing management measures, including year-round closed areas, trip/landing limits, gear restrictions and effort limitations, are acknowledged to have provided habitat benefits. It is important to note, however, that the year-round closed areas were intentionally not closed for habitat and/or EFH protection purposes, and therefore do not constitute habitat closures.

This alternative was not selected because it does not address M-S Act requirements to minimize, to the extent practicable, the adverse effects of fishing on EFH. The Council believes that there are additional measures that are practicable that will minimize any adverse effects.

4.1.6.2 Alternative 3 - Closed Areas Designed to Protect Hard-Bottom Habitats

In this alternative, areas both inside and outside of the existing groundfish closures are identified for habitat closure to better protect complex hard-bottom and other sensitive habitats. The Council approved this alternative with two versions of the Western Gulf of Maine closed area. These have been incorporated as two options:

- Alternative 3A, which has a larger extension of the WGOM to the west.
- Alternative 3B, which has a smaller extension of the WGOM closure to the west.

Figure 27 and Figure 28 provide a graphical representation of the proposed habitat closure options and coordinates for the boundaries of those areas.

4.1.6.3 Alternative 4 –Closed Areas Designed to Protect Hard-Bottom Habitats

Habitat closure areas in this alternative are derived from areas proposed in alternative 3 that overlap modified groundfish closed areas originally proposed as a stock rebuilding alternative for Amendment 13 of the NEFMC Multispecies Fishery Management Plan. While that alternative has been considered and rejected for stock rebuilding purposes, the Council did not expressly reject the closures proposed in Alternative 4 for habitat management purposes. Because these modifications were rejected for groundfish management purposes, adoption of habitat closed area alternative 4 would not affect the boundaries of the existing groundfish closures. The closures proposed in this alternative are intended to better protect complex hard-bottom and other sensitive habitats from any adverse impacts associated with fishing. They are shown in Figure 18.

4.1.6.4 Alternative 5 - Closed areas designed to protect EFH and balance fishery productivity

This alternative establishes closed areas that balance the protection of EFH and fishery productivity. Closed areas were determined on the basis of a model that assigned a value for EFH importance and fishery productivity (in the scallop, groundfish, and monkfish fisheries) in each ten minute square from the southern border of Canada to the northern border of South Carolina. Closed areas were then designated based on four decision criteria for each ten minute square: 1) reliance of the stocks on bottom habitat (life history considerations), 2) stock status, 3) relative value to the fisheries and 4) vulnerability of bottom habitat. The model identified one closed area, based on closure areas of more than eight (or nine, depending on the closure shape) contiguous ten minute squares, for each of the management areas (e.g. Gulf of Maine, Georges Bank, Southern New England and Mid-Atlantic). The following four options were developed:

Alternative 5A: EFH/Productivity tradeoffs using the original working group species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of 37 other managed species.

Alternative 5B: Total EFH value only, using revised species EFH weights (omitting relative importance to the fishery as a factor), with no productivity tradeoff.

Alternative 5C. EFH/Productivity tradeoffs using the revised species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of the other 37 managed species.

Alternative 5D. EFH/Productivity tradeoffs using the revised species EFH weights and productivity for each of the 37 managed species, considered individually.

Figure 30 through **Figure 33** display maps and coordinates for these closures. See Appendix V for a detailed description of the model used to determine these closure areas.

4.1.6.5 Alternative 6 – Habitat Closures consistent with the Framework Adjustment 13 Scallop Closed Areas Access Program

In this alternative the year-round groundfish closed areas (WGOM, , CA I, CA II and NLCA) that were in place during the 2001 fishing year are considered habitat closures with the exception of those areas opened under the Scallop FW 13 Closed Area Access Program.

See Figure 34 for a map of the closures.

4.1.6.6 Alternative 8 - Restrictions on the use of rockhopper and/or roller gear

This alternative will restrict the use of both rockhopper and roller trawl gear to protect areas of high-relief bottom where these gears are frequently employed. It is recognized that rockhopper and roller trawl gear function differently, and that they may interact differently with benthic habitats, but very little information is available with which to distinguish the effects of these gears on fishable bottom and/or EFH. Therefore, these two gears are treated equally for the purposes of this alternative.

Under this alternative, the restriction could extend throughout the Gulf of Maine (only), throughout the Gulf of Maine and Georges Bank, or throughout the entire range of the multispecies fishery and apply to anyone with a multispecies permit.

The following versions of this alternative are proposed. Listed from least restrictive to most restrictive:

8(a) - A prohibition on the use of any rockhopper and roller trawl gear with a diameter larger than the current maximum size (estimated to be between 31" and 36").

This alternative will freeze the maximum size of rockhopper and roller trawl gear at the maximum size currently in use. It is estimated that the maximum size of rockhopper and roller trawl gear currently being used in the New England region is from 31" to 36" in diameter. To more accurately pinpoint the current maximum size, the Council will contact fishermen and gear distributors in the New England region and assess the largest size rockhopper and roller gear that they currently use or stock and sell. Once the maximum allowable size is capped, the Council and NMFS is expected to research the specific effects of various sizes of rockhopper and roller trawl gear on a variety of important groundfish habitats. The Council will use this new information to determine whether the maximum allowable size should be further reduced, maintained at current levels, or eliminated (no size restriction). This research would also target the differences between rockhopper and roller gear, and whether differential size restrictions are a more appropriate management tool to minimize the effects of these gear types on EFH.

8(b) - A prohibition on the use of otter trawl groundgear with a diameter larger than 22"

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 22 inches. Cookies or other types of groundgear configurations 22" or less in diameter, including rockhoppers and rollers, will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 22" or through a step-wise reduction over time.

8(c) - A prohibition on the use of otter trawl groundgear with a diameter larger than 12", consistent with the existing maximum size limit in near shore portions of the Gulf of Maine.

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 12". Cookies or other types of groundgear configurations, including rockhoppers and rollers, 12" in diameter or smaller will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 12" or through a step-wise reduction over time. This alternative allows some configurations of small rockhopper and roller trawl gear to continue to be fished.

This alternative is an extension of a limit already in place in much of the western Gulf of Maine. Currently, the Council prohibits discs, rockhoppers and roller gear larger than 12" between 42° and 43° 30' North latitude from the shoreline out to either 70° or 69° 50' West longitude.

8(d) - A prohibition on the use of all rockhopper and roller trawl gear.

This would be a prohibition of all otter trawl configurations that employ ground gear with a diameter larger than 5" (the use of "cookies" with a diameter of 5" or less would be allowed).

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 5”. Cookies 5” in diameter or smaller will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 5”, or through a step-wise reduction over time. Five inches was identified as an option for the maximum size of cookies based on gear believed to be commonly stocked by gear distributors and used by fishermen in New England. Cookie size is reported to be somewhat variable and may range from 3” to 5” in diameter.

8(e) - A stepwise reduction in the maximum allowable size of otter trawl groundgear.
This could be considered a stand-alone alternative, or it could be incorporated into any of the reductions/prohibitions on rockhopper and roller gear size considered as alternatives above except for Alternative 8(a).

This alternative prohibits the use of any otter trawl groundgear with the following stipulations: From the start of the first new fishing year that begins after the implementation of Amendment 13, the maximum allowable diameter of groundgear will be reduced in stages over a period of six years from a maximum of 24” to a maximum of 5”. For example, if the first fishing year after implementation of Amendment 13 is May 1, 2003, the maximum size of groundgear will be 24” from May 1, 2003 until April 30, 2005. It will then be reduced to 12” from May 1, 2005 until April 30, 2007 and reduced again to 8” from May 1, 2007 until April 30, 2009. Thereafter, beginning May 1, 2009, the maximum size of groundgear will be 5”. The specific dates are examples of a reduction program that could be used. The program may be compressed over less time, stretched out over a longer timeframe, or the individual time period in which each size limit is in place could be varied. Also, the specific gear size increments could be different (e.g., from a maximum size of 30” to 24”, then to 18”, and then to 12”).

4.1.6.7 Alternative 9 - VMS on all groundfish vessels

This alternative requires VMS on all groundfish vessels, a critical step in obtaining high-resolution data on the distribution of fishing effort. The specifications on how best to implement this alternative will be left to the Groundfish Committee and PDT.

4.1.6.8 Alternative 10a

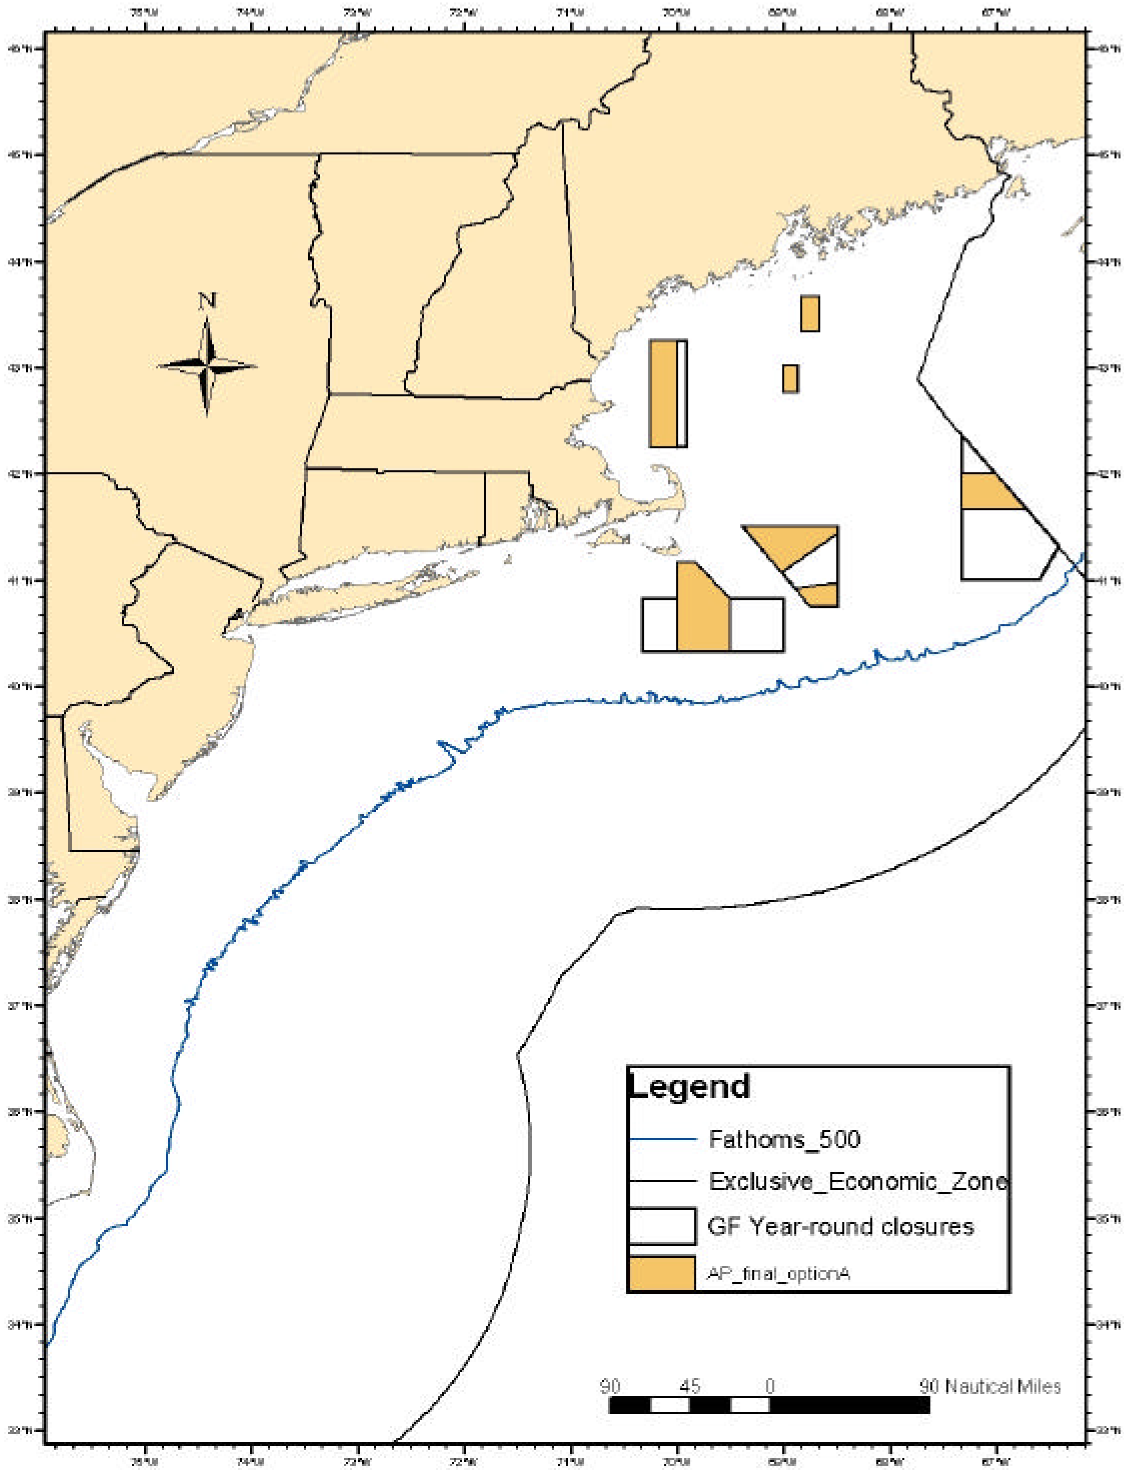

Figure 35 – Alternative 10a: Modified mortality closed areas and other proposed habitat closures including the *expanded* Cod HAPC in Closed Area II.

4.1.7 Other Issues

4.1.7.1 Northern Shrimp Fishery

The Council considered continuing to limit the Northern Shrimp fishery to fishing in the area inshore of the current small mesh fishery exemption line (see Figure 12). This option was not selected because the results of an experimental fishery suggest that shrimping can take place outside this area with little groundfish bycatch.

4.1.7.2 Tuna Purse Seine Access to Groundfish Closed Areas

Two alternatives to the proposed action were considered.

Option 1 – No action
Tuna purse seine vessels will be allowed in the WGOM closed area, seasonal (rolling) closed areas, and the Cashes Ledge Closed area. They will continue to be excluded from the Nantucket Lightship Closed Area and Closed Areas I and II.

This option would maintain the status quo. It does not address concerns of the tuna purse seine industry that their exclusion from three groundfish closed areas increases inefficiency, hampers their ability to pursue tuna, and potentially increases conflicts between different tuna fishing sectors. This option does, however, prevent the possibility that allowing tuna purse seine vessels access to the Nantucket Lightship Closed Area and Closed Areas I and II will increase bycatch of groundfish or cause adverse impacts on habitat. It was not selected because information from an experimental fishery showed that there was little risk of groundfish bycatch if this fishery operates in groundfish year round closed areas.

Option 2 – Access with Restrictions
Tuna purse seine gear is defined as an exempted gear for the purposes of the Northeast Multispecies FMP. Tuna purse seine vessels will be allowed into all groundfish closed areas subject to the following restrictions:

- Purse seine operations may not be conducted in any Habitat Area of Particular Concern (HAPC).
- In groundfish closed areas in the Gulf of Maine and Georges Bank (GOM/GB Regulated Mesh Area), fishing operations can only be conducted in areas that are 30 fathoms or more in charted depth. This restriction does not apply to the Nantucket Lightship Closed Area, or any future closed areas that may be developed in the southern New England and Mid-Atlantic regulated mesh areas unless specifically prohibited when implemented. Alternatively, the height of the net in use must be less than the depth of water.
- Vessels must direct sets to avoid fixed gear wherever possible.
- Vessels may not land or retain multispecies (including non-regulated multispecies or small mesh multispecies), and may not have gear on board capable of catching groundfish
- If the Regional Administrator determines that tuna purse seine vessels are adversely affecting habitat or groundfish stocks, individual vessels, or all vessels, may be prohibited from a closed area or areas.

Discussion: This option provides access to all groundfish closed areas. In the Gulf of Maine and Georges Bank, it provides additional protection to groundfish stocks and habitat by limiting fishing operations to depths that exceed the usual net size. It also prevents fishing operations in any HAPC. This balances the need for access to the closed areas with concerns that purse seine operations may inadvertently impact groundfish rebuilding or habitat.

This option was not selected because experimental results showed little need to impose these restrictions on purse seine vessels operating in the closed areas.

4.2 Alternatives Considered But Rejected

The following alternatives were considered but rejected by the Council because they were determined to not be reasonable. There was limited analysis of these alternatives in the draft amendment and DSEIS.

4.2.1 Constant Intended Catch Rate Rebuilding Strategy

This strategy would use a constant intended catch to rebuild the stock over time. Fishing mortality is reduced as the stock grows. When the stock achieves its target biomass, the formal rebuilding program, adopted because the stock was overfished, will be completed. Once the stock achieves the target biomass, fishing mortality targets will be based on the status determination criteria and MSY control rule. The appropriate constant catch will be based on observed stock conditions and recruitment. The catch for the rebuilding program may be adjusted if there are significant changes in stock status and recruitment from those used in the long-term projections used to estimate this fishing mortality.

This rebuilding strategy was rejected by the Council because it was determined that the costs of the strategy would likely outweigh its utility. A constant catch rebuilding strategy would likely increase discards and utilize increasingly restrictive measures over the course of the rebuilding time period. Additionally, this rebuilding strategy yields reduced long-term economic benefits as compared to the two other proposed strategies.

4.2.2 Measures Implemented August 1, 2002

As a result of a court order in the case of *Conservation Law Foundation et al. v. Evans et al.,* interim groundfish management measures were adopted on August 1, 2002. These measures were not designed to achieve the M-S Act requirements to rebuild overfished stocks and end overfishing. They were specifically designed to temporarily control fishing mortality on a few key stocks while Amendment 13 was developed. As analyzed in an Environmental Assessment (EA), the measures are not expected to achieve the necessary fishing mortality reductions to rebuild several stocks. (Indeed, for some stocks the EA concluded that fishing mortality may increase). Because these measures are not expected achieve M-S Act requirements, the Council does not consider them a reasonable alternative by themselves. In many cases, they serve as the basis for the development of additional management measures. Alternatives to address rebuilding requirements 1, 2, 3, 4, and 8 all incorporate many of the measures implemented August 1, 2002.

A summary of the measures, as implemented, can be found in Appendix 15.

4.2.3 Rebuilding Alternative Based on 50% Reduction in Used DAS

The following alternative begins with the assumption that unused DAS will be controlled This may be accomplished through one of the capacity alternatives, or through the recent settlement agreement. The alternative blends elements of the negotiated settlement agreement, DAS approach to management, and previous PDT alternatives. Unless changed by this alternative, the measures in place August 1, 2002 will continue.

This alternative was rejected by the Council after analysis showed that adverse social and economic impacts would be borne primarily by inshore fishermen from communities between Cape Cod and Maine. The Council believes this alternative is not consistent with National Standards 4 and 8. It also does not comply with the M-S Act requirement that harvest restrictions and recovery benefits be allocated fairly and equitably among commercial, recreational, and charter fishing sectors in the fishery. Restrictions focused on commercial inshore fishermen, who would have less of an opportunity to receive the benefits because of the large inshore closures.

4.2.3.1 Effort Controls

This option uses an actual 50% reduction in DAS as a major element in achieving the mortality reductions in the amendment. The 50% mortality reduction achieves most of the reduction necessary for GOM cod, GB cod, plaice, white hake, and Cape Cod yellowtail flounder. **An actual 50% reduction in DAS from fishing year 2000 and 2001 levels means that only 31,000 DAS will be fished under this option.**

There are a variety of possible ways to achieve the 50 percent DAS reduction. As noted earlier, this option assumes that one of the approaches to controlling unused effort suggested by the Capacity Committee will be adopted. **The smaller the pool of baseline DAS, the less the additional reduction that must be applied to each permit to reach the targeted 31,000 DAS.**

This concept can be illustrated by using information from the Capacity Committee report and other sources. This report includes alternatives for a variety of ways to calculate "effective" DAS – sometimes referred to as "baseline" DAS. Table 32 lists some of these alternatives, shows the number of DAS that result, and the additional reduction for each permit in order to achieve the 31,000 DAS target (ignoring any carry-over DAS). This final column is based on an across-the-board DAS reduction applied to each permit.

Effective DAS Calculation	DAS Allocated (approximate)	Additional reduction for each permit to achieve 31,000 DAS
None	143,300	78%
FW 33 Court Order Baseline	70,000	56%
FW 33 Court Order Baseline less 20%	56,000	45%
Original FW 33Court Order (average DAS used FY 1996 - 2000)	38,000	18%
Capacity Option 4: Maximum DAS FY 1994 - 1999	70,500	56%
Capacity Option 5: DAS used in FY 1999	53,500	42%
Capacity Option 6:	70,500	56%
Capacity Option 7: Maximum DAS FY 1996 – 1999	66,500	53%
Capacity Option 8a: Max. percentage used FY 1996 –1999 (no DAS if no fishing revenues)	72,700	57%
Capacity Option 8b: Max. percentage used FY 1996-1999 (no DAS if no finfish revenues)	71,500	56.5%

Table 32 – Additional DAS reduction necessary to achieve 31,000 DAS under various capacity reduction alternatives

4.2.3.1.1 Management Areas

There are no changes to existing management areas (that is, management areas will still be as revised by the FW 33 court order).

4.2.3.1.2 DAS Restrictions

Class A DAS (DAS that can be used on implementation of Amendment 13) reduced to 31,000.

In the SNE and MA regulated mesh areas, DAS are counted at a differential rate of 1.5:1 during the months of December through April.

Alternative 1A: As an option to avoid closing inshore blocks 124, 132, and 133 year round (see section 4.2.3.1.3.1). Vessels fishing in blocks 115, 116, 124, 125, 132, and 133 may be charged DAS at a 2:1 rate. *In the discussion of impacts (see section 5.0) this is referred to as Alternative 1A.* In order to enforce a 2:1 DAS counting in a particular area there may be a need to have a minimum time obligation to fish and a letter of authorization.

4.2.3.1.3 Closed Areas

See Figure 36 for a chart of the proposed closed areas.

4.2.3.1.3.1 Year-Round Closed Areas

The current year round closed areas are maintained indefinitely. This includes the Nantucket Lightship Closed Area, Closed Areas I and II, Cashes Ledge closure, and the Western Gulf of Maine Closed Area.

Some changes are made to the current year round closed areas:

Closed Area I: Thirty minute square Block 98 is added to the area to provide additional protection to GB cod and Cape Cod yellowtail flounder. This additional area also provides some additional protection to areas of complex habitat outside the existing closed area.

Closed Area II: An additional area is closed at the northwestern side of the area. This additional closure will provide additional mortality reductions for GB cod, and provides additional protection to an area of complex habitat. The southern boundary of the area is moved north ten miles in order to provide access to yellowtail flounder.

Western Gulf of Maine Closed Area: The eastern boundary is moved west to 70 W at the northern part of the area. This provides additional access to haddock, witch flounder and pollock while continuing to provide protection to the areas of complex habitat within the closure.

Additional year round closed areas are implemented in the Gulf of Maine. Thirty minute square blocks 124, 132, 133, 128, and 129 are closed year round *(see section 4.2.3.1.2 for an alternative to the year round closures of blocks 124, 132, and 133 that is being examined*).

Blocks 124, 132, and 133 are closed primarily to provide mortality reductions for GOM cod. In addition, block 124 provides a mortality reduction for CC/GOM yellowtail flounder. The closure of blocks 124 and 132 also provide additional protection to areas of complex habitat just outside the current Western Gulf of Maine closed area (though the entire blocks are not identified as complex habitat*). (See section 4.2.3.1.2 for an alternative to the year round closure of these three blocks).*

Blocks 128 and 129 provide additional protection for GOM cod.

Prohibited Gears

There are two options for determining which gear types are prohibited from these additional year-round closed areas:

<u>Option 1</u>: Gear excluded from the additional year round closed areas established in Amendment 13 will be the same gear that is not allowed in the current year-round closed areas adjacent to these additional areas.

<u>Option 2</u>: Gear excluded from the additional year round closed areas established in Amendment 13 will be the same gear that is excluded from seasonal or rolling closures adjacent to these additional areas. This option will allow, for example, tuna purse seines to fish in block 98 even if it is closed to protect groundfish mortality.

4.2.3.1.3.2 Seasonal Closed Areas

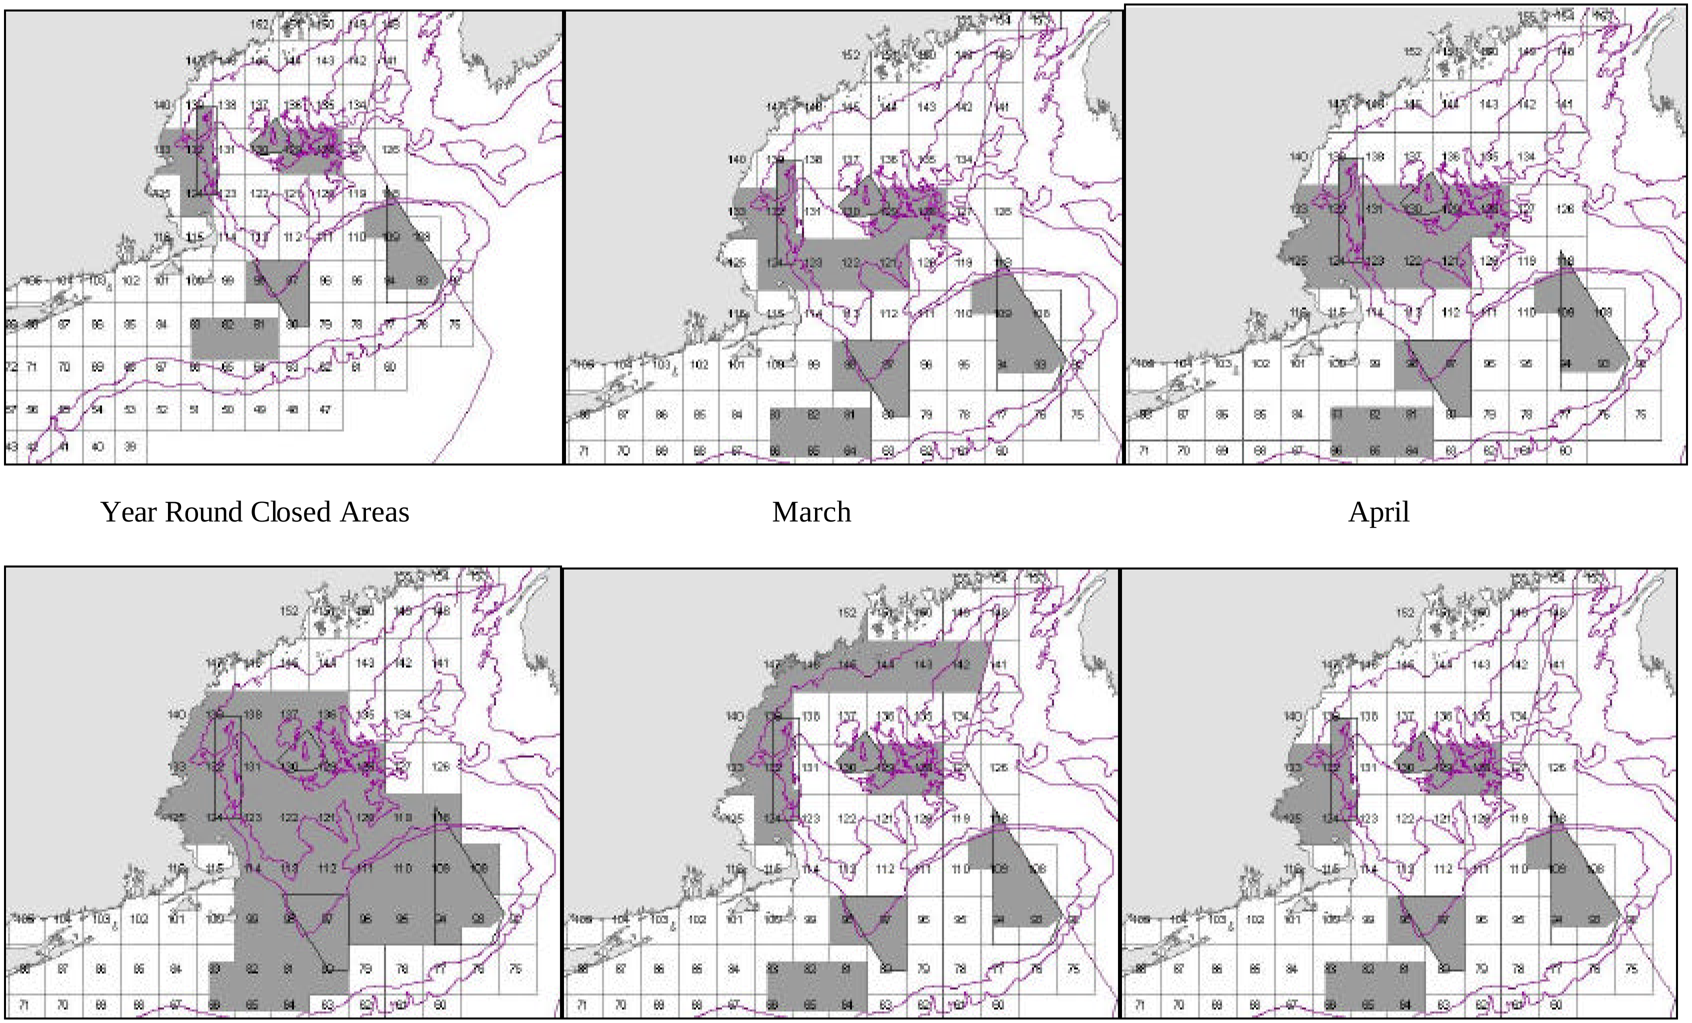
The seasonal closures adopted by the court in the case of *Conservation Law Foundation et al v. Evans et al.* are continued, with some modifications on Georges Bank in May.

Gulf of Maine rolling closures:

March:	121, 122, 123
April:	121-125; 129 – 133;
May:	124,125; 129-133; 136-140
June:	132, 133; 139-140; 141-147; 152
October:	124, 125
November:	124, 125

Georges Bank rolling closure:

May: 80-82; 94-99; 109-114; 118-123



Year Round Closed Areas　　March　　April

May　　June　　October - November

Figure 36 – Proposed area closures (see text for possible alternative to year round closure of blocks 124, 132, and 133 being examined by the PDT)

4.2.3.1.4 Possession Limits

GOM Cod: January – June: 800 lbs/day and 4,000 lbs./trip
July – December: 600 lbs./day and 3,000 lbs./trip

GB cod: 1,500 lbs./day and 15,000 lbs./trip

Haddock: 50,000 lbs./trip; the Regional Administrator can adjust the trip limit, or impose a daily limit, if necessary to prevent exceeding the TAC

SNE yellowtail flounder: There are two options:
March 1 – May 31: 250 pound possession limit;
June 1 – February 28: 750 lbs. possession limit

MA yellowtail flounder: TBD
Note: The SNE and MA yellowtail flounder stocks were assessed during SAW 36. and were combined as a single stock.

4.2.3.1.5 Gear Restrictions

The following minimum mesh restrictions apply:

Trawl net codends:

GOM/GB RMA: 6.5 inch diamond or square
SNE RMA: 6.5 inch square or 7 inch diamond mesh
MA RMA: 6.5 inch diamond or square

Gillnets:

GOM/GB/SNE RMA: 6.5 inch
MA RMA: 5.5 inch mesh
Gillnet vessels are limited to the number of nets implemented through Amendment 7 and subsequent framework actions (i.e. net limits in effect during fishing year 2001)

Longline vessels (under any permit category):
4,500 hooks
12/0 circle hooks

4.2.3.1.6 Minimum Fish Sizes

Maintain minimum fish sizes adopted by settlement agreement among certain parties:

Cod: 22 inches (roughly L10 for 6.5 inch square trawl mesh)

4.2.3.1.7 Large Mesh Program

Vessels may choose to participate in a large mesh program by using mesh that is two inches larger than the mesh specified for the area fished. Vessels participating in the program are limited to a cod possession limit that is one-half the possession/trip limit in effect in the area fished. Vessels participating in the program will be receive a 25 percent increase in their allocated DAS.

4.2.3.2 Other Measures

All requirements to take blocks of time out of the fishery are removed.

4.2.3.3 VMS Requirements

There are three options for VMS coverage:

4.2.3.3.1 Option 1

VMS is required for all limited access groundfish vessels.

4.2.3.3.2 Option 2

VMS is required for vessels allocated more than 10 groundfish DAS.

4.2.3.3.3 Option 3

VMS is required for vessels allocated more than 20 groundfish DAS.

Under all three options, the Thrane & Thrane 3026M ($1550 per unit), Thrane & Thrane PC ($1350 per unit) or a similar device is required. Additionally, the current VMS demarcation line will be moved in to the coastline.

4.2.4 Hard TAC Alternative

In the process of developing the hard TAC alternative (see section 4.1.5.5), several options for managing the TAC were considered and rejected.

4.2.4.1 Directed/Incidental TACs

This option would have established a TAC for each stock. The TAC would have been further broken down into separate TACs for directed and incidental fisheries. This option was rejected because it proved difficult to define a directed and incidental fishery in a manner acceptable to a majority of Council members. In addition, this approach would have resulted in a requirement to monitor and administer numerous TACs, and detailed analysis demonstrates that this would not have been feasible.

4.2.5 DAS Trimester Quotas

This alternative uses the same management measures as the 50 percent DAS reduction alternative with an exception. This alternative does not assume that any measures are taken to reduce or control the availability of unused DAS. Instead, the number of DAS that can be used in the fishery is calculated and then apportioned through the fishing year. As a result, measures to reduce capacity are not necessary to achieve mortality objectives. DAS that can be used in the fishery would have been calculated on an annual basis and apportioned into three trimesters based on historic patterns of DAS use. NMFS would have monitored DAS use in a trimester and prohibit fishing under a multispecies DAS once the DAS allowance for a trimester is attained.

This alternative does not address capacity issues in the fishery, one of the objectives of the amendment. In addition, the limitation on DAS used in each trimester would clearly create an incentive for a "race to fish", would encourage unsafe fishing practices as vessels operators push to use their DAS before the fishery closes, and would likely result in interruptions in supply as most fish would be landed at the beginning of a trimester. For these reasons, the Council determined that this was not a reasonable alternative that should be analyzed.

4.2.6 Open Access Handgear Industry Proposal

This alternative would have converted the current Category H permit into three categories: two limited access (Category A and Category B) and one open access category (C). Fishing opportunities would vary depending on permit qualification. Vessels would have been allowed to possess both a limited access and open access permit at the same time, changing the permit structure of the fishery. Under certain permit categories, vessels would have been allowed to fish in seasonal/rolling closures.

This proposal is not consistent with the objectives of the amendment or the groundfish FMP because it proposed to allow possession of both a limited access and open access permit at the same time, and excluded open access permits from the rolling closures. For these reasons, the Council determined that this alternative was not reasonable and did not warrant further analysis.

4.2.7 Measures to Minimize Impacts of Fishing on Essential Fish Habitat

4.2.7.1 Non-Selected Alternatives

4.2.7.1.1 No Action (No additional habitat-related management measures)

This alternative retains the groundfish year-round closed areas that were in effect during fishing year 2001 prior to the settlement agreement *(CLF et al. v. Evans et al.)*. Under this alternative, no new management measures will be implemented as part of Amendment 13 that are specifically intended to protect essential fish habitat or reduce impacts associated with fishing.

The existing management measures, including year-round closed areas, trip/landing limits, gear restrictions and effort limitations, are acknowledged to have provided habitat benefits. It is important to note, however, that the year-round closed areas were intentionally not closed for habitat and/or EFH protection purposes, and therefore do not constitute habitat closures.

This alternative was not selected because it does not address M-S Act requirements to minimize, to the extent practicable, the adverse effects of fishing on EFH. The Council believes that there are additional measures that are practicable that will minimize any adverse effects.

4.2.7.1.2 Alternative 3 - Closed Areas Designed to Protect Hard-Bottom Habitats

In this alternative, areas both inside and outside of the existing groundfish closures are identified for habitat closure to better protect complex hard-bottom and other sensitive habitats. The Council approved this alternative with two versions of the Western Gulf of Maine closed area. These have been incorporated as two options:

- Alternative 3A, which has a larger extension of the WGOM to the west.
- Alternative 3B, which has a smaller extension of the WGOM closure to the west.

Figure 27 and Figure 28 provide a graphical representation of the proposed habitat closure options and coordinates for the boundaries of those areas.

4.2.7.1.3 Alternative 4 –Closed Areas Designed to Protect Hard-Bottom Habitats

Habitat closure areas in this alternative are derived from areas proposed in alternative 3 that overlap modified groundfish closed areas originally proposed as a stock rebuilding alternative for Amendment 13 of the NEFMC Multispecies Fishery Management Plan. While that alternative has been considered and rejected for stock rebuilding purposes, the Council did not expressly reject the closures proposed in Alternative 4 for habitat management purposes. Because these modifications were rejected for groundfish management purposes, adoption of habitat closed area alternative 4 would not affect the boundaries of the existing groundfish closures. The closures proposed in this alternative are intended to better protect complex hard-bottom and other sensitive habitats from any adverse impacts associated with fishing. They are shown in Figure 18.

4.2.7.1.4 Alternative 5 - Closed areas designed to protect EFH and balance fishery productivity

This alternative establishes closed areas that balance the protection of EFH and fishery productivity. Closed areas were determined on the basis of a model that assigned a value for EFH importance and fishery productivity (in the scallop, groundfish, and monkfish fisheries) in each ten minute square from the southern border of Canada to the northern border of South Carolina. Closed areas were then designated based on four decision criteria for each ten minute square: 1) reliance of the stocks on bottom habitat (life history considerations), 2) stock status, 3) relative value to the fisheries and 4) vulnerability of bottom habitat. The model identified one closed area, based on closure areas of more than eight (or nine, depending on the closure shape) contiguous ten minute squares, for each of the management areas (e.g. Gulf of Maine, Georges Bank, Southern New England and Mid-Atlantic). The following four options were developed:

Alternative 5A: EFH/Productivity tradeoffs using the original working group species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of 37 other managed species.

Alternative 5B: Total EFH value only, using revised species EFH weights (omitting relative importance to the fishery as a factor), with no productivity tradeoff.

Alternative 5C. EFH/Productivity tradeoffs using the revised species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of the other 37 managed species.

Alternative 5D. EFH/Productivity tradeoffs using the revised species EFH weights and productivity for each of the 37 managed species, considered individually.

Figure 30 through **Figure 33** display maps and coordinates for these closures. See Appendix V for a detailed description of the model used to determine these closure areas.

4.2.7.1.5 Alternative 6 – Habitat Closures consistent with the Framework Adjustment 13 Scallop Closed Areas Access Program

In this alternative the year-round groundfish closed areas (WGOM, , CA I, CA II and NLCA) that were in place during the 2001 fishing year are considered habitat closures with the exception of those areas opened under the Scallop FW 13 Closed Area Access Program.

See Figure 34 for a map of the closures.

4.2.7.1.6 Alternative 8 - Restrictions on the use of rockhopper and/or roller gear

This alternative will restrict the use of both rockhopper and roller trawl gear to protect areas of high-relief bottom where these gears are frequently employed. It is recognized that rockhopper and roller trawl gear function differently, and that they may interact differently with benthic habitats, but very little information is available with which to distinguish the effects of these gears on fishable bottom and/or EFH. Therefore, these two gears are treated equally for the purposes of this alternative.

Under this alternative, the restriction could extend throughout the Gulf of Maine (only), throughout the Gulf of Maine and Georges Bank, or throughout the entire range of the multispecies fishery and apply to anyone with a multispecies permit.

The following versions of this alternative are proposed. Listed from least restrictive to most restrictive:

8(a) - A prohibition on the use of any rockhopper and roller trawl gear with a diameter larger than the current maximum size (estimated to be between 31" and 36").

This alternative will freeze the maximum size of rockhopper and roller trawl gear at the maximum size currently in use. It is estimated that the maximum size of rockhopper and roller trawl gear currently being used in the New England region is from 31" to 36" in diameter. To more accurately pinpoint the current maximum size, the Council will contact fishermen and gear distributors in the New England region and assess the largest size rockhopper and roller gear that they currently use or stock and sell. Once the maximum allowable size is capped, the Council and NMFS is expected to research the specific effects of various sizes of rockhopper and roller trawl gear on a variety of important groundfish habitats. The Council will use this new information to determine whether the maximum allowable size should be further reduced, maintained at current levels, or eliminated (no size restriction). This research would also target the differences between rockhopper and roller gear, and whether differential size restrictions are a more appropriate management tool to minimize the effects of these gear types on EFH.

8(b) - A prohibition on the use of otter trawl groundgear with a diameter larger than 22"

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 22 inches. Cookies or other types of groundgear configurations 22" or less in diameter, including rockhoppers and rollers, will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 22" or through a step-wise reduction over time.

8(c) - A prohibition on the use of otter trawl groundgear with a diameter larger than 12", consistent with the existing maximum size limit in near shore portions of the Gulf of Maine.

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 12". Cookies or other types of groundgear configurations, including rockhoppers and rollers, 12" in diameter or smaller will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 12" or through a step-wise reduction over time. This alternative allows some configurations of small rockhopper and roller trawl gear to continue to be fished.

This alternative is an extension of a limit already in place in much of the western Gulf of Maine. Currently, the Council prohibits discs, rockhoppers and roller gear larger than 12" between 42° and 43° 30' North latitude from the shoreline out to either 70° or 69° 50' West longitude.

8(d) - A prohibition on the use of all rockhopper and roller trawl gear.
This would be a prohibition of all otter trawl configurations that employ ground gear with a diameter larger than 5" (the use of "cookies" with a diameter of 5" or less would be allowed).

This alternative prohibits the use of otter trawl groundgear with a diameter larger than 5". Cookies 5" in diameter or smaller will be allowed. This alternative may be implemented through an immediate prohibition on all gear larger than 5", or through a step-wise reduction over time. Five inches was identified as an option for the maximum size of cookies based on gear believed to be commonly stocked by gear distributors and used by fishermen in New England. Cookie size is reported to be somewhat variable and may range from 3" to 5" in diameter.

8(e) - A stepwise reduction in the maximum allowable size of otter trawl groundgear.
This could be considered a stand-alone alternative, or it could be incorporated into any of the reductions/prohibitions on rockhopper and roller gear size considered as alternatives above except for Alternative 8(a).

This alternative prohibits the use of any otter trawl groundgear with the following stipulations: From the start of the first new fishing year that begins after the implementation of Amendment 13, the maximum allowable diameter of groundgear will be reduced in stages over a period of six years from a maximum of 24" to a maximum of 5". For example, if the first fishing year after implementation of Amendment 13 is May 1, 2003, the maximum size of groundgear will be 24" from May 1, 2003 until April 30, 2005. It will then be reduced to 12" from May 1, 2005 until April 30, 2007 and reduced again to 8" from May 1, 2007 until April 30, 2009. Thereafter, beginning May 1, 2009, the maximum size of groundgear will be 5". The specific dates are examples of a reduction program that could be used. The program may be compressed over less time, stretched out over a longer timeframe, or the individual time period in which each size limit is in place could be varied. Also, the specific gear size increments could be different (e.g., from a maximum size of 30" to 24", then to 18", and then to 12").

4.2.7.1.7 Alternative 9 - VMS on all groundfish vessels

This alternative requires VMS on all groundfish vessels, a critical step in obtaining high-resolution data on the distribution of fishing effort. The specifications on how best to implement this alternative will be left to the Groundfish Committee and PDT.

4.2.7.1.8 Habitat Alternative 10, Option (a) – Compromise Habitat Closure Areas

This alternative was developed to incorporate areas that would benefit EFH, but not in the most productive fishing grounds currently available to fishermen. Both existing mortality closures and proposed habitat closures were modified to develop one alternative that closes sensitive habitat and balances the need to provide access to primary fishing grounds. In general, the alternative suggests changing the eastern boundary of the Western Gulf of Maine closure, and modifying the Nantucket Lightship closure. In addition, the access areas used in Framework 13 for Closed Area I were modified slightly. Lastly, the habitat closure proposals for Closed Area II, Jeffrey's, Bank, and Cashes Ledge were included in this alternative, with some modifications. *(Note that this action does NOT change the cod HAPC boundaries but rather identified modified areas of the HAPC as habitat closed areas. The boundaries of the cod HAPC, as implemented under Amendment 11 to the Northeast Multispecies FMP, remain unchanged.)*

Detailed justification of each closed area modification:

Closed Area I (CAI) - According to industry, Closed Area I is very beneficial for rebuilding haddock and may be the primary reason haddock are recovering today. However, CAI does not provide much benefit for cod. Much of CAI is sand, however, there are diverse sediment types scattered within the area. The southeastern portion of CAI contains much of the complex bottom in the closed area. The northern part of the Framework 13 scallop access area in the middle of CAI has important habitat for cod spawning. As such, the Framework 13 scallop access area was shifted southward so that the cod could gain protection in the north for spawning, and the scallop resource would be accessible in the closed area. Both option (a) and (b) include the modified version of the Closed Area I as a habitat closure.

Closed Area II (CAII) - Survey data suggests that young of the year cod are in the HAPC in the summer near the rocky bottom that is along the Northern edge boundary. It was identified that there is a significant amount of sensitive habitat in the middle of the HAPC. For purposes of the habitat closed area boundaries, the existing boundary of the Cod HAPC was moved to the south to include more diverse sediment types that exist. The northern boundary enclosed area deeper than 50 fathoms that does not contain important cod or scallop habitat. This modification is more practical, because it still protects important habitat to the south, but allows access to the north; a true balance of conflicting demands on the area. The southern boundary was established at the southern end of the perceived groundfish spawning area. The new proposed closure is made up of mostly gravel with sand fingers. The lower portion was also identified as an important spawning ground for cod in the winter; in fact this area is still referred to as the “winter fishing ground” on nautical charts. The northern boundary of the Cod HAPC is too high, and if it were moved to the south, more benefit would be generated for cod and other groundfish species that live there. Note that this action does NOT change the cod HAPC boundaries but rather identified modified areas of the HAPC as habitat closed areas. The boundaries of the cod HAPC, as implemented under Amendment 11 to the Northeast Multispecies FMP, remain unchanged.

Western Gulf of Maine Closed Area (WGOM) - The new boundaries proposed in some of the habitat alternatives seem hard to enforce, and the industry would not gain much from the areas that would open. Modify the proposed habitat closure for the WGOM by the eastern boundary to come straight down the 70°W line instead of the irregular boundary proposed in habitat alternatives 3a, 3b, and 4. The main rational behind this modification is that the closed area would be easier to enforce and there are resources in the eastern portion of the closure that should be available to fishermen. Furthermore, the important areas for habitat are along the western boundary. If all the deep areas are closed to fishing then there is nowhere to go to avoid cod bycatch. It was also pointed out that this area is close to Gloucester, and this port depends on this area heavily. Both option (a) and (b) include the modified version of the WGOM as a habitat closure.

Nantucket Lightship Closed Area (NLCA) **-** Anecdotally, the substrate in the Nantucket Shoals is very complex. As such, this area has diverse sediment types and is important for the protection of small fish. An extension of the area north of the Nantucket Lightship would be closed primarily to protect the habitats on which small fish depend. A benthos map completed roughly in the 1960s showed that most of the concentrations of benthos in this area were contained in the central portion of the Nantucket Lightship area. Although this area is mostly sand, it contains many species. The modifications to include the central portion and an extension to the north contain a diversity of sediments and species. Both option (a) and (b) include the modified version of the NLCA as a habitat closure.

Cashes Ledge Closed Area - the closure should be modified to the 42°45W line. The southern boundary should be moved up, because the deeper area to the south does not contain kelp and should be assessable for fishing. Both option (a) and (b) include the modified version of the Cashes Ledge Closure as a habitat closure.

Jeffrey's Ledge Closed Area - Both option (a) and (b) include the version contained in Alternative 3 (a) and (b) of the Jeffries Ledge Closed Area as a habitat closure.

Figure 45 – Habitat Alternative 10a

4.2.7.2 Considered But Rejected Alternatives from DSEIS

4.2.7.2.1 Prohibition on hydraulic clam dredging in GOM, GB and SNE east of the 72^0 W line (Alternative 11)

This gear has been shown to be disruptive of benthic habitats and communities. Since the locus of the clam fishery is in the Mid-Atlantic, it may be appropriate to prohibit this type of gear in areas not dependent on the clam fishery.

Although this gear type is not used in a fishery managed by the New England Council, its use may have adverse impacts on groundfish habitat. Research has demonstrated its effects on habitat, including significant disruption of benthic habitat and communities. Most of the clam fishery occurs off the Mid-Atlantic and not in the Gulf of Maine or Georges Bank, but the fishery and gear type are allowed in both areas. To ensure that groundfish habitat in the Gulf of Maine and on Georges Bank are not adversely affected by hydraulic dredges, this alternative would prohibit the use of this gear type throughout the Gulf of Maine, Georges Bank, east of 72° West longitude to approximately the 42^0 20' North latitude line.

Although there are some Atlantic surf clams that occur in the Nantucket Lightship Closed Area and in the central portion of eastern Georges Bank, the vast majority of this population occurs south of Hudson Canyon. Ocean quahogs are distributed throughout the Northeast region, occurring east of the 70^0 20' boundary on Georges Bank and in the Gulf of Maine. The hydraulic dredge fishery occurs west of this line, on the southern New England shelf and in the Mid-Atlantic. Ocean quahogs are harvested with "dry" dredges and some hydraulic dredges in eastern Maine. This alternative would not be expected to have significant effects on the ocean quahog and Atlantic surf clam hydraulic dredge fisheries.

Hydraulic clam dredging could have significant short-term impacts on the habitat of Georges Bank, Gulf of Maine and Southern New England. Long-term impacts associated with this gear are not known, but the most significant impacts may be on groundfish food webs. This could be considered a proactive approach to managing a gear sector.

There may not be any actual need to implement this type of alternative since PSP concerns prevent fishing for clams on much of Georges Bank anyway and the prevalence of hard bottom in the Gulf of Maine prevents the use of this gear there. May need more information on long-term impacts (such as the duration and extent of chronic effects) before implementing this type of measure.

4.2.7.2.2 - Prohibition on bottom-tending mobile fishing gear (Alternative 12)

This would include all forms of otter trawls, scallop dredges, and beam trawls (there may be other gears and this list should be reviewed to determine what gear types would be prohibited). This alternative would be a straight-forward prohibition on all types of bottom-tending mobile fishing gear. The only bottom-tending fishing gears allowed to be used would be the fixed gears (gillnets, hook and line, pots and traps, etc.). Mobile gears would be allowed if they are not bottom-tending (e.g., midwater trawls). It is possible for this alternative to be area-specific and only apply to the Gulf of Maine, thus avoiding the most significant impacts on the scallop fishery, which at this point only harvests scallops using mobile gear. This alternative would be expected to result in significant adverse impacts on the fishing industry, both in compliance costs and loss of revenue from fishing. For several fisheries, suitable alternative fishing gears do not currently exist (such as shrimp and sea scallops). This alternative may be unnecessary in the extreme, as some bottom-tending mobile fishing gears are not considered to have significant adverse effects on some habitat types.

4.2.7.2.3 Coordinated MPA system (Alternative 13)

The current system of areas that meet at least some of the criteria for marine protected areas (the existing groundfish closed areas, gear restricted areas, etc.) was not established in a coordinated manner. A marine protected area system would allow for a coordinated approach to the protection of important habitat throughout the region. Developing criteria and designation protocols for an MPA system is a complicated procedure and requires cooperation among many agencies and management authorities. Although the Council can establish no-take zones and implement other area-based fishing restrictions which may qualify as MPAs, these types of issues are being considered under many of the management alternatives listed above. The establishment of a coordinated system of true MPAs that address all types of activities and impacts to the marine environment is outside of the purview and jurisdiction of the Council. For example, the Council has no authority or jurisdiction over activities such as sand and gravel mining, oil and gas exploration, channel dredging and dredge disposal, ocean dumping, etc. and yet these are all activities that should be considered, addressed, and possibly restricted in the designation of region-wide MPAs. The Council could participate and cooperate with other federal and state agencies and management authorities and initiate a long-term process to develop such a system, but this is not possible within the context of Amendment 13.

4.2.7.2.4 HAPCs have minimum set of restrictions (Alternative 14)

The process and rationale used to designate each individual HAPC will help identify management issues related to that HAPC. Appropriate management action, if any, is only appropriately considered on a case-by-case basis and tailored specifically to the circumstances of the HAPC. For example, the juvenile cod HAPC on Georges Bank is contained within a groundfish closed area. Trawling restrictions may be appropriate in this area, but they are unnecessary as the regulations for the groundfish closed area already prohibit all types of fishing gear capable of catching groundfish. Also, the Council designated eleven rivers in Maine as an HAPC for Atlantic salmon. Trawling restrictions are not appropriate or necessary in this HAPC, as the intent of the HAPC was to protect these river systems from adverse impacts associated with non-fishing related activities such as pollution and development. Along with the designation of each HAPC, the Council will identify the particular threats to the habitat of the area and propose and consider management actions to minimize those threats. In some cases, action by the Council may be warranted to reduce adverse effects caused by fishing, but in other cases, the threats may be non-fishing related. In these cases, the Council would develop conservation recommendations for the responsible agencies and encourage them the implement reasonable measures. Thus, it would be inappropriate to presuppose the best management measures for any HAPCs in a general sense.

4.2.7.2.5 Gear restrictions in juvenile cod habitat on Georges Bank (Alternative 15)

The Council will consider retaining the existing HAPC for juvenile cod on Georges Bank as well as an additional HAPC intended to protect juvenile cod habitat. The Council will also consider redesigning the existing groundfish closed areas to better protect habitat, and this will include some juvenile cod habitat on Georges Bank. Depending on the management approach selected by the Council and the specific management alternatives considered, there may be additional gear restrictions in juvenile cod habitat on Georges Bank resulting from Amendment 13. The Council will consider these actions in the context of the management objectives for the Amendment and will adopt whatever measures are necessary to achieve those objectives.

4.2.7.2.6 Seeding of epifauna (Alternative 16)

The growth of dense epifauna and related communities can be increased and enhanced by protecting areas where these organisms grow. Seeding of these communities may not be practicable at this time, and in most cases is probably unnecessary as there is no evidence that the abundance of planktonic invertebrate larvae is too low to support dense epifaunal growth. Suitable space with the proper physical and oceanographic conditions free from anthropogenic disturbance is most likely the limiting factor.

4.2.7.2.7 Create shelter and harvest predators (Alternative 17)

Additional shelter may not benefit all species and artificial reefs have not been demonstrated conclusively to add to production but may only serve to aggregate fish. The objective of this comment could be achieved by protecting known areas currently containing shelter. In cases where known shelter has been destroyed, this approach may have utility. Harvesting predators could have unintended adverse effects that could ripple through the food web and actually serve the opposite effect that they were intended. For example, suppose that the adults of resource species A are preyed upon by adults of predator species B, but that the juveniles of resource species A feed upon the larvae of predator species B. Removing adults of B would result in fewer B larvae, reducing the available food for species A, limiting survival and recruitment.

4.2.7.2.8 Precautionary approach (Alternative 18)

The precautionary approach is an approach to decision-making, not a specific management alternative that can be implemented through regulation.

4.2.7.2.9 Prohibit the "flophopper" gear (Alternative 19)

This alternative was a recommendation from scoping. Need to better understand what the "flophopper" gear is. The scoping comment letter suggesting this measure did not describe this gear type.

4.2.7.2.10 Keep groundfish closed areas closed for 10 years (Alternative 20)

The current groundfish closed areas, except for WGOM, are indefinite in duration. Amendment 13 will examine all current groundfish closed areas and explore their effectiveness and whether they should be continued. The actual duration of the closed areas will depend on many factors, including the recovery of groundfish stocks, their fisheries, and changing conditions. It is impossible at this time to say whether the groundfish closed areas will be necessary for ten more years, or even whether ten years will be sufficient to meet the Council's management objectives.

4.2.7.2.11 Remove tuna purse seiners from the list in Alternative 7 (Alternative 21)

This gear type was removed based on the preliminary data that NMFS provided on the experimental tuna purse seine fishery, which showed little or no impact on the bottom habitat.

4.2.7.2.12 Remove 8" maximum size from consideration in Alternative 8 (Alternative 22)

With this alternative, the Council would consider prohibiting the use of rockhopper and roller trawl gear with a groundgear diameter larger than 8". Cookies or other types of groundgear configurations, including small rockhoppers and rollers, 8" in diameter or smaller would be allowed. The implementation of this alternative could be via an immediate prohibition on all gear larger than 8", or could be done through a step-wise reduction over several years. This alternative uses 8" as the maximum allowable size rather than 5", which could allow for some different configurations of groundgear beyond simple cookies.

Setting limits on the maximum allowable size for rockhopper and roller gear could protect rough bottom habitats from any adverse impacts associated with these gear types by limiting the areas where mobile bottom gear can access. Long-term this could be more economically efficient for the groundfish fishery. As the maximum allowable diameter of the gear decreases, more and more rough bottom habitat would be protected from impacts associated with mobile bottom gear. This alternative would offer slightly more flexibility to the fishing industry than the 5" option.

There will be short-term costs to the industry from the loss of gear and having to buy new gear to comply with the measures. There may also be short-term production losses (less fish and less revenue) to the industry, although these losses will be mitigated as stocks recover. The smaller the maximum allowable size for this gear, less area and opportunities will remain for the fishing industry. Also, the remaining areas accessible for fishing may be fished harder as more fishermen move into these areas and this could reduce the availability of suitable habitat in open areas. There may be more competition between fishermen for accessible bottom, with the potential for increases in gear conflicts. This alternative would protect less area than the 5" option. For these reasons, this alternative was considered but rejected.

4.2.7.2.13 Area-based management program (Alternative 23)

Management areas could be differentiated based on habitat type and fish survey and landings distributions. Management (the extent and levels of fishing effort allowed, gear types allowed, seasonal restrictions, etc.) would be area-specific and based on the most appropriate levels given the characteristics of each area. This alternative may be most similar to the area-based management strategy being developed by the Groundfish Committee, but would be focused on habitat protection. The gear-specific areas aspect of this alternative would be based on the known distribution of sediments and other physical characteristics that result in the susceptibility to impacts resulting from specific fishing gear types.

This alternative proposes using sediment types, fish distributions, and landings data to establish distinct management areas for the protection of habitat. As an example, areas with sandy sediments and relatively high levels of flatfish could be allocated for flatfish fishing and the use of bottom-tending mobile gear. Areas of complex rock and boulder habitat with relatively high levels of cod could be allocated for cod fishing and gillnets and hook and line gear. Fishing effort data would be incorporated, along with fish distribution data, to identify different fishing areas. Other measures, such as differential DAS accounting based on area, could be applied as well. Based on available information, much of the region could initially remain unassigned, in which case all fishing activities and gear types would be allowed. As more information becomes available, additional areas could be defined and allocated.

The gear-specific area alternative would establish specific gear areas, based on sediment distribution and other characteristics such as depth, and where only the assigned gear types could be used. For example, a sandy area might be separated from a hard-bottom area and assigned to mobile gear. The hard-bottom area might be assigned to fixed fishing gears. It is possible, with this approach, to have mixed gear areas as well but the primary objective would be to assign different gear types to different areas. Under gear-specific area option, areas would not be differentiated by fishery and management (other than allowable gear types) would not be indicated. This would have both habitat benefits as well as minimize the potential for conflicts.

This alternative could potentially eliminate gear conflicts and problems with single stock management issues. For example, if there is a portion of the Gulf of Maine allocated for cod fishing and the GOM cod stock needs strict management, this area could be shut down, allowing all other fishing to continue. This alternative may encourage fishermen to change the way they fish to use reduced-impact gear more frequently. This alternative would be intended to protect known important habitats that need protection from adverse impacts associated with certain fishing gear types. Gear conflicts, especially between mobile gear and fixed gear fishermen, would be minimized. This measure could be used as an alternative to setting maximum size gear restrictions for rockhopper and roller gear.

Not enough information exists for all areas to implement this measure consistently throughout the region. At present, the distribution of sediment types is poorly known and is not adequate for allocating fishing gears in many areas of the Gulf of Maine and southern New England shelf. Fishing gear areas identified based on our current knowledge of sediment distribution would be unreliable. Given the information limitations, this approach to management may not be possible at this time. Once better (even if it is not perfect) sediment and fishing effort distribution information is available, this approach could be revisited. This type of alternative could complicate actual and perceived allocation issues, especially with the recreational sector. Depending on the areas and assigned gears, this alternative could disrupt traditional fishing practices (traditional gears fishing in traditional areas). For these reasons, this alternative was considered but rejected.

5.0 Environmental Impacts of the Management Alternatives

The impacts of the proposed management alternatives are described in this section. Expected impacts are considered in four broad categories:

Biological impacts: the effect on fishing mortality, bycatch and bycatch mortality, and protected and threatened species

Economic impacts: the effects of the proposed measures on revenues and costs in the fishery, and the impacts of those changes on other entities in coastal communities

Social impacts: the effects of the proposed measures on fishing communities and participants in the fisheries affected by the FMP

Habitat impacts: the effects of the proposed measures and the extent to which they will minimize the adverse effects of fishing on essential fish habitat

5.1 Analytic Approach and Limitations

The Council is proposing changes to address several broad issues: rebuilding overfished stocks, ending overfishing, addressing requirements to minimize bycatch and/or bycatch mortality, tuna purse seine access to groundfish closed areas, expanding the area for the northern shrimp fishery, authorizing a general category scallop fishery exemption area in southern New England, and numerous administrative measures. Analyses are grouped in the same manner, but the emphasis is on analysis of the measures designed to control fishing mortality. In the case of measures designed to control fishing mortality, the impacts of measures are analyzed by combining the measures as much as possible. This is because many of the proposed measures interact with each other and analyzing the measures individually does not capture the true impact of adopting a suite of measures. Where possible, quantitative impacts are estimated, but the Council has limited ability to quantify the impacts of some of the indirect management measures proposed in this framework. As a result, most alternatives are a combination of quantitative and qualitative analysis. Some management measures are included in several alternatives. Where this occurs, the detailed analysis is only described the first time the measure appears in an alternative. In later alternatives, the measure is referenced and its effects summarized.

5.1.1 Closed Area/Effort Control Analysis

One of the primary analytic tools used to analyze both the biological and economic impacts of the proposed alternatives to achieve mortality objectives is the closed area model. Changes in mortality brought about by area closures and revised trip limits were projected through a non-linear programming model using the General Algebraic Modeling System (GAMS). This closed area model allocates effort to specific block, month combinations for each vessel holding a valid year 2001 multispecies permit, and landing groundfish during the time period 1998 - 2001. A four year period is used to smooth out any peaks or valleys in the data. Data used by the model includes average catch per unit effort (CPUE) by species, gear type, block and month, prices by species and month, and effort by vessel and month. Vessels are assigned a specific gear type based on which gear they used to land the majority of their groundfish catch between 1998 and 2001. Cod discards were included in the CPUE figures for each block and time period because cod had several different trip limit regulations during the time period. All prices were deflated to 1996 levels in order to remove the influence of inflation from the analysis. The model attempts to maximize revenue for each vessel by allocating their effort to the highest revenue blocks. However, because the revenue functions embedded in the model are downward sloping, effort stops flowing to a block when marginal revenue hits zero. The model can also be modified to incorporate changes in allowable days at sea, trip limits, differential days at sea and changes in CPUE by species and stock area.

An initial model run was made based on the no action management regime. The no action alternative includes year round and seasonal area closures which are already in place, the 400 pound GOM cod daily trip limit, and caps effort for each vessel at their average effort level between 1998 and 2001. Additional model runs are then made based on proposed changes in seasonal and year round area closures, changes in trip limits, and changes in days at sea under each management option. The estimated catch stream from each option is then compared to the no action catch stream, and the percentage change in landings is calculated. These numbers should be interpreted as the percent change in exploitation brought about by the proposed management action using the conditions which existed during the 1998-2001 time period. Changes in the exploitation rate can then be interpreted as equivalent changes in mortality. However, results should be interpreted cautiously because some conditions may have changed which are not reflected in the base year data. Additionally, there is variability around the estimates which is not fully captured by the model. One weakness of the model is the uncertainty about catch rates that result from opening areas that have been closed for a lengthy period of time. This is most problematic when changing the boundaries of year round closed areas. Because there is limited trip information in the closed area, the closed area model may under-estimate the catch rates that will result when an area closed to year round fishing is re-opened. This is less of a problem for seasonal closures, since the model incorporates recent trip information that reflects the catch rates that result immediately after opening an area. An advantage of the model is that unlike the "no displacement" analysis of closed areas (that is, assuming that effort in a newly closed area does not fish in another location), it assumes fishing effort moves out of a closed area into an open area based on rational decisions to maximize revenue. A second advantage is that the model output can include predicted impacts on revenues, and this can be broken down by gear sector and tonnage class of vessel. *The model is a simulation of behavioral responses to changes in fishery regulations. It should not be interpreted as a precise calculation of future fishing mortality. While the model output results in apparently precise numerical estimates, it is better to interpret these as broad indicators of relative changes, rather than as precise predictions of mortality impacts. Small percentage changes, for example, should be viewed as less likely relative outcomes than large percentage changes. For stocks where the Council is implementing measures to make large reductions in fishing mortality, it should be clear that the results of the measures will have to be carefully monitored to make sure the objectives are achieved. The model may not capture the exact response of fishermen to the regulations and as a result may over or under estimate the realized impacts.*

As noted earlier, the percentage results should be interpreted as indicators of the relative change in exploitation between options, and not as precise predictions of the result. Changes in exploitation must be converted to a change in fishing mortality in order to determine if mortality objectives are being met. When large reductions in mortality are needed, the PDT uses the criteria that if the estimated reduction is within ten percent of the needed reduction, the proposed measures are successful. The closed area output includes information on the revenues of individual vessels, and this is used in the analysis of economic impacts of the alternatives (section 5.4).

5.1.2 Combination of Quantitative Results

While the closed area model is the primary analytic tool used to estimate impacts of management measures, other models are used as well. The closed area model results show changes in exploitation, while the model used for estimating the impacts of mesh change shows reduction in fishing mortality. Prior to combining the results from these two models, the changes in exploitation are converted to percentage reductions in fishing mortality.

When quantitative impacts are calculated for more than one measure, they are not additive because the measures interact with each other. They are combined by first calculating a multiplier value for each, then by multiplying those values together. The multiplier is determined from the following formula:

Multiplier = 1 – (Estimated F reduction)

Both of these issues are considered in the summary of biological impacts at the end of each alternative. The summary tables show impacts on fishing mortality for GOM cod and GB cod.

5.1.3 Limitations

Analysis of the impacts of the proposed management alternatives is complicated by the following factors.

- The range of proposals and the interaction between management measures precludes analysis of the components on both large and small scales.
- The impacts of changes in trawl mesh size on fishing mortality cannot be accurately estimated for reasons explained in following sections.
- The impacts of minor changes in the boundaries of year round closed areas cannot be quantified. In addition, the catch rates that will result from large changes in the boundaries of year round closures are unknown, making it difficult to estimate the impacts of changes to the Closed Area II and the Western Gulf of Maine Closed Area.
- Many of the management measures interact with each other. Whenever possible, the impacts of each alternative are analyzed as a combination of measures, usually by using the closed area model. When estimates of fishing mortality reductions are obtained from different analytic techniques, they cannot be summed to obtain an estimate of the overall impacts. This is partly because the measures interact with each other, even if analyzed separately.
- The impacts of some measures in the alternatives cannot be quantified. When possible, impacts are expressed in a combination of quantitative and qualitative terms.
- There is limited ability to model long-range economic impacts. Any attempt to model economic impacts into the future assumes no changes in the structure of the economy in the interim. This is an unrealistic assumption over the time periods associated with the rebuilding plans.
- There is limited ability to estimate the economic impacts of changes to the recreational fishing measures. There is both a lack of available data and lack of an ability to predict how recreational fishermen will react to changes. The motivations for recreational fishing are many and varied, and predicting changes in recreational fishermen's behavior is nothing more than guesswork.
- Because of very low catches, the closed area model does not calculate changes for ocean pout, halibut, or the southern stock of windowpane flounder.
- The closed are model was designed to estimate impacts of input controls. It is an imperfect tool for modeling the impacts of hard TACs.

5.2 Biological Impacts of the Alternatives

5.2.1 Rebuilding Strategies

The following sections show the expected trajectories of spawning stock biomass for the proposed action and alternative rebuilding strategies. Trajectories are shown for those stocks with required formal rebuilding plans and available age-based projections. The median biomass (or spawning stock biomass) and the inter-quartile range (25^{th} and 75^{th} percentile) are shown on each chart. Projections for stocks assessed through trawl survey and exploitation indices ("index-based stocks") are shown in tables. These tables should be viewed with caution. As noted by SAW 35 (NEFSC 2002c), "Projections are based on linear rates of increase and as such they should not be used to project population trends beyond a few years." This approach, however, is the only one available to indicate likely trends in biomass for index-based stocks.

While the M-S Act measures the success of a rebuilding program as attaining the target biomass level, increases in stock biomass are not the only biological impacts of the rebuilding programs. As fishing mortality is reduced and stock size increases, stocks should see a broadening of the age structure (that is, more individuals at a wider range of ages). Stocks are expected to expand over a broader geographic range, subject to oceanographic conditions. Recruitment – the number of young fish that enter the fishery - is expected to increase for many stocks. Some stocks may expand their geographic range. Density-dependent effects may also develop: for example, slower growth rates due to competition for food, older ages at maturity, etc. There may also be changes in predator-prey relationships. For a general discussion of the type of changes that may occur, see NEFSC (2002a). It is not possible to predict the extent of these changes since many of the target stock sizes (under some of the biomass target options) have not been observed, but the periodic stock assessments should be able to detect them as they occur.

5.2.1.1 Proposed Action

Age-based projections for the proposed action are shown in Figure 46 through Figure 52. These projections reflect a combination of phased and adaptive rebuilding strategies as discussed in section 3.2. For index-based stocks, projected biomass that will result from the phased or adaptive rebuilding strategy are shown in Table 34. As state above, hose tables should be viewed with caution. As noted by SAW 35 (NEFSC 2002c), "Projections are based on linear rates of increase and as such they should not be used to project population trends beyond a few years." This approach, however, is the only one available to indicate likely trends in biomass for index-based stocks.

As noted in the introduction to this section, increases in stock biomass are not the only expected biological effects of rebuilding. See NEFSC 2002a for a general discussion of the likely impacts.

5.2.1.2 No Action

Age-based projections under the No Action alternative (that is, fishing mortality rates observed in FY 2001) are shown in figures Figure 53 through Figure 62, while the index-based stock trajectories are shown in Table 35. Evaluation of the No Action alternative depends in part on the choice of biomass targets (see section 3.1.6.2). Under the No Action alternative, while many stocks continue to increase, most of the stocks with required rebuilding programs will not achieve the target biomass (SSB_{MSY} or B_{MSY}) recommended by the reference Point Working Group (NEFSC 2002a; see Option 1 of section 3.1.6.2). The exceptions are GOM haddock, GB haddock and redfish, because fishing mortality in 2001 was at or below the mortality needed to rebuild these stocks. For different biomass targets, however, the No Action alternative will achieve the target for more stocks. Table 36 summarizes the year that the three biomass target options will be achieved under this alternative.

Year	Northern Windowpane	Gulf of Maine Haddock	Pollock (Area 5 & 6)	White Hake (all sizes)	White Hake (60+ cm)	Southern Windowpane	Ocean Pout
2002	0.86	15.86	1.73	6.70	2.47	0.25	2.46

Table 36 – Year that various biomass targets will be achieved under the No Action rebuilding strategy

Notes:

(1) For stocks marked "never", projections show either a constant or declining stock size in 2026.

(2) For stocks marked " > (year)", projections show stock size continuing to increase to end of projection period, with SSB at end shown in parenthesis. Trajectory after that period is unknown. Index-based projections end in 2014., age-based in 2026 for most stocks.

(3) No method exists to project halibut biomass due to a lack of information.

5.2.1.3 Constant Fishing Mortality (2009)

This alternative is designed to achieve the target biomass for many stocks requiring formal rebuilding programs by 2009. There are exceptions to the list of stocks that must be rebuilt by 2009 for the reasons more fully described in section 3.2.2. GB cod, CC/GOM yellowtail flounder, and redfish have longer rebuilding periods because it is not possible to rebuild by 2009. Plaice and SNE/MA winter flounder rebuild by 2014 because they were not previously identified as overfished. The SSB trajectories for these stocks are the same as those for the constant fishing mortality (2014) option and are not shown in this section.

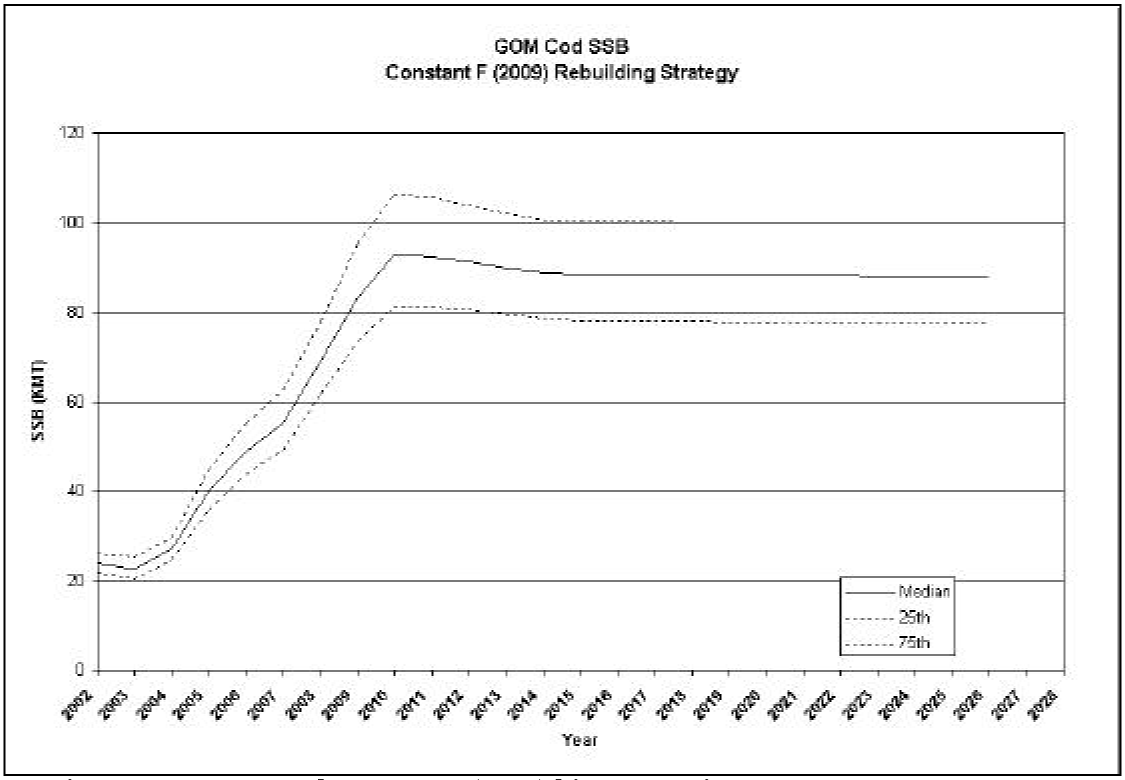

Figure 63 – GOM cod constant F (2009) biomass trajectory

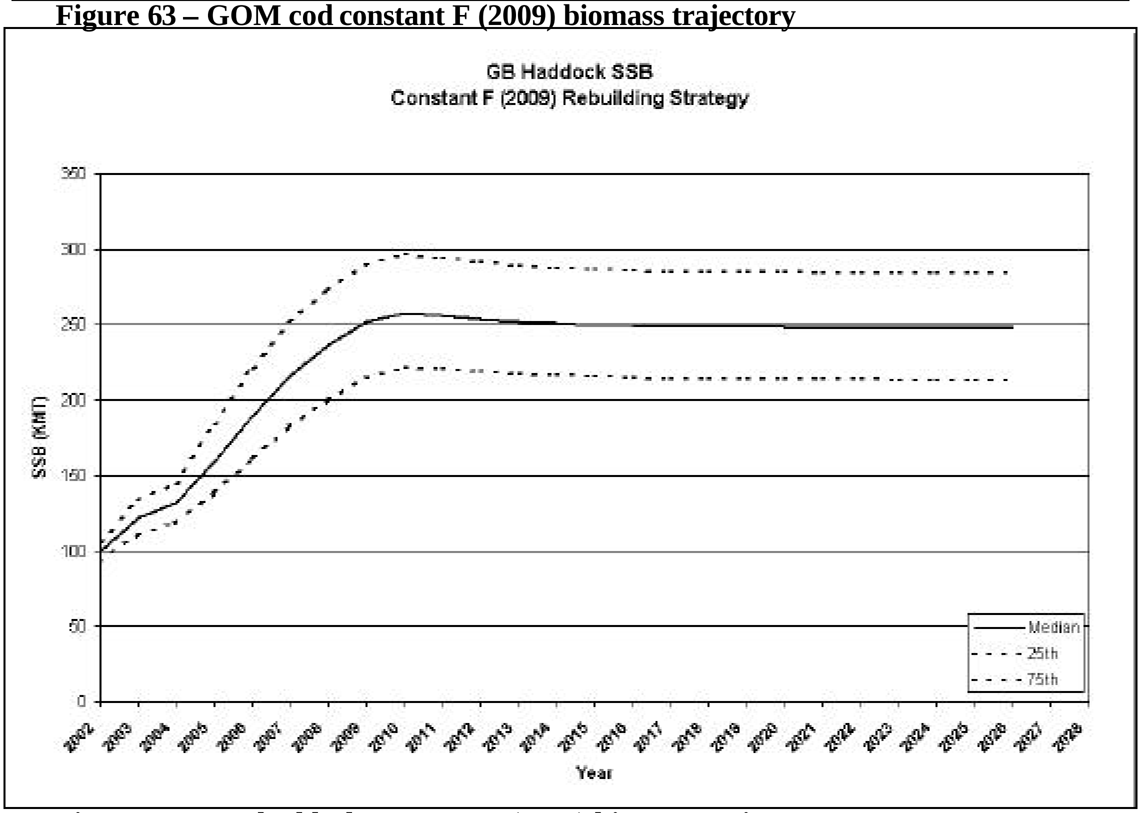

Figure 64 – GB haddock constant F (2009) biomass trajectory

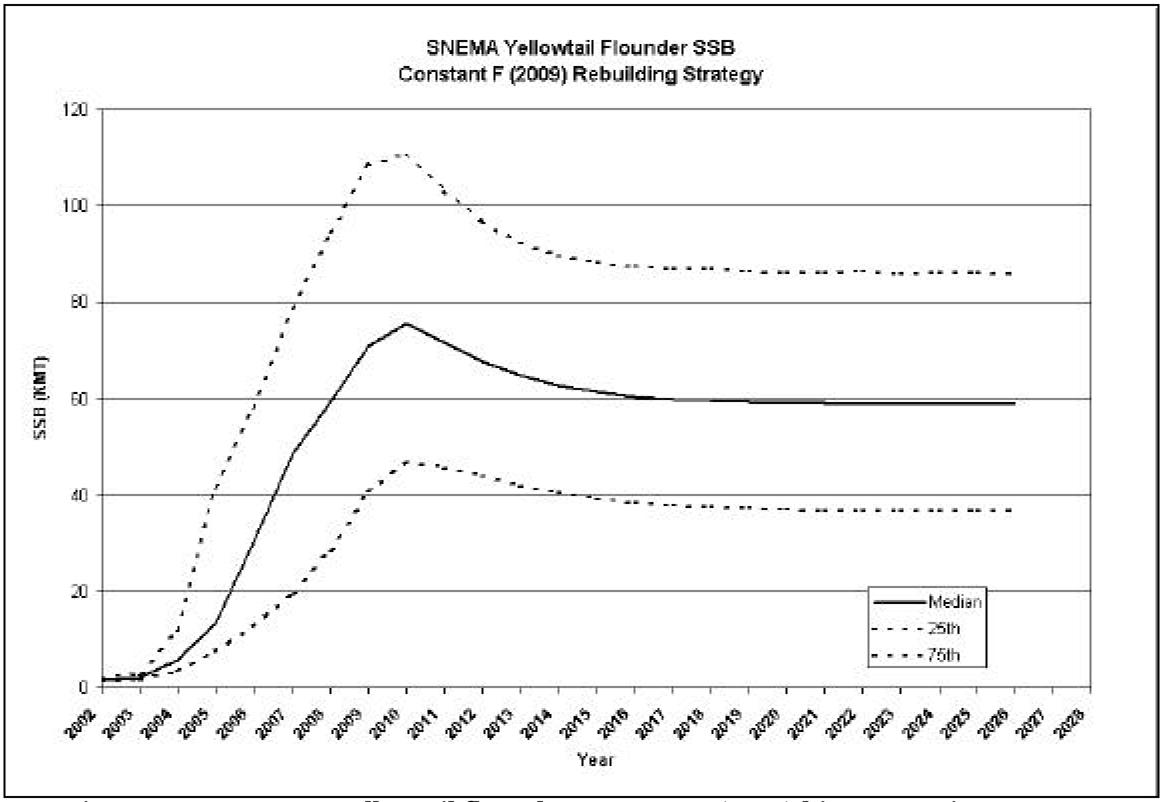

Figure 65 – SNE/MA yellowtail flounder constant F (2009) biomass trajectory

5.2.1.4 Phased Fishing Mortality Reduction (2009)

Biomass targets for many stocks that require formal rebuilding programs are achieved by 2009 under this option. Exceptions include GB cod, CC/GOM yellowtail flounder, redfish, plaice, and SNE/MA winter flounder. Rebuilding trajectories for those stocks are the same as shown for the phased reduction (2014) option and are not repeated.

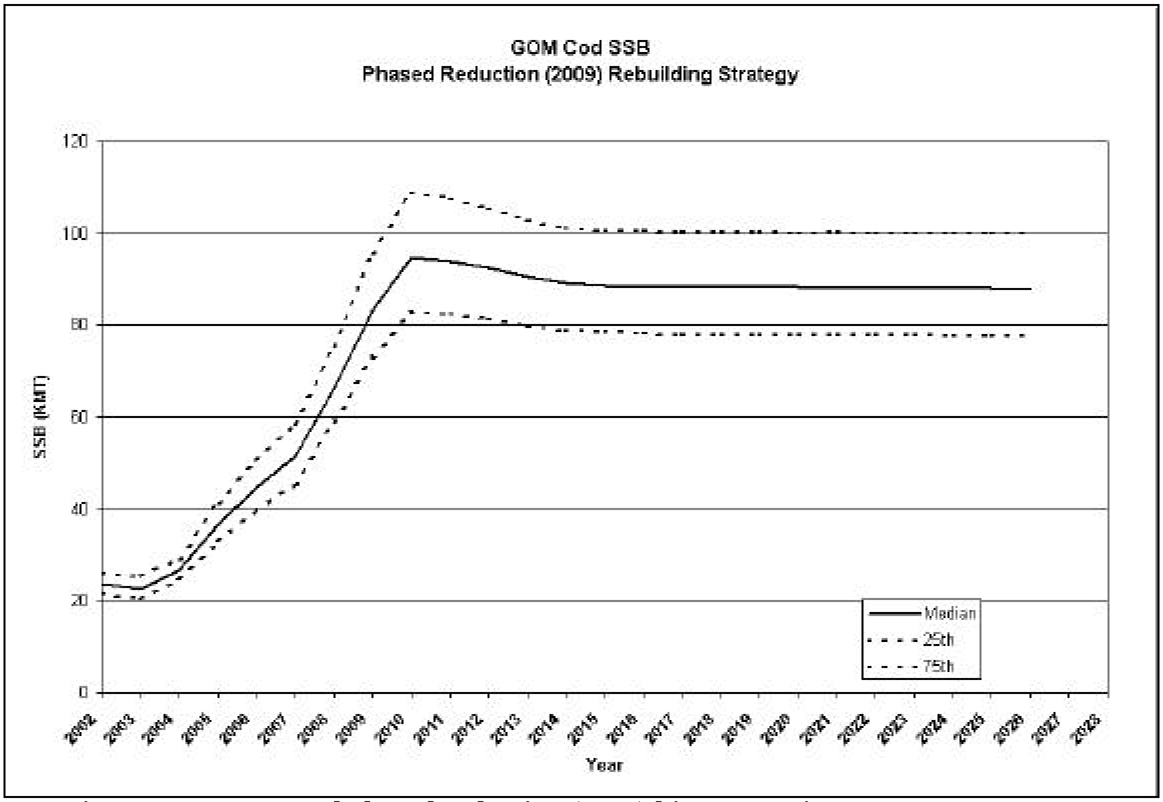

Figure 66 – GOM cod phased reduction (2009) biomass trajectory

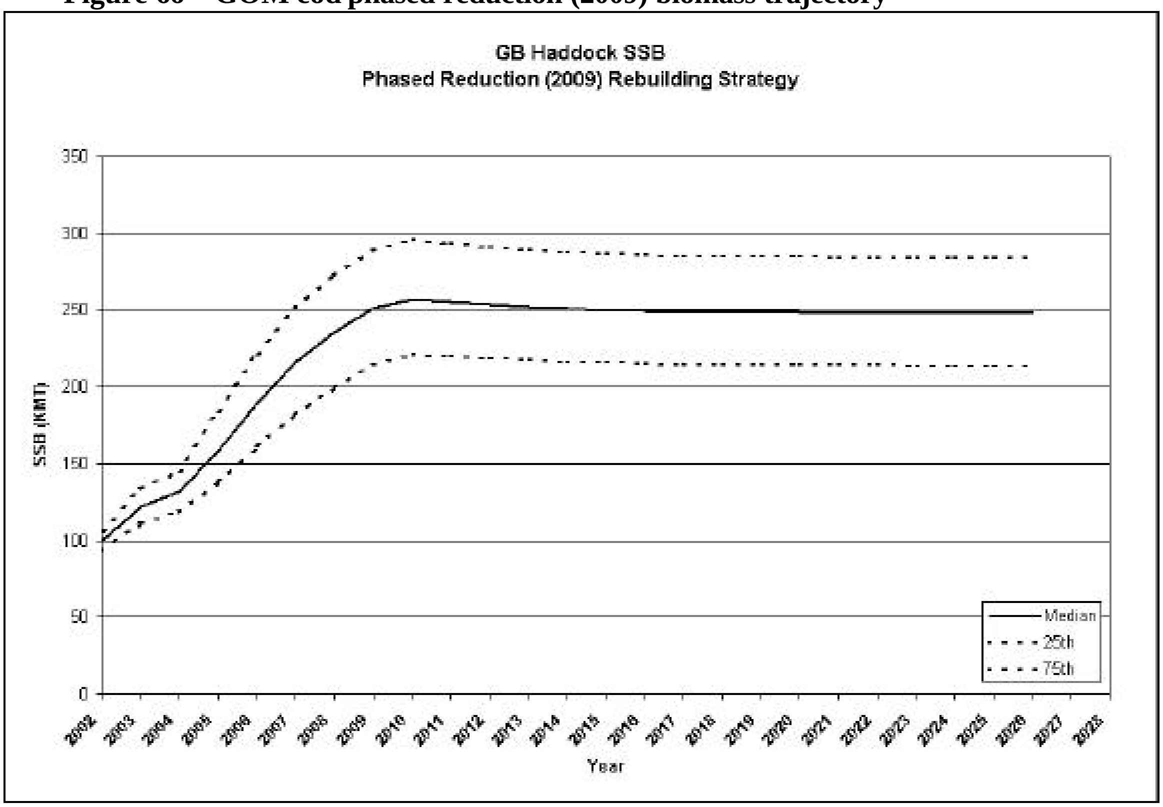

Figure 67 – GB haddock phased reduction (2009) biomass trajectory

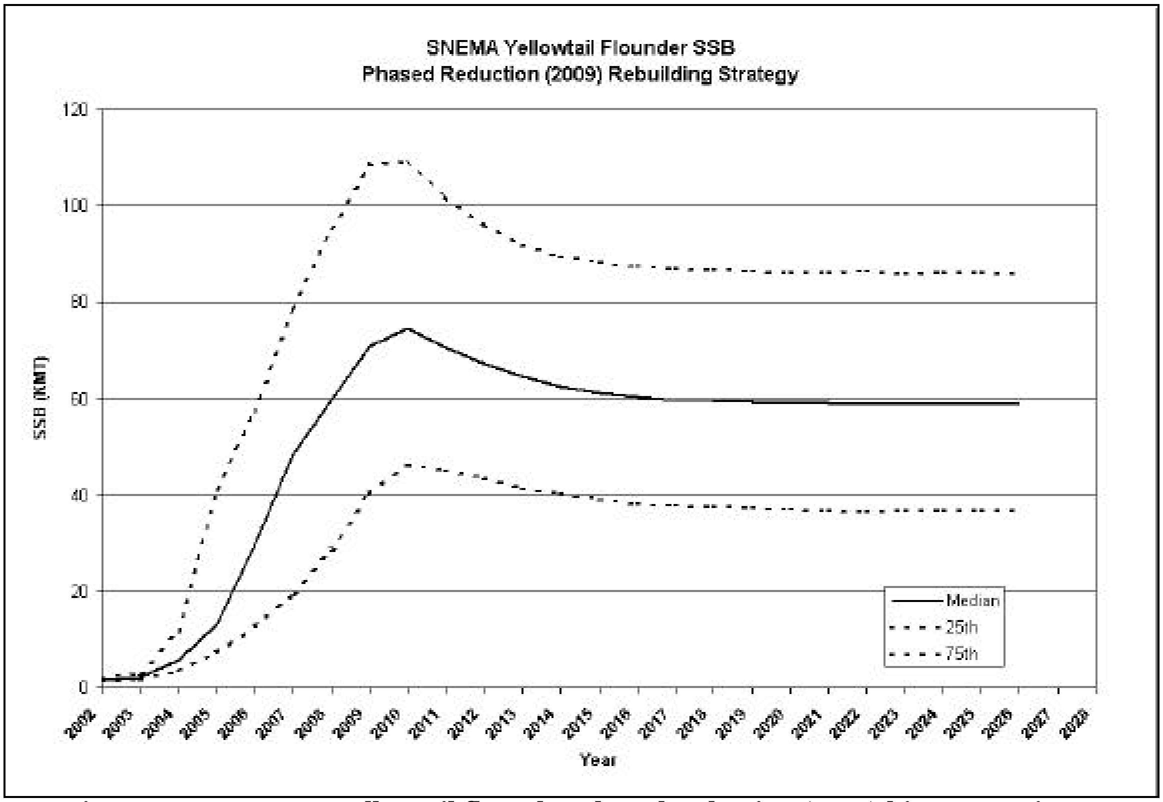

Figure 68 – SNE/MA yellowtail flounder phased reduction (2009) biomass trajectory

5.2.1.5 Constant Fishing Mortality (2014)

Fishing mortality in this option is designed to achieve the target biomass with a median probability by 2014 for most stocks requiring formal rebuilding programs. The exceptions (as described in section 3.2.2) are GB cod, CC/GOM yellowtail flounder, and redfish.

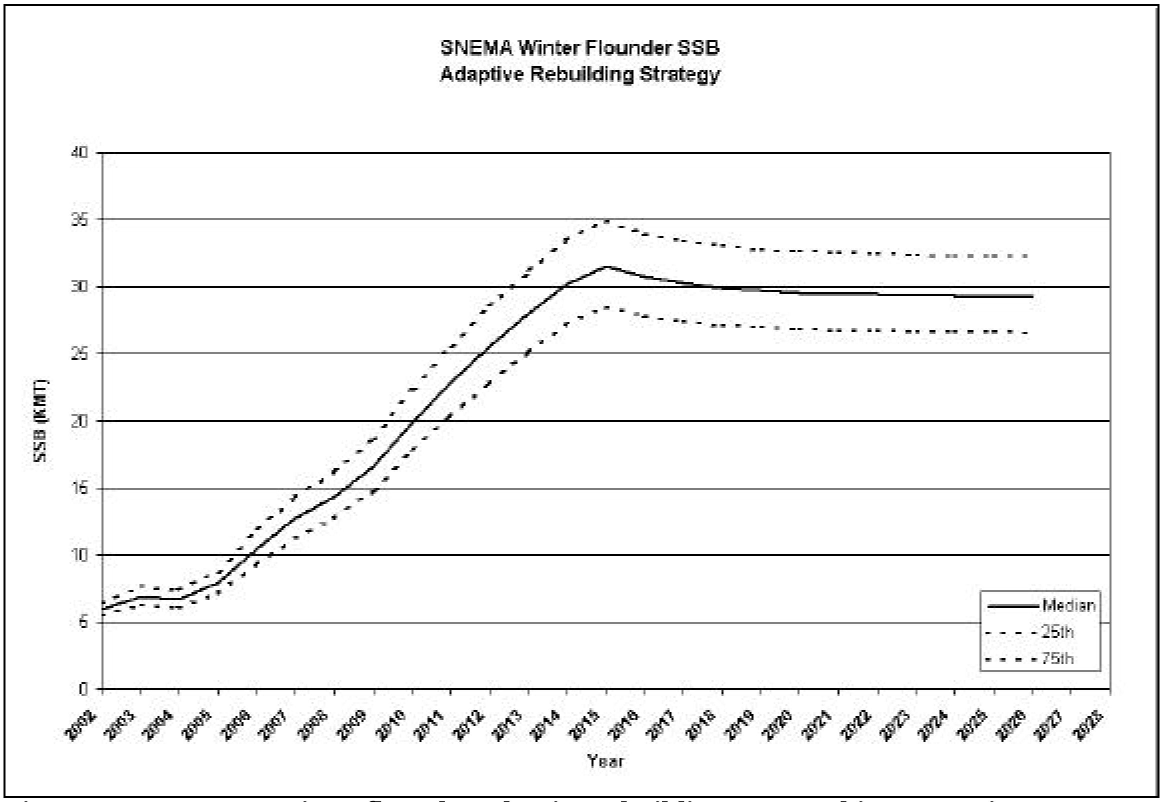

Figure 89 – SNE/MA winter flounder adaptive rebuilding strategy biomass trajectory

5.2.1.8 Comparison of Rebuilding Strategies

Three broad rebuilding strategies (constant fishing mortality, phased reduction fishing mortality, and adaptive) and two different ending dates for rebuilding (2009 or 2014 for most stocks) were considered. The proposed action combines the adaptive and phased strategies. All of the strategies are designed to achieve the target biomass within the rebuilding period with a median (50 percent) probability. For this reason, there is no difference in the final results of the strategies. The projected rate of growth of the stock biomass (or spawning stock biomass) differs, however, and the uncertainty surrounding the projected biomass trajectories may also differ. For most stocks, spawning stock biomass increases most rapidly with the constant fishing mortality rate option and least rapidly with the phased reduction strategy. One measure of the uncertainty of the projected biomass is the inter-quartile range around each predicted biomass (that is, the range between the 25th and 75th percentile, expressed as a percent of the median SSB). The median biomass trajectories are compared in

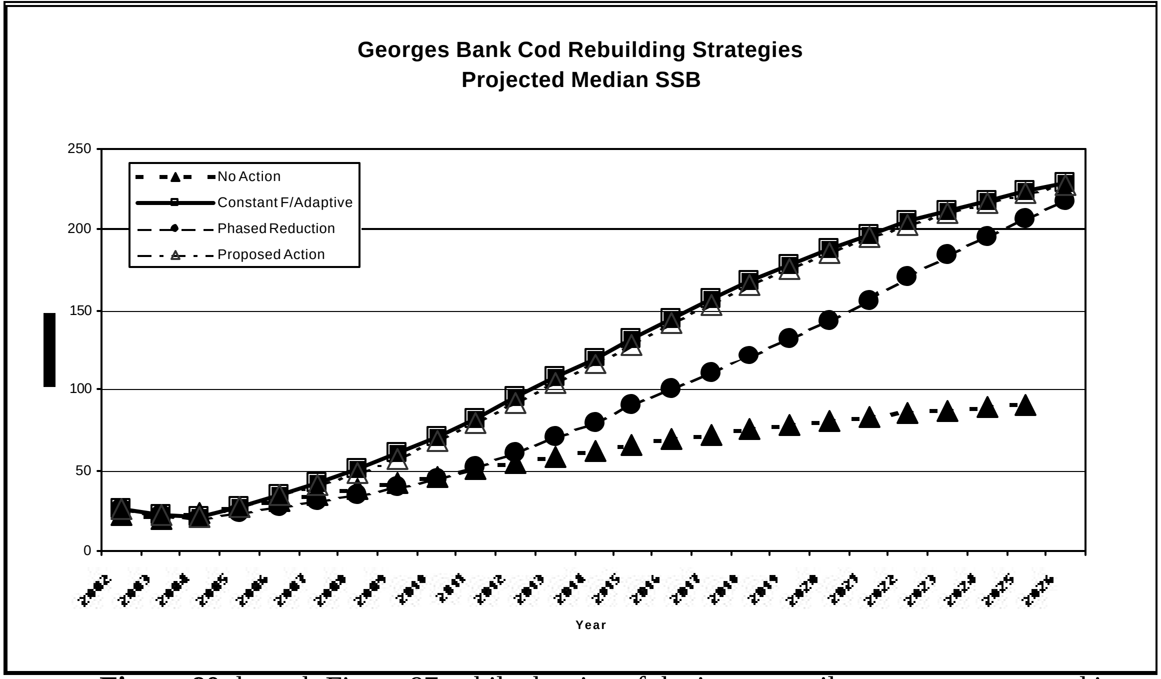

Figure 90 through Figure 97, while the size of the inter-quartile range are compared in Figure 98 and Figure 105. The following discussion summarizes this information for each stock.

<u>Georges Bank cod</u>: The constant F and adaptive approach are the same and rebuild the stock the most quickly. The phased reduction approach allows a slight increase in mortality over no action in the early years of the program, and as a result the biomass trajectory does not exceed the no action biomass until 2010. The inter-quartile range for the constant/adaptive strategies is less than for the phased strategy.

<u>Gulf of Maine cod</u>: The constant F alternatives rebuild most quickly (for both 2009 and 2014 end dates), but there are only slight differences in the projected biomass trajectory for any of the alternatives that have the same end date. Inter-quartile ranges follow a similar pattern: the constant F range is smaller than the phased F range for a given rebuilding period, but the differences are small.

Georges Bank haddock: All of the alternatives result in similar rebuilding trajectories, including the No Action alternative. The No Action alternative actually has a lower fishing mortality rate than some of the rebuilding strategies and will achieve the target more quickly. There are only minor differences in the inter-quartile range for all alternatives.

SNE/MA yellowtail flounder: For the 2009 end date, the phased reduction and constant F strategies result in nearly identical biomass trajectories. For the 2014 end date, the constant F strategy rebuilds more quickly, with the phased reduction and adaptive strategies nearly identical. All rebuilding alternatives have similar and smaller inter-quartile ranges than the no-action alternative.

CC/GOM yellowtail flounder: Constant F approaches rebuild more quickly. The phased approach and adaptive approach have similar biomass trajectories until 2010, when the adaptive approach lags behind the phased approach. With the exception of the no action alternative, the inter-quartile ranges of SSB are nearly identical.

Plaice: The constant F approach rebuilds more rapidly than the phased reduction or adaptive approach. The latter two result in similar biomass trajectories. The constant F and adaptive inter-quartile ranges are only slightly smaller than the phased reduction range.

SNE/MA winter flounder: The constant F and phased reduction result in nearly identical biomass trajectories. The inter-quartile range is nearly identical for all alternatives.

Redfish: The No Action and constant F strategies rebuild more quickly than the adaptive approach, which allows mortality to increase in the near term. There are only slight differences in the inter-quartile range for all strategies.

5.2.2 Ending Overfishing

In addition to the stocks that require formal rebuilding programs, this Amendment is designed to end overfishing on witch flounder. Ending overfishing will also result in increases and stock size and achieving (or maintaining) the target biomass. An age-based projection for witch flounder illustrates this concept. Under the No Action alternative, witch flounder biomass is projected to increase rapidly to over 34,000 mt, but then decline to 10,000 mt by 2012. With overfishing ended, however, the stock is projected to increase to over 42,000 mt and remain above 22,000 mt well into the future.

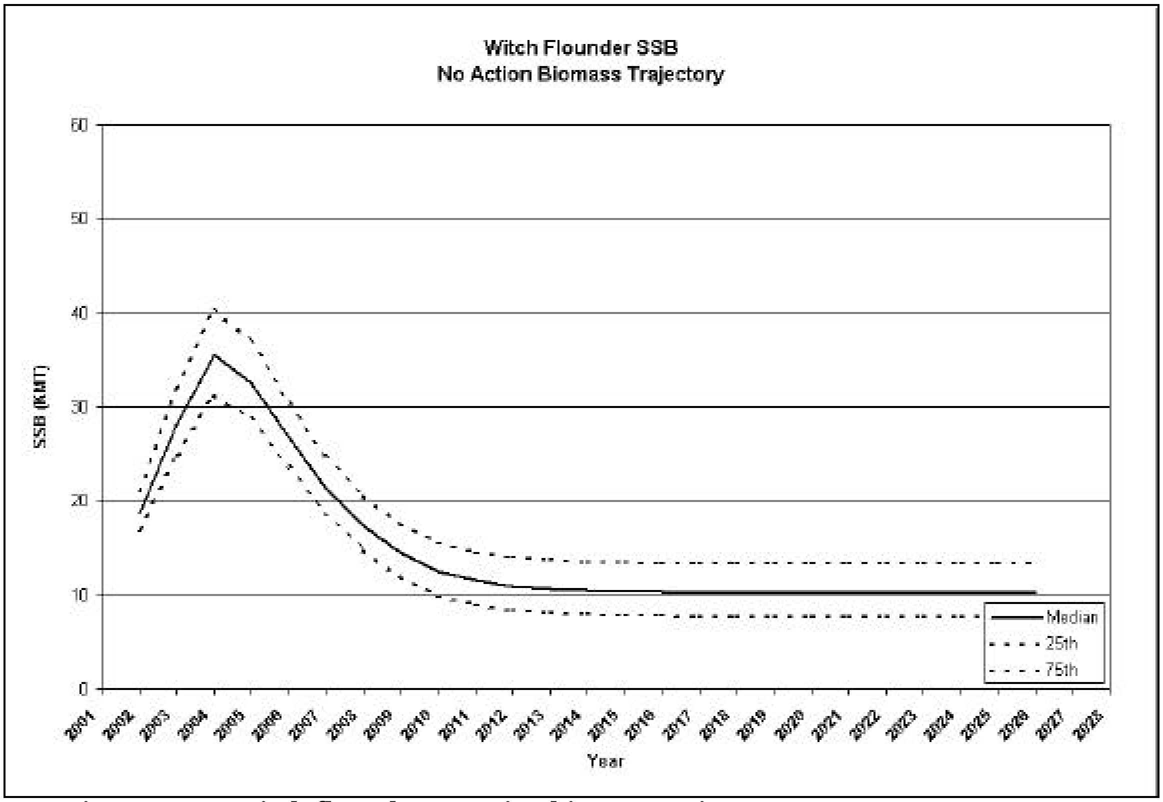

Figure 106 – Witch flounder no action biomass trajectory

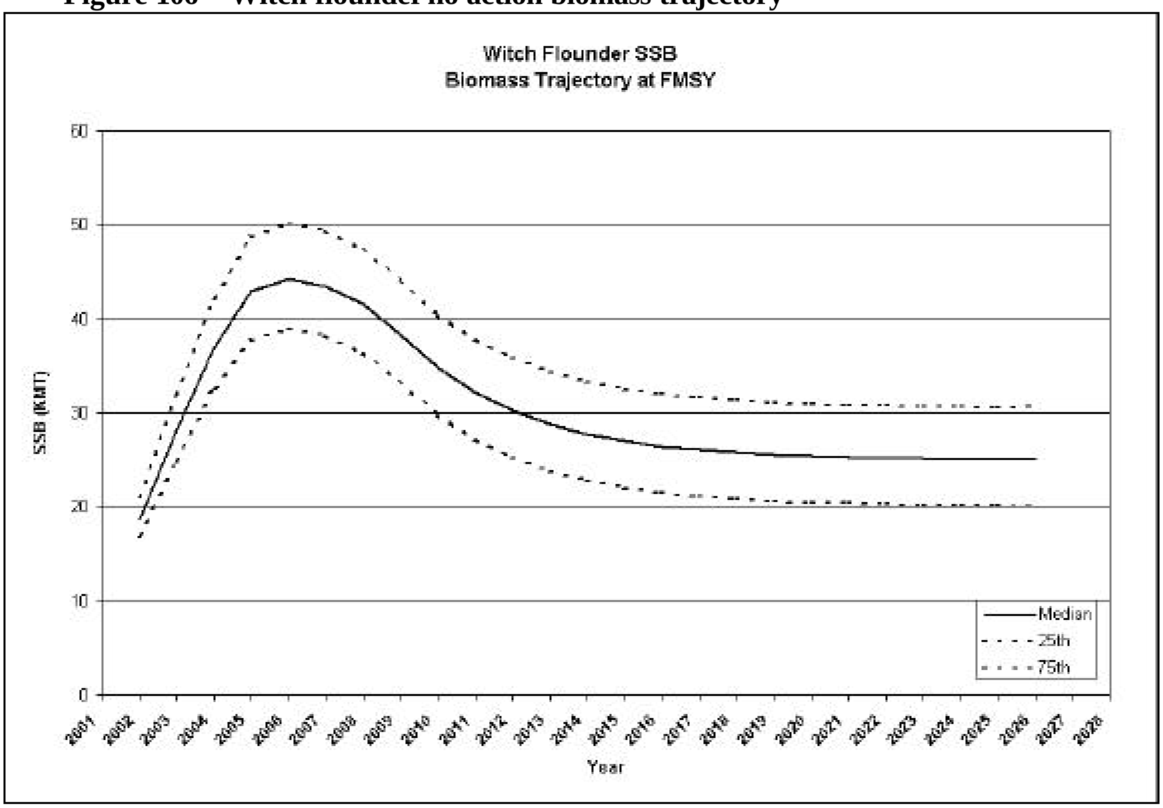

Figure 107 – Witch flounder F_{MSY} biomass trajectory

5.2.3 Groundfish Stocks Not Overfished/Overfishing Not Occurring

Amendment 13 manages all groundfish stocks to prevent overfishing and to prevent the stocks from being overfished. Age-based projections are available for two additional stocks that are not overfished, and where over-fishing is not occurring. GB yellowtail flounder and GOM winter flounder projected stock biomass are shown below. These charts assume a fishing mortality of F_{MSY} for both stocks, the maximum allowed before overfishing occurs, because measures will be adjusted under this amendment to maintain fishing mortality below that level. This fishing mortality rate may be higher than what will result under the proposed management measures, as is shown in 5.2.6. The projection show GB yellowtail flounder should approach SSB_{MSY} by 2013, and GOM winter flounder is currently well above SSB_{MSY} but should decline to that level around 2011.

Trajectories are not shown for index-based stocks (pollock and northern windowpane flounder). Expected biomass proxies are shown in Table 38. These proxies are developed by assuming that the exploitation index is equal to the F_{MSY} proxy. In the case of pollock, this represents an increase in the current exploitation index. For pollock , the proxy for SSB_{MSY} is achieved by 2014 at an exploitation rate equal to the F_{MSY} proxy. This means the No Action alternative would be a successful formal rebuilding program for this stock, if one were required. Northern Windowpane achieves its biomass target in 2012. Once again, the actual exploitation index under these measures may be lower.

Year	Northern Windowpane	Pollock (Area 5 & 6)
2002	0.86	1.73
2003	0.87	1.84
2004	0.87	1.94
2005	0.88	2.05
2006	0.89	2.15
2007	0.89	2.26
2008	0.90	2.37
2009	0.91	2.47
2010	0.91	2.58
2011	0.92	2.68
2012	0.93	2.79
2013	0.93	2.89
2014	0.94	3.00

5.2.4 Biological Impacts of the Fishery Program Administration Measures

The biological impacts of Fishery Program Administration measures are discussed qualitatively.

5.2.4.1 Fishing Year

None of the alternatives (including no action) for changing the fishing year should affect fishing mortality. The fishing year is a purely administrative measure that is defined so that there is a set date for implementing new regulations and issuing DAS allocations. It has no direct or indirect effects on fishing mortality. Some argue (see Appendix XIII) that if the fishing year starts when fish are aggregated for spawning, fishing mortality increases because vessels immediately start using their new DAS allocation. This conclusion presumes that fishermen do not plan their fishing activity to take advantage of seasonal aggregations and market demand, but are tied to an arbitrary starting date.

The Council is proposing to adopt the No Action alternative. The fishing year will not change, and there will be no biological impacts.

5.2.4.2 DAS Proration

The DAS proration options are designed to address how DAS are allocated if the fishing year is changed. Option 1 could lead to a short-term increase in DAS (compared to the Amendment 13 target, not compared to No Action) and a resulting increase in effort because it bases DAS during any transition period on the DAS allocated in fishing year 2003. If this number is greater than the DAS allocated under Amendment 13, then the fishing mortality impacts of any effort reduction will be delayed and rebuilding targets may not be met during the first year of the Amendment. This is more of a problem the longer the transition period is, since not only will a larger share of the 2003 allocation be available, but vessels will have more time to use those DAS. Option 2, on the other hand, immediately uses the Amendment 13 DAS allocation during the transition period so that any mortality reduction that is targeted by changes in DAS will be effective immediately.

Because the fishing year has not been changed, neither of the DAS pro-ration options were adopted. There will be no biological impacts from this measure.

5.2.4.3 Periodic Adjustment Process

There are no expected affects on fishing mortality of modifying the schedule for periodic adjustments to the multispecies plan, or for keeping the current schedule (No Action). Extending the duration of time between each periodic review and adjustment of the multispecies FMP would allow such measures to take effect on the stocks, enabling the PDT to more accurately evaluate their performance in helping to achieve mortality and biomass targets for the managed stocks. There is no concern that a longer period between routine adjustments to the FMP may harm the stocks. As required by the M-S Act, NMFS reviews the status of each stock on an annual basis for a Report To Congress. If necessary, the Council can react to changes in stock status published through this report. In the case of a declaration that a stock is overfished or that overfishing is occurring, the Council is required by law to act within one year, regardless of the annual adjustment cycle.

The proposed action adopts the revised periodic adjustment process, and should not have nay biological impacts.

5.2.4.4 US/Canada Resource Sharing Understanding

The resource sharing understanding between the United States and Canada dos not have any direct impacts on stock rebuilding or fishing mortality. However, this does allow the two nations to more closely coordinate management and scientific understanding of transboundary Atlantic groundfish stocks. In addition, this agreement may encourage closer adherence to quotas (TACs) set for transboundary stocks.

The proposed action adopts this understanding. Indirectly, this understanding may promote adherence to M-S Act requirements to control fishing mortality. Absent this understanding (the No Action alternative), the two nations may not adequately coordinate removals from these stocks. This could result in excessive harvesting if, for example, one nation under-estimates the planned catches that will be allowed by another nation and sets its own harvest levels too high. It is also possible that a nation could over-estimate the harvest of the other nation, resulting in an unnecessary sacrifice in yield. Either result would prevent harvesting of OY in the long-term, preventing the achievement of the primary goal of the M-S Act.

5.2.4.5 Administration of Certified Bycatch/Exempted Fisheries

Regular review of certified bycatch/exempted fisheries will allow the Council to facilitate better compliance of these fisheries with bycatch standards. If it is demonstrated that an exempted fishery can no longer meet the criteria necessary for it to retain its status the Council can take timely action to ensure rebuilding of stocks is not compromised. Closer administration and review of bycatch/exempted fisheries will have indirect, positive impacts on the stocks. If this review reveals that bycatch is increasing, then appropriate changes to the program can be made if necessary to control fishing mortality of groundfish stocks.

The Council is proposing the No Action alternative. This will result in an ad hoc review of certified bycatch/exempted fisheries. The No Action alternative could have negative impacts through increased fishing mortality as a result of increased discards that are not detected because of a lack of a periodic review.

5.2.4.6 Special Access Programs

The Council is proposing to adopt the system of approval and implementation of Special Access Programs.

As stated in the criteria which must be met to participate in a special access program, the proposed SAP *must not increase fishing mortality on a stock of concern (that is stocks that are overfished or where overfishing is occurring)*. In other words, the SAP must be in compliance with biological targets set for all stocks. If implemented and monitored correctly, SAPs should not have negative biological impacts from a rebuilding standpoint. While SAPs will increase F on targeted species, it should not result in increased mortality on stocks of concern either through directed fishing or bycatch. In essence, this measure is conservation neutral. If it is determined that an existing SAP is (a) exceeding the allowable catch for stocks it is targeting, (b) adjusting or changing measures that minimized adverse impacts of fishing on habitat, or (c) increasing fishing mortality on stocks of concern, then that SAP will not be allowed to continue.

The extension of the SAP to other fisheries should not affect groundfish stocks because the criteria for approval is stringent: the SAP cannot affect stocks of concern. By requiring that any framework implementing a SAP be approved by the NEFMC, the Council responsible for groundfish management will be able to carefully evaluate SAPs for other fisheries to ensure compliance with groundfish management goals and objectives.

The no action alternative will not increase fishing mortality. In fact, it may prevent harvesting of some stocks and result in lower fishing mortality on those stocks.

5.2.4.6.1 Georges Bank Yellowtail Flounder Special Access Program

This access program is designed to target Georges Bank yellowtail flounder within the southern portion of CA II (south of 41-30 N). This stock is not overfished and overfishing is not occurring, so it does not meet the Amendment 13 definition of a stock of concern. TRAC 2001 reported the stock was rebuilt, but due to a re-estimated SSB_{MSY} in March 2002, the stock is currently below the target biomass, though stock size continues to increase. Fishing mortality is well below F_{MSY}: the GARM (2002) estimated 2001 fishing mortality as 0.13, and the preliminary estimate of 2002 mortality is only 0.15. Landings from this stock were 7,186 mt in 2001, and declined in 2002 as a result of reduced Canadian landings and reduced U.S. landings due to the measures adopted in the FW 33 court order. U.S. landings declined to about 2,600 mt in calendar year 2002, a thirty-three percent decrease from the previous calendar year. Through August 2003, landings were about nine percent higher than in calendar year 2002, but still twenty-five percent lower than in 2001.

The F_{MSY} fishing mortality threshold is 0.25, nearly twice the current fishing mortality. U.S. landings in fishing year 2001 were only 93 percent of the U.S. target TAC (4,618 mt). U.S. catch, which increased rapidly from 1996 through 2000, reached a plateau in 2000 and 2001 and has declined since (Table 39). Catch declines are likely due to management restrictions (including reduced DAS allocations and increases in mesh) in place as a result of the FW 33 court order and an inability to access yellowtail stocks inside Closed Area II.

Catch	1996	1997	1998	1999	2000	2001	2002
US	0.8	1.1	1.9	2.5	4.1	4.3	2.6
Canadian	0.5	0.8	1.2	2.0	2.9	2.9	2.0
Total	1.3	1.8	3.1	4.4	6.9	7.2	4.6

Table 39 – US and Canadian Georges Bank yellowtail flounder catch (landings and discards), thousands of metric tons (source: GARM 2002, 2002 data from NMFS unpublished dealer data).

Fishing at F_{MSY} – the maximum mortality allowed - in 2004 would produce a catch of almost 12,000 mt (US and Canadian combined). In other words, landings could more than double from recent levels before overfishing occurs. While the exact US and Canadian share of the harvest may be determined by a US/CA resource sharing understanding, a rough approximation is to assume a 60/40 split as observed in 2000 and 2001. US catch in 2004 under these percentages would be 8,000 mt, nearly twice the highest US catch observed in recent years, a level not seen since 1983 – prior to the implementation of DAS restrictions, increased mesh sizes, year round closed areas on Georges Bank, limited entry, and fishing capacity reduction programs.

This Special Access Program allows 320 trips at 30,000 pounds of yellowtail flounder per trip, meaning that if all 320 trips are made, approximately 11 million pounds (5,000 metric tons) of yellowtail flounder may be caught in the SAP area (Figure 110), though higher discard rates than what is assumed in this analysis may shift the total catch upwards. All of these trips must take place during the June through December period authorized for the access program.

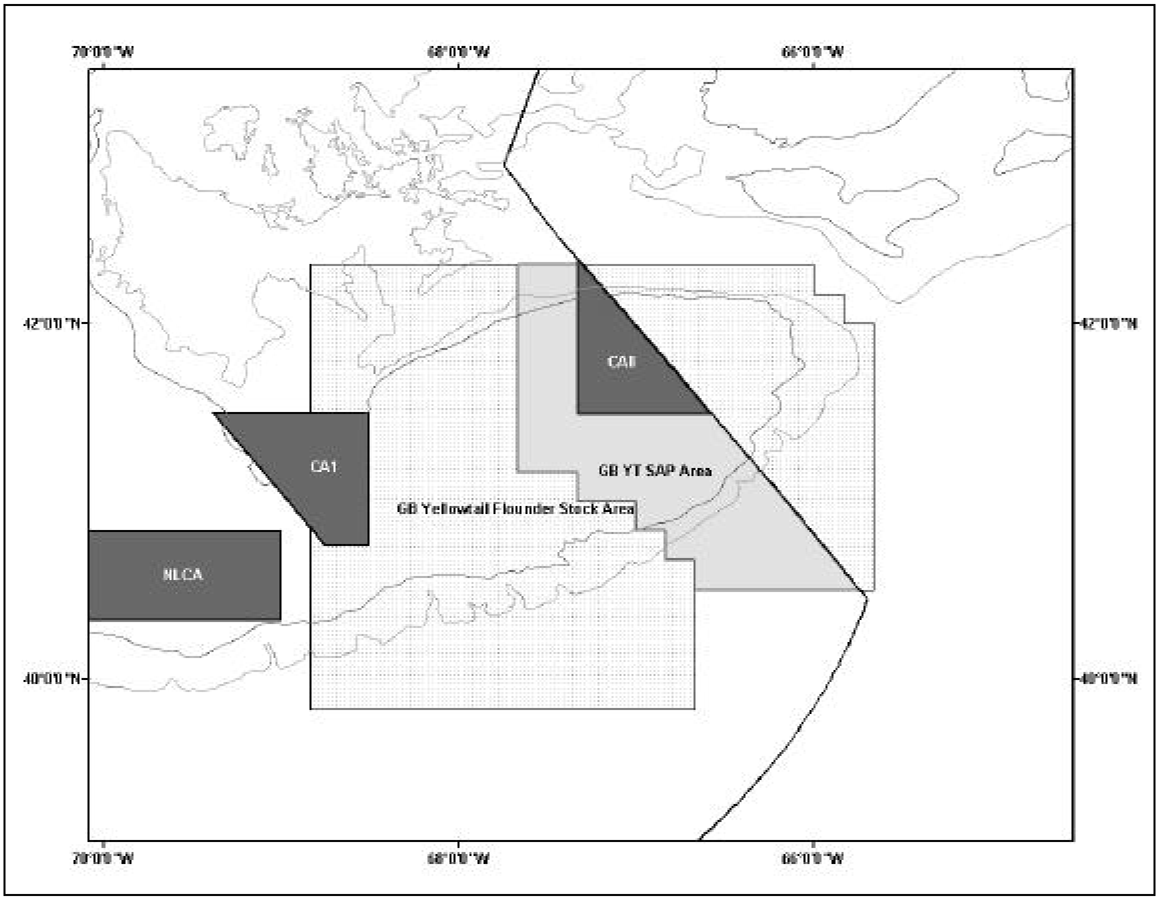

Figure 110 - GB yellowtail flounder stock area and the GB yellowtail flounder SAP area

Trends in the Georges Bank Yellowtail Flounder fishery

To gain a sense of how much of an increase from recent activity may result from this program, VTR records for fishing years 1995 through 2001 were examined to identify trips reported in the GB yellowtail flounder stock area. Since 98 percent of the yellowtail flounder was caught by trawl vessels, only these trips were examined. The number of trawl trips reporting landings of yellowtail flounder increased from 672 (44 percent of trawl trips landing groundfish from this area) in 1995 to 920 (67 percent of trawl trips landing groundfish) in 2001 over this period. In recent years, about ninety percent of the yellowtail trips from this area landed 20,000 pounds or less (Table 40). The proposed CA II access program can accommodate a tripling in the number of trips that land 30,000 pounds of yellowtail flounder compared to recent activity. If a scallop vessel controlled access program is implemented for CAII, then any yellowtail flounder bycatch TAC would be subtracted from the GB yellowtail flounder TAC and may require the RA to reduce the number of authorized trips.

Recent activity outside the closed area may not be a good indicator of future activity inside the area. In particular, yellowtail flounder catch rates in the area are expected to be higher, at least when the program is initiated, because there may have been some aggregation of the stock inside the closed area since fishing for groundfish in the area has been prohibited since 1994. Because vessels will be limited in the number of pounds of yellowtail landed per trip, the increased catch rates will only threaten mortality objectives if there are more trips into the area as a result. The maximum of 320 trips placed on this program should, therefore, control yellowtail flounder mortality.

Results of experimental Georges Bank Yellowtail Flounder fishery inside Closed Area II

Data provided by the Manomet Center for Conservation Sciences, taken during a September through December (2002) experimental fishery inside the yellowtail access area, indicates high catch rates for yellowtail flounder with the potential for significant bycatch of scallops, winter skate, little skate, and, to a lesser degree, winter flounder, haddock and monkfish. Data on bycatch is discussed in detail in section 5.2.8.2.5.

The experimental fishery used two vessels fishing simultaneously inside a grid pattern. The vessels fished paired tows (i.e. both vessels inside the same grid block fishing alongside each other) every fifth grid block, with one vessel fishing alone in each block in between. Vessels began their fishing at the southwest corner of closed area II and proceeded over and upwards in a zigzagging fashion, fishing grid blocks going east, then moving north one row and fishing grid blocks going west, until all blocks were fished. This pattern was repeated once monthly from September through December. It should be noted that in September a number of the northernmost blocks were not fished due to bad weather. Figure 111 shows the locations of each tow and grid pattern used in the experimental fishery. Yellowtail flounder catches were high throughout the access area, but tended to be highest in the northern and central grid blocks. The following table (Table 41) shows descriptive statistics for the per-tow, per-grid block breakdown of yellowtail catch. Table 42 shows the mean, median, std deviation and 75th percentile for each month individually.

Total and average catch for this fishery, including other species, is summarized in Table 115 and includes an analysis of probable bycatch.

Table 42 - Descriptive statistics for mean wt of yellowtail flounder per tow, per grid block for each month of the experimental fishery.

The model for analysis of this SAP assumes that vessels will concentrate in the areas of highest yellowtail abundance. Based on the results of the experimental fishery (Table 42), the yellowtail access fishery is assumed to be concentrated within the grid blocks shown in Figure 113. While Manomet-provided data includes only four months of fishing, and the specific areas of concentration may change from year to year, the co-location of species and bycatch rates observed when fishing in the areas of highest yellowtail concentration are likely to be a superior predictor of anticipated catch rates than rates averaged across the entire fishing area.

To establish the modeled SAP fishery inside Closed Area II, data are refined as follows. Table 42 shows a mean weight per tow of 119 lbs for yellowtail flounder for the entire closed area. Yellowtail flounder mean weight per tow inside the areas in Figure 113 (areas of highest concentration) is 267 lbs, and this is the number used to establish anticipated catch rates. Tow duration for this experimental fishery is known to average 20 minutes. Catch rates from the areas of high yellowtail concentration are therefore multiplied by six to estimate two-hour tows. Eight tows per day are assumed. While this leaves quite a bit of excess time, even considering hauling back and setting out, eight tows per day is thought to be more conservative and may provide a more accurate overall picture given the many assumptions made in modeling this access program.

Allowable yellowtail catch per trip is adjusted for undersized yellowtail flounder discards in order to accurately predict the number of tows and duration of trips inside the exempted area. During the experimental fishery, approximately 90% of all yellowtail sampled were of legal size (greater than 33 cm or 13 inches). Assuming that the sampling was truly random, a yellowtail catch of 34,483 lbs is equal to legal-sized yellowtail landings of 30,000 lbs. Allowable yellowtail catch per trip is adjusted for undersized yellowtail flounder discards in order to accurately predict the number of tows and duration of trips inside the exempted area. Catch rates are assumed to remain constant, an assumption which may overestimate the biological impacts of this SAP.

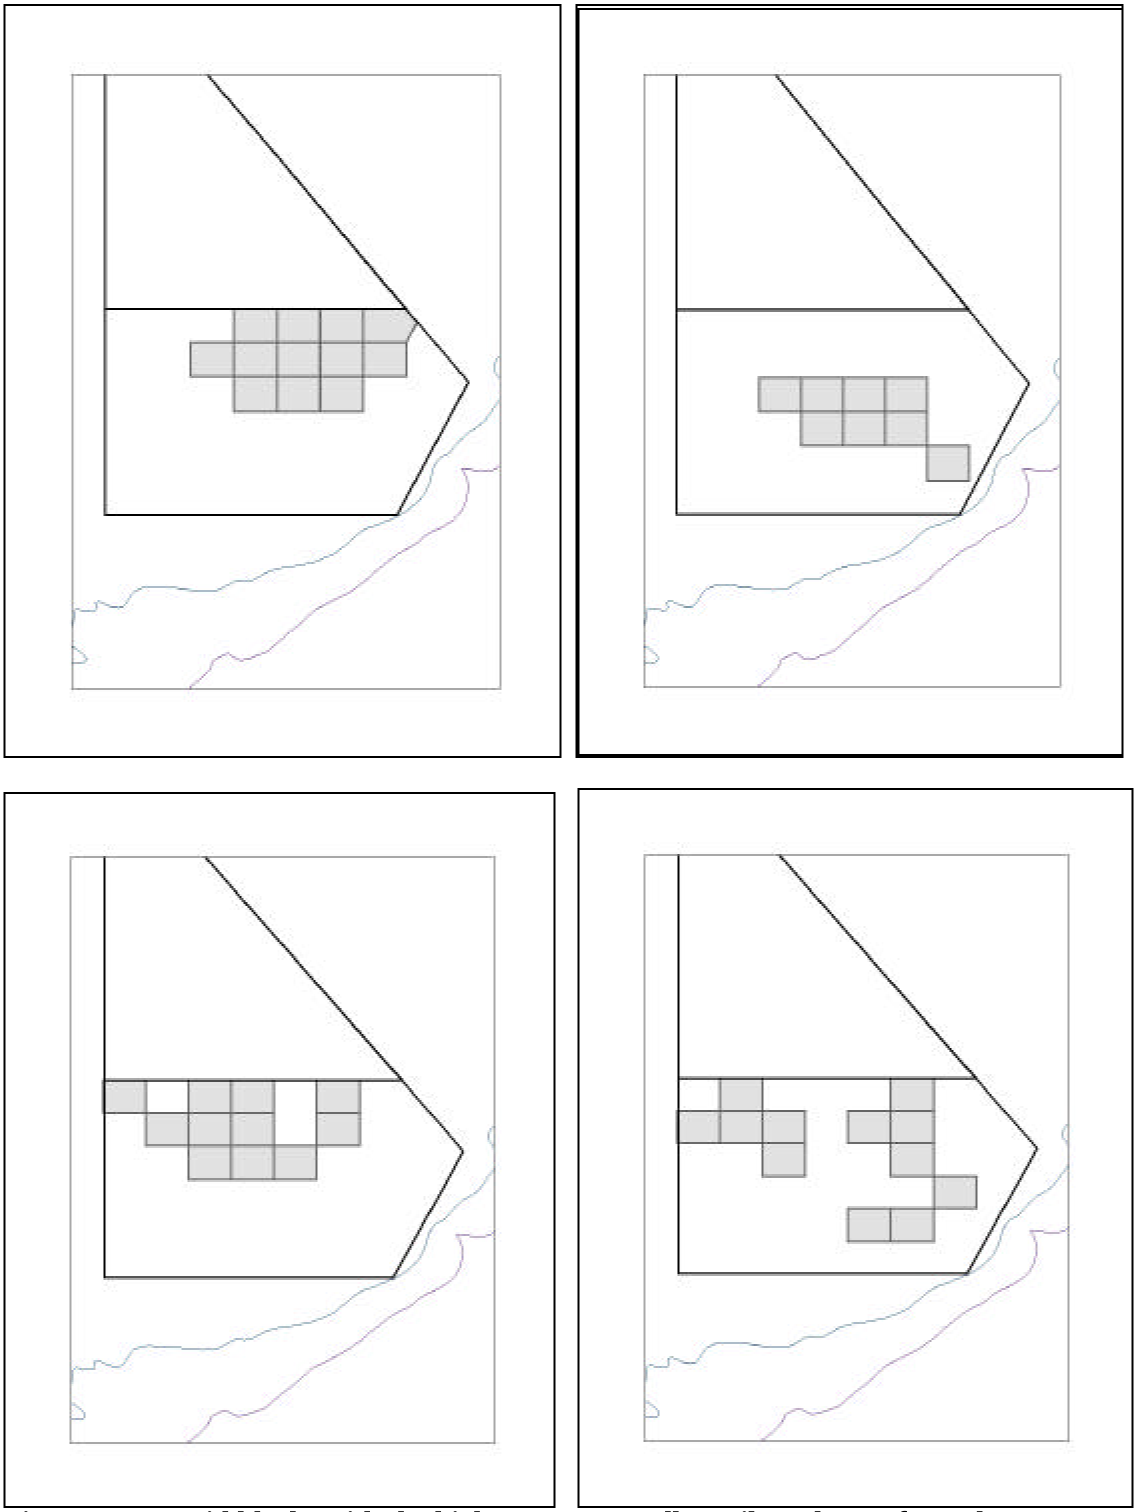

Figure 113 – Grid blocks with the highest average yellowtail catch rate from the experimental fishery in order from September through December, respectively (source: Manomet Center for Conservation Sciences).

This program does not explicitly include a hard TAC on the yellowtail catch, and any catch of over 5,000 mt, coupled with a catch of up to 3,000 mt from trips fishing outside of this SAP, may increase fishing mortality beyond the target.

The program is designed to accommodate two trips per month per vessel. In calendar year 2002, 117 vessels reported landing yellowtail flounder caught in statistical areas 561 and 562 (Table 45—areas inside the SAP). If only these vessels were to participate in the exempted fishery, it could be expected to last anywhere from four to six weeks before 320 trips are taken and approximately 5,000 mt of yellowtail is caught under this program. If additional vessels chose to participate, the duration of the program may be proportionally shorter. On the other hand, only 40 vessels of the 117 fishing in 2002 inside the areas have registered VMS units onboard (a requirement for participation in this SAP). If only these vessels were to participate, and each made two trips per month, the program could be expected to last four months.

The yellowtail closed area access fishery was modeled for the months of September through December under the assumption that the catch rates for all species observed during the experimental fishery would be consistent for vessels fishing in the yellowtail access fishery. Vessel characteristics of the vessels used in this experimental fishery and those of vessels who fished for yellowtail flounder in statistical areas 525 or 562 (the Southeast Part of Georges Bank) are shown in Table 45, Table 46 and Table 47 below. Vessels participating in the experimental fishery had slightly higher average gross tonnage and horsepower. To the extent that horsepower and gross tonnage contribute to catch rates, a model based on landings from the experimental fishery may slightly overestimate catch rates expected from the access program fishery.

Variable	N	Mean	Std Dev	Minimum	Maximum

Catch rates in the SAP area for tows inside and outside Closed Area II

The estimates summarized thus far assume that the SAP fishery will be prosecuted entirely inside CAII. While it is likely that catch rates for yellowtail flounder will be higher inside CAII, the specifications for this SAP allow fishing anywhere in the 5zjm NAFO statistical area (Figure 110). To ascertain the extent to which vessels participating in this program are likely to fish inside the closed area, the differences in yellowtail flounder catch rates inside and outside Closed Area II are examined here.

Variable	N	Mean	Std Dev	Minimum	Maximum
GTONS	30	145.0	33.9	72	199
LEN	31	81.2	9.0	62	96
VHP	31	636.9	209.0	225	1180

Table 48 – Descriptive statistics for all vessels fishing inside area 5zjm carrying observers in months between June and Dec, 2000 through the present (source: NMFS unpublished observer data).

Trips occurring between June and December and carrying an observer are examined. Table 48 shows that the average size and horsepower of observer-carrying vessels fishing in the SAP area is slightly less than the size and horsepower of vessels participating in the CAII experimental fishery but consistent with vessels not observer-equipped that reported fishing in this area. To the extent that there is a relationship between these variables and catch, observed tows may have slightly lower catch rates for a given stock size.

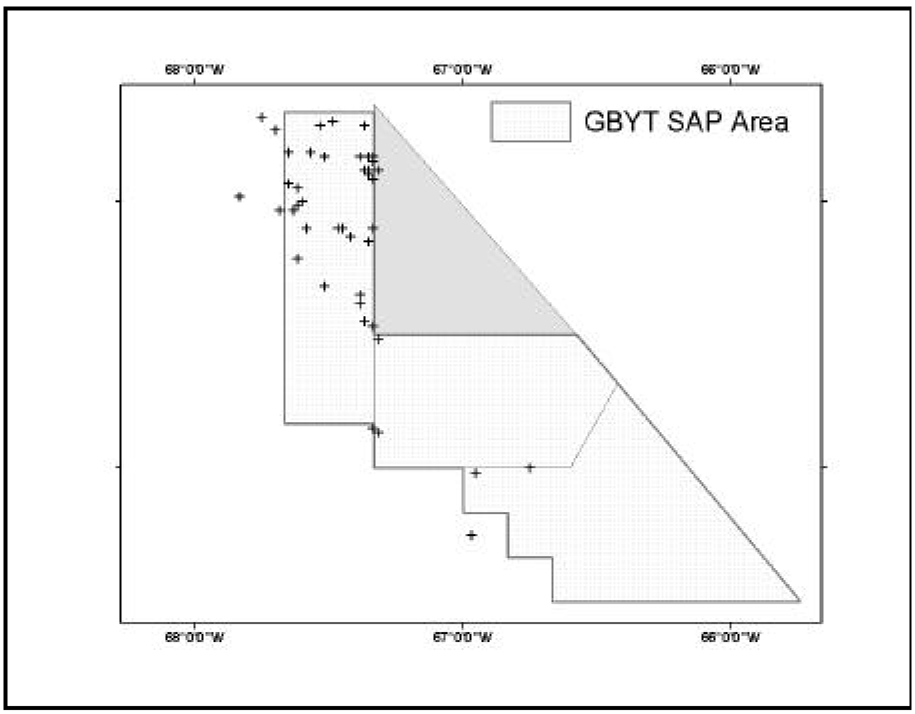

Figure 114 – Locations of observed tows inside area 5zjm (source: NMFS unpublished observer data).

Area	observed trips	observed tows	months	mean yellowtail flounder catch/hour
5zjm	44	327	Jun - Dec	76.7
CAII (experimental fishery)	8	187	Sep - Dec	356.2

Table 49 – Mean yellowtail flounder catch per hour inside CAII and in the SAP area overall (source: NMFS unpublished observer data, Manomet Center for Conservation Sciences).

Area	observed trips	observed tows	months	mean yellowtail flounder catch/hour
5zjm (trips south of 41-30 N only)	14	85	Sep - Dec	94.1
CAII (experimental fishery)	8	187	Sep - Dec	356.2

Table 50 – Mean yellowtail flounder catch per hour inside CAII and in the SAP area south of 41-30 N (source: NMFS unpublished observer data, Manomet Center for Conservation Sciences).

Catch rates for yellowtail flounder throughout the 5zjm area on observed trips differ significantly from those inside Closed Area II (Table 49). Observed trips made in the 5zjm area south of 41-30 N (only) were also examined, revealing a slightly higher catch rate for yellowtail flounder in the southern portions of the 5zjm area outside of CAII, though this rate is still significantly lower than that seen during the CAII experimental fishery (Table 50).

The implication of these data is that vessels targeting yellowtail flounder are likely to fish inside Closed Area II, vice outside the area, while harvesting the 30,000 lbs of yellowtail per trip available under this SAP. Therefore, the data from the experimental fishery appears sufficient (with the notable exception of the months not covered under the experimental fishery--June, July and August) for the purpose of predicting the biological impacts of this program on yellowtail flounder. 320 trips will yield landings of 4,350 metric tons of yellowtail flounder (just over 5,000 mt total catch, including discards) and, if vessels chose only to target yellowtail flounder and not fish in other portions of the 5zjm area, the bycatch impacts discussed in section 5.2.8.2.5, which indicate relatively small impacts on all non-target species, are likely to apply. Table 51 summarizes the potential yellowtail landings at three different numbers of trips, as a basis for comparison.

Avg Trip Duration	YT catch (250 trips)	*YT catch (320 trips)*	YT catch (400 Trips)	# DAS (250 trips)	# DAS (320 trips)	# DAS (400 trips)
2.16	3,916	***5,005***	6,256	540	691.2	864

Table 51 - Modeled trip duration, estimated catch (in metric tons) and estimated DAS (either A or B) usage for yellowtail access program fishery.

Biological impacts on cod, haddock and winter flounder

Vessels that choose to participate in this SAP are allowed to fish inside the 5zjm statistical area while using category A or category B days and either a haddock separator trawl or a flatfish net, and receive credit for steaming time credit (no DAS used in transit). Therefore, vessels are unrestricted in their fishing after (or before, or during) catching their 30,000 lbs of yellowtail, so long as they use a haddock separator trawl or flatfish net when fishing outside CAII.

Observed catch rates inside and outside Closed Area II differ dramatically on all species, and this program may have a significant impact on the overall landings for GB cod, GB winter flounder and haddock in particular. Impacts on other species are addressed in section 5.2.8.2.5.

Analysis indicates that, if vessels fish exclusively in the high-yellowtail catch areas inside CAII (Figure 113), it should take only 2.16 days to catch 34,483 lbs of yellowtail flounder (equivalent to landings of 30,000 lbs). Table 52 shows the anticipated catch that corresponds to various numbers of trips targeting yellowtail flounder exclusively.

Species	250 trips	*320 trips*	400 trips
COD, ATLANTIC	9.4	***12.1***	15.1
FLOUNDER, WINTER (BLACKBACK)	744.1	***952.4***	1,190.5
HADDOCK	135.6	***173.6***	217.0

Table 52 – Estimated catch (mt) of three species while targeting yellowtail flounder (source: Manomet Center for Conservation Sciences).

However, vessels are expected to guard against single-species price fluctuations by "topping off" their SAP trips with catches from outside CAII. Catch rates from observer data are highest in the SAP area for cod, haddock and winter flounder and these are the species that vessels can be expected to "top off" with during their SAP trip. Because the GB cod trip limit is particularly low (1/5 the prescribed trip limit of 500 lbs per day), vessels are likely to target expressly haddock and winter flounder, using either a flatfish net or haddock separator trawl. According to the observer data, catch rates for winter flounder and haddock are highest in the statistical area 562 portion of the SAP area, while catch rates for cod are highest in the statistical area 561 portion of the area.

Analysis of VTR data for trips made within the 5zjm area indicates that the mean trip duration for trips in the specified area is 6.51 days. Assuming, conservatively, 22 hours each way for transit time (an average transit speed of 8 knots), the average fishing time for trips in this area is 4.67 days. If vessels are expected to catch their yellowtail trip in 2.16 days (Table 51), on average it may be assumed that vessels will continue to fish for another 2.5 days while participating in this SAP. This will result in 800 A or B DAS being used under this program (at 250 trips, 625 DAS are estimated to be used while at 400 trips 1,000 additional DAS are estimated to be used).

n	286
Min	0.2
Max	17.25
Mean	6.5
St Dev	2.42

Table 53 – Number of trips and trip duration data for VTR-reported trips occurring inside 5zjm (source: unpublished VTR data).

The haddock separator trawl has been found to reduce cod catches by up to 60%. For this analysis, a conservative estimate of 50% was used since the there is limited experience with the net use by U.S. fishermen on GB. Georges Bank winter flounder catch rates were similarly reduced for trips using the haddock separator trawl. All other catch rates are assumed to be consistent with observer data.

If vessels fish in the 5zjm area for 2.5 additional days, they can be expected to catch a significant amount of haddock, winter flounder and cod (Table 54). *Note that the data in this table reflect what would be expected if all trips fished an additional 2.5 days targeting either exclusively* *haddock or exclusively winter flounder. This bounds the potential impacts on both species, with the expected catches to fall somewhere between the predictions in the two columns.*

Table 54 – Estimated catch for additional 2.5 days fishing time inside area 5zjm based on observer data from tows in areas 561 or 562. *The data from the 561 and 562 columns are not intended to be combined, but rather reflect the estimated maximum if all fishing were to take place entirely inside one area or the other. Anticipated catches would range somewhere between the numbers in the 561 and 562 columns.* (*Assumes 50% reduction in cod and winter flounder catch due to haddock separator trawl, and no change in behavior based on cod discard rates).

Table 55 (below) details the estimated cumulative impacts on cod, haddock and winter flounder for this Special Access Program. If the high-end estimates are assumed for all three species, GB haddock catch in this program may catch roughly 4% of the total GB haddock (US and CA) TAC. Catch of GB cod could may consume roughly 7% of the combined US and CA TAC. Landings of GB winter flounder, however, may achieve 127% of the US TAC if all 320 trips fish for 2.5 days outside CAII targeting winter flounder. Expected catch would be somewhere in between the two estimates below, but it should be noted that the low end estimate, which assumes a 50% reduction in catch due to the use of a haddock separator trawl, achieves 57% of the GB winter flounder TAC.

Table 55 – Cumulative estimated impacts of SAP trips (at 6.5 days per trip) on cod, haddock and winter flounder. (*Assumes 50% reduction in cod and winter flounder catch due to haddock separator trawl, and no change in behavior based on cod discard rates).

5.2.4.6.2 Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program

The Council is proposing to adopt this program. This measure allows the retention and landing of small quantities of winter flounder while fishing with fluke mesh and while not on a DAS. The provision would only apply in the area west of 72-30W. Under Amendment 7 and its subsequent frameworks, vessels landing winter flounder from this area were allowed to use fluke mesh but had to use a DAS. The FW 33 court order changed the definition of the SNE Regulated Mesh Area; as a result, vessels were required to use mesh larger than fluke mesh while fishing on a DAS and landing winter flounder. The impacts of this measure depend on the number of fluke trips that will take place that catch and discard winter flounder. VTRs from this area were examined to determine the number of fluke trips taking place in this area, how often fluke and winter flounder are caught on the same trips, and in what quantities. Observer/sea sampling data was also examined to evaluate the extent of discarding of winter flounder on trips that landed fluke.

Sea sampling data for trips landing fluke from statistical areas 600 (or greater) were examined for the years 2001, 2002, and 2003. These statistical areas are slightly larger than the proposed area for this measure, but using them facilitates analyzing available data. Trips were pooled by quarter (January – April, May – August, September through December) and over all three years. A total of 197 trips were observed, with 61 in the first quarter, 74 in the second quarter, and 62 in the third quarter. There were few observed trips that landed fluke and winter flounder: none in the first quarter, one in the second quarter, and five in the third quarter. Only a few trips discarded winter flounder while landing fluke: one in the first quarter, six in the second quarter, and six in the third quarter. All but one of the trips discarded less than 200 pounds of winter flounder. The percentage of observed trips that discarded winter flounder was 2 percent in the first quarter, 8 percent in the second quarter, and 10 percent in the third quarter (Table 56). Sea sampling data are sparse, but suggest that there is a seasonal component to winter flounder discards and that winter flounder is not often caught by vessels landing fluke.

A different picture emerges from examining VTRs for trips that used fluke mesh (5.5 inch) in statistical areas 600 and above. While only 6 percent of the observed trips landed winter flounder, fully 18 percent of the VTR trips reported landing winter flounder. 2,182 trips recorded discards of between 1 and 100 pounds of winter flounder in calendar year 2001. There were no reported instances of discarding more than 100 pounds of winter flounder. Another 1,938 trips reported landing between 0 and 200 pounds of winter flounder, presumably while fishing on a DAS. The VTRs do show a slight increase in the number of trips encountering winter flounder in the second and third trimesters of the calendar year.

If there are roughly 2,200 additional trips landing 200 pounds of winter flounder as a result of this measure, winter flounder landings would increase by 200 mt. (440,000 pounds). This would not represent an increase in mortality, since this it is a conversion of discards into landings. A possible increase in mortality (as compared to not implementing the program) could occur because the trips that landed winter flounder of between 0 and 200 pounds while using fluke mesh would no longer be required to use a DAS. It should be noted, however, that analysis of the rebuilding alternatives show that this increase is not likely to be a concern. The proposed action is expected to reduce SNE/MA winter flounder mortality more than is necessary.

The 2004 TAC for SNE/MA winter flounder is likely to be about 2,800 mt, so an increase of 200 mt of landings represents less than 10 percent of the TAC. As shown in the biological impacts (section 5.2.6), the proposed action reduces fishing mortality on SNE/MA winter flounder more than is necessary. The additional catches generated by this measure are not likely to be large enough to adversely affect the rebuilding plan.

If this program was not adopted, it will have little impact on fishing mortality. It is likely that the winter flounder that could be landed under this program would be caught and discarded, with the result fishing mortality for this stock would be similar to that expected under the program.

5.2.4.6.3 US/CA Resource Sharing Understanding Special Access Program

The US/CA Resource Sharing Understanding Special Access Program is designed to facilitate catching GB yellowtail flounder and GB haddock. GB yellowtail flounder will be primarily caught in the southern section of CA II, and the biological impacts are described in section 5.2.4.6.1. This proposal would allow fishing in the northern part of CA II for two to ten months in order to facilitate catching the GB haddock TAC. There are options for changes to other management measures as well, such as allowing a smaller minimum mesh size or crediting vessels for time spent transiting to and/or from the area. Other stocks that may be caught include GB cod, GB winter flounder, several species of skates, and scallops. Impacts on cod and haddock are described in this section, while likely impacts on skate species are described in the section on bycatch (see section 5.2.8). Scallop impacts are expected to be minimal since there are few scallops in the deeper water targeted by haddock fishermen.

Fishing for GB haddock is subject to a formal rebuilding program, since that stock was declared overfished and has not yet rebuilt to some estimates of its target biomass. The mortality necessary to rebuild by 2014 is estimated as 0.26 under the adaptive fishing mortality strategy (see section 4.1.2.2). Fishing mortality in 2001 was estimated to be 0.22, suggesting that an eighteen increase in fishing mortality can be accommodated by this stock without exceeding the rebuilding fishing mortality target. Analyses of the management alternatives in this document, however, indicate measures are likely to result in a decrease in GB haddock fishing mortality. Analysis suggests the proposed action may reduce mortality on this stock between 30 and 40 percent. This suggests that increased opportunities can be created without delaying the rebuilding of GB haddock past 2014.

GB haddock is a trans-boundary stock that is also harvested by Canada. The exact proportion allocated to each country may be determined by the US/CA Resource Sharing Understanding that is being considered in this Amendment. The total GB haddock TAC in 2004 is estimated to be 24,885 mt, with the US share assumed to be 10,000 mt. Recent landings of GB haddock are shown in Table 59. For the last four years, U.S. landings have increased an average of 37 percent each year. If this rate of increase continues, U.S. landings in 2004 would approach 11,600 mt. This does not appear likely, given the suite of management measures that are adopted by the proposed action. Indeed, through August 2003, GB haddock landings were about seven percent less than for the same period in calendar year 2002

Catch	1996	1997	1998	1999	2000	2001	2002
U.S.	0.3	0.9	1.8	2.8	3.4	4.6	6.4
Canada	3.6	2.6	3.4	3.7	5.4	6.7	6.5
Total	3.9	3.5	5.2	6.5	8.8	11.3	12.9

Table 59 – US and Canadian GB haddock landings, thousands of metric tons. (Source: GARM 2002, U.S. 2002 catch NMFS preliminary landing estimates)

Whether or not this SAP has adverse biological impacts on stocks of GB cod, GB haddock or GB yellowtail flounder depends in part on the implementation of the US/CA Resource Sharing Understanding (see section 3.4.5.3.3). Hard TACs are used to monitor catches on eastern GB, and the SAP, if adequately monitored, should not increase fishing mortality for eastern GB portions of these stocks above acceptable limits.

Vessels will not be charged any DAS for transit to and from the area, and may use either an A or B DAS while fishing in the area. This is in effect an increase in DAS for those vessels that choose to participate with no limit on where the additional DAS can be used. There is a possibility that these DAS could be used to target other stocks that cannot withstand additional fishing pressure.

Of the stocks in this area, GB cod and plaice are targeted for reduced fishing mortality in this Amendment in order to achieve M-S Act objectives. There is no recent information available on catch rates of groundfish or other species inside CAII. Available information for the area immediately outside of the area suggests that cod and haddock are often caught on the same tows. VTR records for trawl trips in statistical area 561 (adjacent to the northern boundary of CAII) for 1999 – 2001 show that for most months, trips reported landing more cod than haddock (ratios are shown in Table 59 below). This information, however, is on a per trip basis and may not reflect the ability of a vessel to target cod or haddock on specific tows. There does not appear to be a clear seasonal pattern, but this could be obscured by changing haddock trip limits. Calendar year 2002 observer data in statistical area 561 documented 159 trawl tows that caught cod or haddock. 155 of these tows landed cod, and 84 landed haddock. The average catch of haddock for those 84 tows was 193 pounds, and the average cod catch for those same tows was 190 pounds. Only four tows that caught haddock did not catch cod. Few tows caught cod, haddock and plaice, and the plaice catches were all less than 50 pounds. Finally, a preliminary report from an SMAST trawl study (Rothschild and Brown 2002) plotted CPUE for by species for each tow. Cod, plaice and haddock all show high CPUEs near the northern end of CAII, but these charts are for all tows and do not take into account seasonal differences (see Figure 115, Figure 116, and Figure 117).

If catch composition inside CAII is similar to that in statistical area 561, vessels taking advantage of this program are likely to catch cod and haddock on the same tow. If a hard TAC is imposed on the fishery, the TAC should prevent the SAP from raising fishing mortality to unacceptable levels. In the absence of a TAC, if this program is adopted with effort incentives (such as DAS credits, credits for steaming time, etc.) it may raise fishing mortality on GB cod unless vessels can avoid cod through selective fishing practices or gear modifications (such as a separator trawl) are required to fish inside the area. While plaice CPUEs are high outside CAII, it appears from the limited observer data that plaice is only rarely caught with cod and haddock on the same tow. Another groundfish stock that may be caught by vessels fishing in this program include GB winter flounder, but this is less of a concern because the stock was above its target biomass in and fishing mortality was less than F_{MSY} in 2001.

5.2.4.6.4 Hook Gear Closed Area I Special Access Program

This program will allow hook vessels to target haddock in Closed Area I. An experimental fishery is currently being conducted in this area. Data from that experiment are not available so it is not possible to estimate biological impacts. In general, if the experiment demonstrates that haddock can be caught without catching significant amounts of cod or other stocks in need of a mortality reduction, then the program should not increase cod mortality. The proposed program includes a cod TAC of 35 mt, which is less than one percent of the overall GB cod target TAC (including Canadian share) for calendar year 2004. The analysis of the overall management program shows that fishing mortality on haddock is expected to decline by thirty to forty percent. Since haddock fishing mortality is already less than the mortality needed for the adaptive strategy, catches from this hook gear SAP are not likely to threaten the rebuilding program.

5.2.4.7 Closed Area Administration

5.2.4.7.1 Rationale for Closed Areas

The proposed action required that any action that adopts a new closed area specifically identify the rational for the area and what vessels (if any) will be allowed to fish in the area. Clarifying the rationale for closed areas will allow the Council to more accurately assess whether the current utility of the closed areas are meeting the conservation goals for which they were established. This will enable the Council to make adjustments to the closed areas to sustain their effectiveness. A simple documentation for rationale for closed areas will not have an effect on stocks or rebuilding programs, although the later use of this information in a review of closed areas may have positive consequences for stocks that are protected by closed areas.

If the rationale for closed areas is not specified because this measure was not adopted, future changes to closed areas may prove difficult because it will not be clear what the objectives are and how success should be measured.

5.2.4.7.2 Access to Closed Areas

Options 1, 2, 3 and 4 may reduce the effectiveness of closed areas for protecting habitat and stocks because of the minimal levels of bycatch incurred by exempted gears. However, Options 2, 3 and 4 may focus protection of closed areas on targeted species while reducing impacts on other fisheries. Option 5 prevents any access to closed areas, maximizing their effectiveness and simplifying enforcement. It is expected to have the most positive biological effects of any of the closed area access options. The no action alternative will not have any additional impacts on fishing mortality.

None of these alternatives are part of the proposed action.

5.2.4.7.3 Review of Closed Areas

This measure was not selected. It would have established a formal schedule to review closed areas on a regular basis, insuring that they continue to achieve the goals of the FMP. This review would also have served an indicator of whether a particular closed area is serving the purpose for which it was established and if not, determine the nature of its current utility. It may allow the Council to improve the benefits afforded to stocks and habitat by modifying closed areas. The no action alternative will prevent a scheduled, periodic review of closed areas and benefits that accrue may suffer as a result. For example, areas designed to reduce fishing mortality may not be effective and that will not be examined on a regular basis.

5.2.4.7.4 FAAS

The proposed action to eliminate the FAAS will have no biological impacts since the existing system has never been used successfully. The FAAS concept was intended to provide a means for quickly implementing a closure in response to short-term resource conditions (e.g. the presence of a large number of juvenile fish). The system proved unworkable, in part because the regulatory requirements for implementing a closure delayed implementation. The no action alternative will have no impact on fishing mortality because the system has never been used.

5.2.4.8 Leasing of DAS

DAS leasing alternatives are intended to provide increased opportunities to the fishery participants for diversification into other fisheries and greater economic flexibility without having adverse impacts on the stocks. DAS leasing is an economic measure. If the number of allocated DAS are limited to the appropriate level for the targeted fishing mortality rate, leasing of DAS should have a negligible effect on fishing mortality. If the total number of DAS allocated is not controlled, leasing may result in an increase in effort as unused DAS are leased to vessels that are actively fishing, increasing fishing effort and thus fishing mortality. Because the number or type of vessels which may use a leasing program is unknown, it is not possible to predict how leasing may alter DAS use or fishing behavior. However, if a large number of DAS are leased from vessels in one area to vessels in another area or from vessels targeting one stock to those targeting a different stock, the leasing program may result in a shift in fishing effort. Shifts into an area with stocks in need of additional protection could result in increased mortality and could slow rebuilding programs. Once again, if the allocated DAS are appropriately determined and adjusted for such shifts, the leasing program would not result in changes in fishing mortality.

The proposed action relies on days at sea as the primary management tool. As a result of large reductions in days at sea, mortality on key stocks is expected to decline. This will occur even if more productive vessels lease days at sea from less productive vessels. The proposed action allocates more Category A DAS than the target number of used DAS. It is at least theoretically possible that as a result of DAS leasing, all allocated Category A DAS will be used. Analysis of the biological impacts of the plan suggest that if the number of Category A DAS used exceeds 95 percent, biological objectives may not be met for some stocks.

The approved DAS leasing alternative includes the following specifications:

- Term of Lease: DAS would be leased for only one fishing year.
- Vessels may lease DAS from more than one other vessel (conversely vessels may lease DAS to more than one vessel) subject to conservation equivalency provisions.
- DAS may be leased on a unit basis where a unit is defined as being 1 DAS or 24 hour increment.
- Leases are not subject to a "conservation tax."
- Vessels may renew leased DAS on an annual (fishing year) basis.
- Leased DAS must be used in the same fishing year they are acquired.
- Leased DAS may not be used as part of any carry-over.
- DAS available for leasing shall be limited to only Category A DAS; DAS that may be immediately available for use.
- Lease agreements must be registered with the NERO. Administrative process based on two possible approaches 1) internal administration by NERO or 2) external administration by approved "brokers" (for example, permit brokers could be sanctioned by NERO to document exchanges and provide data to NERO for monitoring and enforcement purposes) to be developed.
- Permit History: the lease agreement must clearly state which permit retains the history of the leased DAS
- Provisions for Size: A lessor may not lease DAS to any vessel with a main engine horsepower rating that is 20% more than that of the lessee and may not lease DAS to any vessel that is 10% more than that of the lessee's vessel's LOA.
- DAS cannot be sub-leased
- A vessel can lease the number of DAS equal to its allocation for fishing year 2001 (not including carry-over DAS).

- If a vessel does not use all the DAS that are allocated to it and that it leases, the Leased DAS are considered used first for the purposes of permit history
- The leasing program will expire in two years unless extended by Council action

DAS leasing may be expected to impact mortality rates in three ways. First, it could increase the number of DAS used, reducing the difference between allocated and used DAS. Second, it could increase the overall efficiency of the used DAS through the leasing of DAS from less efficient to more efficient vessels. Third, it could result in used DAS shifting geographically with the potential for proportionally increased pressure on certain stocks.

DAS use

Based on recent trends, Category A DAS use is expected to range from 78 percent to 85% of allocated DAS, or roughly 31,000 to 35,000 used DAS out of 41,000 allocated. The model used to quantify possible economic impacts of DAS leasing predicted a 98-99 percent utilization rate. *This is not intended to be an accurate prediction of DAS utilization under leasing, but is an absolute upper bound on the number of DAS that could be used under a leasing program.* The model used in that analysis is a fleet optimization model that attempts to extract the highest overall fleet revenue via DAS leasing. By definition, all vessels will either fish or lease their DAS under this model--the only vessels that do not (who possess 0.5-1.5 percent of allocated DAS) are those whose predicted revenue falls short of predicted variable costs and who cannot find a more profitable lessee for their DAS. The model also assumes no transaction costs, perfect information and communication, and instantaneous lease trades, each taking place under the most profitable terms. The salient point is that, under the model, vessels expected to clear any profit at all by either fishing or leasing will do so. Historical trends in DAS utilization indicate that this is simply not the case in reality--many trades or fishing days may clear so little profit as to make the effort undesirable. Many vessel owners may choose to not fish and not lease, an outcome that the optimization model cannot accommodate but one that fisherman have shown through their behavior is not unlikely. Furthermore, perfect information, communication, and instantaneous transfers are not realistic assumptions, and there are likely to be transaction costs of some magnitude associated with trades.

Another potentially mitigating factor is DAS carryover. Any category A DAS that are not used in FY 2004 may be carried over to FY 2005 (up to 10 DAS). In calendar year 2002, 991 vessels that used DAS carried over 9,132 DAS, for an average of 9.2 DAS per vessel. We can assume that vessel owners who elect to lease DAS will keep a very small number, if any, of DAS available for carryover in FY 2005. But those vessel owners who do elect to fish will likely keep some DAS for carryover if recent history is any guide. In effect, vessel owners may conclude that it is more profitable to use those DAS in the following fishing year than to use or lease them in the current fishing year. The total amount of DAS carried over into FY 2005 will have a significant impact on the DAS utilization rate in FY 2004. The following three graphs show the anticipated maximum DAS utilization rate achievable if a certain number of DAS per vessel fishing is not fished in FY 2004 (i.e. reserved for carryover). The three tables are based on three estimates of the number of vessels fishing in FY 2004: the model-predicted number (approximately 500), all vessels with DAS allocations (approximately 1,000) and a median estimate (approximately 750).

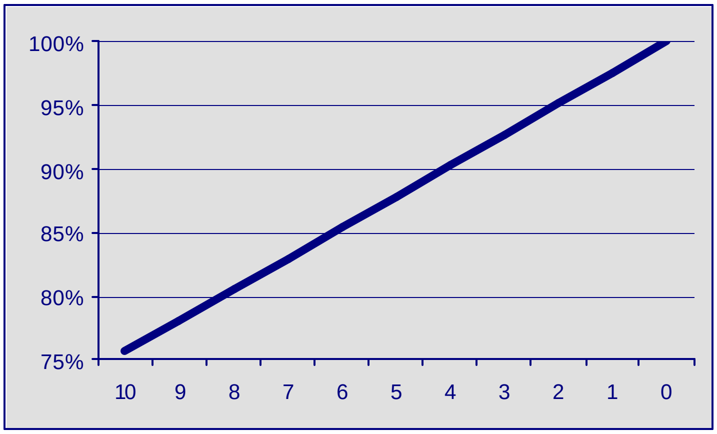

Figure 118 - Maximum potential DAS utilization for a given fleet-wide average number of carryover DAS (on X axis), assuming a 1000 vessel fleet.

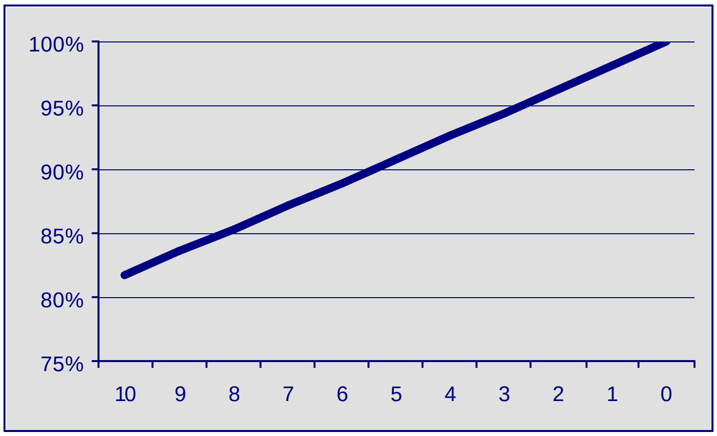

Figure 119 - Maximum potential DAS utilization for a given fleet-wide average number of carryover DAS (on X axis), assuming a 750 vessel fleet.

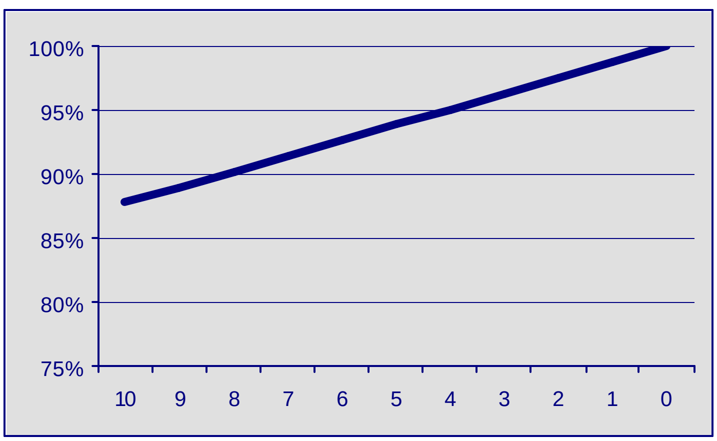

Figure 120 - Maximum potential DAS utilization for a given fleet-wide average number of carryover DAS (on X axis), assuming a 500 vessel fleet.

Figure 118, Figure 119 and Figure 120 show that, depending on what amount of carryover occurs, maximum potential DAS utilization is likely to be well below 100%. If the DAS leasing program is widely subscribed, and results in a dramatic reduction in the number of vessels fishing, then the DAS set aside for carryover will have a less significant effect on overall DAS utilization; conversely, if the program is moderately or lightly used, the number of DAS vessels are likely to carryover will result in a maximum potential use rate significantly lower than 100%.

Increasing fleet efficiency
The shift of DAS from less to more efficient vessels is likely to take place under leasing. However, due to the limited ability for DAS to flow from vessels with lower catching power to vessels with higher catching power, the leasing model shows that leased DAS tend to flow from larger to smaller vessels. In aggregate, this is likely to mitigate any potential increase in fishing mortality for a given number of used DAS.

Geographic effort shifts
The DAS leasing model shows that leased days will flow from the southern and northern portions of the fishery into the more central areas, particularly Massachusetts. This could result in increased pressure on stocks such as GB cod, plaice, and CC/GOM yellowtail flounder. However, due to the trip limits on two of those three stocks, and the overall health of other centrally located stocks such as GB haddock and GB yellowtail flounder, it would be difficult to conclude that this geographic shift in effort would have an adverse impact on stocks of concern.

Additional factors
The permit transfer option (Capacity Reduction Option 3) will also have an impact on leasing and DAS utilization, though not on the utilization rate *per se*. If a substantial number of vessels chose to participate in this program, it will reduce the allocated DAS pool due to the 40% conservation tax. DAS acquired through this program would reduce the DAS available for leasing; there is, therefore, a linear relationship between the number of permits transferred and the reduced potential adverse impact of DAS leasing on target fishing mortality rates. Economic impacts analysis of this alternative shows that a substantial number of DAS (a range of anywhere from 1,000 - 7,500 DAS) may become subject to the 40% conservation tax, which would reduce the allocated DAS pool substantially.

The impacts of these changes can only be discussed qualitatively. If DAS flow to smaller vessels, overall catch rates may decline. This would also be expected to shift effort away from offshore stocks and to inshore stocks. While this would benefit stocks such as GB cod, SNE/MA yellowtail flounder, and white hake, it may increase mortality on stocks such as GOM cod, plaice, and CC/GOM yellowtail flounder. The DAS leasing program will need to be carefully monitored to ensure it does not compromise rebuilding programs. For that reason, the Council has proposed a two year sunset provision.

5.2.4.9 Recreational Fishing Permit

The proposed action does not adopt a recreational fishing permit. Option 1 is no action (no recreational fishing permit). Options 2, 3 and 4 require that a recreational vessel has a permit in order to fish for or possess groundfish. These measures will allow for better data collection about recreational catches and may lead to improved scientific information about fishing behavior and fishing mortality. These measures have no direct biological impacts on groundfish stocks but provide important information about stocks which may lead to better management of the groundfish fishery and closer adherence to rebuilding programs designed to achieve biological targets.

5.2.4.10 "Running Clock" Alternatives

The proposed action did not change the administration of the "running clock." Option 1 (no action) maintains the current modified running clock system and will not result in any change in fishing mortality. Options 2 and 3, which allow a vessel to exceed its daily trip limit, may serve to reduce discards by charging the vessel in DAS to account for the overage. These options promote efficiency without increasing fishing effort. They are likely to have minor positive effects (that is, reduced fishing mortality from lower discards) on the resources that have a trip limit. This is because vessels may choose to end a trip and land the catch under a running clock, rather than continue to fish for other species (not managed by a trip limit) and discard more fish that are limited by a trip/possession limit.

5.2.4.11 Observer Coverage

Observer coverage, like recreational fishing permit requirements, will allow for enhanced data collection about the targeted stocks. Specifically, it will yield important information about the level and species composition of discards. This data may become a means for better estimating stock abundance and take bycatch level into account when establishing measures to achieve rebuilding requirements in the future.

The Council does not control the observer program. The proposed action states the Council's desire for an acceptable level of observer coverage to monitor this fishery.

5.2.4.12 VMS Requirements

VMS is an informational tool which will allow for better enforcement of closed areas and improved information about the fishing patterns of vessels in the northeast groundfish fishery. VMS will not have any direct impacts on the fishery resource, though it may indirectly benefit stocks by improving data quality and management based on these data.

The proposed action allows a vessel that is using a VMS to stop transmitting when not participating in any fishery. This will not have any biological impacts.

5.2.4.13 Day Gillnet Block Out of the Fishery

The proposed action did not change the requirements for day gillnet vessels to take blocks of time out of the fishery. These requirements were originally adopted as part of a package of measures designed to reduce fishing effort by the gillnet fleet, Framework 20 (implemented May 1, 1997) defined day trip gillnet vessels and required them to take 120 days out of the gillnet fishery during the fishing year. The blocks of time out must be a minimum of seven days in length. The 20 day spawning block counts towards this requirement. In addition, day trip gillnet vessels must take 21 days out of the fishery between June 1 and September 30 each year. These vessels are allowed to fish for groundfish with other gear while taking a block out of the gillnet fishery.

This requirement (along with the 15 hour day gillnet minimum and limits on the number of nets) was established because the effectiveness of the Amendment 7 effort reduction program for day gillnet vessels was questioned for two reasons: gillnet vessels were theoretically able to make 140-176 trips by fishing for 12-15 hours (with 88 allocated DAS), and they generally leave their gear to soak overnight or longer. In theory, without extending soak time, a day gillnet vessel could have its gear in the water a minimum of 176 days based on daily trips of 12 hours. This implies that under the 50% effort reduction program adopted in Amendment 5, the baseline for these vessels was to soak gear every day of the year.

The block out requirement was implemented to reduce the possibility gillnet vessels could compensate for other effort reduction measures by extending soak time between trips. The requirement to take time out during the summer months was intended to apply the time out requirement when gillnet activity is highest. Allowing the vessels to take blocks out when they do not normally fish would not have a conservation benefit.

The 120 days out requirement reduces the number of days available to day gillnet vessels to soak their gear by 33% (to 245 days). The impact on actual fishing practices is not clear. By lengthening the time between trips, a fisherman can use the same amount of soak time but fewer DAS. At some point, however, there are tradeoffs between the quality of fish landed, impact of trip limits (fewer trips results in less fish landed under a trip limit), and other factors that restrict a fisherman's ability to use fewer DAS while maximizing soak time. Based on an average soak time of 1.5 days, a gillnet vessel could, in theory, make 163 trips if it was able to fish every available day (discounting weather, unplanned vessel maintenance, seasonal closures, etc.). Assuming an average soak time of 2 days reduces the number of possible trips to 122.5. While it may be possible to increase the number of theoretical trips by changing fishing practices – shortening soak time, for example - since each day gillnet trip counts a minimum of 15 hours, the maximum number of trips is 140 for a fleet DAS vessel that is allocated 88 DAS.

For the June-September period, the requirement to take 21 days out of the fishery reduces the number of available days that gear can be soaked by 17% (to 101 days). As noted above, the impact on actual fishing practices is not clear. Based on an average soak time of 1.5 days, a gillnet vessel could, in theory, make 67 trips during this period, using a minimum of 41.8 DAS (15 hour minimum for day gillnet vessels, discounting weather, unplanned vessel maintenance, seasonal closures, etc.). An average soak time of 2 days results in 50.5 trips, using 31.5 DAS. (As noted above, it may be possible to increase the number of trips by changing fishing practices). Without the block out requirement, a day gillnet vessel could theoretically take between 61 (2 day soak) and 81 (1.5 day soak) trips, using a minimum of 38.1 to 50.6 DAS, during the months of June through September.

These analyses, however, do not account for the additional DAS reductions proposed under this Amendment. With reduced DAS allocations, the blocks-of-time out of the fishery become less effective at reducing fishing activity. For example, a gillnet vessel with 70 allocated DAS under the FW court order can only take a maximum of 112 fifteen hour trips during the course of the year.

Removing the 21 - day gillnet block out of the fishery (Option 2) may increase gillnet fishing effort during the summer months. The number of trips that could theoretically be taken by a vessel (absent weather, market, vessel repair, or other concerns) could increase about 20 percent, from 67 to 81. This will only result in increased fishing mortality on a stock if this is additional effort, or is effort shifted from a less-productive time of the year. About 60 percent of day gillnet vessels currently take less than 60 trips during the summer months. This suggests that there are other factors besides the block-out requirement that limit the number of trips. Since this measure does not change those factors, any increased fishing mortality that results from removing this requirement is likely to be small.

Removing the 120-day blocks out of the fishery is not likely to affect fishing mortality if DAS allocations are the same, or less than, the allocations under the FW 33 court order. The maximum number of trips a day gillnet vessel can make if allocated 70 DAS or less is 112 fifteen hour trips. With a soak time of 1.5 hours, and the 120-day block requirement, a gillnet vessel could theoretically make 163 trips if not constrained by DAS. The limiting factor is thus the DAS allocation and not the number of days available after the block out limitation is applied.

The proposed action is the no action alternative. It will not affect fishing mortality. Rebuilding alternatives implicitly included this option when designed to meet the mortality objectives. This is because in evaluating the alternatives in the closed area model, fishing activity in the model reflects the regulations in place during the period 1998 through 2001 – including the requirement for day gillnet vessels to take blocks of time out of the fishery.

5.2.4.14 DAS Counting

The proposed action does not change the way DAS are counted. The no action alternative will not affect fishing mortality. Rebuilding alternatives were designed and evaluated using the no action alternative for DAS counting.

Changing the way in which DAS are counted, instituting a 15-hour minimum for trips over 3 hours for all vessels in Option 2 and a 24-hour minimum for trips over 3 hours for all vessels in Option 3, may have a slight positive impact on stocks because DAS will be most likely be used up faster with no increase in fishing intensity or overall effort. This may have negative implications for data quality, however. One used DAS as reported under Option 3 does not necessarily represent 24 hours of fishing. The vessel may have fished any length of time between 3 and 24 hours. This makes it more difficult to associate time fishing with the amount of fish harvested. This could impede the ability to analyze the impacts of management alternatives in which DAS are used as a tool to control effort. While this has no direct impacts on mortality, it may adversely affect the precision with which stocks may be managed.

5.2.4.15 Reporting Requirements

The proposed action will implement electronic reporting for dealers and, in the future, electronic reporting for vessels. All of the reporting options will serve to enhance the speed at which fishery-dependent data is processed and stored. This has no direct biological effects but it may indirectly benefit stocks by improving data quality and management based on these data. For those stocks managed by a hard TAC (portions of the GB cod and haddock stocks and the GB yellowtail flounder TAC), electronic reporting will reduce the possibility that landings information will lag behind catches and result in the fishery exceeding the TAC.

5.2.4.16 Hand Gear-Only Permit Alternatives

As noted in section 5.4.9.2.15, very few vessels landing cod, haddock and pollock are associated with open access hand gear only permits (184 permits in 2000). The number of such permit holders landing 500 pounds or more of cod, haddock and pollock is even fewer (65 in 2000). In 2000, all open access vessels landed a total of 868,000 pounds of groundfish. Therefore, the effect that hand-gear vessels in the open access permit category have on fishing mortality of groundfish stocks is minimal. It should be noted, however, that activity by all open access vessels has nearly quadrupled since 1996. Under the no action alternative, this increase would likely continue and could be a future concern. Providing a limited access permit option for hand gear only vessels addresses the potential problem of rapid expansion of the hand-gear fishery by controlling participation.

5.2.4.17 Inshore Gulf of Maine Conservation and Stewardship Plan

The proposed action does not adopt the Inshore Gulf of Maine Conservation and Stewardship plan. This alternative only describes management measures for the Gulf of Maine, with a focus on the inshore areas. As a result, it cannot be adopted as a stand-alone alternative but must be adopted in concert with one of the other alternatives. Biological impacts cannot be analyzed using the Closed Area Model because this model cannot be applied to only one area. This alternative could be implemented with any of the options that use hard TACs to insure biological objectives are met. For example, it could be incorporated into the area management approach proposed in Alternative 4 and could be the specific measures that are adopted in the Gulf of Maine. It could also be adopted with the hard TAC alternative, with the measures proposed replacing or supplementing the measures implemented August 1, 2002 in the Gulf of Maine, or with Alternative 3 (area management) – once again, replacing measures that are proposed in that alternative for the inshore GOM. In these examples, the use of a hard TAC means that the biological objectives will be met, and the measures then take the form of measures implemented to extend the season. Incorporating this alternative into the two alternatives that rely on effort controls (Alternatives 1 and 2) is more problematic. In order to determine if biological objectives are met in these examples, the precise description of all the measures adopted would have to be modeled and a determination made as to whether the goals of the amendment would be met. This has not been done, since the Council has not defined how, or if, it will incorporate the measures proposed in Alternative 5 with either of those two alternatives.

Many of the measures proposed in this alternative can be evaluated qualitatively to determine if they are likely to increase or decrease mortality compared to the no action alternative. This alternative attempts to provide a closer link between an understanding of the resources in the area and the tools used to manage the resources. A discussion of the biological rationale for these measures is included in Appendix XIII. This section will examine the individual measures and describe the expected impacts.

5.2.4.17.1 Fishing Year

The fishing years will begin on July 1. While this may not have direct impacts on fishing mortality, as discussed in section 5.2.4.1 the change may reduce mortality in the short term. New DAS allocations are effective at the start of the fishing year. By moving the start of the year away from the period of aggregations of fish in the inshore GOM, there will be less of an incentive for vessels to use a large number of DAS early in the fishing year, during times of high catch rates. This impact may be temporary, as vessel operators will probably adjust their fishing plans to reserve DAS for fishing during periods the fish are aggregated.

5.2.4.17.2 Possession/Trip Limit

The GOM cod possession/tip limit is increased to 600 pounds. In general, an increase in a trip limit will result in increased mortality. From an economic standpoint, more trips become profitable and thus more cod is landed. The increase in the trip limit, however, also reduces the amount of discards, so this measure will reduce discards of GOM cod. If the increase in the trip limit is enough to encourage vessels to end their trips earlier, the result may be reduced total catch and a reduction in mortality. It is not possible to quantitatively estimate the impacts of this measure.

5.2.4.17.3 Effort Controls

The alternative proposes using the DAS allocated to vessels on August 1, 2002, with the exception that all vessels will receive a minimum of 25 DAS. The total number of DAS that will be allocated to the fishery will be greater than the number used in fishing year 2001. It is likely, however, that this allocation will result in some reductions in DAS used. Fishing year 2002 allocations are higher than the DAS used in 2001, yet actual DAS use through October is roughly 60 percent of the amount used in 2001. This suggests that the distribution of DAS may impact how many DAS are used. While this alternative does increase the minimum number of DAS issued to vessels, it will probably still result in a reduction in DAS used compared to 2001. It is not possible to predict the exact level of DAS use that will result. This measure may reduce fishing mortality on stocks in all areas, not just the GOM.

5.2.4.17.4 Observer Coverage

While an increase in observer coverage to 20 percent of all trips will not directly result in a reduction in mortality, it will lead to an improved understanding of discards, fishing effort and fishing practices that will benefit management in the future.

5.2.4.17.5 Gear Restrictions

Trawl Gear

The alternative adopts minimum mesh size of 6.5 inch codends and promotes the use of a composite cod end with square mesh on the top and diamond mesh on the bottom. The impacts of the mesh increase are discussed in section 5.2.6.3.3 and equate to roughly a ten percent change in the reference points.

Experiments with composite codends show improved selection patterns (Glass, pers. comm.) which may increase the benefit that results from the mesh change. The alternative also will gradually reduce the length between trawl doors and the wings of the net. Presumably at least some vessels fishing in the inshore GOM are currently using cable that exceeds the proposed lengths. (VTR information is available for the sweep width of trawls, but not for the distance between the door and the net wing.) Reducing this distance will reduce the area swept by the ground cables of the trawl. Fewer fish should be "herded" into the net, and catches should be reduced as a result. While fishermen could react by increasing time spent fishing, the reduced DAS allocations limit their ability to respond in this fashion. These changes in trawl net configuration should result in reduced catches, but the amount cannot be quantified.

The proposal also includes a ban on night fishing in the inshore GOM. A ban on night fishing may benefit stocks in several ways:

- The ban will prevent trawling for roughly half of each day, reducing the time available to fish and thus providing an additional control on effort.
- If catch rates are lower during the day, limiting fishing to this time period will result in lower catches for a given amount of effort.
- To the extent fishing activity disturbs codfish spawning behavior, a prohibition on night fishing may improve spawning success.

The following analysis focuses on the impacts of a ban on night fishing on cod catches. The ban could increase fishing mortality as well, if it encourages vessels to fish on stocks closer to homeports, resulting in increased pressure inshore, or to target cod rather than stocks that may be caught at night. A ban on night fishing will reduce fishing mortality if part of the cod catch is currently caught at night in one of two ways:

- Day/night catch rates are different, and/or
- Effort catching cod at night is not shifted to daytime fishing.

If there are benefits from this measure, most will be as a result of the impacts on the trawl fishery. Presumably this measure will have little impact on the catches from gillnet and bottom longline vessels. While the ban on night fishing will prevent fixed gear from being set or retrieved during the night, it is allowed to be in the water.

Day/Night Fishing Activity
In order to determine the current extent of night fishing, VTRs were examined for 1999 and 2000 to determine the number of trips that occurred at night and the number that occurred during the day. Trips were first identified that reported fishing in the Gulf of Maine west of 69-55 W, in a GOM statistical area, between January and June. This does not include the entire inshore area proposed in this alternative, but does focus on the area with the highest reported landings of cod and other inshore stocks. Only trips that reported both a departure and arrival time were examined. Because of errors in reporting, this selection process results in a subset of all trips. It is not known if using this subset this introduces a bias into the analysis.

Trips were first sorted to determine if they were one day or less in length (day trips), or more than one day in length (multi-day trips). Since any trip absent more than 24 hours in length must have taken place at least partially at night, trips less than 24 hours in length were examined to determine if the trip included fishing at night. Any day trip (less than 24 hours in length) that departed after 1500 hours was considered to have fished at night; all others were classified as daytime trips. This time was chosen to allow some time for transit from homeport to a fishing area, and also to characterize trips that may depart in the evening and fish until early the next morning as a night fishing trip. The amount of reported landings was recorded for all gear types.

Most trips in this area are day trips (Table 61). In 1999, there were almost ten times as many day trips as multi-day trips for all gears. Bottom longline trips were reported close to this same ratio, while sink gillnet trips were predominantly day trips. For otter trawl vessels, the ratio was slightly less than 10:1. In 2000, the ratio of day trips to multi-day trips apparently declined to about 6:1, but this may be a result of the way data were selected for this analysis. It is still clear that the number of day trips far exceeds the number of multi-day trips in this area. The difference in days absent is not as dramatic. In 1999, slightly fewer than two-thirds of the days absent were on day trips, while in 2000 there 10 percent days absent on multi-day trips.

		All Gears		Otter Trawl		Sink Gillnet		Bottom Longline	
YEAR	**Data**	**Day**	**Multi-Day**	**Day**	**Multi-Day**	**Day**	**Multi-Day**	**Day**	**Multi-Day**
1999	Number of Trips	5,016	502	2,051	386	1,103	50	344	30
	Days Absent	2,281	1,250	1,052	902	510	100	164	101
2000	Number of Trips	2,786	471	1,145	352	669	73	81	32
	Days Absent	1,233	1,354	575	934	306	241	40	106

Table 61 - Number of trips and days absent by length of trip. (Source: VTRs, unpublished data)

Trips less than 24 hours in length were examined to determine whether the trip was likely to include a period of night fishing. If a trip did not take place at night, it was characterized as a daytime trip. As described above, this was estimated by considering any trip that departed after 1500 hours and before midnight as a night trip. This arbitrary categorization may under-estimate the number of night trips if there are many trips that depart after midnight but early enough that fishing begins before dawn. For trips less than 24 hours in length, the overwhelming majority of trips for all gears appear to take place primarily during daylight hours (**Table 62**). Based on the information in **Table 61** and **Table 62**, the benefits from a ban on night fishing will result primarily from the impacts on multi-day trips. It is likely that there will be little benefit from the impact on day trips.

		All Gears		Otter Trawl		Sink Gillnet		Bottom Longline	
YEAR	Data	Daytime	Night	Daytime	Night	Daytime	Night	Daytime	Night
1999	Number of Trips	4,935	81	2,009	42	1,099	4	341	3
	Days Absent	2,239	42	1,020	32	507	3	163	1
2000	Number of Trips	2,720	66	1,088	57	667	2	79	2
	Days Absent	1,196	37	541	34	305	1	39	1

Table 62 - Number of trips less than 24 hours in length categorized as daytime and night fishing trips.

The impacts of this measure depend on how much cod is caught on day trips as opposed to multi-day trips. If a large amount of cod is caught in multi-day trips, then the ban on night fishing should have more impact as at least some portion of that cod is likely to have been caught at night. The amount of cod reported retained was summed for the vessels on multi-day trips. In 1999 and 2000, between 64% and 70% of the cod retained from each year was caught on trips of less than 24 hours in length. For trawl vessels in both years, day trips accounted for slightly less than 60% of the cod retained during both years. Days trips accounted for 87% of cod retained by gillnet vessels in 1999, and 74% retained in 2000. Longline vessels retained 70% of their cod on day trips in 1999 but only 52% on day trips in 2000.

	Cod Reported Retained							
YEAR	All Gears		Otter Trawl		Sink Gillnet		Bottom Longline	
	Day	Multi-Day	Day	Multi-Day	Day	Multi-Day	Day	Multi-Day
1999	513,243	212,703	222,312	162,183	128,334	18,816	38,100	15,885
2000	679,779	379,305	371,874	272,475	206,133	71,769	24,610	22,369

Table 63 - Cod retained by gear and length of trip.
Source: VTRs, unpublished data

Because most trips are less than 24 hours in length, and most of those trips take place during the day, the benefits of this proposed measure will result from changes in catch rate on multi-day trips. Such trips accounted for between 15 to 23% of otter trawl trips in this area in 1999 and 2000. These trips accounted for between 22 and 25 percent of the cod retained in 1999 and 2000 on those trips examined. How much of the cod on those trips was caught at night as opposed to how much was caught during daylight is not known.

Composition of Catch

A ban on night fishing in the area west of 69-55 W could have a negative impact on cod mortality if it shifts effort of multi-day trips away from other species and onto cod. The VTR data were examined to determine if there was a difference in catch composition between day and night fishing trips. Cod was compared to the catch of groundfish, and to the catch of groundfish plus monkfish. The data were calculated based on both landings (Table 64) and catch including discards (Table 65). In both tables, there is essentially no difference in the amount of cod as a percentage of catch for otter trawl vessels in 1999. In 2000, however, there is a small difference between day and multi-day trips for cod as a percentage of catch. Day trips have a slightly higher percentage of cod in both landings and total catch, whether or not monkfish is included in the catch.

The 2000 data suggest that banning night fishing during this period may slightly bias the catch towards cod. This is not supported by the 1999 data, however. From these limited data, it cannot be determined whether the ban on night fishing will significantly increase the targeting of cod.

		Sink Gillnet		Bottom Longline		Otter Trawl	
Year	Data	Day	Multi-Day	Day	Multi-Day	Day	Multi-Day
1999	Cod/ Groundfish	22%	27%	64%	68%	21%	22%
	Cod/(Groundfish and Monkfish)	18%	22%	64%	68%	20%	21%
2000	Cod/ Groundfish	33%	48%	68%	98%	33%	27%

Day/Night Cod Catch Rates
There appear to be diurnal differences in catch rates for groundfish species. Many studies focused on differences noted during research survey tows, questioning whether such differences affect stock assessment information. Petrakis et al. (2001) summarized day/night differences and depth effects on catch rates for North Sea trawl surveys, focusing on whiting, herring, haddock, and dabs. They noted that differences in day/night catch rates in survey trawls were not the same for all species. The differences were attributed to changes in fish behavior. Shepherd and Forrester (1987) examined diurnal catch differences for NEFSC survey data. For cod, they report a significant effect of time of day on catches for each stock area. They stated that "catches for cod, haddock, pollock and the squid species were generally lower during dusk and night (1601-0400 hrs) and higher during dawn and day (0401-1600 hrs)" and "in all species which had significant differences in catch weight, except flounder, the lowest catches occurred during the darkest periods (dusk and night). The vertical distribution of cod, haddock, and pollock extends into the water column at night, possibly for feeding" (Beamish 1966). The implication is that some cod have a tendency to move off-bottom at night, probably to feed. Since commercial gear differs from survey gear in net size, mesh, footrope configuration, doors, and assembly, one cannot infer that the same must be true for individual commercial fishermen.

There is limited information available on the commercial catch rates of cod during day and night hours. In 1992, the NEFSC examined catch and discard rates for a variety of groundfish species using sea sampling data from 1989 through 1991 (McBride et al. 1992). Samples from otter trawl vessels were examined to determine the following:

- Relative catch rates (catch per tow and catch per hour trawling) within 12 miles, versus outside twelve mile of the coast for the 13 regulated multispecies.
- Diurnal difference in catch rates within and outside the 12 mile zone.
- Relative catch rates of sub-legal sized groundfish inside versus outside the twelve mile zone.

For the purposes of the analysis, daytime was defined as the hours from 0600 hours to 1800 hours. Tows that straddled the day/night criteria were not included. The study also examined whether there were differences in catch rates between tows within 12 miles of the coast, and tows farther offshore. Tows were examined for two areas roughly corresponding to stock areas: the Gulf of Maine defined as "north," and the area south of 42 N defined as "south." The study did not examine whether there were differential catch rates during different times of the year, and did not focus on the January through June period included in the proposed ban on night fishing.

Data were available for 1,217 day tows and 850 night tows catching cod. The general conclusion of the study was that for cod there was an increase in CPUE at night, defined as the ratio of discard/kept portions of the catch. Total catch, in terms of kilograms/tow, was also significantly higher at night. Results for cod are shown in the table below. The study only includes a statistical analysis of the catch rates for combined areas (italicized data); it is uncertain if the differences in the other catch rates are statistically significant.

	Total Catch, kg/tow							
	1989		**1990**		**1991**		**Average**	
	Day	**Night**	**Day**	**Night**	**Day**	**Night**	**Day**	**Night**
Inside North	7.6	10.2					7.4	10.3
Outside North	24.9	37.6	46.7	74.4	55.1	77.6	43.5	62.1
Inside South	15.2				12.8		14	
Outside South	44.2	55.3	47.3	44.9	38.7	55.4	43	52.7
Average	34.4	47.9	47	47.3	43.1	61.6	*41.1*	*53.9*

Table 66 - Catch rates (kg./tow) from observed otter trawl trips. "Inside" refers to tows within 12 nautical miles of the coast. "North" is Gulf of Maine, "South" is south of 42N latitude. (Source: McBride et al. 1992)

Following the methods of McBride et al. (1992), more recent sea sampling data (1995 through 2000) were examined in order to focus on the area and time proposed for the measure. Otter trawl tows during January through June were identified where the end of the tow was west of 69-55 W. Unfortunately, the limited number of observations prevented drawing any conclusions. Only 127 tows (92 day and 35 night) were identified. Because of the limited number of observations in some years, the data were pooled for all years. There was a significant difference in size between vessels that were observed towing during the day and those observed towing at night (average length of 55 feet for vessels towing during the day, 72 feet for vessels towing at night). In addition, the vessels observed towing during the day in 2000 were significantly smaller than those observed towing from 1995 through 1999. Most day observations took place in 2000, so this size difference may skew the day data to lower catch rates.

Conclusions

Based on the analysis, the following conclusions can be drawn concerning the biological impacts of a ban on night fishing in the area west of 69-55 W. As noted earlier, this is not the entire inshore area that will be affected by this alternative, but does focus on the areas of highest catch rates for cod.

- Given the limited data available, it is not possible to provide a quantitative estimate of the impacts of this measure.
- The benefits of the proposal will primarily be the result of the way it affects the behavior of otter trawl vessels that currently take multi-day trips. These vessels accounted for roughly one-fifth to one-fourth of the cod landed from this area in 1999 and 2000. If all of the effort from these vessels moves out of the area, then this proposal may reduce landings of cod by a similar amount. This is unlikely, however. The vessels may choose to make day trips, and unused DAS may enter the fishery, reducing the mortality reduction resulting from this measure.
- There is some evidence of higher catch rates in commercial trawls at night based on a 1992 review of three years of sea sampling data. To the extent this difference is real, preventing trawling at night may reduce catch rates. This will only result in reduced catches of cod if vessels do not increase their targeting of cod and if overall effort does not increase.

Gillnets
An increase of gillnet mesh to 6.5 inches will result in a change in selectivity, as discussed in section 5.2.6.3.3. The reduction in number of gillnets to 50 nets was described in the EA to accompany the measures implemented August 1, 2002. The changes were estimated to result in a reduction of 10 percent for GOM cod, plaice gillnet landings, 12 percent reductions in pollock landings, and 14 percent reductions in GOM haddock gillnet landings.

Hook Gear
The number of hooks allowed for longline vessels is reduced from 4,500 to 2,000 hooks. While this will reduce mortality in this sector, longline landings in this area are so low that this will have a negligible impact on mortality.

5.2.4.18 Sector Allocation Updated

The sector allocation alternative is not a stand-alone alternative and cannot be analyzed as such. A key element of any sector approach, however, is the allocation of a specific amount of a resource to a particular sector. As long as that allocation is consistent with target fishing mortality rates, this alternative is consistent with the biological objectives of the amendment. The proposed action will allow for the creation of voluntary self selecting sectors in the fishery.

5.2.4.19 GB Hook and Gillnet Sector

The proposed action only adopts the GB hook sector.

Over time, the GB hook and gillnet sector alternative should have only minor biological impacts. This alternative is based on assigning an appropriate share of the resource to the participants in this sector. The share is consistent with the rebuilding targets and the sector must remain within its share or be penalized in following years. It is possible that in a specific year the sector may catch more than its share, but this results in reductions in following years. Over time, the catch by the sector should be consistent with rebuilding goals.

5.2.5 Biological Impacts of Measures to Control Capacity

Each of the capacity alternatives is designed to achieve a long-term reduction in the number of vessels permitted to fish in Northeast fisheries. While these alternatives are intended to reduce fishing effort in the long term, some, such as permit transfers, may increase effort in the short-term. It is unknown how many permit holders will participate in capacity reduction programs, although these numbers are estimated in section 5.4.9.4, Economic Impacts of Measures to Control Capacity. If few participate in these programs, capacity reduction alternatives will do little to benefit stocks. In general, permit transfer and absorption alternatives are intended to be conservation neutral, complying with vessel upgrading restrictions and imposing a conservation tax on transferred DAS.

In one sense, capacity issues are strictly related to the economic performance of the fishery and have no impacts on the biological status *if appropriate mortality controls are adopted and implemented*. For example, if a hard TAC or quota system is in place, is adequately monitored, and adequately enforced, then it does not matter if the quota is caught by one vessel or one thousand vessels from a biological standpoint, though the economic performance of the industry would be vastly different. In reality, however, excess capacity has a bearing on achieving biological objectives because the excess capacity makes it more difficult to design appropriate management measures.

One factor that must be considered in evaluating all of these alternatives is whether a rebuilding alternative will be selected that uses a hard TAC system and whether allocated DAS will be reduced. Under a hard TAC, the number of permits or DAS becomes less of a factor in achieving the biological objectives. If allocated DAS are reduced to levels that are appropriate for the target fishing mortality rates, then the capacity alternatives will have less impacts on

5.2.5.1 No Action

This alternative was not selected.

Under this alternative, there would be no measures adopted in Amendment 13 that would specifically address capacity issues, though Rebuilding Alternative 2, if adopted, would reduce DAS allocations from the no action level of approximately 131,000 DAS. In recent years, DAS use has increased by about 10 percent per year, suggesting that mortality controls would have to be increasingly more stringent in order to meet rebuilding objectives.

5.2.5.2 Alternative 1 – Permit Absorption

This alternative was not selected.

Because some duplicate permits will expire under this alternative, the number of permits in the fisheries will be reduced minimally.

This alternative is not likely to cause a large short-term increase in fishing effort because it is so restrictive. Permits would have to be transferred as a bundle and could not transferred individually. In example, one permit for each of monkfish, squid scup and whiting would expire and the scallop and herring permits would have to be used by the same vessel, probably limiting the amount of time the vessel would have to possibly conduct a directed fishery for each of these species.

This proposal probably will increase effort in the short-term and cause some latent effort to be activated. However, the effort increase would be limited by the relatively few vessels that are likely to participate and by the fact that the permits are likely to be acquired by vessels that are already fishing. For example if a scallop vessel acquired a Fleet Category groundfish permit, it might not fish all of its available groundfish DAS in addition to scallop DAS.

5.2.5.3 Alternative 2 – Permit Transfer

This alternative was not selected.

Because this proposal does not allow DAS to be combined (“stacked”), the multispecies DAS would have to be acquired by vessels not already holding limited access multispecies permits. This would remove DAS from the multispecies fishery. This may reduce fishing effort in the groundfish fishery but increase effort in other fisheries.

This alternative differs only slightly from no action, in that most of the transfers allowed can already take place.

5.2.5.4 Alternative 3 – Days-At-Sea Transfer

The proposed action adopts the DAS transfer alternative. This alternative may result in a long-term reduction in fishing effort if it is adopted so that transferred DAS are reduced in some fashion. If DAS are not reduced through a conservation tax or other means, then it will not reduce DAS and could result in an increase in used DAS. This is more of a problem if DAS allocations are not reduced to appropriate levels and there are a large number of unused DAS that can be transferred to vessels that use them. If that happens, then mortality may increase in the short term.

5.2.5.5 Alternative 4 – Freeze on Unused DAS

This alternative was not selected. Under this alternative, permit holders electing to freeze their permits would not be able to reactivate effort for a predetermined amount of time or until stocks improved to predetermined levels. This alternative is likely to have little effect on fishing mortality. Permit holders are likely to only freeze DAS that they did not plan on using. An unused DAS –whether frozen or not – does not contribute to fishing mortality.

This alternative does not have any impacts on fishing mortality that are different than the no action alternative.

5.2.5.6 Alternative 5 – Days-At-Sea Reserve

The proposed action adopts the DAS reserve program. Because the reactivation rate of Category B and C DAS under this alternative will be based on stock conditions, this alternative should not increase fishing mortality. The various options for categorizing DAS may make it easier to reduce allocations and achieve an effort reduction under the proposed action. The actual capacity alternative itself, however, will not have any impact on fishing mortality as in all cases the number of category A DAS is higher than the DAS used in recent years and higher than the number necessary for achieving the rebuilding targets.

5.2.5.7 Alternative 6 – Mandatory latent effort categorization with voluntary flexibility options

This alternative was not adopted. Alternative 6, which combines a number of capacity reduction alternatives and defines the order in which they are implemented, should have similar biological impacts as its component alternatives. Depending on the specific capacity reduction alternatives adopted within Alternative 6, days-at-sea may or may not be reduced. It is not likely that this alternative will result in substantial reductions in fishing effort or have more than a negligible impact on the stocks.

5.2.6 Alternatives to Achieve Rebuilding Objectives

One of the major focuses of this amendment is to achieve M-S Act objectives for rebuilding overfished stocks and ending overfishing. In the following analysis, the effectiveness of the alternatives is compared to the fishing mortality necessary under a constant fishing mortality rebuilding strategy (see section 3.2 and section 3.2.3.1.2). Under a constant catch or a phased reduction strategy, the reduction needed in the first year after implementation would be less, but until the precise measures for subsequent years are defined, it is not possible to determine if the alternative will meet the objectives in following years.

5.2.6.1 Proposed Action

5.2.6.1.1 Closed Area Model

The Closed Area Model (section 5.1.1) was used to estimate the biological impacts of the following elements of this alternative:

- Year round closed areas
- Seasonal closed areas
- Trip/possession limits
- Reductions in used DAS

The proposed action includes measures to minimize, to the extent practicable, adverse effects of fishing on essential fish habitat. The model has been revised to include the area closed to mobile gear north of the NLCA (see section 3.7.3). The area closed to mobile gear in the northern Gulf of Maine has not been included in the model because of its small size.

A major element of the proposed action is a control on the number of DAS that can be used to target any groundfish species. This is done by limiting the number of Category A DAS that are allocated. While in fishing year 2002 and 2003 there were about 71,200 DAS (including carry-over DAS) that could be used to target any groundfish stock, the proposed action limits the number of Category A DAS to approximately 41,000. Evaluating the effects of this control is critical to using the closed area model to estimate the impacts of this action.

In past years, the number of DAS actually used has been a low percentage of allocated DAS. These percentages are likely to increase as allocations are reduced. A review of Table 474 reveals that while the percentage of DAS used by active permits was relatively constant from 1999 through 2001, in fishing year 2002 the percentage increased to 67 percent of the allocated DAS (including carry-over), from 59 percent in 2001. Preliminary analysis of fishing year 2003 DAS use suggests that the percentage of DAS used is increasing. A possible counter to increased use, however, would occur if the lower allocations result in some vessels not choosing to use their DAS at all because they have too few to remain in the fishery.

In addition to increases in the percentage of DAS used that may result from reduced allocations, at least two other factors may affect DAS use: the use of DAS reserve effective effort definition 9, and the implementation of a DAS leasing program. Effective effort definition number 9 allocates DAS to active groundfish vessels – those most likely to use their DAS. Implementation of a DAS leasing program means there is an incentive for a permit holder to profit from unused DAS by leasing them to a vessel that will use DAS – and reduced allocations will create an incentive for other vessels to lease the DAS. The restrictions on leasing between vessels of different sizes may help control the leasing market, but to what extent is not known. A simulation model (see section 7.3.3.7.2) suggests that even under perfect conditions, not all DAS will be used.

It is unlikely that every DAS allocated will be used. This proposed allocation of DAS grants a specific DAS allocation to every permit holder based on recent fishing history. This is very similar, in effect, to the allocations in the Individual Vessel permit category. Even after allocations were reduced in 2002, this permit category did not use ten percent of its allocated DAS, a figure that was remarkably consistent with prior years. While it's reasonable to conclude from this comparison that not every allocated Category A DAS will be used, it is not possible to predict exactly how many will not be used.

Other possible effects from DAS leasing are not reflected in this analysis. The closed area model uses several years of data, so it reflects the distribution of fishing vessels over an extended period. If DAS leasing causes changes in catch rates because the type of vessels fishing changes rapidly, this will not be captured in the model results until additional years of data are added. It should be noted that simulations of DAS leasing suggest that contrary to common expectations, DAS may actually move from larger to smaller vessels (see section 5.4.9.2.7). This could affect which stocks are targeted by the DAS being used, as smaller vessels may be less likely to fish in offshore areas.

In order to capture the uncertainty associated with the number of DAS that will be used, the closed area model was run with three different assumptions. Since the model does not include every vessel, these assumptions on the number of DAS used were converted to a reduction from the average DAS used in fishing years 2000 and 2001. By comparing these different results, it is possible to get a sense of how sensitive the results of the model are to relatively small changes in the number of DAS used. More importantly, this approach helps to characterize the likelihood that the proposed action will meet the biological objectives of the rebuilding strategies should there be changes in the number of Category A DAS used for any reason. The use rate and equivalent reduction in used DAS used in the model runs are shown in Table 67.

Because the model was run three times, there is a range of changes in exploitation and consequently a range of biological impacts (see Table 68 through Table 70). The changes in exploitation predicted by the model are shown in below. These changes in exploitation will be combined with the impacts of measures not included in the closed area model to provide an estimate of the expected change in fishing mortality. Model results are based on Category A DAS only. Available information on the likely catch of groundfish stocks in special access programs will be discussed in a following section.

Assumed Percentage of Allocated DAS Used	Assumed DAS Used	Percentage Reduction from FY 2000/2001
78 %	31,826	50 %
85 %	34,860	45 %
95 %	38,760	39 %

5.2.6.1.2 Gear Restrictions

5.2.6.1.3 Mesh Size Changes

This alternative includes measures that would change mesh regulations for trawl and gillnet vessels, increasing both trawl and gillnet mesh compared to the No Action alternative. Expected impacts were analyzed in the Environmental Assessment (EA) accompanying the Interim Action to Implement Measures to Reduce Overfishing of the Northeast Fishery Complex Under the Northeast Multispecies Fishery Management Plan (NMFS 2002), but is repeated here for clarity and supplemented with additional information. Mesh selectivity is only one of a number of factors that influences the overall selection pattern in a fishery. Fishermen can influence the size of fish they catch by fishing at different times of the year, in different locations, or by using different gear or techniques. Most mesh selectivity studies have examined smaller mesh sizes and have focused on trawls. Indeed, in one experiment that examined the performance of 6.5-inch square mesh in selecting winter flounder in southern New England (DeAlteris et al. 1999), the results suggested that scaling up earlier mesh experiments over-estimated the retention of winter flounder--that is, the mesh allowed more escapement than predicted by the earlier experiments at smaller mesh sizes. Even with adequate experiments that evaluate the selection pattern of a particular size of fish, mesh selectivity in commercial fishing operations may not match experimental results. There is evidence that selectivity can vary considerably based on different characteristics at the vessel level (Tschernej and Holst 1999). There are several mathematical models for fitting results of mesh experiments to a selectivity curve. Using a different model can result in different estimates for the selection of fish at a certain size. Studies done in different locations, or using different experimental techniques, may give different results. The exploitation pattern is only one element of fishing mortality. If effort increases, even as the exploitation pattern is shifted to older fish, it is not clear what the final impact on fishing mortality will be. For all of these reasons, it is not possible to accurately predict how an increase in mesh size will affect fishing mortality.

In addition to the difficulty in predicting the impacts of a change in mesh size, a review of past attempts to manage exploitation patterns in North Atlantic groundfish stocks indicate only partial success. Pinhorn and Halliday (2001) examined changes in partial recruitment patterns for 26 cod, haddock, and pollock stocks between the immediate period after the extension of jurisdiction (1979-1988) and the last decade of international regulation (1967-1976). While the data reviewed showed widespread, modest improvements in partial recruitment patterns, the authors were not able to correlate the improvements with the expected changes based on regulations. Problems with compliance and poor data on size of removals are two of the factors they note may obscure the impacts of mesh changes. A preliminary review of GOM cod exploitation patterns since 1981 shows that, in spite of several increases in mesh size, the partial recruitment pattern for age 4-6 fish is essentially unchanged, while fishing mortality on age 4-5 fish has declined. In contrast, a recent assessment for witch flounder found that the partial recruitment vector for the period 1999-2002 moved to older fish, leading to an increase in F40% of forty percent, from 0.164 to 0.23 (SAW 37). While many factors may have lead to this change, the SAW noted it was consistent with a change in mesh size that was implemented in 1999.

This does not mean that increases in mesh size do not have positive impacts, or that the impacts may be inconsequential. The following positive impacts should result from an increase in mesh size.

- A likely increase in spawning stock biomass per recruit.
- Discards may be reduced, as larger mesh would capture smaller numbers of fish below the minimum size limits. The impacts of this benefit also depend on the type of mesh, as square and diamond mesh have different selection patterns for flat and round fish.
- "Harvesting at a delayed PR…" [partial recruitment, i.e. harvesting at older ages] "… enables the stock to maintain a high spawning biomass with an expanded age structure, while supporting a sustainable fishery" (O'Brien 1999). To the extent that a mesh change contributes to a delayed PR, it contributes to an expanded age structure and potentially a higher spawning biomass at a given level of removals from the fishery.
- A likely increase in the number of times each fish spawns prior to capture. If the mesh size results in an increase in older spawners in the stock, there may be improvements in recruitment, since there is evidence that the eggs and larvae of older fish have higher survival rates (Trippel and Morgan 1994, Knutsen and Tielseth 1985, Kjesbu et al. 1996). Vallin and Nissling (2000) showed that, for Baltic cod, older, repeat spawners produce more, and larger, eggs than first time spawners, and showed that the number of age 2 cod recruits was positively related to the fraction of eggs produced by older females. There are some genetic data that suggest that male fertilization success increases with male body size (Hutchings et al. 1999), though other studies question this conclusion. All of these factors suggest that an increase in mesh size, to the extent it increases the age distribution and size of fish in the population, may lead to improved spawning success and recruitment.

Predicted Changes in Exploitation Pattern

As noted in the previous section, there are a number of difficulties with estimating the impacts of a change in mesh size. In order to provide a qualitative picture of the changes in exploitation that may result, selection patterns for trawl gear were calculated using the average mesh selectivity results from mesh studies as summarized in DeAlteris and Grogan (1997a). The selectivity characteristics of the mesh were plotted using a simple logistic selection curve for both diamond and square mesh. In order to show the range of possible estimates, this table also includes estimates based on specific studies used in DeAlteris and Grogan (1997a). The alternatives were chosen to illustrate the range of results from the studies using the mesh closest to the mesh under consideration, without considering location or type of experiment. Their use is not meant to imply they are the "right" values, but to illustrate the variability between results from various experiments. Age at length was converted using the Von Bertanlanffy growth parameters from various sources, as summarized in NEFMC (1994). Length was calculated at the mid-year point to consider growth over the course of the year. This section focuses on the impacts of changes in mesh size on cod.

Regardless of the specific selection factors used, the proposed mesh change has the most impact on fish in the range of 3 to 4 years. For GOM cod, this is the age when the proportion of mature fish increases from about 88 percent females/76 percent males, to about 99 percent females/94 percent males (O'Brien et al. 1993). All of the examples from the aforementioned scientific studies show that changing the minimum mesh size from the current 6-inch diamond mesh to 6.5-inch or 7-inch square mesh should reduce the probability of selection for age 3 fish. Generally, the examples show that changing the minimum mesh size from 6-inch diamond to 6.5-inch square mesh moves a given probability of selection at a certain size about 1 year into the future. An increase in trawl codend mesh from 6-inch diamond to 6.5-inch diamond, or from 6.5-inch square to 7-inch square, moves the probability of selection at a certain size less than a year into the future. That is, a fish is likely to live longer, and grow larger, before it would be retained by the larger mesh. Changing from 6-inch diamond mesh to 7-inch square mesh moves a given probability of selection at a certain size about 18 months into the future. Changing the minimum mesh size from the current 6-inch diamond mesh to 6.5-inch or 7.0-inch square mesh should reduce the probability of selection for age 3 fish.

Using the same mesh studies, the impacts on GB cod can also be illustrated. While the selectivity of the mesh does not change, the age at selection is different because of the different growth rates for GOM and GB cod. Changing mesh from 6-inch diamond to 6.5-inch square shifts the pattern about 1 year.

There are a several ongoing mesh selectivity experiments, and some additional information was provided to the Groundfish PDT by researchers working on those studies. In general, the information provided supports the relative shift in selectivity resulting from an increase in mesh size (that is, the change resulting from a mesh increase), but in some instances the absolute selectivity is different from the values obtained from DeAlteris and Grogan (1997a). Skrobe et al. (2003) calculated the Southern New England. Mid-Atlantic yellowtail flounder selectivity of 6 and 6.5 inch diamond, and 6.5 and 7 inch square mesh. Results are summarized in Table 71. These results suggest that changing the minimum mesh size in Southern New England from 6 inch diamond to 6.5 inch square mesh may result in increased retention of small yellowtail flounder (6.5 inch square mesh retains more small yellowtail flounder than 6 inch diamond mesh). Since fishermen were able to use 6.5 inch square mesh previously, it is not likely this change will have any effect on yellowtail flounder selectivity in this area.

From Skrobe et al. (2003)

Effect on GOM Yield per Recruit (YPR)
YPR calculations can be used both to show the change that results from the change in exploitation, and to estimate the impact of the change on the reduction in fishing mortality for GOM cod. An increase in mesh size will not affect the full force of fishing mortality, as the increase tends to affect only a narrow range of size classes and therefore would not significantly impact fully recruited F. For GOM cod, the first age at full recruitment has been, and remains age 4, despite recent increases in codend mesh size, and the 2000 fully recruited F is 0.73. Although the stock is presently dominated by predominantly young fish, the age structure in a rebuilt stock under a low-F regime will be considerably broader. Therefore, it is important to consider the effect of the full force of fishing mortality on all fully recruited ages. An increase in mesh size will not have any impact on the fully recruited F. If a mesh increase were to shift the first age at full recruitment from age 4 to age 5, the definition of fully recruited F would simply shift from ages 4 and older fish to ages 5 and older fish, so the actual fully recruited F would remain unchanged.

Given this, it is more illustrative to examine the effect of a mesh increase (and therefore change in partial recruitment over the incompletely recruited ages) on the F reference points that can be derived from a simple YPR analysis. In this way, the impact of the mesh change can be examined from the perspective of reducing the distance between the current F and the management target F, advantageous because both Fs are in the same fully recruited units.

SAW-33 examined changes in F_{MAX} and $F_{0.1}$ reference points for GOM cod, given varying assumptions in changes in partial recruitment patterns associated with mesh change (see Table 84). The partial recruitment pattern in this analysis was calculated from the average 1999-2000 virtual population analysis (VPA) Fs at age. These years were chosen so that the calculated PR could reflect the most recent increase in mesh size.

The effects of the proposed mesh change were based on an examination of the possible impacts on selectivity at age of a ½-inch mesh size increase. It appeared that the overall effect of a ½-inch increase in mesh was a 1-year shift in the selectivity at age. However, given the incremental changes in partial recruitment that has been observed based on the VPA Fs over the past decade, it is likely that a less than full 1-year shift in partial recruitment will occur, even if the selection at age information is accurate.

Changes in mesh selectivity do not translate directly into equivalent changes in the partial recruitment pattern for several reasons:

1. Targeting behavior;
2. Illegal adjustments to the mesh;
3. Incomplete application of the regulated mesh to all gear sectors; and
4. Incomplete translation of selectivity experiments to actual field applications.

Given this, two additional YPR analyses were done. In each of these, the base partial recruitment pattern was adjusted to reflect the possible effects of the mesh change. The YPR runs were as follows:

Run 1. Base run with 2001 assessment partial recruitment pattern.
Run 2. Partial recruitment pattern from base run adjusted by ½ year.
Run 3. Partial recruitment pattern from base run adjusted by 1 year.

The 1-year shift in partial recruitment was accomplished by shifting the original PR up one full age. The ½-year shift in partial recruitment was accomplished by averaging the PR values for adjacent ages and applying the average to the higher of the two ages. All other input data to the analyses remained the same. The results are summarized below.

Estimates of F_{MAX}	Base Run	½ Year Shift	1 Year Shift
	0.27	0.30	0.34
Estimates of $F_{0.1}$	Base Run	½ Year Shift	1 Year Shift
	0.15	0.17	0.18

These reference point Fs were then compared to the calendar year 2000 F (0.73) for GOM cod. Differences between the reduction multiplier based on the current reference point with existing partial recruitment pattern and the re-estimated reference points corresponding to the adjusted partial recruitment patterns were used as the basis for percentage contributions attributed to the proposed mesh increase.

Overall, the results suggest that a ½-inch increase in mesh size may contribute, at best, 9.6 percent to the required reduction from the current F for GOM cod to F_{MAX} (63 percent) and 4.1 percent to the required reduction from the current F for GOM cod to $F_{0.1}$ (79 percent). If the mesh increase serves to shift the partial recruitment pattern by only ½ year, the contributions are about halved, to 4.1 percent and 2.7 percent for F_{MAX} and $F_{0.1}$, respectively. The estimates were based on an assumed ½-inch mesh increase for all nest fished throughout the GOM. While the proposal would increase the required mesh on diamond mesh, the square mesh provision would not change. This means that the biological impact of the mesh change estimated above would be diminished by some unknown amount.

	No change	½-year shift in PR	1-year shift in PR
$F_{0.1}$	0.15	0.16	0.18
F_{MAX}	0.27	0.30	0.34
$F_{20\%}$	0.36	0.42	0.53

Table 72 - Changes in F reference points (for GOM Cod), given varying assumptions in changes in partial recruitment patterns associated with mesh change

Impacts on Other Regulated Groundfish

There is a limited amount of selectivity information available for plaice, yellowtail flounder, pollock, and winter flounder for trawl mesh, and even less for gillnet mesh. This information is subject to the same caveats as were described in previous sections. Using the average selection factors from DeAlteris and Grogan (1997), and with the same cautions regarding the use of these data, selectivity curves comparing diamond and square mesh of different sizes for plaice (see Table 73), pollock, and GOM haddock (see Table 74) are shown below. Selection of plaice with square mesh is roughly the same as with diamond mesh that is ½ inch smaller.

	Theoretical Plaice Probability of Mesh Selection at Age			
Age/Length				
	6" diamond	6.5" diamond	6.5" square	7" square
1.5/5.2 in.	0	0	0	0
2.5/8.4 in.	0	0	0	0
3.5/11.0 in.	.08	.02	.03	.02
4.5/13.3 in.	.40	.20	.30	.10
5.5/15.1 in.	.79	.56	.78	.51
6.5/16.7 in.	.94	.85	.96	.87
7.5/18.0 in.	.98	.95	1.0	.97
8.5/35.4 in.	1.0	1.0	1.0	1.0

Table 73 - Theoretical exploitation at age for plaice. Trawl mesh selectivity from DeAlteris and Grogan (1997) using average mesh characteristics.

The selectivity results for pollock are not definitive. DeAlteris and Grogan (1997) list only one square-mesh experiment for pollock. Comparing these results to the average diamond-mesh characteristics from the same paper suggests that 6.5-inch square mesh selects a higher percentage of pollock at a given age than does 6-inch diamond mesh. This difference, however, is not consistent with other roundfish (e.g., cod, haddock) selection patterns and later experiments. Halliday et al. (1999) conducted experiments with 5.5-inch (140-mm) square and diamond mesh, and 6.1-inch (155-mm) diamond mesh. In these experiments, the length at 50-percent selection was larger for 140-mm square mesh than for either size diamond mesh. A data review of other studies by the same authors found another study, using much smaller mesh, that showed square mesh selects larger pollock than diamond mesh. Based on this paper, it is likely that square mesh will select larger pollock than diamond mesh. Halliday et al. (1999) developed the following formulas relating size at 50-percent selection (L50) to the size of mesh for pollock:

$$\text{Square: } L50 = 0.529m - 12.243$$
$$\text{Diamond: } L50 = 0.256m + 15.036$$

Based on this relationship, the pollock L50 for 7-inch square mesh is about 32 inches, and for 6.5-inch square mesh is about 29.5 inches. For 6-inch diamond mesh, the L50 is 21.2 inches. Generally, any increase in size of square mesh will provide positive biological benefits to pollock.

GOM haddock selectivity patterns are shown below. Because of the slow growth of GOM haddock, it will take longer to recover the loss in yield for this stock.

Theoretical GOM Haddock Probability of Trawl Mesh Selection At Age*				
	6-inch diamond	6.5-inch diamond	6.5-inch square	7-inch square

Table 74 - Theoretical probability of selection at age for GOM haddock using trawl gear. Average mesh characteristics.

Source: DeAlteris and Grogan, 1997a.
** Note: GOM haddock growth slows significantly after age 7.5, little change in selection expected after that age.*

Gillnet selectivity curves are usually assumed to be roughly bell-shaped, or "Gaussian." These curves have a fish length that is the "optimal" length of selection (L_{opt}) – that is, a length that has the highest probability of selection of all lengths, usually equal to 1 – and then the probability of selection tapers off as fish size increases or decreases from this optimal length. The precise shape of these curves is subject to considerable debate, and reflects choices on the mathematical model and techniques used to describe the fish caught in the net, as well as different opinions on whether both gilled and non-gilled fish should be considered when determining selectivity. At this point, it is not clear that any one model is better than another, and the choice of model rests primarily with the data obtained and the preference of the individual researcher (Pol and Hovermale, 2000). One of the differences between the various models is how they treat fish that are at the extremes of L_{opt}. Some models assume that there is a minimum and maximum size that have a very low probability of retention in the mesh. Other models recognize that some fish at these extremes may get tangled in the mesh and still be caught, and thus these models conclude that the fish at the extremes have higher probability of retention than does the first model. These latter models explicitly recognize that "gilling" is only one way that fish are caught in gillnets.

DeAlteris and Grogan (1997) summarized available gillnet selectivity information in addition to that for trawl mesh. They used a simple, rescaled normal probability curve to estimate selection patterns. Using this model, change in probability of selection at age can be estimated using a process similar to that used for trawl gear. Unlike trawl gear, however, the theoretical exploitation pattern for gillnets shows a peak probability at some interim age, and then declining probability at both younger and older ages. The primary source used for gillnet selectivity summarized in this study is a 1992 study by DeAlteris and Lazar. One advantage of these gillnet data, compared to the available trawl data, is that the earlier study examined mesh from 6 inches to 9 inches, covering the range of mesh considered in this action. Using the average mesh characteristics from DeAlteris and Grogan (1997), the theoretical probability of selection at age for GOM cod is shown in Table 75. This table shows that the theoretical L_{opt} for gillnet mesh is roughly the same as the theoretical length at full exploitation for diamond mesh of the same size. A ½-inch increase in mesh size shifts this age/size less than 1 year into the future. For Alternative 1, then, a ½-inch increase in gillnet mesh will shift the gillnet exploitation pattern less than 1 year into the future for GOM cod.

Dynamic Effects of Mesh Change

The yield-per-recruit analysis in the previous section reflects the biological impacts of a mesh change once equilibrium is reached. The impacts shown are not realized immediately, but are achieved once the current year classes move through the fishery. In general, it should take one mean generation before the results shown are realized. This will occur at different times after implementation of the change for different species, depending on growth rates and initial stock conditions. If a mesh change is implemented, there are dynamic impacts that depend on the new selectivity pattern and current stock conditions. For example, if a mesh change shifts the exploitation pattern away from a large year class of fish, there may be an immediate loss in yield that is not accurately reflected in the YPR analysis. As those fish grow and move through the fishery, however, catching those fish at larger sizes will eventually result in the YPR predicted in the previous section.

To illustrate this concept, two projections were run for GOM cod. The first assumed the existing exploitation pattern in the fishery, and the second assumed a shift in exploitation of about one year. Both projections were run at the same fishing mortality rate and with the same initial conditions in order to isolate the effect of a change in exploitation. The projection results show that catch with the new exploitation pattern is slightly lower than under the existing pattern in the early years of the projection, with the difference narrowing over time. More importantly, they also show that the probability of achieving the target SSB in 2009 increases from just over 50 percent to 69 percent, and there is nearly a 50 percent probability of achieving the target in 2008 (Table 76). This is likely due to the presence of a strong year class and its movement through the fishery. The dynamic effects of a change in mesh size for other stocks will depend on stock conditions, the exploitation pattern that results, and the realized fishing mortality rate.

The management alternatives developed in this amendment consider the impact of a mesh change as calculated by the YPR analysis, and take these expected impacts into account when designing the alternative to meet a specific objective. Table 76 is an illustration of the dynamic effects of a shift in exploitation pattern for a given fishing mortality rate and does not indicate results expected under this amendment.

Year	Ptarget(2009) (1)	Ptarget(2009) (2)	Catch (1)	Catch (2)
2002	0.000	0.000	9,236	6,932
2003	0.000	0.000	2,688	2,380
2004	0.000	0.000	4,006	3,724
2005	0.002	0.008	5,620	5,452

2007	0.108	0.232	8,307	8,191
2008	0.315	0.495	9,523	9,416
2009	0.507	0.688	10,557	10,475
2010	0.660	0.814	11,438	11,418

Table 76 – Probability of achieving SSB target for GOM cod (Ptarget) and expected catch (mt) under two mesh scenarios: (1) existing exploitation pattern; (2) exploitation pattern shifted one year, while fishing at the rebuilding mortality rate

Species without Selectivity Information

For some groundfish species that do not have selectivity information available, it is possible to use the YPR model to determine whether an arbitrary change in the exploitation pattern will result in a shift in the biological reference point. It is also possible to use the result of the YPR model to determine if, once equilibrium conditions are reached, the yield from the stock will increase or decrease. If the yield increases, long-term economic impacts from the mesh change should be positive (though there will likely be a loss of yield in the short term because of dynamic effects). This can only be done for stocks with a current age-based assessment and YPR model. If YPR declines, then the increase in mesh is resulting in a sacrifice in yield.

Concerns about potential loss of yield per recruit with increased mesh size have been raised. In order to address these concerns, the sensitivity of yield per recruit to a one year increase in selectivity at age was conducted for American Plaice, witch flounder, Georges Bank haddock, Southern New England/ Mid-Atlantic winter flounder, Georges Bank yellowtail, Cape Cod yellowtail, Southern New England yellowtail, and redfish. Yield per recruit analysis is used to evaluate the impact of age selectivity and fishing mortality rates on the expected yield per recruit over the lifetime of a cohort. The method incorporates fishing mortality rates, selectivity at age, natural mortality rate at age, somatic growth rates, and percent mature at age to determine yield per recruit.

Method

Yield per recruit input data for American Plaice, witch flounder, Georges Bank haddock, Southern New England/ Mid-Atlantic winter flounder, Georges Bank yellowtail, Cape Cod yellowtail, Southern New England yellowtail, and redfish were taken from NEFSC (2002a). Yield per recruit analyses in that report were duplicated using the NEFSC Yield and Stock size per recruit program, PDBYPRC PC ver. 2.0 found in Fishery Assessment Compilation Toolbox ver 1.50 (NEFSC 2001). New yield per recruit analyses were completed with fishing mortality at age advanced 1 year and the proportion of F in the first age in the YPR was set to zero. (Note: The advancement of fishery selectivity at age by one year is only for the purpose of conducting sensitivity analyses and is not related to expected change in selectivity of the proposed mesh size change for these species).

NEFSC 2002a recommended $F_{40\%}$ as a proxy for all the above stocks except Southern New England/ Mid-Atlantic winter flounder (F=0.32, from parametric SSB model) and Acadian Redfish ($F_{50\% MSP}$). Fmsy reference point for Southern New England / Mid-Atlantic winter flounder was estimated using a parametric spawning stock-recruit relationship combined with SSB/R analysis model. This reference point was not recalculated for a one-year increase in age selectivity. Therefore, the sensitivity of the Fmsy and yield per recruit at Fmsy to a one year shift in selectivity was not evaluated for this stock. However, sensitivity of F_{40} and $F_{0.1}$ and the corresponding yield per recruit to a one year shift in selectivity for Southern New England Mid-Atlantic winter flounder was evaluated.

Results

Results are summarized in Table 77**.** Yield per recruit increased at recommended fishing mortality threshold for all stocks (average 6.4%, range: 0.3 to 10.2%). Yield per recruit increased at $F_{0.1}$ for all stocks except Georges Bank haddock (-2.8%) and Southern New England/ Mid-Atlantic winter flounder (-0.10%). Overall, yield per recruit increase by an average 2.3%, range: -2.8 to 7.8%) with an increase of selectivity of one year. The recommended fishing mortality rate threshold increased by an average of 32% (Range: 0 to 48) and the $F_{0.1}$ increased 14% (Range: 6.8 to 17.8%)

Conclusion

Yield per recruit increased at $F_{40\% MSP}$ fishing mortality for all stocks and for 6 of 8 stocks at F0.1 for a hypothetical one year increase in age selectivity. Concerns about decreases in yield per recruit due to losses from natural mortality through increases in fishery selectivity are not supported by these sensitivity analyses. This analysis reflects results once equilibrium is achieved; as noted earlier, some loss in yield can be expected when the mesh change is first implemented.

Table 77 – Predicted changes in YPR assuming a one year shift in selectivity at age for eight groundfish stocks

[1] The Working group on Re-evaluation of biological reference points for New England Groundfish recommended $F_{40\%}$ as a proxy for all the above stocks except Southern New England/ Mid-Atlantic winter flounder (F=0.32, from parametric SSB model) and Acadian Redfish ($F_{50\% \, MSP}$). Fmsy reference point for Southern New England / Mid-Atlantic winter flounder was not recalculated for a 1 year increase in age selectivity.

5.2.6.1.4 Impacts of Changes in Gear Limits

This alternative would implement several gear changes that differ by area. With one exception (under this action trip gillnets in GB can use 150 nets), these changes are similar to those interim measures adopted August 1, 2002. These changes were analyzed in the EA accompanying those interim measures. The analysis is repeated here for clarity. The level of complexity involved with potential changes in gear and the myriad adaptive strategies that may result made it impossible to incorporate the biological impact of gear changes into the math programming model. To assess the potential impact of these changes, VTR data for trips landing regulated groundfish during fishing year 2000 were queried to ascertain area fished, catch, gear type, gear quantity, and mesh size. Each of these trips (approximately 22,500) was classified as being either a trawl, trip gillnet, day gillnet, or bottom longline trip. Each record was then examined to determine if the trip in question was already using conforming gear in terms of amount and size of gear; was using the conforming amount of gear but non-conforming size; was using conforming size but not conforming amount; or was not in conformance with either size or quantity of gear. Since hook size is not recorded on the VTR records, no analysis was possible on the minimum hook size. However, note that there is little available information on the selectivity of different size hooks. In fact, what information is available suggests that selection for larger fish is correlated with the size of the bait, rather than hook size.

Logbook records do not provide sufficient information about the size of catch. Therefore, no attempt was made to estimate the forgone yield associated with the proposed mesh size changes. However, the proportion of trips using conforming gear was estimated to provide a relative measure of what proportion of groundfish activity might be affected by the mesh size changes.

For gillnet and hook vessels, the change in numbers of nets or hook size may be more significant and provide greater biological impact than the change in mesh. In the absence of an explicit behavioral model to predict how vessels may adapt to these changes in amount of gear an estimate of the impact was developed by assuming that average landings rates (discards were not included) by species/stock per unit of gear fished (by net panel, or per hook) would be constant for all gear fished on the trip. In this manner, the biological impacts on trips where the observed quantity of gear fished would be greater than under the proposal may be estimated by multiplying the average landings by the gear limit. The resulting product provides a rough estimate of the biological impact of the changes in gear limits, exclusive of mesh.

Of the VTR-reported trips in the Northeast region, the largest proportion were taken by otter trawl vessels in the GOM (38.4 percent) (Table 78). Among other species, trawl trips landed 56.9 percent of GOM cod, 81.8 percent of GOM winter flounder, and 82.6 percent of GOM haddock. Compared to Trip gillnet vessels (4.7 percent of all trips), Day gillnet vessels accounted for proportionally more effort in terms of trips (16.1 percent), but Trip vessels landed almost as much GOM cod (18.4 percent as compared to 22.3 percent) as Day boats.

According to reported activity, 37 percent of all trips taken in the Northeast region would not be affected by either mesh or gear quantity, because both mesh size and quantity of gear used would be consistent with this alternative (Table 79). An additional 55.2 percent of trips would only be affected by the mesh change. These values include otter trawl vessels that would not be affected by any changes in quantity of gear fished. For the subset of vessels (hook and gillnet) that may be affected by changes in both mesh and quantity of gear, 55 percent of the 7,800 trips taken by these vessels were already in conformance with the proposed gear changes. An additional 22 percent of fixed gear trips would have to change mesh size, but would not be affected by the nominal reductions in gear. This leaves 23 percent of all fixed gear trips that would be affected by reductions in gear. In terms of landings, the fixed gear sector accounted for 18.3 percent of total groundfish landings, of which 12.9 percent of total landings would not be affected by a change in quantity of gear used, leaving a maximum biological benefit of approximately 5.4 percent for all regulated groundfish combined. This maximum benefit would only occur if all trips that used more than the proposed gear changes would allow were to be abandoned. Should vessels choose to fish with the reduced gear allowance, the biological impacts would be lower.

Based on the assumption that vessels do not abandon any trips, applying the average landing per unit of gear set results in an estimated aggregate reduction in regulated groundfish landings of 1.7 percent (Table 80). Across the species in the groundfish complex, estimated reductions exceeded 1 percent only for GOM cod (2.61 percent), GB cod (5.06 percent), pollock (3.99 percent), and redfish (1.99). Although the relative reduction for some species in some trip categories appears relatively large, the total reduction is low because the given category only accounts for small quantities of total landings. For example, the reduction in GB cod from Trip gillnet vessels was estimated to be almost 36 percent. However, cod landings from these trips only accounted for 1.1 percent of total GB cod landings in FY 2000. This means that the effective reduction in total GB cod landings is only 1.1 percent of 36 percent, or 0.4 percent. As noted at the beginning of this section, the proposed action differs from this analysis in that trip gillnet vessels are allowed to use 150 nets rather than 50 nets (the number of nets was limited only be vessel size prior to the interim action). If it is assumed that this does not represent any change in the way trip gillnet vessels fished in FY 2001, then the effective reduction for GB cod from this sector would be 0 percent rather than 1.1 percent, reducing the overall impacts of the gear changes to about 4 percent. It is more likely that at least some trips will be affected and the overall impacts would be between 4 and 5 percent.

Table 80 - Biological impact of gear quantity changes by trip type and species/stock

5.2.6.1.5 Other Measures

In addition to the changes noted above, this alternative will continue several measures implemented August 1, 2002 and analyzed in the accompanying EA. These include a prohibition on front-loading of the DAS clock, an increased minimum size for cod, prohibition on the use of de-hookers in the longline fishery, and changes to the large mesh permit category. The EA estimated that these changes would have little overall biological impact, with the exception of the increased minimum size. The increased minimum size may have resulted in an initial mortality benefit, but as cod grow and become susceptible to the gear, the benefits become similar to those that result from the mesh change (see above). The increase in minimum size may result in an increase in yield per recruit and an increase in the estimate of the F_{MSY} proxy, F40%.

5.2.6.1.6 Expected mortality reductions

For the measures that can be quantified, the expected reductions in fishing mortality upon implementation of the amendment are shown in Table 81. Refer to the discussion in section 5.1 for guidance in interpreting these tables. The three columns illustrate the range of reductions in fishing mortality that can be expected if different levels of Category A DAS can be used. The last column reflects the reduction needed to comply with the appropriate rebuilding strategy. These reductions have been adjusted to account for changes in selectivity for some stocks that are expected to result from the increases in mesh size. In some cases, the reduction in mortality expected from the proposed measures is greater than that required. The Council selected these measures fully understanding that these differences would occur.

The fishing mortality rates that are expected are shown in Table 82. *These expected rates do not reflect the impact of the proposed mesh changes*. As discussed earlier, mesh changes should result in a change in the partial recruitment pattern for most stocks. This will change the yield-per-recruit and will alter biological reference points. The dynamic effects of the mesh changes may also have more impact in the early years of the rebuilding program. To reiterate, the changes in mesh are evaluated based on how they will affect reference points. This is reflected in the "necessary reductions" column of Table 81, rather than in the expected fishing mortality rates shown in Table 82. The results in this table show that for almost all stocks and under all scenarios considered for the impact of the proposed action on the number of DAS used, the mortality objectives will be met for the appropriate rebuilding strategies.

There are two stocks that the model results indicate will need careful monitoring. The closed area model predicts that fishing mortality for GOM cod, if 95 percent of allocated DAS are used, may be twenty-six percent higher than the current estimate of $F_{MSY.}$ This current estimate of F_{MSY} does not take into account the mesh increases proposed in this amendment. If the change in mesh selectivity is as effective as expected, then the mortality predicted by this scenario will meet the objectives of the amendment. In the case of witch flounder, the results suggest that overfishing may not be ended immediately for this stock, though the dynamic effects of the mesh increases on this slow growing species may be more than predicted. In the short term, the witch flounder stock is growing rapidly and is projected to increase above SSB_{MSY} with a fishing mortality rate well above F_{MSY}. The proposed action includes a default DAS reduction that will be implemented in 2006 that should insure that overfishing is ended on this stock

5.2.6.1.7 Category B DAS

The proposed action defines some DAS as Category B (regular) or Category B(reserve) DAS. Catches of groundfish on a Category B DAS are not estimated in the closed area model and must be evaluated outside the model. In concept the B (regular) DAS can be used to target healthy stocks outside of a special access program. The restrictions and opportunities for using Category B (regular) DAS outside of a special access program have not yet been defined. Either type of Category B DAS can be used in an approved special access program.

There are three SAPs proposed that are available for Category B DAS (a fourth program does not require the use of Category B DAS). Estimates of the likely catch of groundfish while participating in the Closed

Area II GB Yellowtail Flounder SAP are described in section. Estimates of the catch of winter flounder in the SNE/MA winter flounder SAP are described in section 5.2.4.6.2. Because of a lack of experimental data, estimates are not available for the other two SAPs.

Vessels participating in the CA II yellowtail flounder SAP are allowed to fish in statistical areas 561 and 561 (Canadian areas 5zjm) using B DAS while participating in the SAP. Based on observer and experimental data, they can be expected to catch GB haddock, GB winter flounder, and GB cod while fishing in this area. The analysis in section 5.2.4.6.1 suggests that vessels participating in this SAP may catch 301 mt of cod, 709 mt of haddock, and 2,355 mt of winter flounder while using roughly 800 B DAS on 320 trips. These estimates are subject to uncertainty over the exact impacts of the haddock separator trawl, which is known to reduce cod and flounder catches while fishing for haddock. Given that the proposed action is expected to reduce mortality for both GB haddock and winter flounder more than is necessary under all three assumed used DAS scenarios, the catches resulting from this program should prevent achieving the biological objectives for those two stocks. If the US/CA Resource Sharing Understanding is implemented, both GB cod and GB haddock in the area will be subject to a hard TAC. Assuming adequate observer coverage to estimate discards, the catch of GB cod should remain within targeted limits. There is a strong incentive for vessels fishing in the area to avoid GB cod since if they do not, most of the area will be closed to fishing for groundfish and they will be unable to target healthy haddock and yellowtail stocks in the area.

The proposed SAP that allows retention of small amounts of SNE/MA winter flounder while fishing for fluke is discussed in section 5.2.4.6.2. This SAP does not require the use of any DAS. It is intended to convert discards of winter flounder into landings, thereby reducing bycatch consistent with the requirements of the M-S Act. While limited sea sampling data suggests that fluke and winter flounder are rarely caught on the same trips, VTR data suggests the opposite. Based on this analysis, it appears that this program may convert about 200 mt of discards into landings. This does not represent an increase in mortality. It is possible, however, that fishing effort could increase. Some fluke vessels have used a groundfish DAS in the past to land small amounts of winter flounder while on a fluke trip. This SAP will exempt them from having to do so. Those DAS are thus available for the fluke vessels to use on targeted groundfish trips taken at some other time, using groundfish mesh. The proposed action, however, is expected to reduce fishing mortality on SNE/MA winter flounder more than is necessary. The target TAC will be approximately 2,800 mt in the first year of the program. Landings in calendar year 2002 reached this amount, but landings in calendar year 2003 through August were about half the previous year, even though overall DAS use had increased. The proposed measures are more restrictive than the current measures. These observations suggest that it is not likely the target TAC for SNE/MA winter flounder will be exceeded if this SAP is authorized.

The US/CA Resource Sharing Understanding SAP allows vessels to fish for ten months of the year in the northern part of CA II to target haddock. Vessels on these trips can also fish in statistical areas 561 and 562 (5zjm). There is little data available to estimate catches on these trips. Observer data show that cod and haddock are frequently caught on tows in statistical area 561 and 562. While the haddock separator trawl should help reduce cod catches, the main control on this program will be the hard TAC adopted for the area. This will prevent the program from threatening the rebuilding programs for GB cod and GB haddock.

5.2.6.2 No Action Alternative (not selected)

Under the no action alternative, fishing mortality is expected to remain at 2001 levels, described in section 9.2.1.1. M-S Act requirements to achieve rebuilding and end overfishing will not be met. Age-based projection results are shown in the no action fishing mortality levels in Table 83. This table illustrates the expected stock size and catch if the no action mortality (2001 fishing mortality) is maintained. Projected stock size and landings are shown for 2026, after the end of the proposed GB cod rebuilding period but well before the end of the redfish rebuilding program. For these ten stocks with age-based projection results, SSB should more than double, while catch of these stocks will increase by 64 percent. Stocks and landings of plaice, witch flounder, and CC/GOM yellowtail flounder are projected to decline, and stock size and landings for the other seven stocks will increase. For those stocks that are projected to increase, the projected stock size in 2026 approaches or exceeds the highest levels estimated in the VPA time series. (Projected stock size over long time periods are subject to error as a result of the difference between projected and observed recruitment).

Stock	Median SSB ('000 mt)		Median landings ('000 mt)	
	2002	2026	2002	2026

SSB = spawning stock biomass

5.2.6.3 Alternative 1 – Up to 65 percent reduction in DAS

This alternative incorporates up to a 65 percent reduction in used DAS with the management measures implemented August 1, 2002. These measures were previously analyzed in an EA (NMFS 2002). Additional possession limits and gear restrictions are also applied.

This alternative was not selected.

5.2.6.3.1 Closed Area Model

The Closed Area Model (section 5.1.1) was used to estimate the biological impacts of the following elements of this alternative:

- Year round closed areas
- Seasonal closed areas

- Trip/possession limit.
- Reductions in used DAS: There are two alternative DAS reductions. The first option is a 55 percent DAS reduction designed to meet the mortality objectives of the constant F or adaptive rebuilding strategies. The second option phases in a 65 percent DAS reduction over time. For the second option, only the impacts of the first year's mortality reduction are modeled. Results for these two options are shown separately.

The changes in exploitation predicted by the model are shown in Table 84 below. These changes in exploitation will be combined with the impacts of other measures to provide an estimate of the expected change in fishing mortality.

	GOM	GB	SNE	Cape/GOM	SNE/Mid-Atlantic	All Loc
Cod	-45.5%	-43.4%				
Haddock	-47.7%	-44.2%

Table 85 – Changes in exploitation for first year Alternative 1 under the phased reduction rebuilding strategy, with a 35 percent reduction in used DAS the first year

5.2.6.3.2 Gear Restrictions

5.2.6.3.3 Mesh Size Changes

This alternative includes measures that would change mesh regulations for trawl and gillnet vessels, increasing both trawl and gillnet mesh compared to the No Action alternative. Expected impacts were analyzed in the Environmental Assessment (EA) accompanying the Interim Action to Implement Measures to Reduce Overfishing of the Northeast Fishery Complex Under the Northeast Multispecies Fishery Management Plan (NMFS 2002). Refer to the gear impacts under the proposed action for this information

5.2.6.3.4 Impacts of Changes in Gear Limits

This alternative would implement several gear changes that differ by area. With one exception (under this action trip gillnets in GB can use 50 nets), these changes are similar to those described for the proposed action. The difference in the number of trip gillnets on Georges Bank means that the gear changes in this alternative have a slightly greater impacts on GB cod. Refer to the proposed action discussion for information on the effects of gear changes.

5.2.6.3.5 Additional Gear Restrictions

This alternative includes two options for the requirement to use a raised footrope trawl in the inshore GOM in order to reduce catches of CC/GOM yellowtail flounder. The raised footrope trawl was designed to facilitate whiting fishing while avoiding the catch of flounders, especially CC/GOM yellowtail flounder. A series of experimental fisheries demonstrated its effectiveness. The raised footrope trawl has proven effective at reducing yellowtail landings, meeting the 5 percent exempted fishery standard in block 124 for a whiting fishery (see Framework 35). This requirement differs from the net used in the experimental and exempted fisheries, as vessels will be required to use the net with large mesh rather than the smaller whiting mesh. The design has not been tested with large mesh, but it is not likely that more flounders will be caught than with the whiting mesh. The impacts of this requirement depend on the area where the net is required, as well as the amount of effort expended in that area.. Rather than estimate the number of trips, or tows that will use the net, the following analysis assumes the relative proportion of effort on yellowtail flounder remains the same by area., and reflects a relative change in exploitation for this stock. In this way the change in exploitation can be combined with the results from the closed area model to estimate the total change in exploitation for this stock.

Option 1 requires the net in specific thirty-minute blocks. Trawl landings from these blocks account for approximately 40 percent of the total CC/GOM yellowtail flounder landings. If the net reduces these landings by 95 percent, the expected reduction in exploitation would be about 38 percent, assuming that there is no shift of effort into the area.

Option 2 requires the net in statistical areas 514 and 521. Trawl landings from these two areas averaged 75 percent of the total CC/GOM yellowtail flounder landings (fishing years 1995 through 2001). If the net reduces these landings by 95 percent, the expected reduction in overall landings would be about 70 percent, assuming that there is no shift of effort into the area.

While this requirement is designed to reduce yellowtail catches, it can also be expect to reduce landings of other species. The most likely species to be affected are flatfish such as plaice, which are also targeted in this area (this stock is also in need of a mortality reduction). The impact of the net on cod or other roundfish is not certain. Massachusetts DMF conducted an experiment that compared catches of a raised footrope trawl to a normal whiting trawl in 1997. A total of 68 paired tows were observed on three different vessels, with all fishing conducted in the inshore GOM. While cod catch rates were generally low, ranging from 0 to 140 lbs/hour for both nets, no significant difference in cod catches were found between the two types of net, suggesting that this net will still allow catches of cod (Mike Pol, pers. comm.). If there is any impact, however, it is likely the net may reduce cod catches.

One factor that cannot be evaluated is the impact of the net on fishermen's behavior. If the net is successful in reducing yellowtail flounder catches significantly, it may result in a redirection of effort onto other stocks.

5.2.6.3.6 Other Measures

In addition to the changes noted above, this alternative would continue several measures implemented August 1, 2002 and analyzed in the accompanying EA. These include a prohibition on front-loading of the DAS clock, an increased minimum size for cod, prohibition on the use of de-hookers in the longline fishery, and changes to the large mesh permit category. The EA estimated that these changes would have little overall biological impact, with the exception of the increased minimum size. The increased minimum size may have resulted in an initial mortality benefit, but as cod grow and become susceptible to the gear, the benefits become similar to those that result from the mesh change (see above).

5.2.6.3.7 Summary

Four tables present the expected biological impacts of this alternative. The combined impacts of Alternative 1A (for the measures that can be quantified) are estimated in Table 86 for the 55 percent DAS reduction necessary to meet the constant fishing mortality and adaptive fishing mortality rebuilding strategies. Impacts of Alternative 1C, using the same DAS reduction but with a different GB cod trip limit, are shown in Table 88. There are only minor differences in the expected results. With the exception of white hake, the reductions in mortality expected in these alternatives meet or exceed the necessary reduction for all rebuilding alternatives. Measures that will reduce white hake mortality that cannot be quantified primarily include the mesh increase. Selectivity information for white hake is not available. Selectivity of white hake will likely change given the mesh increases proposed. If this results in a change in reference points of 10 percent or more (as explained above for other stocks), the fishing mortality reductions expected from this alternative will be very close to that needed for this stock.

The combined impacts for the first year of the phased reduction strategy – Alternative 1B, using a phase-in of the DAS reduction – are shown in Table 87. Impacts of Alternative 1D, using the same DAS reduction but a lower GB cod trip limit, are shown in Table 89. (Note that reductions necessary under other rebuilding strategies are not shown in these tables because this alternative is not consistent with those strategies). With the exception of white hake and witch flounder, these alternatives meet the necessary reduction for all stocks. DAS reductions in future years should address the concern over ending overfishing on witch flounder, and additional reductions can be expected for white hake due to the mesh increase as explained in the previous paragraph.

5.2.6.4 Alternative 2 – Reduction in Allocated DAS/Gear Modifications

Alternative 2 builds on the measures implemented August 1, 2002 by adding additional gear requirements, reducing the GB cod trip limit, and by providing two approaches to DAS use in the GOM. In addition, in order to insure that the biological objectives are met, a hard TAC system is overlaid as a backstop. Both the closed area model and the hard TAC/trip limit models were used to quantify potential impacts. These models attempt to quantify impacts differently; both sets of results are reported and, while they differ in magnitude, the direction of the impacts is essentially the same. Many of the measures in this alternative were analyzed in the EA accompanying the measures implemented August 1, 2002 and are not re-analyzed in this section. This alternative was not selected.

5.2.6.4.1 Closed Area Model

The Closed Area Model (section 5.1.1) was used to estimate the economic impacts of the following elements of this alternative:

- Year round closed areas
- Seasonal closed areas
- Trip/possession limits
- Reductions in allocated DAS
- Hard TAC

The use of the closed area model differed from its use in the EA. For the measures implemented August 1, 2002, the EA assumed that because the total number of allocated DAS exceeded the DAS used in the previous fishing year, the reduction in allocated DAS would not have any impact on DAS use. Since May 1, 2002, DAS use has been about 60 percent of DAS use in the previous year, suggesting that the EA assumption on DAS use may have been incorrect. In this analysis, the reduction in allocated DAS is assumed to result in a similar reduction in used DAS. Thus, this analysis may be a best-case scenario.

The modeling of a hard TAC also created difficulties for the use of the model. The Hard TAC options were approximated by individually allocating each vessel quota based on their landings in the status-quo model run and percentage change in expected landings under a quota. It should be noted that in theory the expected biological outcomes should be similar for all options using an overall hard TAC. However, this may not hold when modeled at the individual vessel level due to the influence of other management measures on each vessel. In effect, what has been modeled are individual vessel quotas. This was necessary to simulate the economic impacts of these alternatives. In essence, the TAC was assigned to each vessel according to its past catch history, and a vessel stopped fishing for that species when its allocation was caught. Even though the hard TAC should assure that the biological objectives are met, the model was run both to help in the analysis of distributive impacts and to see how overall mortality might be affected. Because the model optimizes each vessel's fishing patterns, interactions between vessels were not possible to capture, meaning the "race to fish" which is prevalent in many quota systems was not part of the model. The model chose locations and times for each vessel to fish in order to maximize its revenue, while meeting their individual quota constraints. For stocks which were caught in the same space and time as those constrained by the quota for a vessel, the model would not allow that vessel to fish at those locations once TAC constraints were met. This is similar to the option that would require an area to close when a TAC is caught, though that decision would be based on the performance of all vessels, rather than one vessel. While it may be possible that future changes in gear or fishing technique might allow fishing for one stock after the TAC for a different stock is caught, at present there are few, if any, such adaptations identified. Therefore, the model would project reductions in mortality for those stocks. Whether these reductions actually occur depends on how the TAC system is administered. Mortality could increase on all stocks if fishing were allowed to continue in areas once TACs were met, but with high levels of discards.

The use of hard TACs reduces the need to estimate the biological impacts of this alternative. The predicted changes in exploitation from the closed area model and a summary of the biological impacts without the inclusion of the hard TAC are shown below. This information can be used to show how likely it is that the hard TAC backstop will be imposed. For stocks where the effort control measures fall short of the necessary mortality reduction, it is more likely that a hard TAC will be imposed during the fishing year. The greater the gap between the necessary reduction and the amount of a reduction expected from the effort controls, the earlier in the fishing year the TAC will be reached.

5.2.6.4.2 Hard TAC/Trip Limit Model Results

As noted above, the closed area model does not capture any derby impacts of the proposed alternative. Under the closed area model, each vessel is allowed to catch its "share" of the quota without regard to the performance of other vessels. Derby impacts are well documented in the literature for fisheries that do not assign quotas to individual vessels (for example, Morgan 1997). The hard TAC/trip limit model was also applied to the measures in rebuilding Alternative 2 to attempt to capture derby impacts associated with this alternative, and to quantify the impacts of trip limits that take effect once a portion of a TAC is reached. These derby impacts are well documented in the literature for fisheries that do not assign quotas to individual vessels (for example, Morgan 1997). This model is more accurately tuned to the specifications of the rebuilding alternatives in that it accounts for increased fishing pressures early in the fishing year, and estimates trip limits and consequent discards that correspond to the TAC thresholds specified in the management measures. Specifically, the model was calibrated in the same manner as the closed area model to account for the raised footrope trawl in areas 514 and 521 and the haddock separator trawl on Georges Bank. If the more specific 30 minute square option is chosen for the raised footrope trawl, then the impacts will be lessened and TACs likely will be achieved sooner.

Because the model is based on actual fishing behavior from FY 2001, it does not account for changes in fishing practices that may occur as TACs are reached and trip limits are instituted; this is a major advantage of the closed area model (see previous section).

GOM haddock, GB haddock, Pollock, redfish, GOM winter flounder, GB winter flounder, northern and southern windowpane flounder, GB yellowtail flounder and witch flounder are not predicted to reach the TAC threshold. If the option to close a stock area once TACs are achieved for a particular stock is selected, alternative 2 may meet biological objectives (though areas could be closed as soon as one week into the fishing year). However, if retention of impacted species is prohibited, analysis indicates that TACs may be legally exceeded by large amounts.

5.2.6.4.3 Other Measures

This alternative builds on the measures implemented August 1, 2002. Those measures were analyzed in the EA that accompanied them, and pertinent parts of that analysis are repeated in Alternative 1. For those measures that can be quantified, the estimates from the EA will be combined with the closed area model to estimate reductions in fishing mortality.

A number of additional gear requirements are proposed in this alternative and the likely biological impacts are described below. Much of this discussion is moot if the TACs are appropriately set and effectively monitored, as the fishery for a species will close when the TAC is caught.

Trawl Gear Requirements

The proposed action requires the use of a haddock separator trawl or a flounder net on Georges Bank and in the area of the GOM inshore of 70W. The haddock separator trawl minimizes the catch of cod through a design which considers the behavior of fish in response to the gear. Generally, haddock swim to the upper part of a net and cod swim to the lower part of the net. By inserting a mesh panel in the net, and using two cod ends, the catch can be effectively divided. If the cod end on the lower part of the net is left open, the cod escape. This net has been in use for some time by Canadian vessels fishing on Georges Bank under a quota system. With low cod quotas, Canadian vessels have had to develop ways to minimize cod catch in order to take advantage of higher haddock quotas. A Canadian DFO project studied the effectiveness of a haddock separator trawl while conducting over 150 tows in 1990 and 1991. These experiments showed about 60% of the cod caught in the bottom of the trawl, with a range from 75 percent to 40 percent. Additional data was collected on pollock, silver hake, plaice, yellowtail, winter flounder, halibut, and mackerel. Nearly all pollock was caught in the top cod end, silver hake was split evenly between the two, and most flounders were caught in the bottom cod end. The report also notes that skates and sculpins were caught almost entirely in the bottom cod end and were nearly completely absent in the top cod end, though data were not reported on numbers and weights of these two species (DFO 1992). Engas et al. (1998) conducted experiments in Norwegian trawl fisheries using a separator panel and found similar results. 90 percent of the haddock were caught in the upper cod end, and between 60 and 70 percent of the cod were caught in the lower cod end. Engas et al. also noted some shifts in size selectivity, and commented that the height of the separator panel was critical and may differ from area to area. One Canadian fleet owner recently reported that when effectively tuned, the net caught 95 percent of the haddock in the top end and 60 percent of the cod in the lower end (which would be released with an open cod end) (d'Entremont, per. comm. 2002).

A large percentage – approximately 60 percent in recent years - of both GB and GOM cod is caught on trawl trips (see MSMC 2001, Appendix VI and Table 78). In the GOM, a large percentage is caught in the inshore areas (about 50 percent of the total is trawl caught in this area) that will require the use of this net (see Volume II). While the documented evidence is that 60 percent of the cod caught will be in the bottom half of the net and will escape, there may be some time until the appropriate height is determined for the panel in this area. Still, even if the panel is only half as effective as documented, the use of the panel could reduce GB cod catch by about 20 percent of the total catch and GOM cod by 15 - 30 percent of the total catch. There will likely be benefits as well to flounders, as the behavior of these fish is to stay low in the net, a trait used effectively in the design of the raised-footrope trawl. There is no documentation, however, on how effective this will be.

The impacts of the required flounder net are more difficult to analyze. A normal, two–seam flounder net without heavy ground gear can be used to target cod in certain areas. According to fishermen the net is not as effective as a traditional cod net, and may preclude vessels from fishing in some areas, depending on the design specified by the RA. Other flounder net designs, however, have proven very effective at minimizing cod catch. Two net designs tested by Massachusetts DMF – the so-called topless net and a net with a square mesh panel first designed by a local fisherman – were able to reduce cod catches by 70 to 90 percent (Carr et al. 2001).

This alternative also requires use of a raised footrope trawl in the area where most CC/GOM yellowtail flounder is caught. About 80 percent of CC/GOM yellowtail landings are by trawl gear. The raised footrope trawl has proven effective at reducing yellowtail landings, meeting the 5 percent exempted fishery standard in block 124 for a whiting fishery (see Framework 35). This option requires the net in specific thirty-minute blocks. Trawl landings from these blocks account for approximately 40 percent of the total CC/GOM yellowtail flounder landings. If the net reduces these landings by 95 percent, the expected reduction in exploitation would be about 38 percent, assuming that there is no shift of effort into the area. See section 5.2.6.3.5 for an additional discussion of this measure.

In summary:

- The haddock separator net may reduce GB cod catches by a conservative estimate of 20 percent of the total catch, but could range as high as 40 percent
- The separator trawl may reduce GOM cod overall catches by 15 to 30 percent.
- The required use of a flounder net may reduce cod catches, but it is uncertain how much until the required net design is identified by the RA.
- The raised footrope trawl could reduce total CC/GOM yellowtail flounder catches by approximately 40 percent.
- The impacts of these changes in trawl gear on other species are unknown.
- The attribution of catch reductions based on gear changes is somewhat speculative given the lack of documented results for some for some of the gear suggested.

Gillnets
The number of gillnets proposed (50) in the inshore area was analyzed in the EA. This alternative also prohibits use of tie-down gillnets in the primary stock area for CC/GOM yellowtail flounder. While gillnets catch 15 – 20 percent of the CC/GOM yellowtail flounder in this area, it is not known how the prohibition on tie-down nets will affect their catch. In addition, this may encourage gillnet fishermen to target cod or other roundfish, benefiting one stock while harming another.

Longlines
Longline vessels are limited to 1,000 hooks per day. This will have no significant impact on GOM stocks, as the longline fishery catches very little in this area. In GB, longline vessels are a key component of the cod fishery, taking between 10 and 20 percent of the catch in recent years. The number of hooks proposed is 22 percent of the hooks allowed under the no action alternative. A preliminary estimate, then, is that this alternative could reduce GB Cod catches by 80 percent of the longline catch, or 8 to 15 percent of the total cod catch.

5.2.6.4.4 Summary

The use of a hard TAC insures that this alternative will meet the biological objectives, though if fishing is permitted after the TAC is achieved (the zero-retention option) then TACs are likely to be exceeded. The other measures provide additional insurance that the TAC will not be rapidly exceeded. In addition, some changes could not be estimated but are believed to provide additional mortality benefits (prohibition on the use for gillnet tie-down nets in the certain areas in the GOM, for example). Both alternatives meet the mortality objectives for all stocks. In some cases, this alternative results in the least reduction on stocks (such as GB yellowtail and GB winter flounder) that do not need significant reductions.

The two tables that follow show a large gap between the expected biological impacts that result from the effort control measures in this alternative for SNE/MA yellowtail flounder, SNE/MA winter flounder, white hake, and witch flounder. This suggests that the TAC for these stocks will be the primary constraint on fishing mortality.

5.2.6.5 Alternative 3 – Area Management

This alternative adopts an area management approach. Until/unless implemented and new regulations are adopted for specific areas, the alternative layers an area-specific hard TAC system onto the measures implemented August 1, 2002. The combination of a hard TAC and the August 1, 2002 measures is analyzed in section 5.2.6.6.

5.2.6.5.1 Closed Area Model

The Closed Area Model (section 5.1.1) was used to estimate the economic impacts of the following elements of this alternative:

- Year round closed areas
- Seasonal closed areas
- Trip/possession limits
- Reductions in allocated DAS
- Application of hard TAC

The use of the closed area model differed from its use in the EA. For the measures implemented August 1, 2002, the EA assumed that because the total number of allocated DAS exceeded the DAS used in the previous fishing year, the reduction in allocated DAS would not have any impact on DAS use. Since May 1, 2002, DAS use has been about 60 percent of DAS use in the previous year (see Volume II), suggesting that the EA assumption on DAS use may have been incorrect. In this analysis, the reduction in allocated DAS is assumed to result in a similar reduction in used DAS. That is, the twenty percent reduction in allocated DAS is expected to result in a similar reduction in used DAS. This assumption appears valid based on DAS use in 2002 and 2003. In fishing year 2003, total DAS used declined by thirty-seven percent from the previous year. In fishing year 2003 to date, DAS use is running 16 percent higher than in 2002, which would result in a DAS reduction of about twenty-seven percent fro 2001 if that rate continues.

This alternative uses a hard TAC to ensure the biological objectives are met. The changes in exploitation that result from the closed area model without the hard TAC incorporated can be used to indicate the stocks for which the hard TAC is the primary mortality control (similar to what was done for Alternative 2).

	GOM	GB	SNE	Cape	Mid-Atlantic	All Loc
Cod	-18.9%	-8.9%				
Haddock	-13.1%	-10.0%				
Winter Fldr.	-15.5%	-10.5%	-0.1%			
Yellowtail		-6.6%		-13.8%	-14.9%	
Windowpane	-4.4%					
Plaice						-14.7%
Witch Fldr.						-11.8%
Pollock						-8.4%
Redfish						-11.7%
White Hake						-11.3%

Table 96 – Changes in exploitation for Alternative 3 without applying the hard TAC.

5.2.6.5.2 Additional Measures

This alternative extends the measures implemented August 1, 2002 that were analyzed in an EA accompanying the measures. The measures implemented August 1, 2002, and continued forward in this alternative, included:

- Changes in gear requirements: mesh size increases, changes in the number of gillnets, changes in the number of hooks and hook size, limits on the use of de-hooking devices, etc.
- Prohibition on front-loading of the DAS clock
- Changes to the large-mesh program
- Changes in minimum cod size

The most significant of these measures is the change in mesh size in almost all areas, coupled with the reductions in number of gillnets for various gillnet categories. The EA determined that the prohibition on front-loading of the DAS clock will have few impacts because of the restricted DAS levels. The mesh change will achieve, at best, an additional 10 percent reduction in mortality once equilibrium is achieved. The impacts of changes in gear requirements are explained in the previous section, and are relatively minor for most stocks.

5.2.6.5.3 Summary

The application of a hard TAC will achieve all biological objectives. One possible adverse outcome of the area and species specific TACs may result if areas are selected that do not align closely with stock boundaries. The catch of a species in an area may be a combination of several stocks. For example, under some alternatives, the Western Georges Bank area includes Cape Cod, Southern New England, and Georges Bank yellowtail flounder. These are combined into one yellowtail flounder TAC for the area. If fishing patterns focus on one stock of fish in an area, then it is theoretically possible to overfish one stock of yellowtail in this area while remaining below the overall species/area TAC. To some extent, this may be mitigated by the fact the calculation of the TAC takes into account – in a crude way – the distribution of fishing effort on each stock.

Similar to the other options that use a hard TAC, the following table shows the expected reduction in fishing mortality that results from the effort control measures that can be quantified. Once again, the difference between the expected reduction and the necessary reduction indicate the stocks where the TAC will be the primary constraint on fishing mortality. For this alternative, it is clear that the TAC is critical to achieving the biological objectives. This is consistent with the conclusion that the court-ordered measures, by themselves, are not sufficient to rebuild overfished stocks and thus those measures were rejected by the Council (absent a hard TAC – see section 4.2.2).

Table 97 – Estimated mortality reductions under Alternative 3, without application of hard TAC. This table illustrates the mortality reduction expected from the effort control measures in this alternative.

5.2.6.6 Alternative 4 – Hard TAC

This alternative layers a hard TAC approach over effort controls. There are two options for effort controls: measures in place in fishing year 2001, and measures implemented August 1, 2002. The results are incorporated into the analysis of this approach using both the closed area model and the hard TAC/trip limit models. These models attempt to quantify impacts differently; both sets of results are reported and, while they differ in magnitude, the direction of the impacts is essentially the same.

5.2.6.6.1 Closed Area Model Results

The closed area model (GAMS, section 5.1.1) was used to estimate the economic impacts of the following elements of this alternative:

- Year round closed areas
- Seasonal closed areas
- Trip/possession limits
- Reductions in allocated DAS
- Application of hard TAC

The use of the closed area model differed from its use in the EA. For the measures implemented August 1, 2002, the EA assumed that because the total number of allocated DAS exceeded the DAS used in the previous fishing year, the reduction in allocated DAS would not have any impact on DAS use. Since May 1, 2002, DAS use has been about 60 percent of DAS use in the previous year (see Volume II), suggesting that the EA assumption on DAS use may have been incorrect. In this analysis, the reduction in allocated DAS is assumed to result in a similar reduction in used DAS. Thus, this analysis may be a best-case scenario.

The modeling of a hard TAC also created difficulties for the use of the model. In essence, the TAC was assigned to each vessel according to its past catch history, and a vessel stopped fishing for that species when its allocation was caught. Even though the hard TAC should assure that the biological objectives are met, the model was run both to help in the analysis of distributive impacts and to see how overall mortality might be affected.

The use of hard TACs to insure the objectives are met eliminates the need to estimate the impacts of this alternative. Changes in exploitation, and a summary table of the biological impacts, are not presented for this reason.

5.2.6.6.2 Additional Measures

This alternative extends the measures implemented August 1, 2002 that were analyzed in an EA accompanying the measures. The measures implemented August 1, 2002, and continued forward in this alternative, include:

- Changes in gear requirements: mesh size increases, changes in the number of gillnets, changes in the number of hooks and hook size, limits on the use of de-hooking devices, etc.
- Prohibition on front-loading of the DAS clock
- Changes to the large-mesh program
- Changes in minimum cod size

The most significant of these measures is the change in mesh size in almost all areas, coupled with the reductions in number of gillnets for various gillnet categories. The EA determined that the prohibition on front-loading of the DAS clock will have few impacts because of the restricted DAS levels. The mesh change will achieve, at best, an additional 10 percent reduction in mortality once equilibrium is achieved. The impacts of changes in gear requirements are explained in the previous section, and are relatively minor for most stocks.

5.2.6.6.3 Hard TAC/Trip Limit Model Results

The hard TAC/trip limit model was applied to the measures in rebuilding alternative 4 to attempt to capture the derby impacts associated with hard TAC fisheries, and to quantify the impacts of trip limits that take effect once a portion of a TAC is reached. These impacts are well documented in the literature (for example, Morgan 1997). This model is more accurately tuned to the specifications of the rebuilding alternatives in that it accounts for increased fishing pressures early in the fishing year, and estimates trip limits and consequent discards that correspond to the TAC thresholds specified in the management measures. Because the model is based on actual fishing behavior from FY 2001, it does not account for changes in fishing practices that may occur as TACs are reached and trip limits are instituted; this is a major advantage of the closed area model (above).

The hard TAC/trip limit model was run two ways for rebuilding alternative 4. The first assumes that effort controls (DAS) in place in FY 2002 are utilized, while the second assumes that effort controls (DAS) in place in FY 2001 are utilized. The principal difference is the lower trip limits that result from the great DAS allocations under the FY 2001 effort control measures.

GOM haddock, GB haddock, Pollock, redfish, GOM winter flounder, GB winter flounder, northern and southern windowpane flounder, GB yellowtail flounder and witch flounder are not predicted to reach the TAC threshold. If the option to close a stock area once TACs are achieved for a particular stock is selected, alternative 4 may meet biological objectives (though areas could be closed as soon as one week into the fishing year). However, if retention of impacted species is prohibited, analysis indicates that TACs may be legally exceeded by large amounts. For example, under the constant mortality rebuilding strategy, discards after the TAC is reached may be as much as 2.5 times the TAC itself.

5.2.6.6.4 Summary

The use of a hard TAC insures the biological objectives are met for all stocks. If the TAC is applied to the measures in Alternative 2 (as a hard TAC backstop), the analysis of the impacts in section 5.2.6.4 shows the stocks for which the TAC is the primary mortality control. If the TAC is used with the FW 33 court-ordered measures, section 5.2.6.5 shows similar information. If the TAC is applied to the no action management measures, the TAC becomes the primary restriction on mortality for all stocks that need a reduction. The following tables shows the expected mortality reductions that will result if the TAC is applied to the FW33 court ordered measures.

Stock	2001 Fishing Mortality	Needed Reduction 2014 Rebuilding Date for Most Stocks			Expected Reduction
		Constant F	Phased F	Adaptive	
GB Cod	0.38	53%	+13%	53%	64%

5.2.6.7 Recreational Fishing Measures

The biological impacts of the proposed recreational fishing measures are presented in this section. At present, recreational harvest is only included in the estimates of fishing mortality for GOM cod and SNE/MA winter flounder. The proposed measures focus on reducing cod catch, so the following analysis focuses on the impacts on GOM and GB cod. The impacts on haddock stocks are also of interest, but the recreational data for haddock catches is sparse.

The biological impacts of the recreational measures were estimated using a simulation model of recreational trips where Atlantic cod were harvested (MRFSS Type A+B1 catch) by stock area. Data included landings distributions by catch class (numbers of fish harvested) and size class by stock area and mode (party/charter and combined private boat and shore). The harvest distributions were estimated from pooled 1998-2000 weighted average MRFSS data (see Figure 121 through Figure 128). For any given trip, the harvest distribution describes the number of cod that may be retained and the size distribution provides an estimate of the size composition of retained catch. By repeatedly sampling from the harvest distribution and applying the size distribution the expected value (or average) of numbers of cod harvest per trip and the average size is obtained. Further, by applying a length-weight equation, the average weight of harvested cod can also be estimated. Given these averages, total harvest in numbers can then be calculated by multiplying average harvest by total number of trips. Total harvest by weight can be similarly calculated.

The proposed action adopts Option 3.

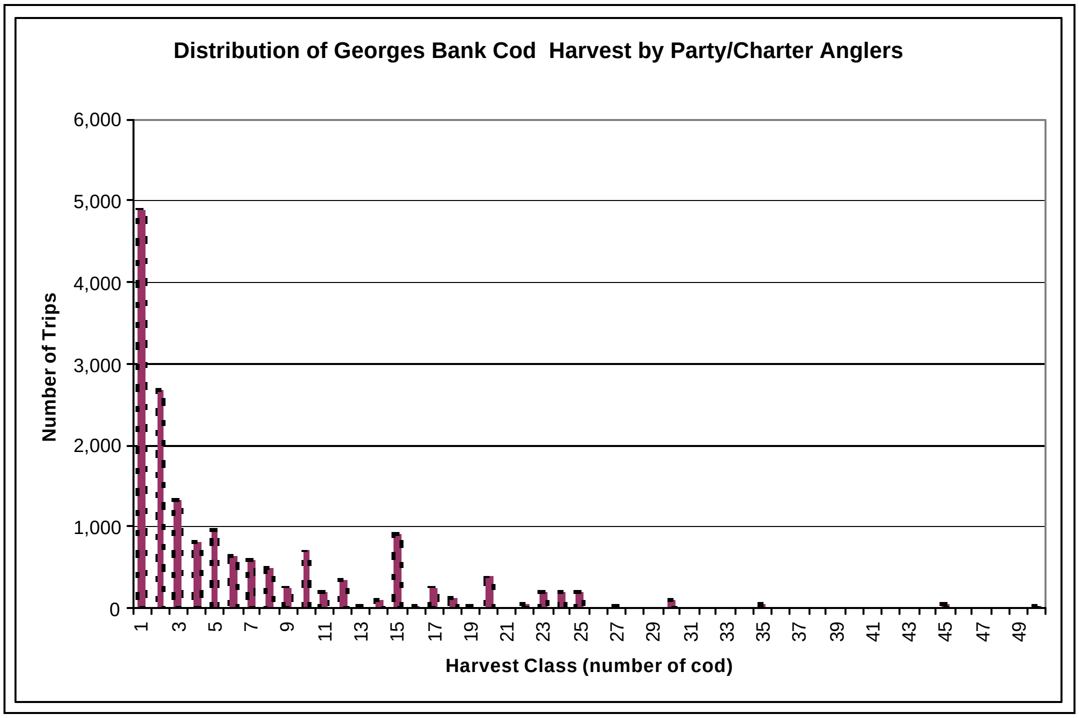

Figure 121 – Harvest distribution, GB cod, party/charter anglers

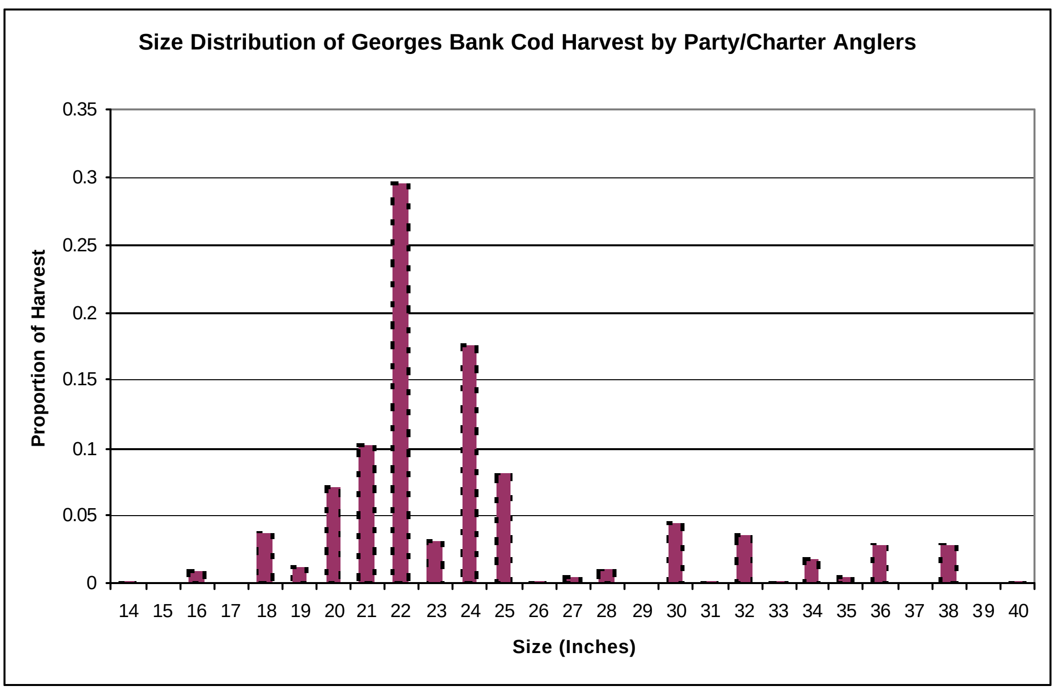

Figure 122 – Size distribution, GB cod, party/charter anglers

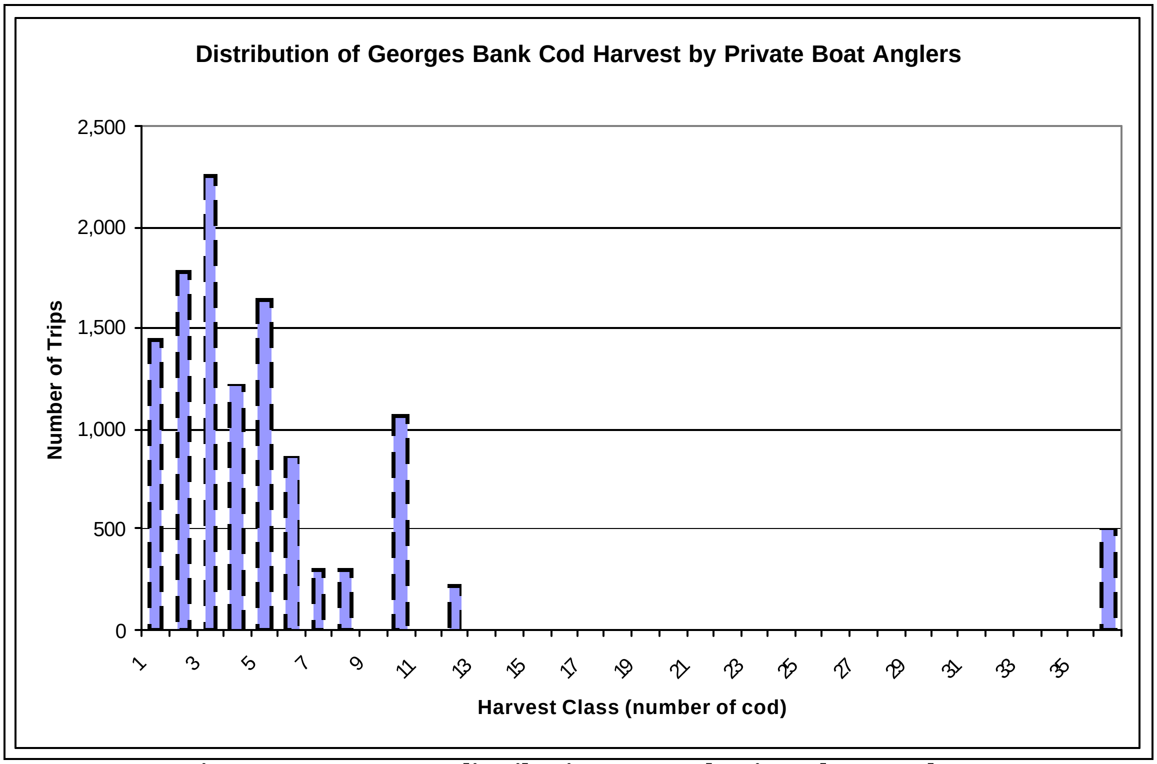

Figure 123 – Harvest distribution, GB cod, private boat anglers

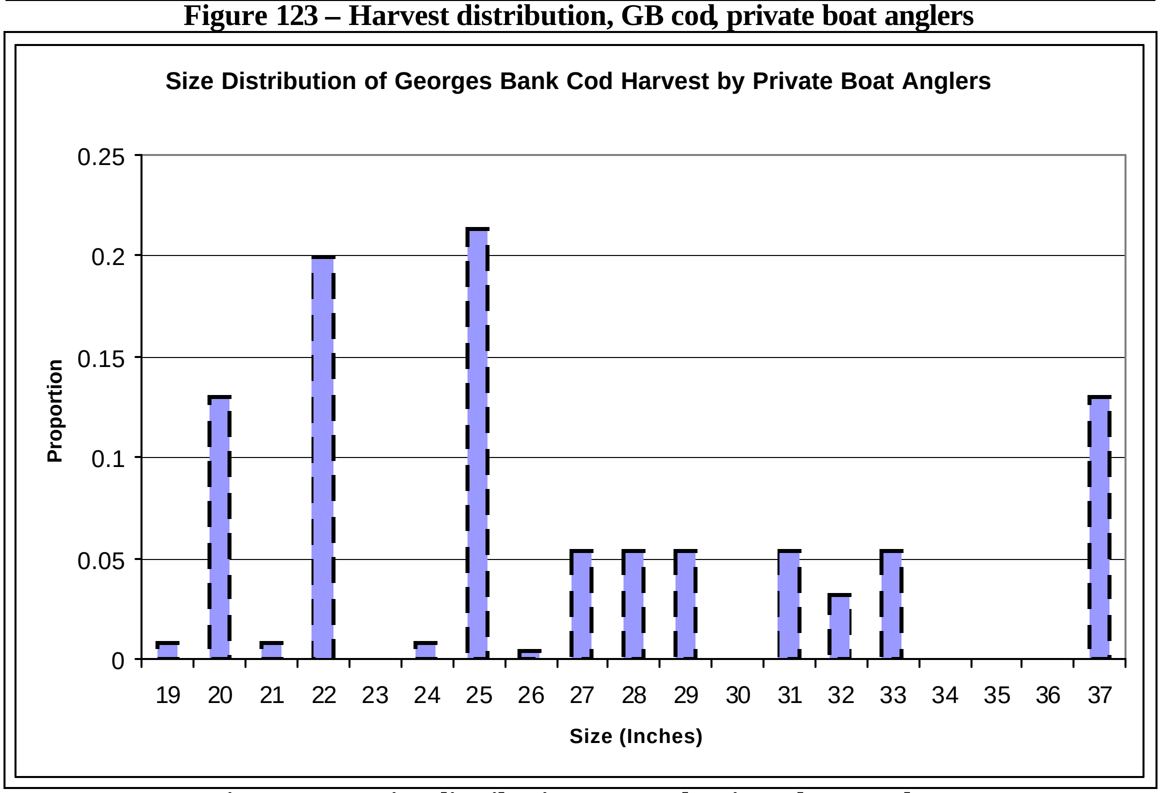

Figure 124 – Size distribution, GB cod, private boat anglers

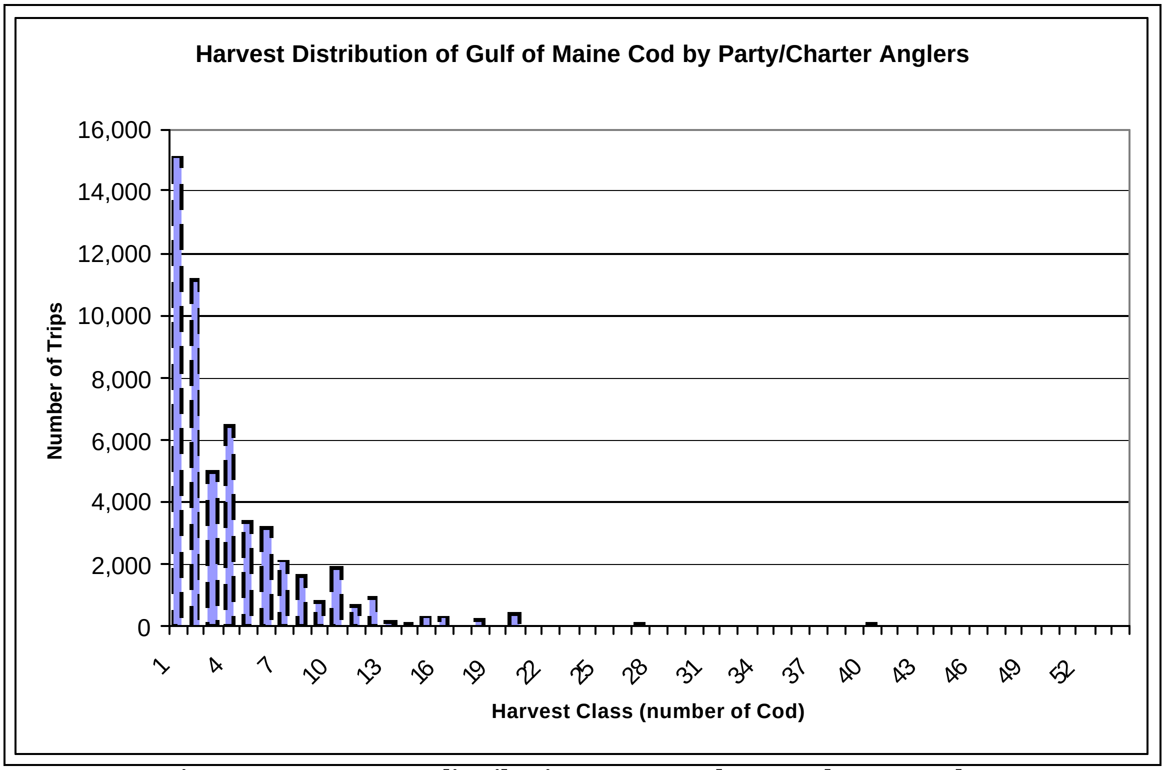

Figure 125 – Harvest distribution, GOM cod, party/charter anglers

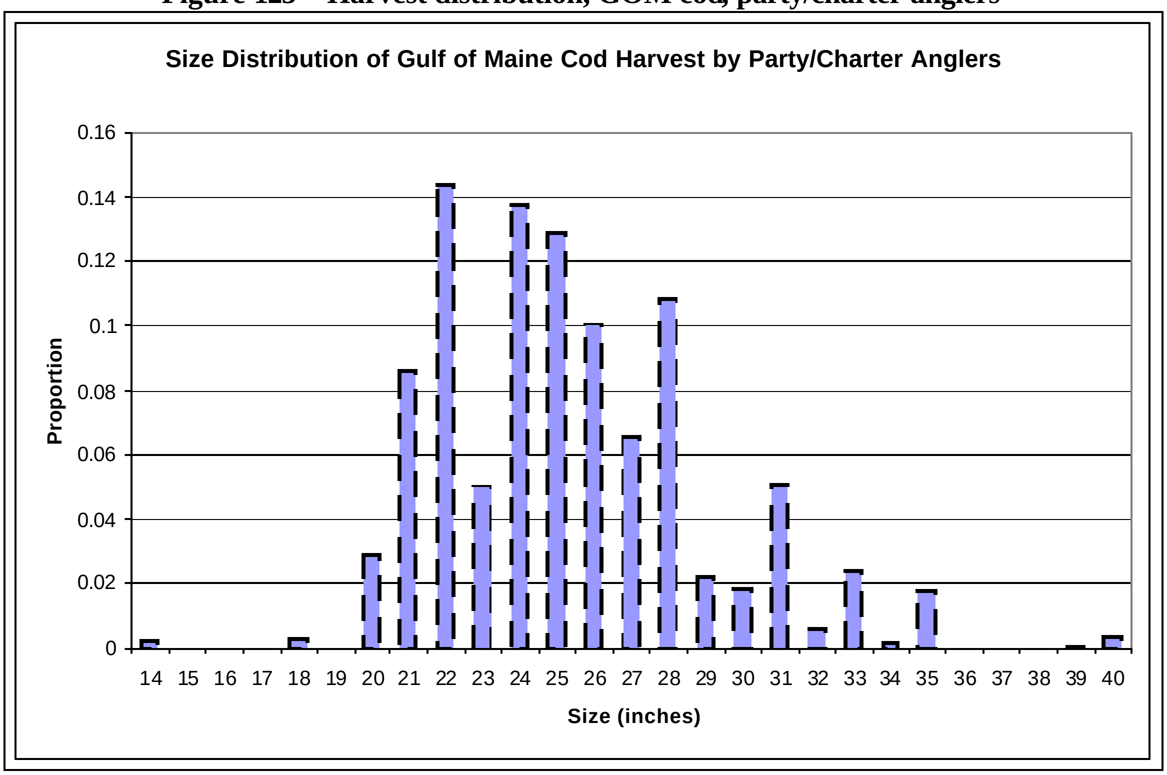

Figure 126 – Size distribution, GOM cod, party/charter anglers

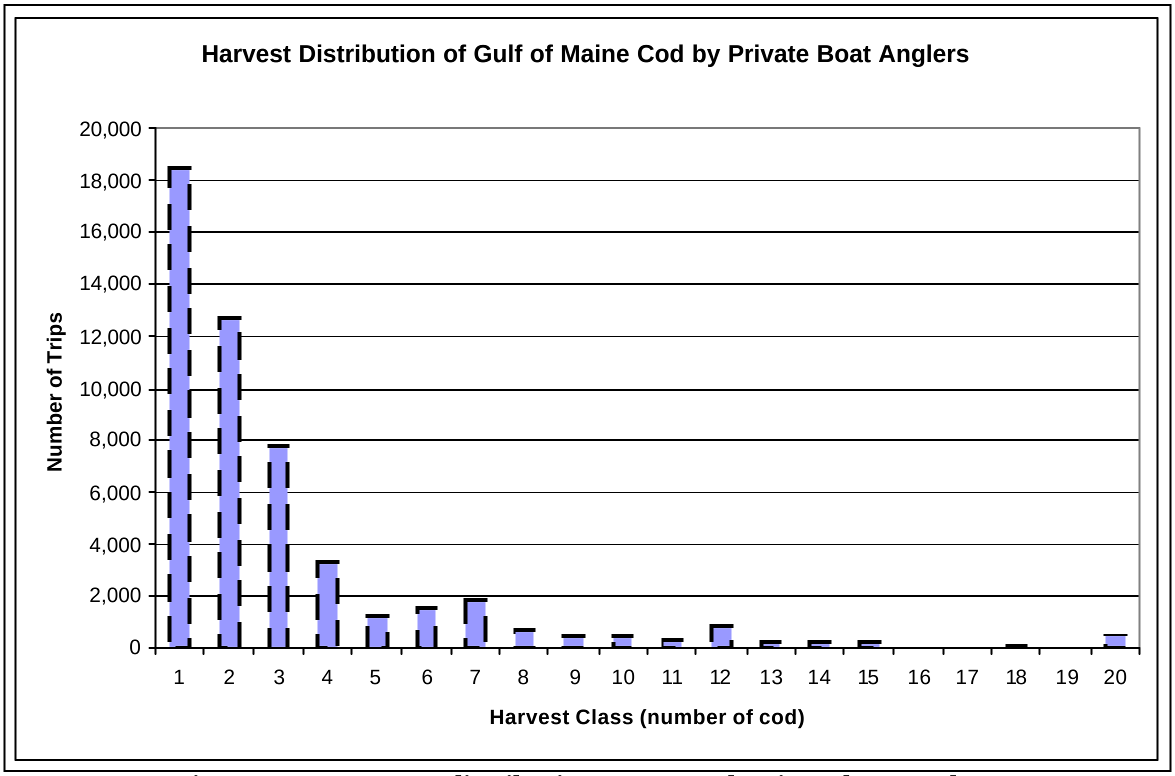

Figure 127 – Harvest distribution, GOM cod, private boat anglers

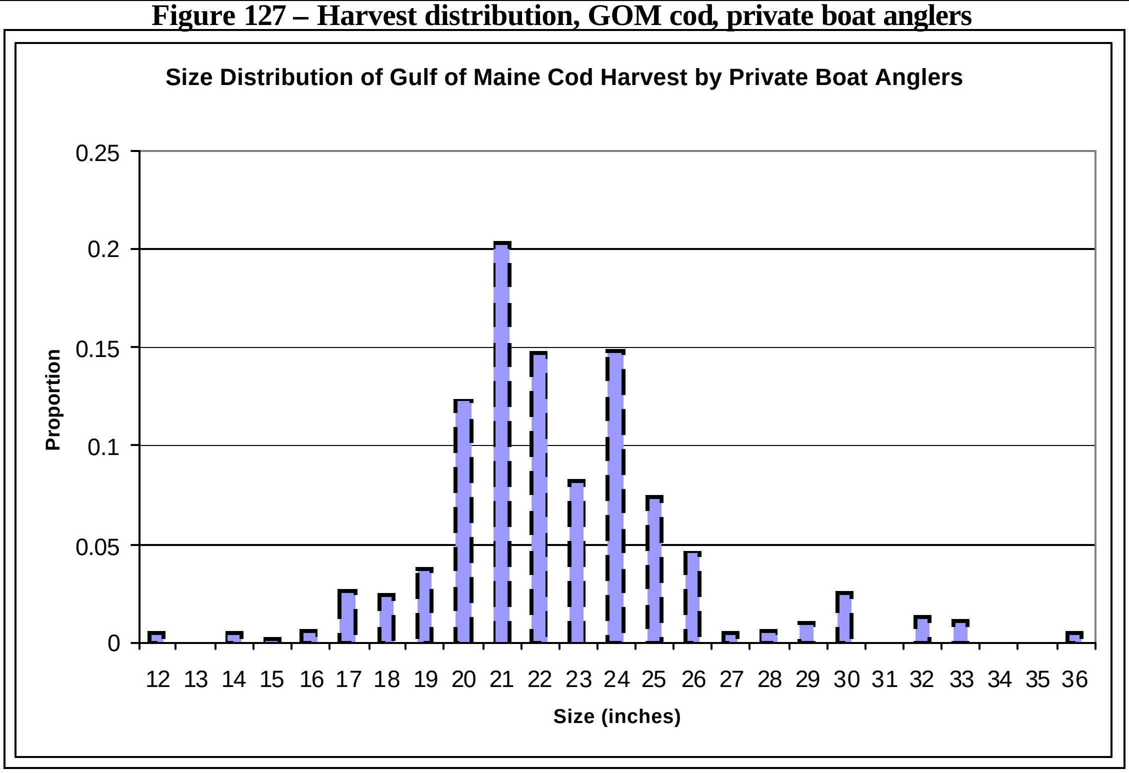

Figure 128 – Size distribution, GOM cod, private boat anglers

Bag and size limits affect change the numbers of cod that may be retained. Assuming perfect compliance and zero release mortality, a change in either bag or size limits results in a truncation of the harvest distribution or size distribution or both. By repeatedly sampling from the truncated distributions a new average catch, average size, and weight results. The biological impact of the new limits may then be measured by comparing the total harvest with and without the limit.

The observed harvest and size distributions for recreationally harvested cod indicate varying levels of conformance with Federal regulations in effect for the 1998-2000 time period by stock and mode. Approximately 17% of the Georges Bank cod party/charter harvest was not in conformance with Federal size regulations while 10% of private boat harvest was above the bag limit or under the size limit or both. Party/charter harvest in the Gulf of Maine had the lowest rate of non-compliance with Federal regulations while private boat harvest had the highest rate of non-compliance (25%). To the extent that these conformance rates continue, the biolo gical benefits of any more restrictive recreational measures may be compromised. These biological benefits may also be further compromised as release mortality is not likely to be zero.

To account for non-compliance rates and release mortality three scenarios were developed. First, maximum biological benefit would be realized if compliance rates were 100% and release mortality were zero. This scenario provides an upper bound estimate of biological benefit. A lower bound estimate was obtained under the assumption that observed non-compliance rates would continue and release mortality were 50%. An intermediate scenario was developed where non-compliance rates were assumed to be improved y 50% and release mortality was assumed to be 25%. In addition to these considerations, the proposed recreational restrictions may result in a reduction in demand for recreational fishing trips.

To account for possible changes in trips directing on Atlantic cod, the total number of trips that would be affected by either a trip limit, bag limit or both were estimated from the observed (1998-2000) harvest distributions. To be affected by a recreational measure does not necessarily mean that a given angler will no longer take a fishing trip or that cod will not be targeted. However, some response to more restrictive recreational regulation may be expected, at least in the short term. To develop some measure of this effect, a sensitivity analysis was conducted assuming that 25% and 50% of affected cod trips would not be taken. Note that these possible changes in number of trips were also used to form the basis for assessing the economic impacts of the proposed recreational fishing options in Section 5.4.7.

Results

A baseline for measuring the biological impacts of the recreational options was developed by simulating 1998-2000 average conditions including observed non-conformance rates and applying the resulting average harvest to the observed number of trips taken by stock and mode. Regardless of fishing mode, this simulated baseline tended to overestimate the observed number of cod harvest by approximately 6% and 12% for Georges Bank and Gulf of Maine cod respectively (Table 103).

	1998-2000 Average Number of Trips	Simulated Average Number of Cod Harvest per Trip	Simulated Total Harvest	Observed Harvest	Difference
Georges Bank Party/Charter	16,577	6.6	109,492	103,218	6.1%
Georges Bank Private Boat	11,576	6.0	69,995	65,895	6.2%
Gulf of Maine Party/Charter	53,778	4.4	237,521	214,051	11.0%
Gulf of Maine Private Boat	50,729	3.4	174,417	155,560	12.1%

Table 103 - Simulation baseline results for recreational measure analysis

Option 1 – This option was not selected. Assuming no change in number of trips harvesting cod the upper bound estimate of biological impact was a reduction of 47.8 and 37.1% respectively for Georges Bank and Gulf of Maine cod in terms of numbers (Table 104). The lower bound estimate was a reduction of 20.4 and 15.3% respectively. In terms of weight, the option 1 measures would reduce from a high of 29.8% to a low of 12.8% for Georges Bank cod. For Gulf of Maine cod the estimated reduction in total weight ranged from 24.8 to 10.3%. Note that the Option 1 biological benefits may be underestimated because the impact of the seasonal bag limit of 5-cod per angler from December to March could not analyzed since the MRFSS survey is conducted in two-month waves and January and February are not sampled in the New England states. Recreational effort during the December to March time period has historically been low, the underestimate of the Gulf of Maine cod biological benefits is likely to be small.

	Georges Bank		Gulf of Maine	
Scenario	Numbers	Weight	Numbers	Weight
No Reduction in Affected Trips*				
Upper Bound	-47.8%	-29.8%	-37.1%	-24.8%
Intermediate Bound	-33.2%	-20.8%	-25.4%	-17.0%
Lower Bound	-20.4%	-12.8%	-15.3%	-10.3%
25% Reduction in Affected Trips				
Upper Bound	-50.7%	-33.6%	-42.5%	-31.3%
Intermediate Bound	-37.0%	-25.1%	-31.8%	-24.2%
Lower Bound	-25.0%	-17.6%	-22.6%	-18.1%
50% Reduction in Affected Trips				
Upper Bound	-53.5%	-37.4%	-48.0%	-37.8%
Intermediate Bound	-40.8%	-29.4%	-38.3%	-31.4%
Lower Bound	-29.5%	-22.3%	-30.0%	-25.9%
* 6,400 affected trips for Georges bank cod and 36,500 affected trips for Gulf of Maine cod.				

Table 104 – Recreational measures Option 1 biological impacts for Atlantic cod

If anglers decide to reduce the number of trips where cod was targeted the biological impacts would be greater as fewer fish would be caught and subject to release mortality or illegal retention. A reduction in number of trips that would have been affected by one or more of the Georges Bank cod measures would increase the biological impacts on Georges Bank cod by 3-5% or 4-9% depending the assumed reduction in trips. A reduction in trips harvesting cod would improve the biological impact on Gulf of Maine cod by 5 to 15% in terms of numbers of cod and from 7 to 16% in terms of weight.

Option 2 – This option was not selected. Option 2 would implement the same Georges Bank cod measures as that of Option 1. Therefore, the estimated Georges Bank cod biological impacts were unchanged. However, Option 2 would implement a seasonal closure on Gulf of Maine cod but not Georges Bank cod. To avoid this closure anglers may switch to targeting of Georges Bank for the duration of the closed season. In this event the Gulf of Maine closure could increase recreational effort directed on Georges Bank cod and could have a negative impact on that cod stock. Note that imposition of a bag limit on party/charter anglers in the Gulf of Maine while having no limit on Georges Bank cod may have a similar effect, as party/charter anglers may switch to Georges Bank.

The biological impact of Option 2 would be greater than that of Option 1 because of the closed season. With a closed season, fish are not subject to being caught, and so, are also not subject to release mortality. The reduction in number of trips was estimated the sum of 50% of the total number of Gulf of Maine cod trips taken in MRFSS wave-2 (March-April) and 50% of the total number of cod trips taken in wave-6 (November-December); 14,700 trips.

Across all scenarios, Option 2 would reduce Gulf of Maine cod harvest by at least 28.3% in terms of numbers and 25.3% in terms of total weight. The estimated upper bound impact was as much as a 54.3% reduction (Table 105).

	Georges Bank		Gulf of Maine	
Scenario*	**Numbers**	**Weight**	**Numbers**	**Weight**
No Reduction in Affected Trips**				
Upper Bound	-47.8%	-29.8%	-47.5%	-37.8%

Lower Bound	-33.1%	-30.1%	-37.8%	-34.9%

* 6,400 affected trips for Georges bank cod and 26,600 affected trips for Gulf of Maine cod that are not affected by the closed season.

** All scenarios include reduction of 14,700 trips due to closed season.

Table 105 – Recreational measures Option 2 biological impacts

Option 3 – This option is the proposed action. Option 3 would implement a lower size limit than either Option 1 or Option 2 and would change the trip limit in the Gulf of Maine to a limit based on number of cod per person per day. The impact of implementing the Gulf of Maine cod bag as a per person per day could not be evaluated using available data. The MRFSS data is based on an angler-trip and does not take into account the duration of the trip. The party/charter VTR data were queried to identify the frequency of reported trips that would meet the proposed criteria (a trip of more than 15 hours and covering two consecutive calendar days). This query resulted in almost no trips that met these criteria taken by Gulf of Maine party/charter vessels. This does not necessarily mean that overnight party/charter trips do not occur, but it does appear to be common.

The biological impact of Option 3 would be lower for both Georges Bank and Gulf of Maine cod under all scenarios (Table 106). Unlike Options 1 and 2 there were no scenarios where the estimated change in recreational cod harvests were commensurate with that of the estimated commercial reductions needed to achieve the conservation objectives for either cod stock. Given the proposed change in the Gulf of Maine cod bag limit the conservation benefits may be overestimated since the proposed measure is likely to provide an incentive for party/charter operators to change their trip scheduling to take advantage of the higher keep that a daily bag would provide.

5.2.7 Other Issues

5.2.7.1 Northern Shrimp Fishery Exemption Area

The proposed action eliminates the area restriction for the northern shrimp fishery.

5.2.7.1.1 Background

The northern shrimp fishery is managed by an Interstate Fishery Management Plan implemented by the Atlantic States Marine Fisheries Commission (ASMFC). Major management measures adopted by the ASMFC include a minimum mesh size of 1 and 7/8 inches, the requirement to use a finfish excluder device (Nordmore grate), and seasonal restrictions on fishing activity that are adjusted each year. In addition, because the minimum mesh size is less than that specified in the Northeast Multispecies Plan, the Council established an exempted fishery for northern shrimp that allows this fishery to take place. The exempted fishery requirements include restrictions on allowable incidental catch and limits on the area that can be fished.

Most of the landings for this fishery are made by offshore trawlers. Landings averaged over 11,000 mt from 1969-1972, but then declined to 400 mt in 1977. In recent years, landings peaked at 9,200 mt in 1996, but declined over the next three years to 1,816 mt in 1999. Landings increased slightly to 2,390 mt in 2000. Trends in landings have been determined primarily by recruitment of strong year classes. For the past eight years, seasonal trends in the offshore fishing effort have been evaluated. Mature female shrimp move inshore in early winter and offshore following larval hatching. Seasonal shifts in effort, however, may also be due to changes in fishermen's choices for targeting concentrations of shrimp. The pattern of inshore/offshore fishing shows considerable variability over the last eight years (Armstrong et al. 2000).

The Northern Shrimp Technical Committee (NSTC) assessed the resource in October, 2000 and again in October, 2001. Fishing in the 2000 season was limited to a 51 day season that began January 17, 2000 and ended March 15, 2000. Various catch per unit effort indices (CPUE) all showed increases in the 2000 season, reversing declines noted from 1996 to 1998. The 2000 CPUE based on logbook data was similar to the levels noted in 1995 and 1997, while the CPUE based on information collected from Maine and New Hampshire port sampling programs was the highest on record. The number of trips in 2000 showed a decline from 1999 and was about 28% of the number of trips in the 1996 season (Armstrong et al. 2000).

The NSTC noted in October 2000 that all resource indices are well below historic levels, but show a turn-around from the decline seen since 1996. The NSTC believes the sharp reduction in landings in recent years has resulted in a relatively low fishing mortality and has stabilized population abundance. The stock is estimated to be at 7,400 mt, compared to the average 1985-1995 biomass of 16,600 mt, and recruitment continues to be below the time series average. Exploitable biomass increased about 21% from 1999. While the 1999 year class appears strong, the 1997 and 1998 year classes remain below average. The NSTC suggested stock rebuilding may slow or cease if landings are allowed to rise sharply. The NSTC recommended a 61-day season for 2001, targeting an increase in landings to 2,850 mt. The ASMFC's Northern Shrimp Section considered the advice of the NSTC and industry comments and approved an 83-day season.

Fishing in 2001 was increased to an 83 day season, composed of an open period January 9, 2001 through March 17, 2001, and a spring season between April 16 and April 30. Landings declined to 1,083 tones, the lowest since 1983. The proportion of landings from New Hampshire more than doubled from the previous year. CPUE declined to 771 pounds per trip, the lowest since 1993, based on logbook data. In general, CPUE has been dropping since 1996, with the exception of the 2000 season (Glenn et al. 2001).

In October 2001, the NSTC concluded that the abundance of shrimp, as measured by the state/federal survey, analytic models, and landings and CPUE information, is at or near its lowest level since the early 1980s following the stock collapse in the 1970s. There have been recruitment failures in three of the last four year classes. Only the 1999 year class is relatively strong as compared to the 1996 year class that supported lower than average landings in 1999, 2000, and 2001. The NSTC recommended that no fishing be conducted in the 2002 season. The Northern Shrimp Section of ASMFC, however, chose to allow a 25 day season in order to maintain markets and infrastructure of the fishery, as well as provide some opportunities for shrimp fishermen.

In October, 1999, NMFS advised the Council that northern shrimp were approaching an overfished condition and directed the Council to develop measures for this fishery by October 28, 2000. The Council notified NMFS that because the ASMFC was active in shrimp management and was beginning to develop an amendment to its shrimp plan, the Council did not intend to develop management measures for shrimp. NMFS accepted this reply but cautioned the Council to closely monitor ASMFC progress to ensure appropriate action. In January, 2001, the NMFS again reported to Congress that northern shrimp is approaching an overfished condition (NMFS 2001a). The ASMFC continues to develop its amendment, with tentative plans to review it for approval in October, 2001. The NSTC will update the stock assessment in fall, 2001.

Because northern shrimp is managed by the ASMFC, the Council assumes that any action necessary to protect the shrimp resource will be taken by that group. This includes any adjustments to the ISFMP necessary because the area allowed for the fishery is increased. For that reason, the following analysis of biological impacts focuses on the impacts of the proposed options on groundfish stocks.

As background for this analysis, the results of an experiment conducted by the Maine Department of Marine resources in April through May, 2001 are briefly described (excerpted from the Executive Summary of the Report). The full report of this experiment is in Appendix III. The goal of this experiment was to determine whether a shrimp fishery can be conducted southeast of the Loran 25600 line within acceptable bycatch limits in order to provide additional economic opportunity to the shrimp fleet and alleviate pressure on shrimp in inshore waters.

During May, 2001, six commercial shrimp vessels completed two trips each of three days duration (except for one vessel trip curtailed by equipment failure) in waters southeast of the Loran 25600 line in the vicinity of Cashes Ledge (west to 69°40'W, east to 68°30'W, south to 42°30'N). The vessels completed a total of 132 commercial tows (average length of approximately 2 hours) with a 1" Nordmore grate and 24 control tows (average length of approximately 30 minutes) without the grate. Key findings were as follows:

Data summary:	132 Tows with Grate	24 Control Tows without Grate
Total catch (lbs.)	79,769.5	16,395.1
Total Whiting Catch (lbs.)	72,513.6	6,650.2
Total Shrimp Catch (lbs.)	1,960.3	64.7
Total Regulated Species Catch (lbs.)	1,689.5	5,432.2
Total Bycatch Regulated Species	2.1%	33.1%
Average Total Catch per Tow (lbs.)	604.3	683.7
Average Shrimp Catch per Tow (lbs.)	14.9	2.7
Average Regulated Species per Tow (lbs.)	12.8	226.3
Average Bycatch per Tow	3.6%	32.2%
Std Deviation Average Bycatch per Tow	8.8%	26.0%
Median Bycatch per Tow	1.6%	21.1%
Average Total CPUE per Tow (lbs./hr.)	296.2	1,748.4
Average Shrimp CPUE per Tow (lbs./hr.)	7.2	5.4
Average Reg. Species CPUE per Tow (lbs./hr.)	7.2	701.1

Bycatch in tows using the Nordmore grate was below 5% for regulated species, despite the minimal catches of shrimp. The comparative bycatch and CPUE data from Nordmore grate tows vs. control tows without the grate indicate that the Nordmore grate was effective at minimizing bycatch of regulated species present.

The low catch of shrimp was disappointing. It was the result of the small 1998 year class of male shrimp (smallest on record since 1983 inception of the summer ASMFC Shrimp Survey) and a delayed offshore migration of female shrimp. In a "normal" year for the May shrimp fishery, Maine Department of Marine Resources port sampling records indicate that shrimp catch per unit of effort would be closer to 200 lbs./hr.

Table 107 - Experimental Shrimp Fishery, May, 2001. Catch by Species in Numbers and Weight for Experimental and Control Tows.

5.2.7.1.2 Northern Shrimp Exemption Area Option 1 - Status Quo

This option was not selected. Maintaining the status quo will not change or adversely affect groundfish stocks. The requirement to use a Nordmore grate has significantly reduced the groundfish bycatch in the northern shrimp fishery. For example, discards of American plaice ranged from 149 mt to 380 mt annually during the period 1983 through 1990, while in 1999 discards were only 26 mt (NEFSC 2001a). While some of this variation may be attributed to changes in effort in the shrimp fishery, the 1999 plaice discards from the shrimp fishery were estimated to be less than 5% by weight of the plaice discards that resulted from the large mesh otter trawl fishery. In terms of number of fish, however, the bycatch of plaice in the shrimp fishery was about 20 percent of the discards in the large mesh fishery. In 1996 the discards of plaice in the shrimp fishery were higher (by number) than in the large mesh trawl fishery, and in 1997 they were only slightly lower.

5.2.7.1.3 Northern Shrimp Fishery Exemption Area Option 2 – Eliminate Area Restrictions for the Northern Shrimp Fishery

The impacts of eliminating the area restriction for the Northern Shrimp Fishery cannot be estimated with certainty but should be minimal. The experimental fishery suggests that the total weight of regulated groundfish bycatch in this fishery will be minimal because of the use of the Nordmore grate. This experiment, however, took place in only one small area and during a brief time period. While it is not likely that fishing in another area or time will result in catching larger fish, it is possible that in different seasons or areas there may be a higher rate of bycatch of juvenile groundfish that the grate does not exclude. There have been years when the plaice bycatch in the shrimp fishery accounted for a large percentage of total bycatch. The catch of silver hake (whiting) observed in the experiment is another cause for concern from the standpoint of M-S Act requirements to minimize bycatch and bycatch mortality. This is not a concern from the standpoint of whiting mortality. The northern stock of whiting was above its threshold and target levels in 2001. Thus, it was not overfished and was considered rebuilt. In 2001, biomass of northern whiting was relatively high (176% of the biomass target value). Relative exploitation indices for whiting in the northern stock indicate that exploitation levels were low. Based on surplus production analyses presented in SAW 32, the MSY of the northern stock of whiting may be up to 45,000 mt, with an 80% confidence interval of roughly 39,000-52,000 mt (2001 SAFE Report). The 2002 SAFE Report indicates that landings of whiting from the northern stock averaged about 3,300 mt from 1999-2001. Arguably, economic considerations in the shrimp fishery will deter vessels from continuing to fish for shrimp if whiting bycatch is high – it is difficult to separate the whiting and shrimp and the mix of whiting and shrimp reduces the condition and value of the shrimp that are caught. The low value, limited markets available, and low trip limit for whiting make it unlikely that fishermen will intentionally fish in areas where the whiting bycatch is high. If bycatch of whiting is a problem, it could be readily addressed by adjusting the amount of whiting that shrimp vessels are allowed to land.

Impacts of this exemption on the shrimp fishery can be controlled through the ASMFC Interjurisdictional Fishery Management Plan for shrimp.

5.2.7.2 Tuna Purse Seine Vessel Access to Groundfish Closed Areas

The Council considered three primary options for tuna purse seine vessel access to groundfish closed areas. These are described in section 3.8.2 and 4.1.7.2. A thorough description of the tuna fishery, including the purse seine fishery, is provided in the Atlantic Highly Migratory Species FMP (NMFS 1999). Additional information specific to the tuna purse seine fishery in the vicinity of groundfish closed areas is contained in an environmental assessment prepared for an experimental tuna purse seine fishery in Closed Area 1 (NMFS 2001b). Prior to discussing the biological impacts of each option on the multispecies fishery, a short summary of the fishery and available information on bycatch is provided.

Tuna purse seine vessels use large nets (500 fathoms long and over 50 fathoms deep) to encircle schools of tuna. Due to the manner in which the net is deployed, the bottom of the net never extends to its full depth. One captain stated that his 45 fathom net will not contact the bottom in 31 fathoms of water.

Contact with the bottom can damage the net severely, resulting in expensive repairs and lost fishing time during a short season (NMFS 2001b).

The tuna purse seine fishery is managed through an individual transferable vessel quota system established in 1982. Five vessels are given an equal share of an annual bluefin tuna quota that is 18.6 percent of the U.S. bluefin tuna landings quota. Each vessel must stop fishing when it catches its quota, and cannot fish for other species of tuna after that since there is the possibility of catching additional bluefin. Under current regulations, fishing begins on August 15 of each year. According to the Atlantic Highly Migratory Species FMP (NMFS 1999), each vessel typically catches its quota within a matter of weeks, fishing entirely in mid-Atlantic and New England coastal waters (see Table 108). Testimony at NEFMC Groundfish Oversight Committee meetings said that the total number of tuna sets in a year is frequently only 50 sets for all five vessels, and is almost always less than 100 sets (Ruais, pers. comm.). Typically, the fishery is over by mid-October either because the vessels catch their quota or the fish migrate out of the area. Purse seine vessels have found large concentrations of tuna in the vicinity of CA I, and they have traditionally fished near this area (NMFS 2001b).

Year	Quota (mt)	Amount Landed (mt)	Last Landing Date
1996	251	245	October 19
1997	250	250	September 29
1998	250	248	October 8
1999	260	247	October 18
2000	271	275	October 3

Table 108 – Quota, landings, and last landing date for the tuna purse seine fishery, 1996 – 2000 (round weight). Season opens August 15. (NMFS, unpublished data)

Because this fishery is managed by a strict quota, the options under consideration by the Council should not have any additional biological impacts on the target tuna species. In recent years the fishery generally harvests, but does not exceed, its entire quota. None of the proposed options will change the amount of tuna landed by this fishery. With respect to groundfish management, however, allowing tuna purse seine vessels into groundfish closed areas could result in groundfish bycatch.

There is a limited amount of sea sampling and observer data on this fishery that documents the catch of non-target species. In 1996, observers on four vessels observed a total of 39 tuna purse seine sets on 42 trips (some trips had no sets). The trips occurred on Stellwagen Bank, northern part of Cape Cod Bay, and west of Closed Area I. The groundfish bycatch species caught on nineteen of those sets is summarized in Table 109. In addition to finfish bycatch, 20 of the 39 purse seine sets had bycatch of benthic habitat such as sponges, rockweed, empty shells, kelp, and rocks. This indicates the purse seines had contact with, partially removed, and caused disturbances to bottom habitats (Kurkul 2000). Section 5.2.8.5 analyzes the impacts of the management options on habitat.

In the fall of 2000, an experimental fishery was authorized that allowed tuna purse seine fishing in Closed Area I. After considering the observations from the trips observed in 1996, and after conducting an Essential Fish Habitat Consultation (Kurkul 2000), the experimental fishery was authorized subject to the following restrictions:

- An observer was required when fishing in Closed Area I.

- Vessels were required to fish in locations where the depth of water was greater than 30 fathoms or greater than the depth of the net. Alternatively, the net used had to be modified so that its depth was less than the depth of the water.
- Vessels could not fish in Closed Area II or the NLCA.
- All catch or incidental catch had to be available for identification, weighing, and measuring.
- Vessels were prohibited from retaining or landing multispecies finfish.
- Nets have to be set to avoid fixed gear wherever possible.

Some of the sets from this fishery were also observed. While because of the small number of sets the data would normally be confidential, vessel operators from two vessels provided the data to the Council for consideration. Five sets were observed, with no groundfish bycatch and only small amounts of other species. A summary of the observed sets is provided in Table 110. One difference between the observations in 2000 from those in 1996 is that all of the recent sets took place in water depths deeper than the net depth, while in 1996 many of the sets were in water depths shallower than the net depth. The location of all observed sets for 1996 and 2000 is shown in Figure 129. None of the sets observed in Closed Area I resulted in groundfish bycatch.

5.2.7.2.1 Option 1 – No Action

This option was not selected. Under this option, tuna purse seine vessels would not be allowed access to Closed Areas I, II, or the NLCA. This option provides the greatest protection to groundfish located in those areas. There is no possibility that additional groundfish mortality will result from tuna purse seine operations in the closed areas. While there is the possibility of groundfish bycatch in the other closed areas, the amount is insignificant based on the observed purse seine sets.

Allowing an exempted fishery into a closed area could increase groundfish mortality and weaken the effectiveness of a closure by complicating enforcement efforts. This option does not increase the number of fishing activities allowed in these closed areas. As a result, enforcement efforts are not complicated and there should not be any additional impacts on groundfish mortality.

5.2.7.2.2 Option 2 - Access With Restrictions

This option was not selected. Based on purse seine sets observed in 1996, there is the possibility of some groundfish and bycatch impacts from purse seine vessels operating without restrictions (habitat impacts are discussed in section 5.3.7.2). The limited number of sets observed in 2000, however, did not have any groundfish bycatch, suggesting that the restrictions applied to the experimental fishery can essentially eliminate the possibility of groundfish bycatch.

A review of Table 109 shows that most of the groundfish bycatch occurred when sets were made in less than 30 fathoms. Limiting purse seine operations to depths of more than 30 fathoms, then, can be expected to reduce significantly the possibility of groundfish bycatch in the closed areas. Coupled with the limited number of sets that are made in this fishery, and the likelihood that not all sets will be made in closed areas, the amount of groundfish bycatch in this option is likely to be insignificant, though marginally higher than that for the status quo. This option also changes the current access of tuna purse seine vessels to the areas of the seasonal closures in the Gulf of Maine, and the WGOM closed area. There may be some positive benefits to groundfish as a result, this restriction is not applied to the NLCA for several reasons. First, almost the entire area is less than 30 fathoms deep; it would be easier to simply prohibit seine operations from this area. Second, there is less reason for this restriction to protect habitat because of the sandy composition of most of this area, as opposed to the areas of hard bottom habitat within Closed Area I and Closed Area II.

Prohibiting purse seine operations in any HAPC will also benefit groundfish stocks if the HAPC is defined for their protection. The existing HAPC was designated in part to protect juvenile cod settlement areas. By preventing purse seine operations in this area, there is no possibility that this fishing activity will adversely affect juvenile cod in this area.

The tuna purse seine fishery does not begin until mid-August. Since most groundfish spawning activity occurs in the winter or spring, allowing purse seine operations to take place in the closed areas will have minimal impacts on spawning activity.

Finally, the ability of the Regional Administrator to place additional restrictions on the fishery, or prohibit a vessel or vessels from the closed areas, provides an additional incentive for vessel operators to avoid all groundfish bycatch.

5.2.7.2.3 Option 3 – Access Without Restrictions

This option is the proposed action. Under this option, purse seine vessels can operate in all groundfish closed areas, limited to a prohibition on possessing or catching groundfish and on having gear on board capable of catching groundfish. These limitations are routinely applied to fisheries that are allowed into closed areas.

Because tuna purse seine operations will be allowed without restriction in Closed Areas I, II, and the NLCA, there is the possibility of some increases in groundfish bycatch in those areas. Based on the sets observed in 1996, these impacts are likely to be small. The number of sets in the entire fishery is far less than 100 according to public testimony, and not all sets are likely to occur in the closed areas. This option may slightly increase groundfish bycatch in the closed areas, but the impacts are judged to be insignificant. Indeed, since purse seine sets outside the area can also occasionally catch groundfish, it is not clear that this option will actually increase groundfish bycatch; rather, it may just move the location.

One indirect effect on groundfish areas may result by allowing an additional group of vessels into the areas. Enforcement agencies have repeatedly noted that each exception to a closed area reduces their ability to effectively patrol the area. As a result, it may become easier for other vessels to illegally fish in the closed areas and groundfish mortality could increase. This particular exception, however, only applies to five vessels. Purse seine operations are significantly different than groundfish fishing activities. The small number of vessels (five), type of operations, and limited season (generally August through mid-October) should reduce the impacts of this closure on enforcement operations.

The tuna purse seine fishery does not begin until mid-August. Since most groundfish spawning activity occurs in the winter or spring, allowing purse seine operations to take place in the closed areas will have no impact on spawning activity.

5.2.7.3 SNE General Category Scallop Exemption Program

The proposed action adopts this scallop exemption program. The designation of a SNE General Category Scallop Exemption Program should not have significant impacts on groundfish mortality. An examination of observed sea sampling dredge trips conducted in statistical areas 537, 538, 539, and 613 for he period 1994 through 2000 found that scallop trips in this area had little regulated species bycatch. 36 trips in all were observed, including dredges both smaller and larger than 15 feet. For all observed trips, the regulated species mean catch was 136 pounds, or less than 1 percent of the total catch by weight. For dredges less than 15 feet, the mean regulated species catch was only 48 pounds, again less than 1 percent of the total catch. The regulated species catch on any of the observed trips never exceeded more than 1 percent of the catch by weight. It should be noted that many of these trips took place before the requirement to use an 8 inch twine top was adopted, a measure that has been demonstrated to reduce groundfish bycatch in a scallop dredge even further. This requirement is included in this proposed alternative. Additional evidence is available in the 2001 scallop SAFE report that supports the lack of impacts on groundfish mortality that will result from this program. In the scallop fishing year from March 1999 through February 2000, 69 General Category Permit scallop vessels used dredges, landing a total of 61,339 pounds of scallops. Total reported regulated groundfish landings for these vessels was about 40 pounds, far less than 1 percent.

This program may have impacts on scallop mortality and management that are discussed in a qualitative way in the section on impacts on other fisheries.

5.2.8 Impact of Alternatives on Bycatch

National Standard 9 of the M-S Act requires that conservation and management measures shall, to the extent practicable, minimize bycatch and to the extent bycatch cannot be avoided, minimize the mortality of bycatch. Bycatch is defined as fish harvested in a fishery but which are not sold or kept for personal use. The NSGs provide further advice on bycatch, noting that it includes economic and regulatory discards, and fishing mortality due to an encounter with fishing gear that does not result in capture of fish (unobserved fishing mortality). It is important to note neither the M-S Act nor the NSGs place restrictions on how bycatch can be reduced. For example, simply allowing or requiring the retention of all species caught would be an acceptable way to minimize bycatch if it can be done without violating other biological objectives: changing measures so that more of the bycatch can be retained is just as valid an approach under the M-S Act as changing measures to reduce the catch of some species.

The NSGs place the emphasis on minimizing bycatch – that is, avoiding the catch of bycatch species. Guidance is also provided for assessing whether management measures minimize bycatch to the extent practicable. Councils must:

(1) Promote development of a database on bycatch and bycatch mortality in the fishery to the extent practicable;
(2) For each measure, assess the effects on the amount and type of bycatch and bycatch mortality in the fishery (qualitative discussions are allowed when quantitative estimates are not available);
(3) Select measures to the extent practicable that will minimize bycatch and bycatch mortality;
(4) Monitor selected measures for impacts on bycatch;
(5) Consider other applicable law (MMPA, ESA, etc.).

The NSGs provide guidance on determining if measures minimize bycatch "to the extent practicable." The NSGs suggest this practicability determination should be based on such factors as the ecological changes that result from bycatch of a species, effects on marine mammals and birds, changes in fishing, processing, and marketing costs, changes in research and other administrative costs, and changes in the social and cultural values of the fishing activities. All of these criteria for this making the practicability determination assume the ability to know precisely how particular measures will influence bycatch and fishermen's behavior and what the impacts of those changes will be. This information is not available for the multispecies fishery. As discussed in section 9.4.2.8, most bycatch information currently collected and reported by the NMFS is based on broad gear categories (large mesh otter trawl, gillnet, longline, etc.) without regard to specific fishery. With the possible exception of trawl mesh selectivity studies and a few studies on specific gear requirements (such as the raised footrope trawl or haddock separator trawl), there is little information with which to estimate the impacts of a specific management measures on bycatch. For example, there is no information available to estimate how a specific area closure might affect bycatch, and what the resulting impacts of that change have on marketing or harvesting costs. Because of these data limitations, the following analysis focuses on identifying whether proposed measures will increase or decrease bycatch as compared to the no action alternative.

The total mortality resulting from bycatch can be reduced in at least three broad ways. First, the **rate** of bycatch can be reduced. As an example, the discard rates of sub-legal fish can be reduced by increasing mesh size, since larger mesh will allow more sub-legal fish (that must be discarded to comply with the minimum size regulations) to escape. Bycatch could also be reduced by allowing retention of smaller fish, though this may have other adverse impacts. Regulatory discards caused by trip limits can be reduced by increasing trip limits or by requiring use of gear that does not catch as much of a particular species. Gear that does not catch as much of a particular species could be required - for example, the haddock separator trawl reduces the catch of flatfish and skates. Second, reducing fishing effort can reduce **total bycatch** (even if the rate remains the same or increases). If, for example, each longline set catches a percentage of juvenile fish that must be discarded, reducing the number of sets would reduce the total catch of juvenile fish even if the percentage caught per set remains the same. Neither the M-S Act nor the NSGs assign a preference to either of these approaches. Finally, the **mortality of species caught** as bycatch may be reduced through changes in fishing techniques. The M-S Act, however, assigns this a lower priority than reducing bycatch.

Current information available on bycatch in the multispecies fishery is summarized in section 9.4.2.8. This section assesses the impacts of the proposed management measures on bycatch. There is little information available on how to estimate the impacts of specific measures on bycatch and bycatch mortality, so much of the discussion is qualitative. All proposed measures are compared to the measures in place during fishing year 2001 and are compared relative to each other. This section focuses on bycatch of fish and shellfish; impacts of the measures on protected species (including the bycatch of protected species) is in section 5.2.9.

5.2.8.1 Proposed Rebuilding Programs

The Council considered three possible rebuilding strategies: a constant fishing mortality rate, and a phased reduction fishing mortality rate, and an adaptive management strategy (see section 3.2). In concept, measures can be designed that will minimize bycatch and bycatch mortality to the extent practicable for any of the proposed rebuilding strategies. If fishing mortality has to be reduced while stocks (and presumably catch rates) are increasing, designing and choosing appropriate measures may be more difficult. The selection of a rebuilding strategy may thus have an indirect effect on attempt to minimize bycatch to the extent practicable.

Each of the rebuilding strategies will require significant reductions in catch in the initial years of the program. The constant mortality rate strategy requires the largest reduction which means reducing bycatch under this option may initially be the most difficult. The phased reduction approach reduces mortality to the lowest levels in the middle of the rebuilding program, but ameliorates this situation somewhat by allowing mortality to increase slightly in the later years of the rebuilding program. It may also be easier under the phased reduction approach to design measures for the early years of the program, as mortality does not have to be reduced as much as under the constant fishing mortality rate approach. The adaptive strategy keeps mortality at the highest levels through 2008, which may make it easier to design measures to minimize bycatch in the early years of the program. If mortality must decline significantly in 2009, the it will be more difficult to reduce bycatch with larger stock sizes. If appropriate measures can be designed and implemented with the adoption of the amendment, the constant fishing mortality approach may require few changes to address bycatch over the rebuilding period.

In summary, designing management measures to minimize bycatch is likely to be most difficult in the middle years of the phased reduction strategy. The phased reduction approach ameliorates some of these problems by allowing an increase in mortality in the later years as stocks increase. Minimizing bycatch under the constant fishing mortality strategy may prove most difficult in the early years of the rebuilding program. These impacts should be considered in the context of the benefits that are likely to accrue under the different strategies in order to determine practicability.

The proposed action combines the adaptive and phased reduction strategies for overfished stocks. For most stocks in the adaptive strategy, fishing mortality rates do not need a large decline in 2009. For those stocks in the phased strategy, the stock that has the lowest mortality in the next decade is CC/GOM yellowtail flounder. This suggests that bycatch prevention measures may have to be designed for this stock in the future.

5.2.8.2 Fishery Program Administration

Most of these measures will not directly impact bycatch or bycatch mortality. Some of the measures, however, reflect Council efforts to promote improved understanding of bycatch and bycatch mortality or monitor the impacts of management measures on bycatch. Some of the measures may also have indirect effects on bycatch. The following sections only discuss those measures that are believed to have an impact on bycatch or bycatch mortality.

5.2.8.2.1 Fishing Year

The proposed action does not change the fishing year. Any change to the fishing year should not have a direct effect on bycatch or bycatch mortality. It is possible that fishing years that begin when fish are aggregated may have indirect effects on bycatch. DAS allocations for vessels are available at the beginning of the year, and it is possible that vessels may choose to fish a large number of their DAS when fish are aggregated. Based on the assumption that bycatch is highest when fish are aggregated, a fishing year that gives vessels a new DAS allocation at such a time may result in higher levels of discards. Under Amendment 7, the fishing year begins in May, when many groundfish are aggregated just prior to or after spawning. The alternatives that change the fishing year to January, July, or October may indirectly result in reducing bycatch, while keeping the start of the year in May will have no change from the current situation.

5.2.8.2.2 Modified Periodic Adjustment Process

Adopting these changes, as proposed, will not influence bycatch. The periodic adjustment process does enable the Council an opportunity to monitor and respond to bycatch issues. While at first an annual adjustment process may appear to provide more opportunities in this regard, none of the alternatives proposed preclude the Council from taking action to address a bycatch problem at other times. In addition, an annual process does not necessarily mean better information will be available, as the collection and analysis bycatch information is time consuming. In summary, there should not be any difference among the alternatives for the adjustment process.

5.2.8.2.3 United States/Canada Resource Sharing Understanding

The proposed action adopts a resource sharing understanding for eastern GB cod, haddock, and yellowtail flounder. While on the surface the agreement would not be expected to have any impacts on bycatch, measures adopted to implement the agreement may. Fishing activity in statistical areas 561 and 562 (5zjm) will be subject to a hard TAC for cod, haddock, and yellowtail flounder. Because of the low cod TAC and the need to minimize catches of cod while harvesting the other two species, vessels are required to use gear that is designed to minimize the catch of cod. The use of a haddock separator trawl has been demonstrated to reduce catches of cod by up to sixty percent while fishing for haddock (see section 4.1.5.3).

5.2.8.2.4 Administration of Certified Bycatch/Exempted Fisheries

These alternatives should not have any direct impacts on bycatch or bycatch mortality. All may have indirect effects, however.

Standards for Certification
This change is part of the proposed action. The proposed measure provides additional flexibility to the Council to minimize bycatch and bycatch mortality. Current standards for certification of exempted fisheries do not allow retention of regulated groundfish and some other species, generating regulatory discards. This alternative provides the Council the flexibility to allow retention of other species, converting discards into landings. This alternative also increases the Council's commitment to monitor these fisheries as groundfish stocks increase.

Review of Exempted Gears and Certified Bycatch/Exempted Fisheries
The Council did not adopt this alternative. This alternative would have established a schedule for reviewing exempted gears and exempted fisheries. This expands on the Council's commitment to monitor these fisheries for bycatch, to alter the restrictions on these fisheries as necessary to reduce bycatch, and to promote the development of data on bycatch and bycatch mortality in these fisheries.

5.2.8.2.5 Special Access Programs

The provisions in this alternative are designed to ensure approved programs do not have an adverse impact on bycatch or bycatch mortality. As such, it is an additional commitment by the Council to monitor and assess bycatch in the groundfish fishery. As a general rule, a special access program could increase the opportunity for bycatch to occur because it allows fishing activity that is otherwise not allowed under the management program. Bycatch mitigation/reduction measures should be a component of any special access program. This could be through the adoption of specific measures to reduce/mitigate bycatch, or by demonstrating the special access program does not increase bycatch.

There are also specific special access programs contained in this alternative. The likely bycatch impacts of each proposed SAP are described below.

Georges Bank Yellowtail Flounder Special Access Program
Allowing access to CAII may increase bycatch for many of the same reasons as moving the southern boundary of CAII. The increase must be considered in light of the strict limits on number of trips and the overall reduction in DAS.

This program will allow otter trawling in a small area of Closed Area II. There is no information in the bycatch of other species that will result from otter trawls, though an experiment is being conducted in the area (fall 2002). The primary bycatch from three observed otter trawl trips just outside Closed Area II suggests the primary bycatch is likely to be skates of various species (Table 111). It is not likely that bycatch rates will be the same as in these observed trips. In addition, it is not clear if any bycatch from within the closed area will be in addition to bycatch outside the area, or will merely reflect an effort shift without any increase in bycatch (unless the rate increases inside the closed area). From observed tows during the sea scallop exemption program in 2000, however, it is clear that little, winter, and barndoor skates will be encountered.

As indicated from the observer data, otter trawls can also be expected to take sea scallops. Current regulations limit trawl vessels to 400 lbs. of scallop meat per trip. Based on the size and density of sea scallops in the proposed access area, vessels using flounder nets are likely to encounter considerable scallop bycatch. Flounder nets can be easily modified to catch scallops if vessels wish to target them rather than yellowtail flounder. However, the low trip limit may act as a deterrent. Under certain conditions (high temperatures during summer months and long sorting times on deck), groundfish vessels may incur significant scallop mortality.

	Weight (lbs)		
Species	**Discarded**	**Kept**	**Grand Total**

800 – Sea Scallop	53	1002	1055

Table 111– Primary bycatch from three otter trawl trips near Closed Area II

High concentrations of scallops were observed in 2000 and 2001 in the east-central portion of the proposed access area. In 2000, the scallops were less than 80 mm and generally would not be retained by large mesh trawls. The scallops are projected to grow to around 100 mm by 2002, a size typically targeted by scallop trawl vessels. It is likely that these scallops will be retained in trawl nets targeting yellowtail flounder. Based on yellowtail flounder bycatch distribution and yellowtail flounder catches during scallop surveys in 1998 and 1999, yellowtail flounder abundance appears to be as high or higher in the five blocks to the north and east of the proposed access area. Allowing yellowtail fishing in this area may increase flounder catch rates and reduce the scallop bycatch. There is a risk , however, of increased cod and winter flounder bycatch in these blocks based on the observed tows in the 2000 sea scallop exemption program (Figure 132 and Figure 133).

In summary, the proposed access program is likely to result in the catch and discard of little, winter, and barndoor skates. Whether the catch rates will be higher than outside the closed area is unknown. Scallop bycatch is also likely to increase, and given the density of scallops within the close area, will likely increase from the rates observed outside the closed area. A mandatory observer program (at some level of coverage) would facilitate collection of information on the catch rates of all species.

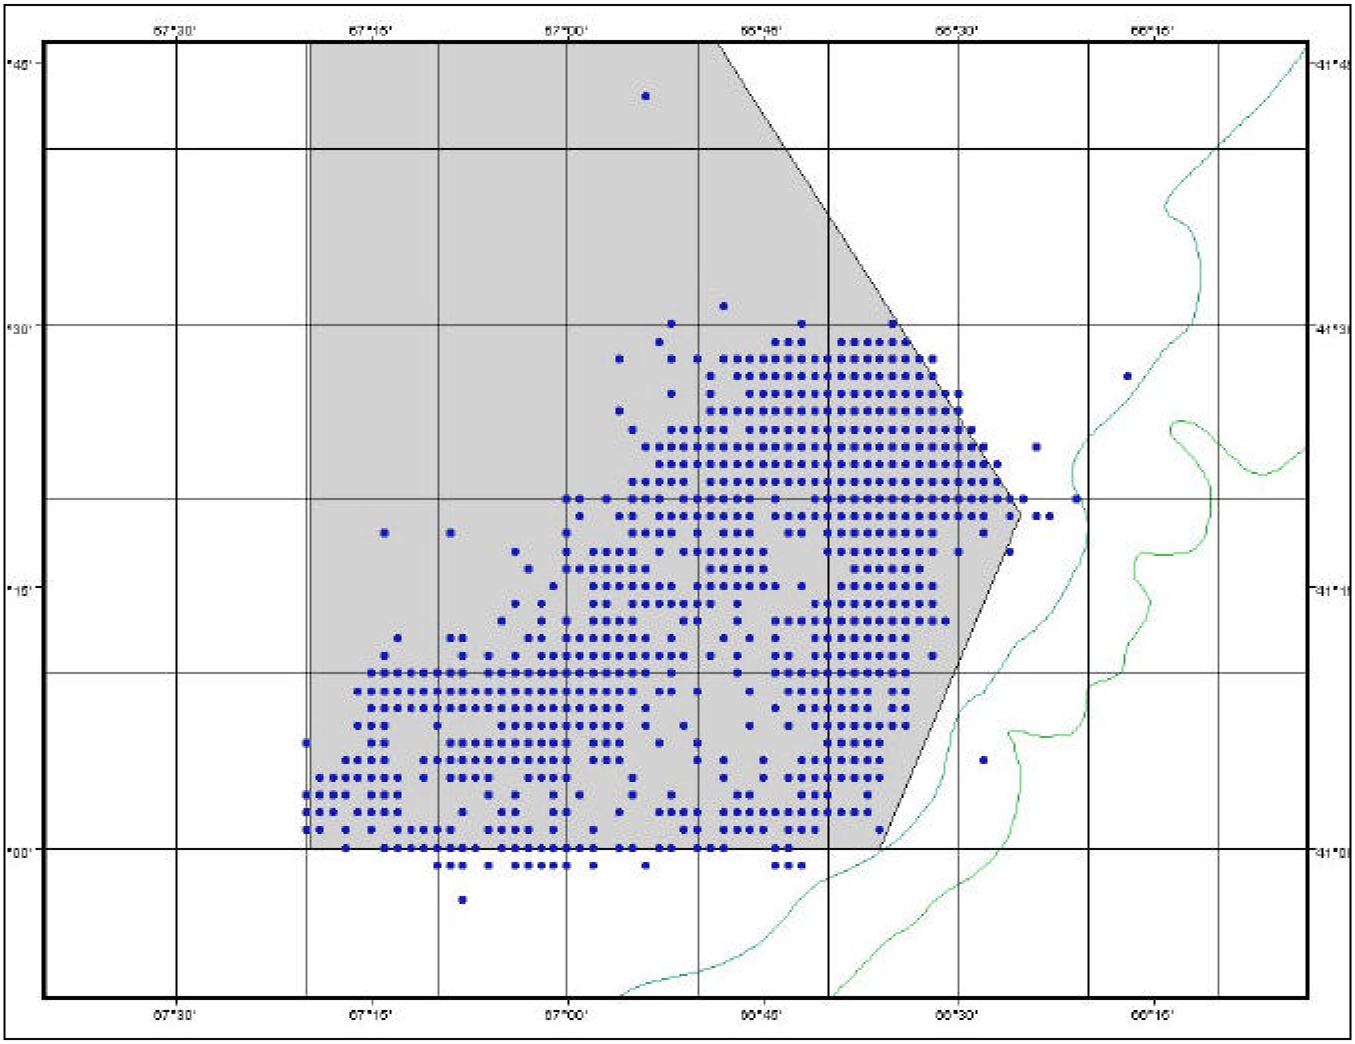

Figure 130 – Location of observed tows in Closed Area II, 2000 Sea Scallop Exemption program. Multiple tows at each location

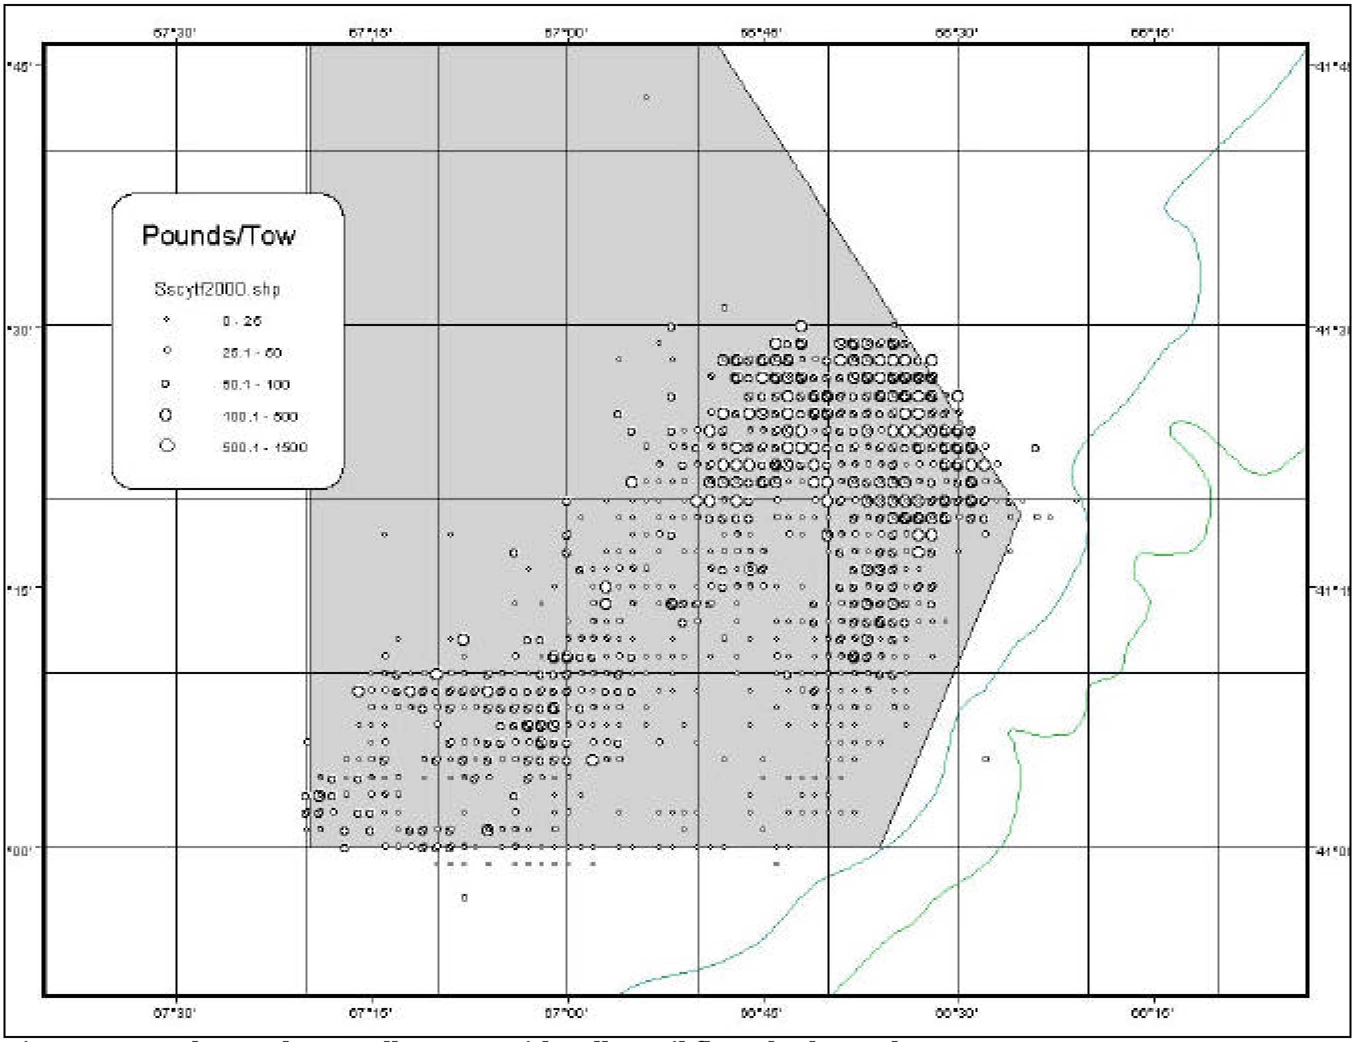

Figure 131 – Observed sea scallop tows with yellowtail flounder bycatch

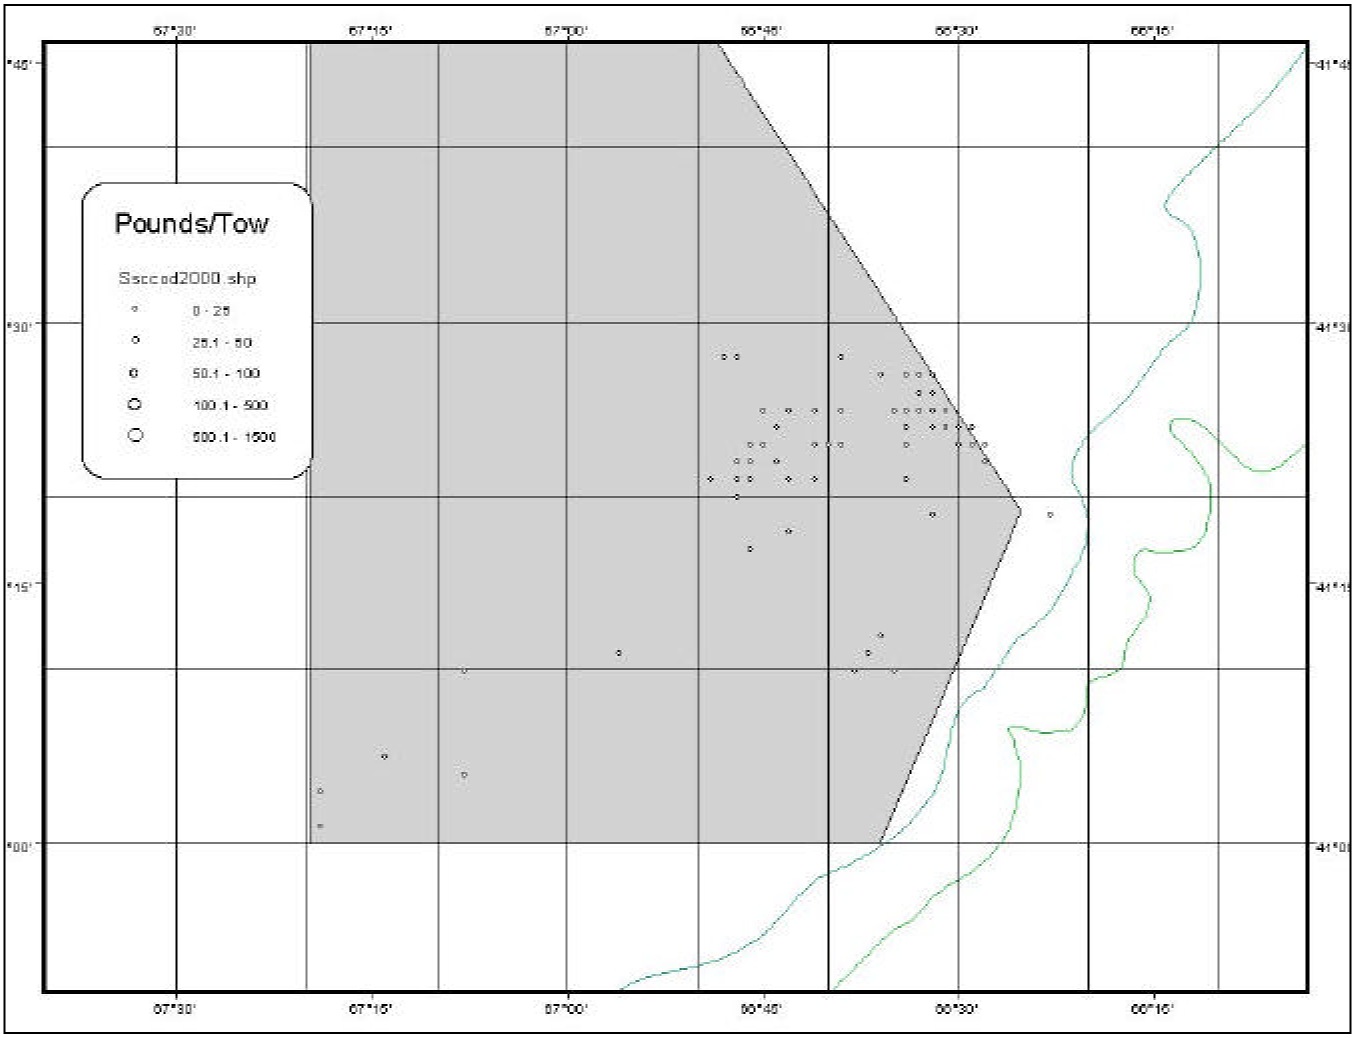

Figure 132 –Observed sea scallop tows with cod bycatch, 2000

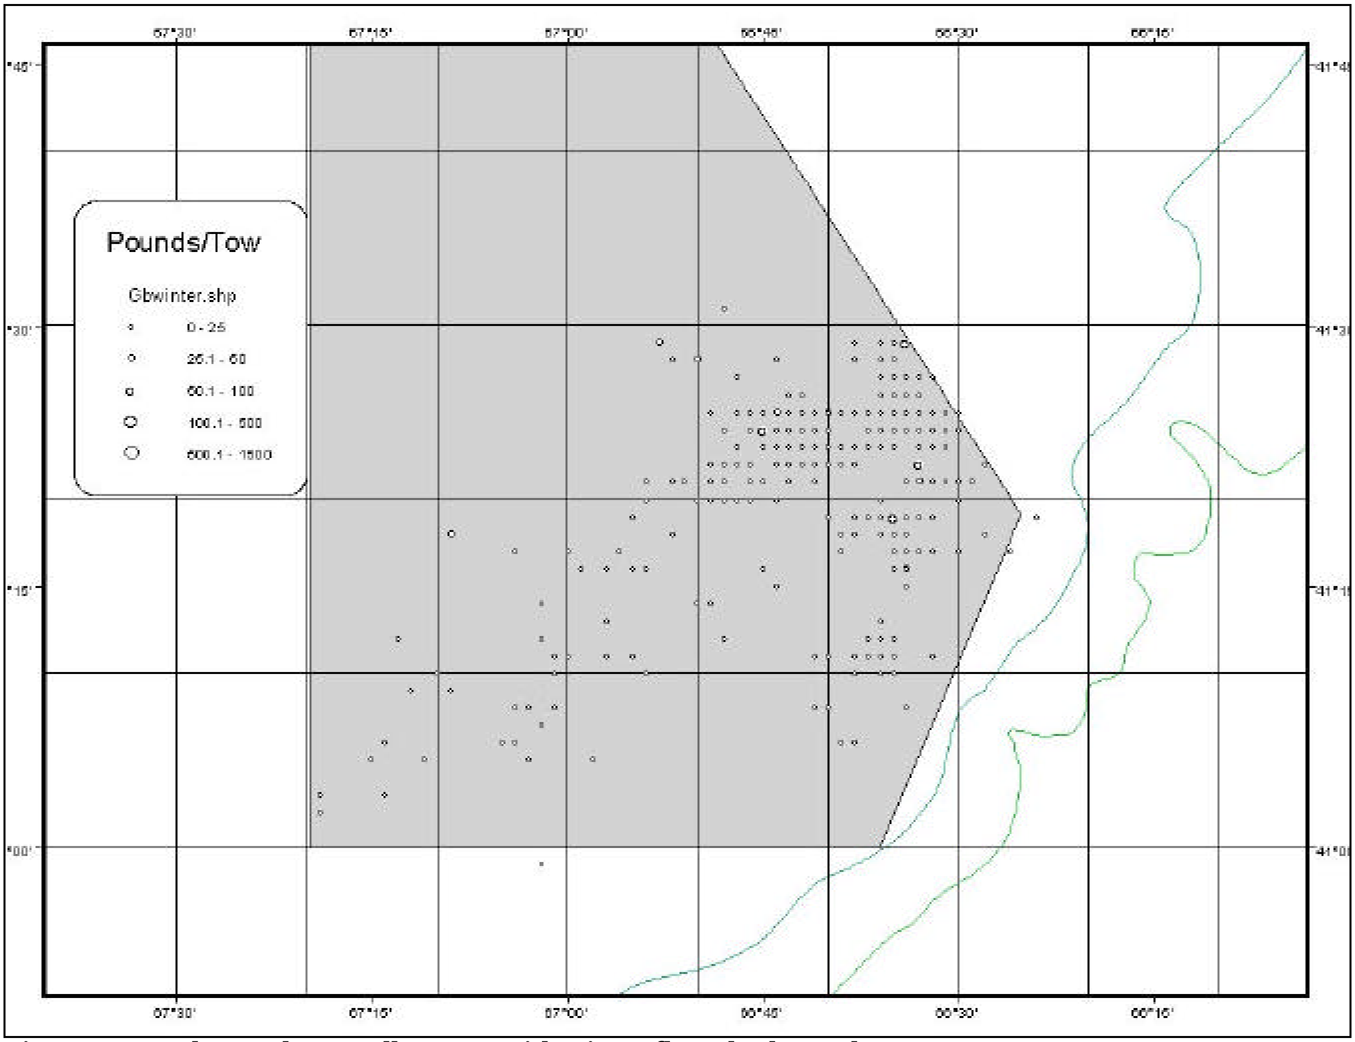

Figure 133 – Observed sea scallop tows with winter flounder bycatch

The analysis of the biological impacts of the yellowtail flounder Closed Area II Special Access program in section 5.2.4.6.1 describes expected yellowtail flounder catch based on the preliminary results of a an experiment conducted by the Manomet Center for Conservation Sciences. Information on bycatch was collected during this same experiment. While locations and densities of the various species encountered during this fishery changed slightly when aggregated by month, the yellowtail access fishery proposed here is intended to occur throughout the duration of the experimental fishery. Therefore, the following figures summarize observed catches for key species aggregated over the four-month duration of this fishery.

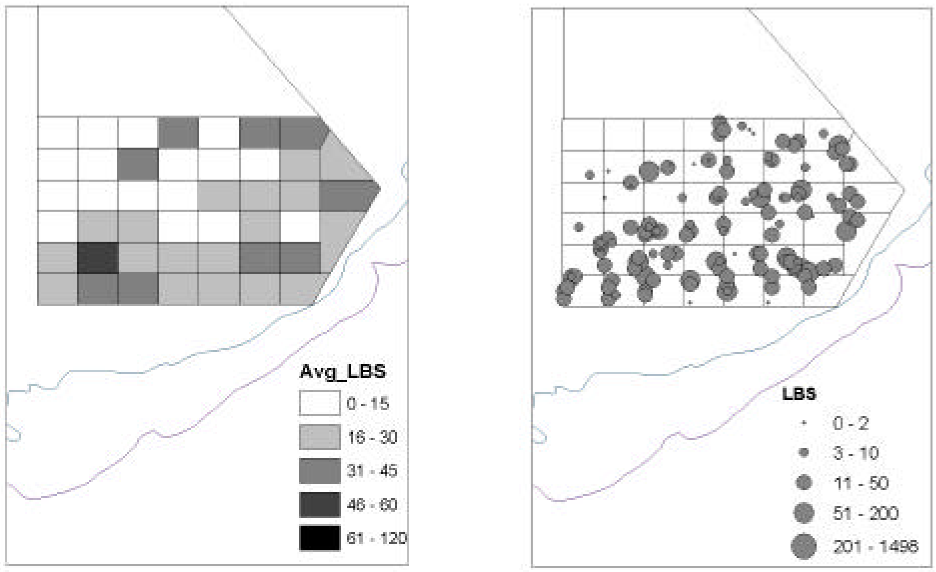

Figure 134 – Mean wt per tow per grid block, total wt per tow for Barndoor Skate.

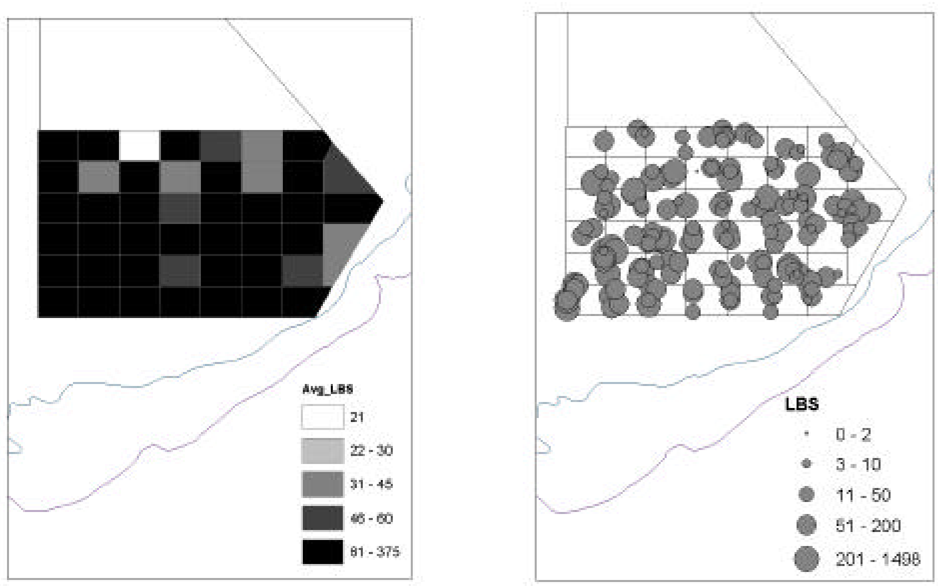

Figure 135 - Mean wt per tow per grid block, total wt per tow for Little Skate.

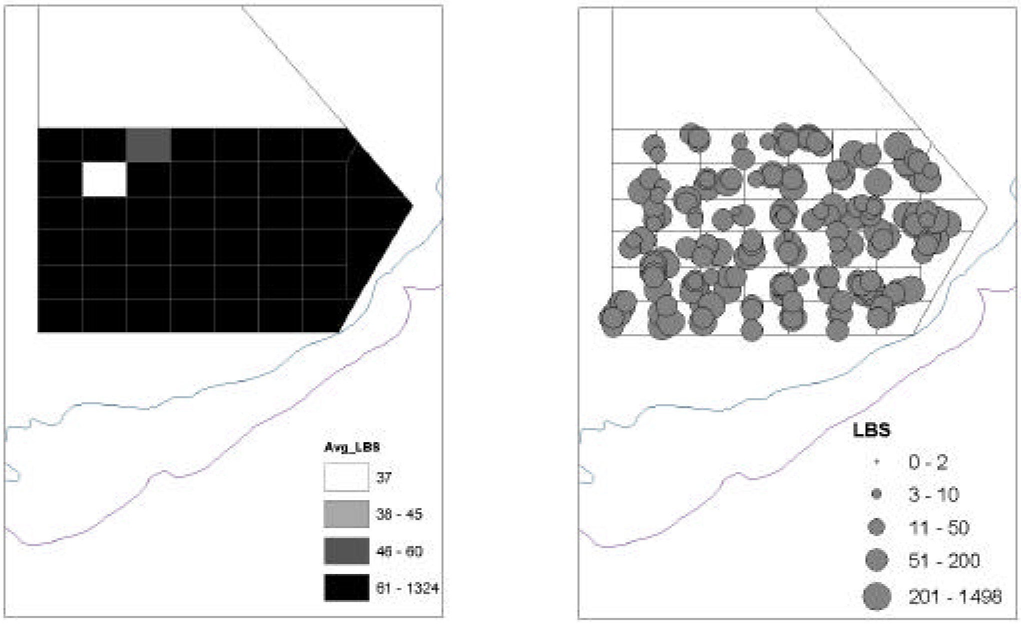

Figure 136 - Mean wt per tow per grid block, total wt per tow for Winter Skate.

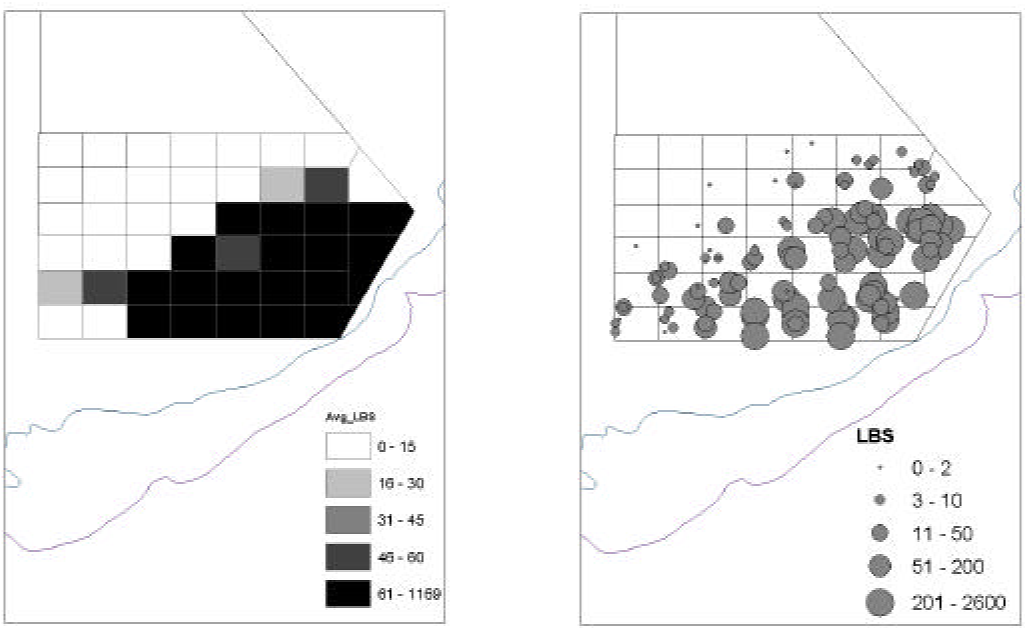

Figure 137 - Mean wt per tow per grid block, total wt per tow for Sea Scallops (wt in shell).

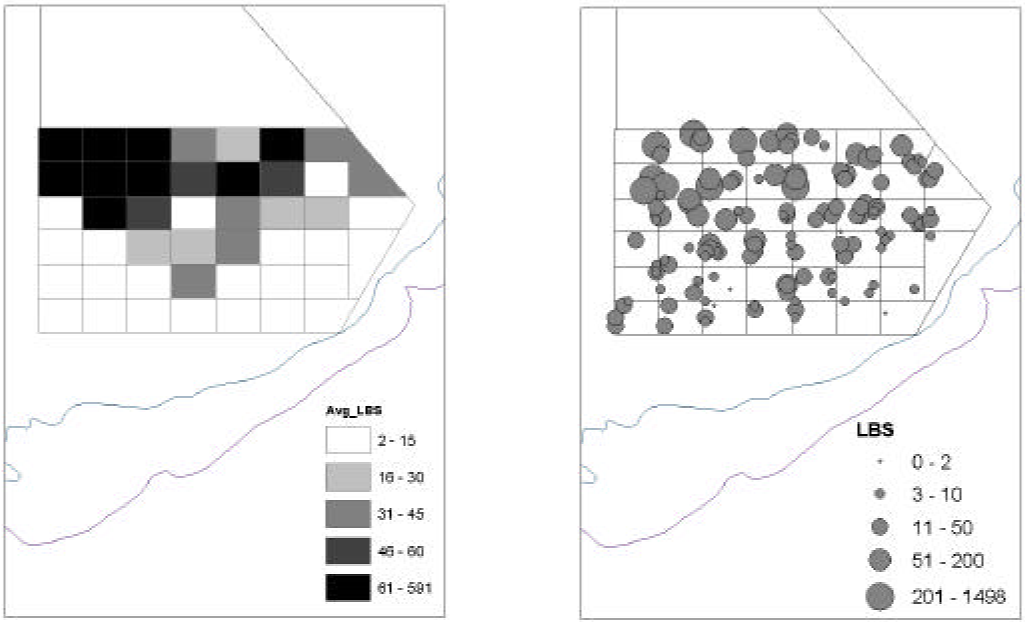

Figure 138 - Mean wt per tow per grid block, total wt per tow for Winter Flounder.

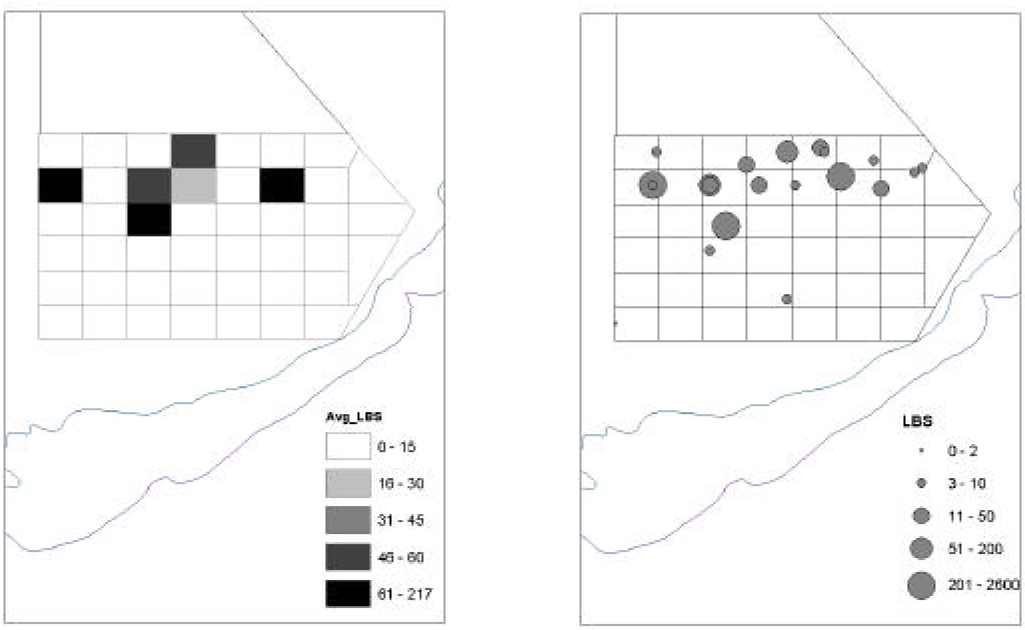

Figure 139 - Mean wt per tow per grid block, total wt per tow for Haddock.

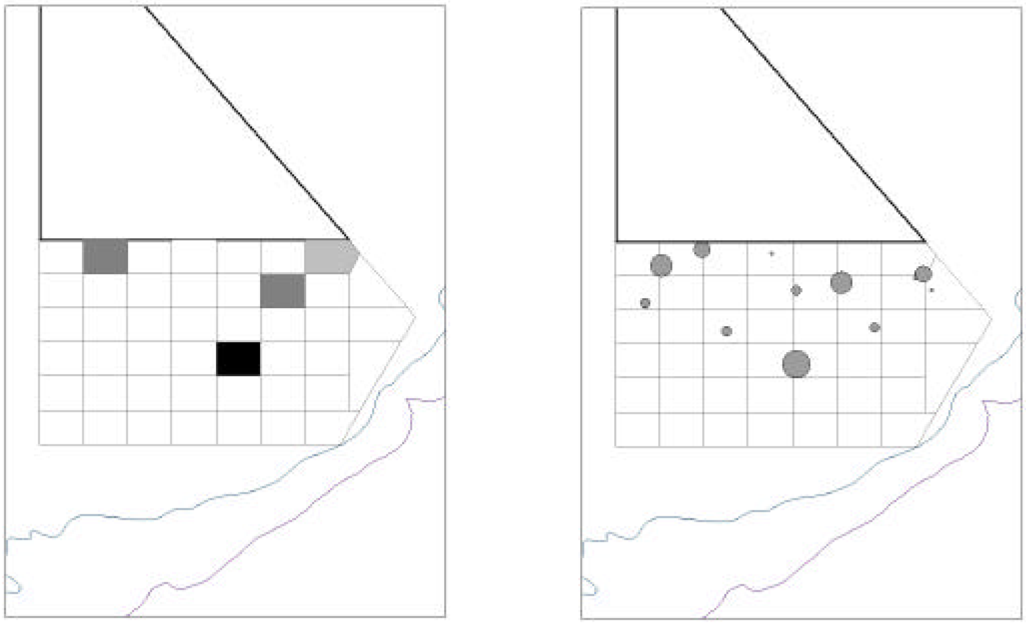

Figure 140 – Mean wt per tow per grid block, total wt per tow for Cod.

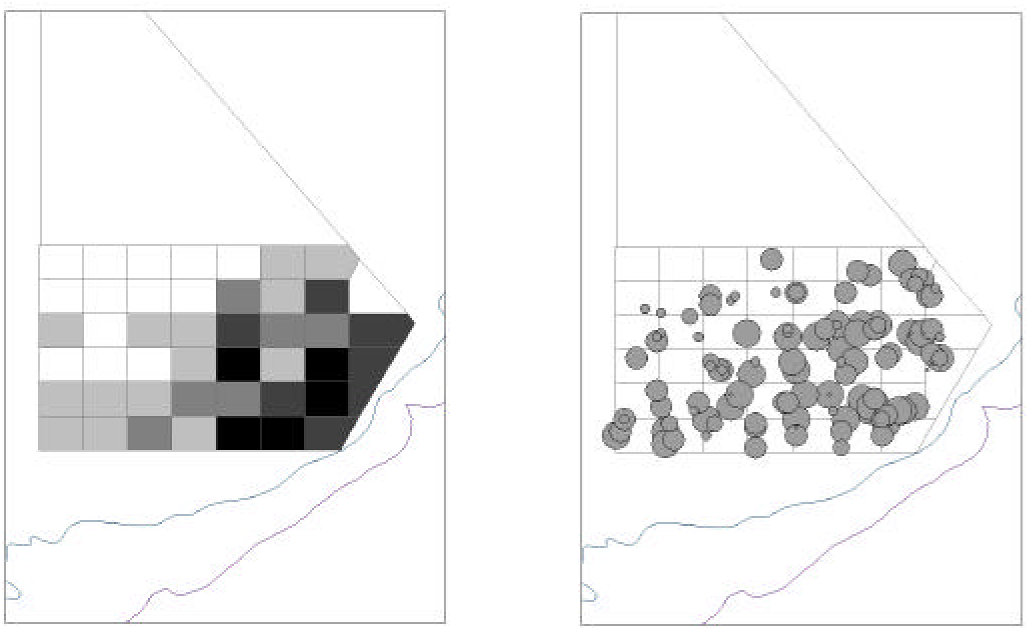

Figure 141 – Mean wt per tow per grid block, total wt per tow for Monkfish.

Bycatch rates inside the grid blocks with the highest yellowtail flounder yield tended to be lower for most key species. Cod, monkfish, barndoor skate and little skate all had a lower mean weight per tow value inside the potential area for targeting yellowtail flounder. Haddock and little skate both showed marginal increases in this area.

Using the same approach as in section 5.2.4.6.1, estimates of likely bycatch were developed for a number of species. Table 112 shows the mean weight per tow, total weight, and number of tows for bycatch species. The figures in the left column represent the mean weight per tow per grid block for seven key species (including yellowtail flounder). Those in the right represent the total pounds caught on each individual tow. Locations marked are the latitude/longitude for the start of each tow. The assumed amount of yellowtail available to this access program fishery is between 4,000 and 5,000 metric tons. If the entire Georges Bank yellowtail TAC were to be caught inside the access program area, a potential maximum of 8,000 metric tons could be caught. If the US/CA Resource Sharing Understanding is implemented, it would cap yellowtail catches in this area according to the terms of the agreement. Table 114 estimates number of trips, and builds on Table 113 to establish upper and lower bounds for bycatch of selected species. These bycatch estimates are not necessarily additional discards of these species. It is not known how much of the effort inside CAII will substitute for trips that previously occurred outside the area, and the amount of bycatch outside the areas is not know with as much detail. For example, if all the trips inside the area represent additional effort, then the bycatch estimates do represent additional discards. If they replace trips with bycatch that previously occurred outside the area, then the entire amount may not be additional discards.

Bycatch of skate species can be expected in this access program. Two skate species that are overfished – thorny and smooth skates – were not identified in the experimental fishery data analyzed to date. Winter skate is also overfished, and was caught in the experiment. Finally, bardnoor skates are also overfished and a potential candidate for ESA listing. Both winter and barndoor skates were caught in the experimental fishery and can be expected to be caught in a commercial fishery in this area.

Table 115– Modeled bycatch estimates for yellowtail access program fishery (totals in metric tons).

SNE/MA Winter Flounder Incidental Catch Program
This special access program is specifically designed to convert discards of small amounts of winter flounder into landings. As such, it should reduce bycatch of winter flounder. In calendar year 2001, roughly 2,000 trips reported discards of small quantities of winter flounder totaling about 200 mt.

US/CA Resource Sharing Understanding Special Access Program
This program alters management measures in the eastern area of Georges Bank in order to facilitate harvesting of the U.S. share of eastern Georges Bank cod and haddock, and Georges Bank yellowtail flounder. The impacts of these measures on bycatch are difficult to estimate. Viewed in isolation, some of the proposed measures will probably increase discards of cod, skates, and other species. If effort shifts into the eastern Georges Bank area as a result of this program, it is possible that effort will move off of stocks or out of areas that have more serious discard concerns. For example, if vessels chose to fish in this area rather than an area with a low yellowtail flounder trip limit, it is very possible that overall discards of yellowtail flounder will decline. There is not enough information to predict this type of interaction with any certainty.

<u>Effort Adjustments:</u> Credits for steaming time, or differential DAS counting, will result in increases in fishing effort. In general, increases in effort are expected to increase the total amount of discards (assuming discard rates do not change).

<u>Gear</u>: Trawl cod end mesh requirements may be lowered to match those used by Canadian vessels. Absent changes in minimum fish sizes, reductions in mesh size are likely to increase discards as more undersized fish will be retained.

<u>Access to Closed Area II</u>: Allowing access to the northern part of CA II may increase discards, but there is little information available to objectively evaluate this concern. Given the experience obtained from several experiments in the southern part of CAII, higher concentrations of cod and skates are likely in the closed area and, if they cannot be avoided by vessels fishing for haddock, will be discarded in increased numbers.

The proposed US/CA Resource Sharing Understanding Special Access Program will, if approved, allow fishing in the northern part of CAII. Vessels fishing in this area will probably catch several skate species. Rothschild and Brown (2002) plotted skate CPUEs for tows conducted during a trawl fleet study. The data suggest that high skate CPUEs are more broadly distributed than haddock CPUEs (see Figure 116 and Figure 142). Areas for high skate CPUEs are found along the northern edge of GB, but are also found up on the bank itself. There is no information on catches inside the northern half of CAII itself. Whether this program will increase bycatch of skates and other species depends on what incentives are offered to fishing in the area. Generous credits for steaming time or DAS differentials may result in an increase in overall effort. Any increase in effort would probably result in an increase skate catch. The use of specific gear (such as a haddock separator trawl) would be expected to reduce the catch of skates, but ongoing studies have not been completed so the exact reduction is unknown.

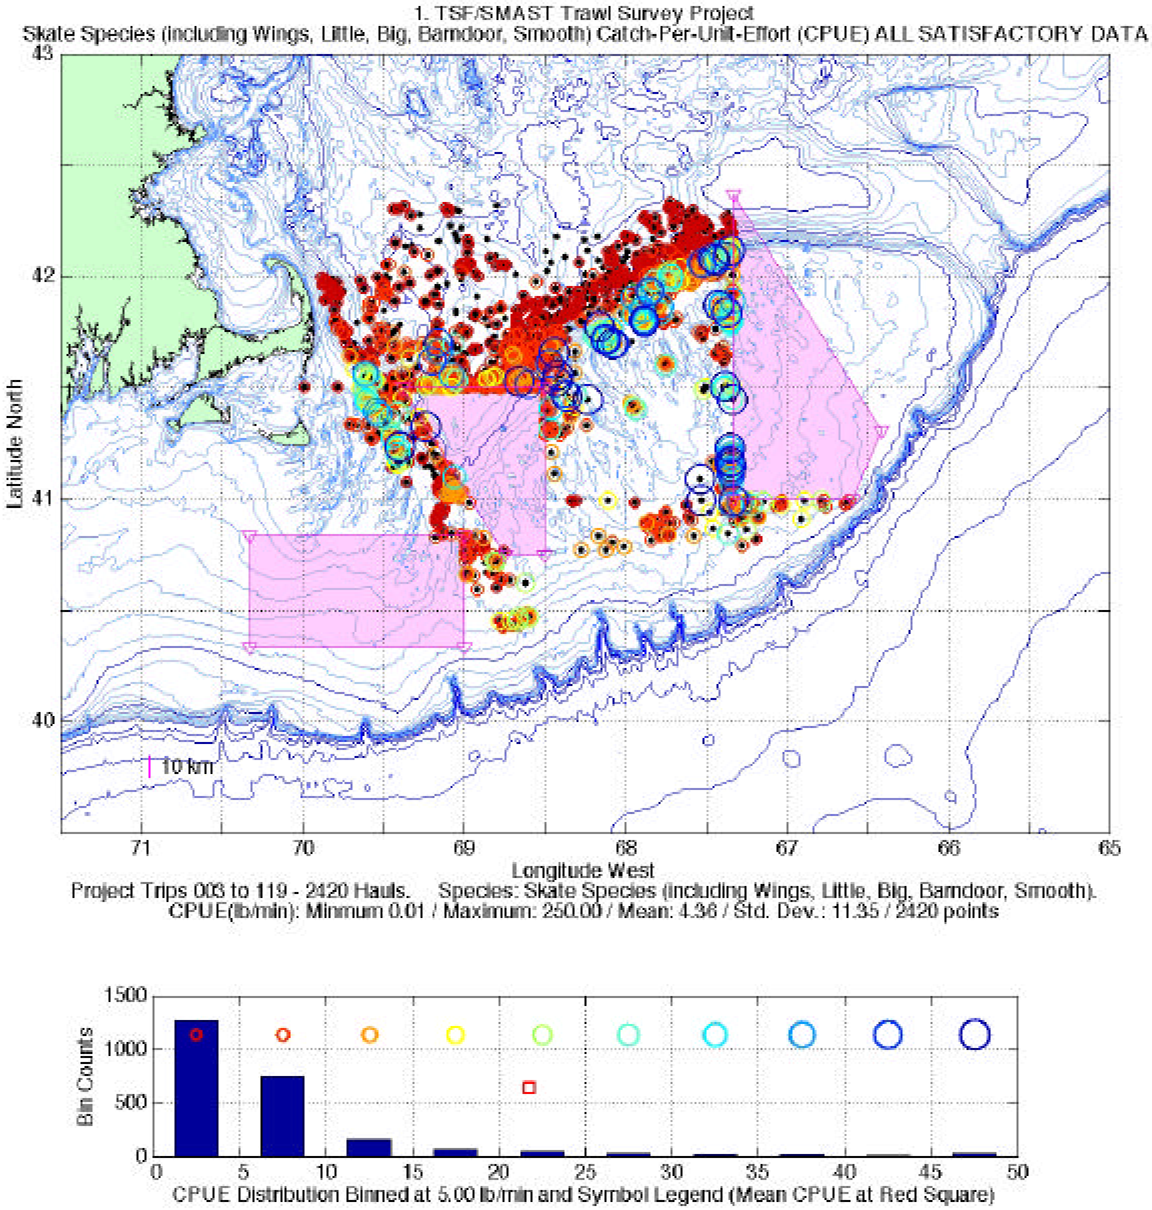

Figure 142 - Observed skate CPUE from TSF/SMAST Trawl Survey Project (from Rothschild and Brown 2002)

Hook Gear Closed Area I Special Access Program

This program will allow hook vessels to target haddock in a defined area of Closed Area I. An experimental fishery is being conducted for this program, but results are not yet available. There is no information available to determine the impacts of this program on bycatch.

5.2.8.2.6 Closed Area Administration

The proposed action does not make any changes to the gear allowed in closed areas (except for habitat protection, see below). Alternatives in this category are not likely to have direct impacts on bycatch. Some of the alternatives may increase the number of gears allowed into closed areas. It is possible there may be some increase in bycatch as a result, but the requirements for access are that the gear demonstrates it does not retain groundfish so these impacts should be minimal. Impacts on other species may not. For example, aggregations of skates in the closed areas may be susceptible to harvest by gear that does not take groundfish. This will have to be evaluated on a case-by-case basis.

5.2.8.2.7 Flexible Area Action System

The proposed action eliminated the FAAS. The flexible area action system was designed to rapidly implement a closed area in response to transient conditions in the fishery – such as unexpectedly high discard rates resulting form concentrations of juvenile fish. The alternative that eliminates this system removes a tool that could be used to reduce bycatch or bycatch mortality. In reality, however, a closure has never been implemented under this system and there is, in effect, no differential impact on bycatch for either keeping or eliminating the system.

5.2.8.2.8 DAS Leasing

The proposed action adopts a DAS leasing program. The amount of bycatch is related to both fishing and regulatory practices. With respect to fishing activities, the amount of bycatch is a function of at least these factors:

Gear (both type and size/quantity)
Target species
Area fished
Effort
Season/time of the year
Stock status/year class effects

Murawksi (1994) analyzed factors affecting discard rates in the mixed species otter trawl fishery from 189 through 1992 and concluded that the main factors affecting all species discard rates were year (reflecting the influence of stock conditions), primary species sought, mesh size, and tow duration (longer tows resulted in less discards).

DAS leasing alternatives would allow the transfer of DAS from one permit to another. The proposed measures include a wide range of possible restrictions on the transfer of those DAS. DAS leasing could affect bycatch or bycatch rates if it results in changes in fishing activity, such as:

Transfer of inactive DAS to a vessel actively fishing
Transfer of DAS from a vessel with a low bycatch rate (due to gear, target species, or area fished) to a vessel with a higher discard rate

As noted at the beginning of the discussion on bycatch impacts, the proposed measures are compared to the no action alternative. Under no action, most permits do not have any limits on the type of gear fished. In addition, there are no limits on where a permit can fish, when it can fish, or what it targets. Finally, permits are routinely transferred between owners – some permits becoming more active, others less so.

From this standpoint, the changes possible under any proposed DAS leasing program are not significantly different than those that can occur under the no action alternative, and thus the DAS leasing alternative is not expected to increase bycatch.

In addition, days at sea leasing only makes sense if an option is chosen which reduces effort. DAS leasing does not make sense to the fishermen under a hard TAC alternative, because it is possible that the TAC may be caught before the opportunity to use leased DAS. Given that there will be less effort in the fishery, bycatch will decline. Additionally, if more efficient vessels lease days at sea from less efficient vessels, bycatch will also decline. This is because efficient vessels are likely to have lower bycatch rates because it is costly to dispose of unwanted fish in terms of downtime from fishing. Therefore, any system which shifts effort from inefficient vessels to efficient vessels is likely to reduce bycatch.

5.2.8.2.9 Recreational Fishing Permits

The proposed action does not adopt a recreational fishing permit. The four options for a recreational fishing permit are unlikely to have a direct impact on bycatch or bycatch mortality. Three of the options require a federal fishing permit for groundfish. This may indirectly improve the understanding of recreational fishing bycatch. As discussed in section (Section 9.4.2.8.3.1), recreational fishing generates considerable bycatch for GOM cod and SNE winter flounder., though it is believed mortality in some cases is quite low. Requiring a recreational fishing permit will improve information on the number of fishermen. This may eventually improve the precision of recreational fishing landing and discard estimates.

5.2.8.2.10 "Running Clock" Alternatives

The proposed action does not change the current modified running clock. Trip or possession limits in this FMP are based on the time elapsed on a vessel's DAS clock. A "running clock" refers to a vessel allowing time to accumulate on its DAS clock in order to land a higher trip limit for a given amount of time actually spent fishing. This can be done either at the end of a trip if the vessel returns to port with more that the allowed trip limit for the time since sailing, or prior to a vessel leaving on a trip by starting its clock before departure (front-loading the clock). "Running clocks" provide fishermen a way to land fish that would have to be discarded under restrictive trip limits. They reduce bycatch by converting regulatory discards of a target species to landings. A more subtle way they may reduce discards is by allowing a way for fishermen to rapidly catch a high value species, which may reduce time spent actually fishing. "Running clocks" may not be a practicable measure for two reasons. First, some versions are considered difficult to enforce and administer. Second, trip limits are supposed to reduce mortality by modifying fishermen's behavior and encouraging them not to target a species. Measures that allow continued targeting weaken this effect.

No Action – Modified Running Clock
Retaining the current "running clock" provides a limited opportunity to convert discards to landings on short trips.

Industry Funded Weighmaster
This alternative expands the ability of a vessel to land more of its catch of a species with a trip/possession limit. No limit is placed on the amount that can be landed on one trip as long as the landing is monitored and verified. The verification process removes some of the enforcement concerns, making this a more practicable alternative. It should result in reduced bycatch for those species with trip limits by converting regulatory discards to landings. Vessel operators, however, may not choose to use this option if they

determine the requirements are too stringent (all trips must be landed at an approved weighmaster) or if the value of the landed catch is not sufficient to justify being charged additional DAS.

Extended Modified Running Clock
This proposal would extend the current "running clock" into one extra day, providing vessel operators additional flexibility to convert some discards into landings. This may provide a slight reduction in bycatch.

5.2.8.2.11 Observer Coverage

Two options to No Action were considered. The No Action option would not specify a desired level of coverage, while Option 2 expresses the Council's desire for a minimum level of coverage. Option 3 does the same, but provides NMFS more flexibility in responding to the Council's desire for improves observer coverage. No Action clearly does not improve understanding of bycatch. While the Council does not have mechanism to implement an observer program, the second and third options indicate the Council's promotion of adequate observer coverage for monitoring the fishery. A better understanding of bycatch should result from a minimum acceptable level of observer coverage. This should lead to the design and implementation of measures to address bycatch issues. The practicability of a minimum requirement for observer coverage depends on the level necessary for statistically valid estimates and the cost of that program. These are not issues within the Council's control. The proposed action adopts Option 3.

5.2.8.2.12 Day Gillnet Blocks out of the Fishery

The proposed action does not adopt any changes to these requirements. Alternatives in this section should not have any impacts on bycatch or bycatch mortality of groundfish. As discussed in the protected species section, removing the requirement to take blocks of time out of the fishery may increase bycatch of protected species, though the extent of that change in unclear.

5.2.8.2.13 DAS Counting

DAS counting alternatives are unlikely to have direct or indirect impacts on bycatch or bycatch mortality. The proposed action does not adopt any changes to DAS counting

5.2.8.2.14 Reporting Requirements

The proposed reporting requirement changes should not have any impacts on bycatch or bycatch mortality.

5.2.8.2.15 Open Access Handgear Permit Alternatives

There were four options for an open-access handgear permits. None of the options considered were expected to impact bycatch or bycatch mortality. The proposed action adopts Option 3.

5.2.8.2.16 Sector Allocation

This alternative is not a stand-alone alternative and must be implemented with one of the other alternatives. It establishes a structure for future consideration and approval of a cooperative sector within the groundfish fishery. As such, it does not immediately implement any specific measures and should have no impacts on bycatch. A sector system that relies on assigning a quota, that allows sector members to design the most efficient means to take that quota, while keeping in place any measures specifically designed to reduce bycatch, should further reduce bycatch. Sector participants will have an incentive to design measures that maximize their returns by reducing, as much as possible any discards. If a sector is implemented in the future, the specific measures adopted will have to be evaluated for their impact on bycatch.

5.2.8.2.17 Georges Bank Hook/Gillnet Sector

The proposed action adopts a GB hook sector, but does not adopt a GB gillnet sector. A specific sector alternative would be implemented in concert with another management alternative if this is adopted. In addition to the general benefits to bycatch that may result (as discussed in the previous section), the specific measures adopted by the sector may reduce bycatch. These provisions must be explained in the sector operating plan submitted for NMFS approval.

5.2.8.2.18 Gulf of Maine Inshore Conservation and Management Stewardship Plan

This proposal was not adopted. As discussed in the description of proposed measures, this alternative does not propose measures throughout the range of the fishery and must be adopted in concert with another alternative. The specific measures proposed can be evaluated for their impact on bycatch, but the overall impacts will depend on which other alternative is adopted.

Fishing Year
Starting the fishing year in July may reduce bycatch for the reasons discussed in section 5.2.8.2.1. The impacts may prove to be temporary as vessels adjust their DAS use to the new fishing year.

Possession/Trip Limit
Increasing the trip limit for GOM cod to 600 lbs./6,000 lbs. should provide a marginal reduction in bycatch compared to the no action alternative as explained in previous sections.

Effort Controls
Similar to Alternative 3, DAS allocations are reduced, but the allocated DAS will still be more than were used in 2001. Only if these reductions result in less DAS used can bycatch reductions be expected.

Observer Coverage
Observer coverage should improve understanding of bycatch, as explained in section 5.2.8.2.11. the level proposed in this alternative – 20 percent – is higher than any other proposal. This may result in estimates of bycatch that are more accurate and more precise, ultimately leading to better design of management measures that reduce bycatch. In addition, the recommendation to increase observer coverage on mid-water trawl vessels will expand the understanding of bycatch in other measures.

Gear Restrictions
The gear restrictions proposed in this alternative apply only to the inshore GOM. Any effects on bycatch will be limited to this area and the stocks caught in this area: primarily GOM cod, but also plaice, CC/GOM yellowtail , witch flounder, pollock, white hake, and GOM winter flounder.

<u>Trawl Gear</u>
Minimum mesh size proposed in this alternative is 6.5 inches and should reduce discards compared to the no action alternative. In addition, the alternative proposes a composite cod end, with square mesh on top and diamond mesh on the bottom. Preliminary information (Glass, pers. comm.) indicates these nets are

more selective for roundfish and flatfish, further reducing retention of undersized fish that must be discarded to comply with minimum size limits. The alternative also restricts the length of ground cables for trawl vessels in the inshore area. This will reduce the sweep width of a trawl, reducing catch rates and bringing them more in line with the daily possession limit. This should further reduce bycatch in the inshore area.

Impacts on bycatch of the ban on night dragging are unclear. There is some evidence from the limited data available that catch rates for many stocks are higher at night. Fishermen have repeatedly testified that this is particularly true for cod. A ban on night fishing, then, may reduce catch rates so that it is easier for fishermen to comply with the daily trip limit for cod, reducing discards.

Gillnets
The number of nets is reduced to 50 for both trip and day gillnet vessels. To the extent that this results in catch rates that are more closely matched to the daily possession limits, this measure should reduce bycatch compared to the no action alternative.

Hook Gear
The number of hooks per boat is reduced roughly in half from the no action alternative. This is effectively a reduction in effort for longline vessels and can be expected to reduce bycatch.

Summary
This alternative will reduce bycatch as compared to the no action alternative, primarily as a result of gear modifications but also due to limits on night fishing and effort controls.

5.2.8.3 Measures to Control Capacity

None of the alternatives to control capacity are expected to have a direct impact on bycatch or bycatch mortality. If a suite of measures is chosen that improves the matching of fishing capacity to the resource, there may be indirect benefits. With an appropriate pool of harvesters, the design of management measures may be simplified. Concepts such as "full-use" policies can be considered. Efforts to control capacity, then should reduce bycatch and bycatch mortality if successful. The form of those measures is unimportant, as long as capacity is better matched to the available resource.

The proposed action adopts the DAS reserve and DAS transfer alternatives.

5.2.8.4 Management Measures to Address Rebuilding Requirements

The alternatives evaluated in this section are designed primarily to reduce fishing mortality using a variety of tools. Many of these alternatives may have a direct impact on bycatch and/or bycatch mortality. In the following evaluation, the elements of each alternative are discussed and the probable impacts on bycatch or bycatch mortality evaluated. If a specific measure is used in more than one alternative, the bycatch impacts are only discussed in detail for the first occurrence, and then this discussion is referenced in later sections. There is very limited ability to provide quantitative estimates of the impacts of the measures. Alternatives are compared to the No Action alternative (regulations in place in fishing year 2001).

5.2.8.4.1 Proposed Action

Many of the measures proposed will reduce bycatch.

Effort Controls/DAS Restrictions

The proposed action adopts a DAS reserve baseline and then categorizes DAS into A, B, and C categories. B DAS are further categorized into B (regular) and B (reserve) DAS, with limits on their use.

The DAS reserve baseline reduces allocated DAS from about 131,000 in FY 2001 to about 68,000 in FY 2004. The allocated DAS in FY 2004 are further restricted. Sixty percent, or about 40,800, are classified as Category A DAS and can be used to target any groundfish stock, subject to other restrictions in the plan. The remainder are classified as B DAS and can only be used under certain conditions. On implementation of the plan, they can only be used in approved special access programs, though future framework actions may provide opportunities to use them to target healthy stocks.

In FY 2001, 65,275 DAS were used. While in FY 2002 DAS use declined to 41,410 DAS, DAS use increased by about sixteen percent early in fishing year 2003. If all available Category A DAS are used, it represents a thirty-seven percent reduction in effort. This is likely to significantly reduce discards and discard mortality from that in FY 2001 and probably compared to FY 2003. Compared to FY 2002, the level of effort is similar so there would not be expected to be much change in the discards as a result of a change in effort.

The use of Category B DAS could alter this conclusion. There are limited opportunities to use B DAS in special access programs, and those programs have tight limits on the amount of bycatch allowed. For this reason, the use of B DAS in special access programs is not expected to increase discards or discards mortality compared to FY 2001. The details have not been developed for the use of B (regular) DAS outside of a special access program. The concept is that those opportunities will be narrowly defined so as to avoid concerns over both discards and adverse effects on rebuilding programs.

Closed Areas

Closed areas as implemented August 1, 2002 are maintained. With the exception of closing the Cashes Ledge closed area for an additional six months, they are identical to the closed areas in place in fishing year 2001 and will not provide further benefits to bycatch reduction. The seasonal closed areas may result in additional bycatch reduction in the inshore GOM because of the May closure, as well as some small reductions in bycatch because of the expansion of the GB closure in May (compared to FY 2001).

Possession Limits

Trip/possession limits are proposed for GOM cod, GB cod, CC/GOM yellowtail flounder, haddock, and SNE/MA yellowtail flounder. In general, all trip/possession limits can be expected to increase bycatch if fishermen are unable to avoid catching that species. These regulatory discards can be avoided by using other measures. The following discussion compares the impact of trip/possession limits to the no action alternative. Any conclusions with respect to trip limits must be revisited as stock size changes. An increase in stock size is likely to increase catch rates, and, if trip limits are not adjusted, can be expected to result in increased discards unless effort shifts onto some other stock.

GOM cod: The no action alternative limit is 400 lbs./day and 4,000 lbs. per trip. This proposed action increases the trip limit to 800 lbs./4,000 lbs. The higher trip limit is specifically designed to reduce bycatch. By doubling the current trip limit, the discard rate should decline. The increased trip limit may encourage fishing effort to shift onto GOM cod. This may reduce discards on other stocks (such as CC/GOM yellowtail flounder). Future increases in the trip limit may be necessary as the stock (and presumably catch rates) increase. Additional analysis of the cod trip limit can be found in section 5.2.8.4.3.

GB Cod: This alternative reduces the GB cod trip limit to 1,000 lbs/day – 10,000 lbs/trip. Alternative 2 proposed a 500 lbs/day trip limit for this stock. The bycatch implications of that change are discussed in section 5.2.8.4.4. This analysis provides information on the likely impacts of the proposed action. While a trip limit model (based on catch per trip, not tow) suggests that any reduction of a GB cod trip below 2,000 lbs per day will increase discards, available observer and research program data suggest otherwise. Based on examination of observer and trawl study fleet catches, it appears that there is a limited ability for trawl vessels to reduce bycatch of cod on GB by targeting other species. The average catch of cod per tow, on tows not targeting cod but targeting other multispecies, averages just under 200 lbs per tow over the course of the year. Assuming vessels average five tows per day fishing, the 1,000 lb cod limit should not increase discards or discard mortality significantly.

SNE/MA yellowtail flounder: SNE/MA yellowtail flounder landings are not constrained by a trip/possession limit under the no action alternative, while the proposed action imposes a seasonal trip limit of 250 pounds from March through May, and 750 pounds the remainder of the year. Figure 145 shows the results of a trip limit analysis for this stock. While the analyzed alternatives are based on a year round trip limit and not the seasonal proposal, it is clear that the 250 pound trip limit is likely to significantly increase discards compared to the no action alternative – discards may prove to be twice as high as landings, unless some unknown seasonal effect limits the impacts. The limit of 750 pounds for the remainder of the year will not result in bycatch as high as the 250 pound limit, but will still increase bycatch over that in under the no action alternative.

CC/GOM yellowtail flounder

This alternative establishes a low trip limit for this stock. Absent other measures, it will increase discards. One change that may mitigate these impacts is the raising of the GOM cod trip limit. This may shift effort off CC/GOM yellowtail flounder and, to the extent cod can be caught without catching yellowtail, it may reduce discards.

Gear Restrictions

In all management areas, the proposed action increases the minimum size of permissible diamond mesh by one-half inch for trawl gear. It also increases the minimum size for gillnet gear in the GOM-GB and SNE mesh areas. Increases in mesh in the New England multispecies fishery reduce discards, as reported by Murawski (1996). This general observation is also supported by an examination of the discard data presented in Volume II. There is a general trend in reduced discards, particularly of juvenile fish, since 1994 and the adoption of increased mesh sizes in the multispecies fishery.

This alternative also continues the prohibition on the use of de-hooking devices on longline vessels, which may serve to reduce bycatch mortality in this fishery, though the impacts are not well documented.

Minimum Fish Sizes

This alternative increases the minimum fish size for GOM cod to 22 inches for commercial fishermen. This is approximately the size where 10 percent of the cod that encounter a net are expected to be retained. This is a lower percentage than the standard use for Amendments 5 and 7, which set minimum fish size at the point that 25 percent of the cod encountering the net were expected to be retained. This measure may actually increase discards compared to those that would result with a 19 inch minimum size.

Some small amounts of fish between 19 and 22 inches are likely to be retained even in the increased mesh size, and the increase in minimum size will require those fish to be discarded.

Summary
The proposed action will reduce bycatch and bycatch mortality compared to the no action alternative, primarily because of reductions in effort and additional gear restrictions. The provisions for the use of B regular DAS, and careful monitoring of the use of B DAS in special access programs, will be necessary for this conclusion to continue to be valid.

5.2.8.4.2 No Action Alternative

This alternative was not selected. The No Action alternative continues the measures in place during fishing year 2001 (see Section 4.1.5.1). The impacts of those measures on bycatch are reflected in the observed levels of bycatch described in section 9.4.2.8. These measures reduced bycatch in this fishery by a significant amount in recent years through a combination of seasonal and year round closed areas, effort controls, and gear modifications (large mesh, limits on number of hooks and gillnets, etc.).

5.2.8.4.3 Alternative 1 – Up to 65% Reduction in Used DAS

This alternative was not selected. Many of the measures proposed for this alternative would have impacts on bycatch.

Effort Controls/DAS Reductions
This alternative reduces fishing effort by up to 65% from that used in fishing year 2001. This measure is likely to significantly reduce discards and discard mortality of all bycatch species by reducing time fishing and by reducing total catch. It may also reduce the rate of discards. Fishermen with limited time available to fish will attempt to maximize their return on every trip and will attempt to convert any discards into landings. There is also differential DAS counting in the SNE/MA yellowtail flounder stock areas. These further effort reductions will also contribute to reduced bycatch.

Closed Areas
Closed areas as implemented August 1, 2002 are maintained. With the exception of closing the Cashes Ledge closed area for an additional six months, they are identical to the closed areas in place in fishing year 2001 and will not provide further benefits to bycatch reduction. The seasonal closed areas and may result in additional bycatch reduction in the inshore GOM because of the May closure.

Possession Limits
Trip/possession limits are proposed for GOM cod, GB cod, CC/GOM yellowtail flounder, haddock, and SNE/MA yellowtail flounder. In general, all trip/possession limits can be expected to increase bycatch if fishermen are unable to avoid catching that species. These regulatory discards can be avoided by using other measures. The following discussion compares the impact of trip/possession limits to the no action alternative.

GOM cod: The no action alternative limit is 400 lbs./day and 4,000 lbs. per trip. This alternative proposes increasing the trip limit to 800 lbs./4,000 lbs. The higher trip limit is specifically designed to reduce bycatch during a period that cod aggregate for spawning. By doubling the current trip limit, the discard rate should decline. The increased trip limit may encourage fishing effort to shift onto GOM cod.

The change in the trip/maximum possession limit is incorporated into the closed area model. This measure can also be analyzed independently, however, to estimate the different impacts between various trip limits. A range of trip limit alternative were examined using this. The results suggest the changes in discard rate that may result from revising the trip/possession limit. Trip/possession limits reduce mortality only if fishermen alter behavior because of the limits. If they continue to fish in a way that catches cod, and merely discard the overage, there is no benefit to a trip limit. It is not possible to predict how fishermen will react to changes in a trip limit. In order to gain a sense of the mortality and bycatch impacts that may result from changing the GOM cod trip limit, trip-level behavior of fishermen was modeled using the observed trips that took place in fishing years 1996 and 1997. These years were chosen because fishing activity was not constrained by low trip limits. The trips were examined to determine how the proposed trip limit would affect fishing activity if fishermen are assumed to base their decision to fish on maximizing revenue. The basic premise is that a trip would continue to take place, and catch cod, if the value of other species caught on the trip is sufficient to cover costs. Three different assumptions were made for labor costs. In this instance, cod over the trip limit is assumed discarded. If the catch of other species will not cover costs, the trip is ended and the additional cod caught is considered "savings."

The analysis indicates that all of the trip limit alternatives (except for the no action 400/4,000) evaluated are virtually indistinguishable from one another in terms of total catch but that they all are greater than the status quo (under three different scenarios for labor costs). This illustrates that changing the trip limit will not be mortality- or catch-neutral. Thus, changing the trip limit is not merely a case of converting discards into landings. There is, of course, an element to this effect for many trips, but an increase in the trip limit makes formerly marginal trips profitable and results in increased effort. These results are also illustrated in Figure 143. Examining this figure shows that there are generally "clouds" of results from the various models, indicating the range of results for the different trip limit options and the different assumptions of costs. The line marking a 10% mortality reduction shows the lowest mortality reduction likely to result from the current trip limit. To be equivalent to the current trip limit's effect on mortality, all the points of one of the options should be to the right of this line. Clearly, the options are likely to result in an increase in fishing mortality. Increasing the trip limit will make more trips profitable and will provide an incentive for more targeting of cod.

Changing the trip limit does, however, significantly reduce the ratio of fish discarded to fish kept. All of the alternatives should cut in half the discard to keep ratio. The results of the analysis indicate that the maximum cap is not as effective as holding the cap down while increasing the daily limit. All alternatives in the 700 - 800 pound range result in discard levels that range between 35 and 50 percent regardless of the maximum cap. The discard to keep ratio declines as the daily trip limit is increased. The results indicate that if the Council is seeking to get some control over discarding increasing the maximum cap is not as effective as holding the cap down while increasing the daily limit. There is a consistent pattern where all sensitivity runs generate discard rates in excess of 60 percent of landings when the daily limit is 500 pounds or less. All alternatives in the 700 - 800 pound range result in discard levels that range between 35 and 50 percent regardless of the maximum cap.

The model may under-estimate one possible behavioral response that may result in additional bycatch reductions. If fishermen end a trip after reaching a targeted revenue level that is lower than that expected by the model, then additional "savings" of cod and other discarded species may result. Fishermen have testified at Groundfish Committee meetings that a cod trip limit in the range of 800 to 1,000 pounds per day is enough for a "day's pay," and that after catching this amount many fishermen will choose to end their trip, avoiding further discards. As a result, the increase in mortality (relative to the status quo) may not be as great as that predicted using the model.

To summarize the results of the analysis for the options under consideration:

- The proposed increase in trip limits will result in higher catches than the current trip limit (400 pounds per day/4,000 pounds per trip). This may not occur if fishermen end their trips after reaching the new trip limit because they have earned enough revenue to make the trip profitable.
- The proposed increase will convert some discards to landings, and all should cut the discard to kept ratio roughly in half compared to a 400 lb./4,000 lb. trip limit.

GB Cod
This alternative keeps the GB cod trip limit at 2,000 lbs. day/20,000 lbs. trip and will not change the impact on discards. Reductions in the daily limit will increase bycatch, as demonstrated in Figure 144.

SNE/MA yellowtail flounder
SNE/MA yellowtail flounder landings are not constrained by a trip/possession limit under the no action alternative, while Alternative 1 imposes a seasonal trip limit of 250 pounds from March through May, and 750 pounds the remainder of the year. Figure 145 shows the results of a trip limit analysis for this stock. While the analyzed alternatives are based on a year round trip limit and not the seasonal proposal, it is clear that the 250 pound trip limit is likely to significantly increase discards compared to the no action alternative – discards may prove to be twice as high as landings, unless some unknown seasonal effect limits the impacts. The limit of 750 pounds for the remainder of the year will not result in bycatch as high as the 250 pound limit, but will still increase bycatch over that in under the no action alternative.

CC/GOM yellowtail flounder
This alternative establishes a low trip limit for this stock. Absent other measures, it will increase discards. The trip limit is combined with gear requirements that should minimize discards.

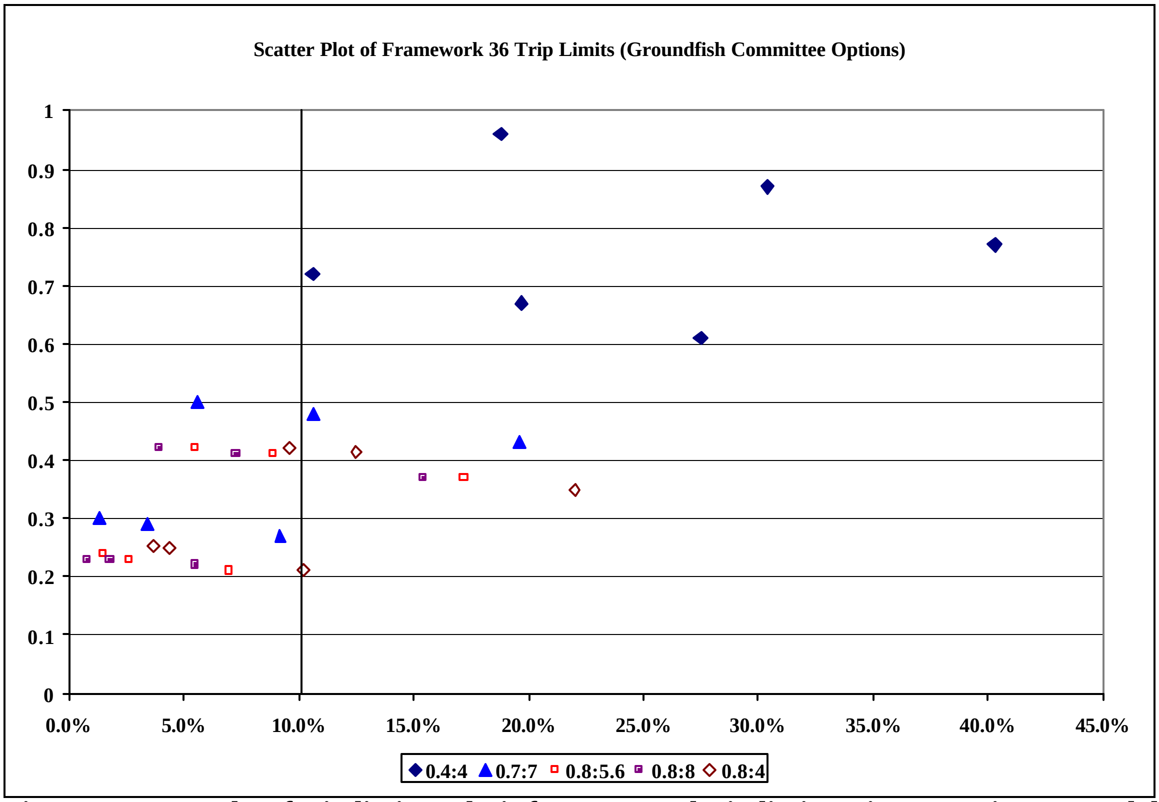

Figure 143 – Results of trip limit analysis for GOM cod trip limit options. Y-axis: expected discard rate. X-axis: reduction in mortality compared to no trip limit.

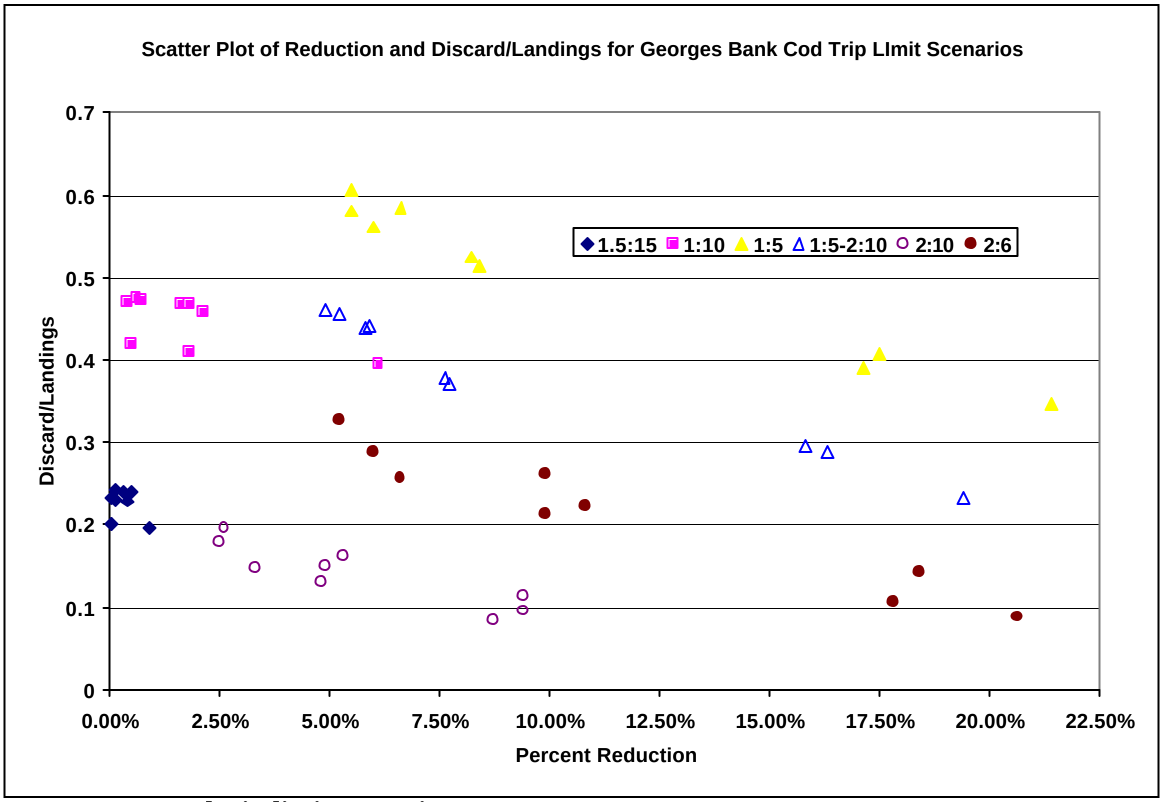

Figure 144 - GB cod trip limit scenarios

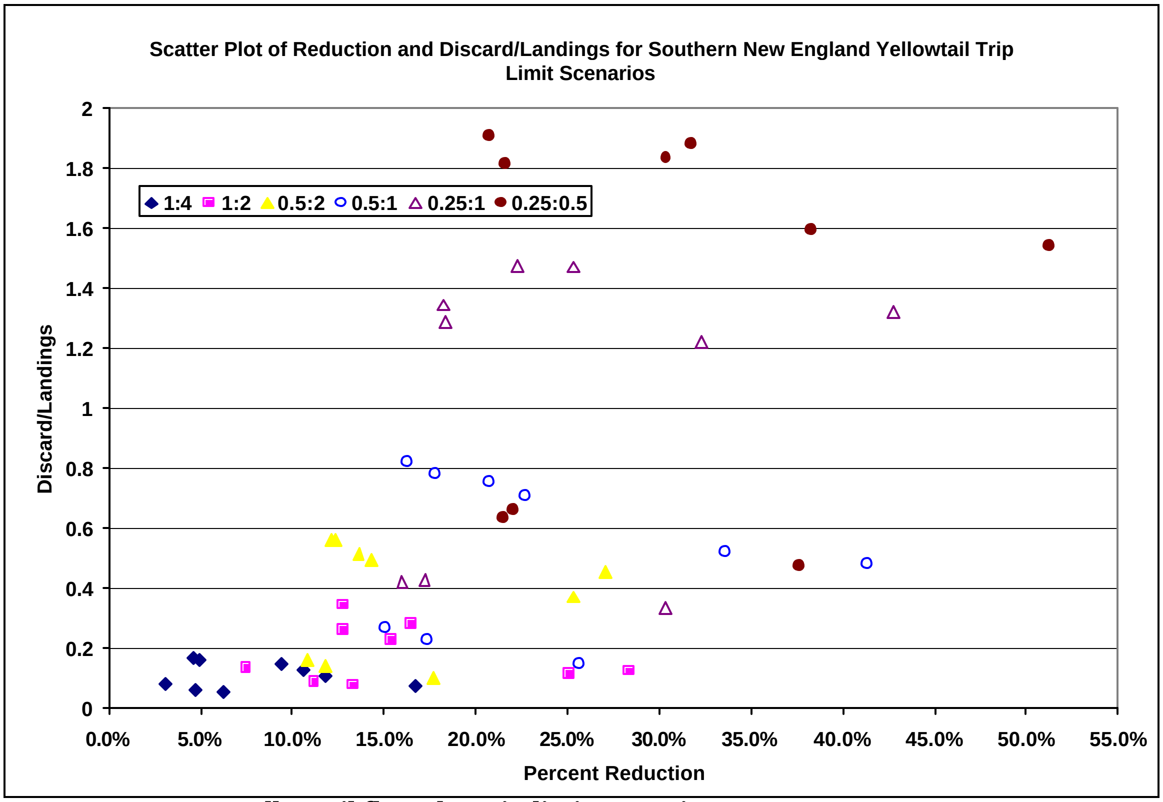

Figure 145 –SNE/MA yellowtail flounder trip limit scenarios

Gear Restrictions

In all management areas, the proposed action increases the minimum size of permissible diamond mesh by one-half inch for trawl gear. It also increases the minimum size for gillnet gear in the GOM-GB and SNE mesh areas. Increases in mesh in the New England multispecies fishery reduce discards, as reported by Murawski (1996). This general observation is also supported by an examination of the discard data presented in Volume II. There is a general trend in reduced discards, particularly of juvenile fish, since 1994 and the adoption of increased mesh sizes in the multispecies fishery.

This alternative also continues the prohibition on the use of de-hooking devices on longline vessels, which may serve to reduce bycatch mortality in this fishery, though the impacts are not well documented.

Other gear restrictions that may reduce discards include the use of raised-footrope trawl in certain areas. This should reduce discards of CC/GOM yellowtail flounder that would other wise result from the low trip limits. In addition, there may be some reduction in discards resulting from the allowance of fewer gillnets.

Minimum Fish Sizes

This alternative increases the minimum fish size for GOM cod to 22 inches for commercial fishermen. This is approximately the size where 10 percent of the cod that encounter a net are expected to be retained. This is a lower percentage than the standard use for Amendments 5 and 7, which set minimum fish size at the point that 25 percent of the cod encountering the net were expected to be retained. This measure may actually increase discards compared to those that would result with a 19 inch minimum size. Some fish between 19 and 22 inches are likely to be retained even in the increased mesh size, and the increase in minimum size will require those fish to be discarded.

Summary
Alternative 1 will reduce bycatch and bycatch mortality compared to the no action alternative, primarily because of reductions in effort and additional gear restrictions.

5.2.8.4.4 Alternative 2

Many of the measures proposed in this alternative are similar to those in Alternative 1 and the impacts will only be briefly described. This alternative was not selected.

Effort Controls
This alternative reduces DAS allocations rather than DAS used. Allocations are reduced 20 percent from the baseline allocations implemented August 1, 2002, with a possible additional 10 percent reduction for vessels fishing in the GOM. If all allocated DAS are used, the number of DAS used will be similar to DAS used in 2001 and there would only be marginal reductions expected in bycatch. Based on DAS use during the first six months of fishing year 2002, all allocated DAS are not likely to be used unless a DAS leasing program is implemented. To the extent DAS use is less than that in 2001, bycatch may be reduced, but it is not clear that this will actually occur.

Closed Areas
The same year round and seasonal closed areas are used that are in Alternative 1 and should have similar impacts on bycatch.

Possession Limits

<u>GOM Cod</u>
The proposed limit of 500 lbs./4,000 lbs. should marginally reduce discards compared to the no action alternative. Compared to Alternative 1, more GOM cod discards should be expected.

<u>GB Cod</u>
Previous analyses suggest the proposed trip limit of 500 lbs./4,000 lbs will significantly increase discards of GB cod. Examination of Figure 144 shows that daily trip limits of 1,000 pounds result in discard to landings rations of 40 to 60 percent. A further reduction to 500 lbs./day will likely result in even higher discard ratios in the absence of any other measures adopted to reduce discards. This alternative will increase GB cod discards more than either the no action or other alternatives under consideration.

There has been some comment that trawl fishermen can alter behavior to reduce the increase in discards resulting from this lower daily trip limit. Earlier analyses were completed on a per trip basis, and thus did not capture the possibility that only certain tows of a trip are used to catch large amounts of cod – that is, that tows are used to "top off" the vessel's allowable cod possession limit. Examination of 2002 observer data determined that the average cod caught per tow on 1,301 tows from trips where cod was a target was 158 pounds. For those tows on trips where cod was not a target, the average was 120 pounds. Cod catches were not correlated (in any manner) with any other groundfish species, suggesting that the ability to avoid cod may in fact be limited. No cod was caught on only one-fifth of the tows, regardless whether cod was a target for the trip or not. On roughly 30 percent of the tows, the amount of cod caught was between 100 and 500 pounds. Less than 6 percent of the observed tows caught more than 500 pounds. Further analysis of the observed data – based on seasons or areas – may shed additional light on this issue. The data also reflect behavior that took place on observed trips in 2002, and may not completely describe the types of behavior that are possible.

The School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth recorded tow-by–tow catches from trawl vessels during a research program in December 2000 – October 2001, and again from August 2002 through March 2003. In addition to recording detailed information on the location, catch, and duration of each tow, the target species for each tow was also identified. The results of this analysis clearly show that catches of cod are higher on tows where cod was the target species, averaging 597 pounds per tow. Consistent with the observer data, however, the catch of cod on tows targeting multispecies, but not cod, averaged 194 pounds over the course of the study. There was considerable variability over different quarters, with average cod catches ranging from 30 to 241 pounds per tow on tows targeting multispecies (but not cod). (Jakubiak, pers. comm.)

Both the observer data and the SMAST data suggest that it is difficult to completely avoid cod while fishing on Georges Bank, regardless of the target species. Both data sets show cod catches averaging between 100-200 pounds per tow. If vessels have a t least 4 tows per day, it is likely, then, that a trip limit of 500 pounds per day will increase discards from trawl vessels. The amount of increased discards will depend in large measure on how effectively trawlers can target their tows and avoid cod bycatch. While the SMAST study shows that targeting cod can increase cod catches, it also shows that is difficult to eliminate cod catches completely.

CC/GOM yellowtail flounder

There is no trip limit analysis available for CC/GOM yellowtail flounder. The proposed limit of 50 pounds is likely to significantly increase bycatch in the absence of other measures. It should be noted that there are gear requirements that may reduce the bycatch impacts of this proposed low trip limit, however, even with these gear modifications factored in, Table 117 and Table 118 show that discards are predicted to exceed landings by a wide margin under this trip limit.

In FY2001 9,916 trips landed yellowtail flounder. 6,302 of these trips landed greater than 50 lbs. Of these, the trip limit model predicts 9,113 trips will be profitable based on total landings of other species. Table 116 confirms that landings of species other than CCGOM yellowtail ensures that trips are profitable even under situations with high yellowtail discards.

CCGOM yellowtail	all other groundfish	days absent	n
> 50	3,655	1.97	3,724
50 - 100	1,655	1.40	1,306
101 - 250	2,210	1.60	1,951
251 - 500	3,099	1.82	1,132
501 - 1,000	3,796	1.92	865
1,001 - 5,000	9,844	3.11	736
5,001 - 10,000	17,377	5.80	118
> 10,000	16,922	6.25	84

Table 116 – Mean landings (lbs) per trip where CC/GOM yellowtail flounder was landed.

SNE/MA yellowtail flounder

The proposed trip limit for SNE/MA yellowtail flounder is the same as for Alternative 2. It is likely to significantly increase the discard rate for this stock, particularly during the months with a 250 pound limit (see Table 120 - Table 123, below).

Gear Restrictions

Mesh requirements and limits on the number of hooks and gillnets are the same as for Alternative 1. These should help to reduce bycatch in the same fashion. In addition, the requirement for a haddock separator trawl net on GB and in certain areas of the GOM should reduce discards of cod and flatfish. These nets may help vessels remain under the restrictive cod trip limits. The alternative also requires use of a flounder net, as specified by the Regional Administrator. Certain designs of net have been demonstrated to reduce cod catches and may also help reduce discards of these fish.

TAC Backstop

If TAC levels can be appropriately determined to take into account expected bycatch, then the hard TAC backstop in this alternative will further reduce bycatch. If the appropriate level cannot be determined, the TAC may increase discards as vessels are forced to discard catch of species for a TAC that has been reached while continuing to fish for species that have not met their TAC. The Hard TAC/Trip Limit model results for rebuilding alternative 2 are summarized below.

Table 118 - Estimated landings and discards for stocks anticipated to reach the TAC thresholds (70 or 90%) under rebuilding alternative 2 input controls and the phased reduction rebuilding program.

Summary

This alternative is likely to increase total discard mortality relative to other options, due mostly to the trip limits imposed on GB cod, CCGOM yellowtail and SNE/MA yellowtail . Factoring in allowances for the raised footrope and haddock separator trawls mitigated the discard rates somewhat, but discards still exceed landings by margins ranging from 2:1 to 13:1. If retention of species is prohibited once a TAC is achieved, analysis shows that those discard to landing ratios may reach as high as 160:1.

5.2.8.4.5 Alternative 3 – Area Management

This alternative was not selected. This alternative adopts most of the measures use in Alternative 2, with the exception of a DAS reduction. In addition, it may result in measures designed for specific areas in the future. Species-specific TACs are assigned to each of these areas, with various options for restricting the fishery in an area as a TAC is reached.

Summary
Compared to the no action alternative, Alternative 4 should result in reduced discards as a result of changes in gear requirements. The application of species-specific TACs in areas, if they can be set at appropriate levels, should also serve to reduce discards. One difficulty in setting these TACs at the appropriate levels is that there is limited information on discards by area. This alternative is not likely to reduce overall discards as much as Alternatives 1 through 4 because effort is not controlled to the same extent as in those options. Future changes to measures in a specific area will need to be evaluated as to their impacts on bycatch when they are proposed.

5.2.8.4.6 Alternative 4 - "Hard" Total Allowable Catch

This alternative was not selected. This alternative would have established TACs for all groundfish stocks. Management measures in place August 1, 2002 (see Appendix XV) will continue until changed in the future. These measures are the same as those in Alternative 2 with the exception of the 65 percent DAS reduction. The bycatch implications of those measures are described in section and are not repeated here. In general, the effort controls and gear changes should reduce bycatch compared to the no action alternative.

The implications of TACs are discussed in section 5.2.8.4.5. If correctly designed to take into account incidental catches, a TAC should not result in an increase in bycatch. If the TAC is not set correctly, however, it may force discards of one stock while fishing continues on another stock. As discussed in other sections, for some stocks there is limited information on current bycatch levels. This will make it difficult to set TAC levels appropriately. The application of a TAC is likely to increase bycatch until additional information is collected that precisely estimates discards in the fishery.

5.2.8.4.7 Alternative 4 - "Hard" Total Allowable Catch

This alternative establishes TACs for all groundfish stocks. Effort controls in place August 1, 2002 (see Appendix XV) could continue until changed in the future, or the TAC may be combined with rebuilding Alternative 2 or the measures in place in FY 2001. The bycatch implications of the Alternative 2 measures are described in section 5.2.8.4.4, and the bycatch implications of the August 1, 2002 measures are described in section 5.2.8.4.3; neither discussion is repeated here. In general, the effort controls and gear changes should reduce bycatch compared to the no action alternative.

The biological implications of hard TACs are discussed in section 5.2.6.6. TACs estimated based on the Phased-F and F-Rebuild rebuilding schedules (chosen as upper and lower bounds for their short-term impacts on landings) are lower than predicted FY04 landings for seven out of 17 stocks (Table 119). This alternative calls for stock-based trip limits to take effect at the time "threshold" somewhere between 70 and 90 percent of the TAC is caught. The intention of this threshold is to shift fishing pressure off affected stocks while still maintaining the ability to fish for other species in the same areas. Trip limits, in this regard, are intended to minimize discards of incidental catch.

Table 119 – Predicted FY04 landings (under Status Quo) and TACs estimated based on the F-Rebuild and Phased-F rebuilding schedules.

The trip-limit model discussed in Section 5.2.6.6 indicates that trip limits will be instituted very early in the fishing year, allowing for lengthy periods of fishing under trip limits and the potential for heavy discards. Table 120 and Table 121 show high portions of the remaining TAC (after trip limits take effect at either the 70 or 90 percent threshold) being discarded. The trip limit model assumes that fishing behavior does not change based on TACs (trips are either profitable, in which case they discard, or they are not profitable, in which case they are assumed to not occur) and therefore is likely to overestimate discards providing fisherman elect to fish in other areas once trip limits take effect. Similarly, the trip limit model does not account for trips occurring under simultaneous TACs, which would presumably make more trips unprofitable and shifting effort to other stocks or regions. However, the results of the trip limit model indicate that it is very often profitable to continue fishing in areas where high discards of stocks under a trip limit are likely.

GOM haddock, GB haddock, Pollock, redfish, GOM winter flounder, GB winter flounder, northern and southern windowpane flounder, GB yellowtail flounder and witch flounder are not predicted to reach the TAC threshold.

Analysis shows additional regulatory discards falling in a range between 20 and 35% of total (unrestricted and trip limit limited combined) landings assuming that fishing areas close once the TAC is reached. If the areas remain open under the zero-retention option, predicted total regulatory discards approach total landings and, in the case of GB Cod under F-Rebuild, discards exceed landings by a factor of three.

Discards under the TAC-based trip limits tend to exceed landings by a wide margin in most cases, and exceed 50% of trip limit limited landings in all cases.

5.2.8.5 Measures to Minimize the Adverse Effects of Fishing on Habitat

The measures proposed to minimize adverse effects of fishing on habitat include areas closed to protect habitat, changes to the gear allowed into closed areas, restrictions on the use of rock hopper and roller gear, and a requirement for all vessels to have VMS. The only measures that may have impacts on bycatch are the habitat area closures and the restrictions on rock hopper and roller gear.

5.2.8.5.1 Habitat Area Closures

Section 4.1.6.2 includes eight alternatives for closing areas to protect habitat. Area closures, for any reason, may have impacts on bycatch. If the area closed is an area of high catch rates for a species with a trip limit or that has little economic value, the closure may reduce regulatory or economic discards and thus lower bycatch mortality. If the areas shifts effort into higher catch rate areas, the reverse may occur. The proposed habitat closures are not specifically designed to reduce catches, but may have that impact. The analysis of the habitat closures (see section 5.3.8.3.2) ranks the closures on the basis of five criteria:

- by total area protected (nm^2),
- percent of each sediment type protected,
- percent of each species' EFH protected,
- percent of species' aggregations protected based on distribution (biomass protected),
- percent of species' guilds protected based on the food they eat.

Specific information is not available on how each area alternative will affect bycatch. It is likely, however, that impacts on bycatch will be related to the amount of area protected and the percent of species aggregations protected. Alternatives that protect more area and more of a species aggregation are likely to result in greater reductions in bycatch. The relative ranking of each of the habitat alternatives is in section 3.7. Generally, habitat area alternatives 5a and 5c may provide the greatest bycatch reduction, but any of the alternatives should also reduce bycatch.

5.2.8.5.2 Rockhopper and Roller Gear Restrictions

Restrictions on the use of rockhopper and roller gear may change the area that can be trawled. This could affect catch rates. It is not clear whether this measures will reduce or increase bycatch. There is limited information available on the type of gear currently being used, so the impact of the restrictions cannot be determined. In addition, it is not clear how vessels will respond to the restrictions. For example, they may move into areas that have a greater abundance of fish with no economic value, resulting in increased discards of those species, or they may move into areas with less of an abundance or the target species that is managed through a trip limit, reducing discards of that species. The implications of this measure on bycatch are uncertain and cannot be described, even in a qualitative fashion.

5.2.8.6 Other Issues

5.2.8.6.1 Northern Shrimp Fishery Exemption Area

The Council is proposing to remove the area restriction for the Northern Shrimp Fishery Exemption Area. Approval of this measure may increase discards of groundfish and silver hake, particularly if it results in increase effort in the shrimp fishery. An experiment conducted by the State of Maine (see Appendix XIV) determined that the bycatch of groundfish in this fishery is less than the 5 percent standard typically used as a criteria for exempted fishery approval (a standard that may be changed in the future if an alternative in this amendment is adopted). During the experiment, the catch of silver hake far exceeded the catch of any other species - over 72,000 pounds of silver hake were caught compared to less than 2,000 pounds of shrimp and about 1,700 pounds of regulated groundfish. Current regulations limit shrimp fishermen to landing silver hake in an amount equal to the catch of shrimp, which means in this instance that nearly 70,000 pounds of silver hake were discarded. The argument is made that shrimp fishermen will avoid high concentrations of silver hake because of the lack of a market and the physical damage caused to the higher valued shrimp catch. Absent the large silver hake catch, however, the experiment would not have demonstrated that the catch of regulated groundfish is less than 5 percent. In fact, if the silver hake catch was equal to the shrimp catch, the bycatch of regulated groundfish in this experiment would have been roughly twenty percent of the catch. One interpretation of the experiment is that the 5 percent standard will only be met if the fishery catches more silver hake than can be retained, though higher concentrations of shrimp could also result in meeting the bycatch standard. The discards of silver hake that may result can be easily prevented by increasing the amount that can be landed by shrimp fishermen.

The expansion of the shrimp fishery into deeper water may also change the composition of bycatch in this fishery. In the Maine experiment, one-fourth of the regulated species discards were redfish. Plaice and witch flounder were the other primary regulated species caught. Because of the limited time and area of the experiment, it is not possible to accurately determine the overall impacts of this measure. Expanding the area for the fishery is likely to increase overall bycatch.

5.2.8.6.2 Tuna Purse Seine Vessel Access to Groundfish Closed Areas

Two alternatives were considered for allowing tuna purse seine vessels access into groundfish closed areas. The tuna purse seine fishery is managed on an individual quota basis. Vessels fish until the quota is reached. The alternatives do not change the amount of effort that will be in the fishery, but do increase the area eligible. Since tuna purse seine fishing is a mid-water gear for highly mobile pelagic species, it is unlikely that the proposed action will have any impacts on bycatch, unless the concentrations of fish are so different in the areas that will be open.

5.2.8.6.3 SNE General Category Scallop Vessel Exemption Program

The proposed action will allow fishing by general category scallop fishing vessels in an area in the SNE Regulated Mesh Area. The proposal implements a requirement that these vessels use an eight-inch twine top, which has repeatedly demonstrated that it reduces groundfish bycatch in scallop dredges. This requirement is a specifically designed to reduce groundfish bycatch in this fishery to the minimum that is practicable. This measure may increase bycatch of both regulated groundfish and skates, but the impacts are expected to be minimal due to the use of the large mesh twine top.

5.2.8.7 Summary

This amendment proposes many management measures that will affect bycatch. A general overview of techniques available to reduce bycatch is provided in Alverson (1998). While generally complete, the list does not include reductions in effort as a means to reduce total discard mortality. Effort reductions are similar to decreased quotas for target species in that if correctly designed and implemented they reduce the total catch.

- International legislation of suitable gears and areas (not applicable to domestic management of the groundfish fishery)
- Time and area closures
- Establishment of discard quotas
- Use of new technology and operational modes (gear modifications, restrictions on operation, etc.)
- Full use strategies
- Establishment of authorized discard rates
- Marine parks
- Incorporation of bycatch into catch quotas
- Prohibition on retention
- Incentive-based programs
- Decreased quotas for target species

Many of these bycatch reductions strategies are incorporated into the alternatives under consideration. The following table summarizes the strategies used in the major alternatives under consideration (Table 124).

Bycatch Reduction Strategy	Fishery Program Administration	Alt. to Control Capacity	Mortality Reduction Alternatives					Northern Shrimp Fishery	Tuna Purse Seine Vessel Access to Closed Areas	SNE General Category Scallop Exemption Program

5.2.9 Impacts on Protected Species

The impacts of the existing Multispecies fishery to endangered and threatened whales, sea turtles, and fish has been discussed in the existing biological opinion and further Section 7 consultation actions conducted by NMFS. In addition, the EIS and EA documents prepared for each Multispecies fishery management action have addressed the impacts of existing fishery actions on other protected species, namely marine mammals. The conclusions contained in these documents describe the current baseline assessment of impacts to protected species from Multispecies fishing activities and are summarized below and at the end of this section.

Many of the factors that serve to mitigate the impacts of the multispecies fishery on protected species are currently being implemented in the Northeast Region under either the Atlantic Large Whale Take Reduction Plan (ALWTRP) or the Harbor Porpoise Take Reduction Plan (HPTRP). In addition, the Multispecies FMP has undergone repeated consultation pursuant to Section 7 of the Endangered Species Act (ESA), with the most recent Biological Opinion dated June 14, 2001. The conclusion in that Opinion states that the multispecies fishery is likely to jeopardize the continued existence of the North Atlantic right whale, and required NMFS to implement a set of Reasonable and Prudent Alternatives (RPAs) to remedy the jeopardy finding. As described below, the regulatory measures of the ALWTRP and the HPTRP have been implemented in direct response to the ESA and MMPA concerns expressed regarding the fishing operations taking place under the Multispecies FMP (and others) and must be adhered to by any vessel fishing for multispecies.

We recognize that measures contained in the Multispecies FMP could change at any time, potentially changing the degree of protection afforded all marine mammals as well as species listed as threatened or endangered under the ESA. However, once an FMP is in place, most changes to its measures occur through further Council action that require NEPA documents, and would be reviewed by NMFS for possible re-initiation under the ESA.

Atlantic Large Whale Take Reduction Plan

The ALWTRP contains a series of regulatory measures designed to reduce the likelihood of fishing gear entanglements of certain large whale species in the North Atlantic namely the right, humpback, fin, and minke whales. The RPA's called for three key regulatory changes: 1) new gear modifications; 2) implementation of a Dynamic Area Management system (DAM) of short-term closures to protect unexpected concentrations of right whales in the Gulf of Maine; and 3) establishment of a Seasonal Area Management system (SAM) of additional gear modifications to protect known seasonal concentrations of right whales in the southern Gulf of Maine and Georges Bank. All of the above changes have now been implemented. In addition, regular meetings are held to seek improvements to the ALWTRP, and additional measures are being discussed for further action.

Harbor Porpoise Take Reduction Plan

The gear used to catch multispecies includes sink gillnet gear that has been found to entangle and kill harbor porpoise. The HPTRP was developed to reduce the impact of this gear type on harbor porpoise populations to acceptable levels as defined under the MMPA. The measures implemented under the HPTRP include time/area closures combined with the use of acoustical devices (pingers) on nets. These measures have been shown to be effective in reducing the serious injury and mortality of harbor porpoise in the sink gillnet fishery as shown in the table below.

	Northeast Sink Gillnet	Mid-Atlantic Coastal Gillnet	TOTAL
1994-1998 Average	1163	358	1521
1999	270	53	323
2000	507	21	529
2001	51	26	80

Table 125 – Harbor Porpoise Takes in Gillnet Fisheries 1994 - 2002
1999, 2000, 2001 represent the years since implementation of the HPTRP.
Data from NMFS as published in the FEDERAL REGISTER on August 7, 2002.

5.2.9.1 Protected Species Summary

The following paragraphs contain summaries of the impacts of fishing activities conducted under the Multispecies FMP to protected species. Detailed information regarding the impacts described herein can be found in Section 9.2.2 and in the discussion of the impacts of the specific Amendment 13 alternatives in the sections that follow.

Right Whale
Given the known anthropogenic sources of right whale mortality, their low population size, and their poor reproductive rate, the loss of even one northern right whale because of gear operating in the multispecies fishery may reduce appreciably the likelihood of both survival and recovery of this species. Although there have been some large whale interactions with trawl gear in Alaska, there are no documented takes of large whales in New England bottom trawl gear. However, right whale interactions with sink gillnet gear are more common (See Table 111 below). Documented entanglements in any fishery are considered an underestimate of the extent of the entanglement problem since not all entanglements are likely to be observed. Consequently, although the total level of interaction between fisheries and right whales is unknown, recent studies have estimated that over 60% of right whales exhibit scars consistent with fishery interactions.

New gear modifications required by the ALWTRP regulations are designed to further reduce the amount of serious injury and mortality from an encounter, but do not eliminate the threat of entanglement. The recent implementation of the DAM system and SAM program described above, will further separate multispecies gear from most known or predicted right whale concentrations, but cannot be expected to be 100% effective. Therefore, fisheries that utilize sink gillnet gear (including the multispecies fishery) will continue to pose a risk of entanglement to right whales.

The bulk of the measures to be implemented under Amendment 13 are designed to achieve specific fishing mortality reductions for cod, haddock and yellowtail flounder. The tools selected by the Council include effort reduction in all components of the fleet through DAS restrictions and closed areas. These measures are likely to reduce fishing effort across all gear types, including sink gillnet gear. However, due to the ability of gillnet vessels to shift to non-multispecies target species, the effort reduction is not likely to achieve the same percentage anticipated in the multispecies fisheries. Regardless, Amendment 13 will reduce by some degree the existing adverse impacts of multispecies fishing activities to all large whales including the right whale.

The Council is confident that the impacts to right whales will continue to be assessed under the ALWTRP process, as well as the FMP process. Further, any modifications required to further relieve adverse effects will be applied to both the multispecies fisheries, (through framework actions and other future management measures) as well as other fisheries that are known to interact with right whales.

Humpback, Fin, and Minke Whales

Humpback, fin, and minke whales are taken in the sink gillnet fisheries that catch many commercially sought species, including multispecies (see Table 126 below). The humpback and fin whales are listed as endangered under the ESA. The minke whale, although not protected under the ESA, is protected under the MMPA and is one of the species that the provisions of the ALWTRP are designed to protect. As with the right whale, the impacts of these fisheries on the humpback and fin whales have been assessed in ESA consultations for the Multispecies FMP as well as other FMPs that interact with these species. The Opinion concluded that the fisheries would not jeopardize the endangered humpback and fin whale. The Environmental Assessment for the ALWTRP determined that the ability of the minke whale populations to maintain optimum levels would not be compromised by the existing Multispecies and ALWTRP measures. The ALWTRP measures, recently revised to meet the RPAs established to protect the right whale, are expected to further reduce the potential for mortality and serious injuries that are occurring in all large whale populations in the Northeast Region.

Table 126 – Large Whale Entanglements 1997 – 2001*

* Data from NMFS entanglement reports where some gear was recovered and/or observed allowing experts to attempt to ID gear. Other entanglement records exist but gear was not recovered or observed.

The measures selected by the Council include effort reduction through DAS restrictions and closed areas that will affect all components of the fleet, including the sink gillnet component. As stated above, Amendment 13 will reduce by some degree the existing adverse impacts of multispecies fishing activities to all large whales including the humpback, fin and minke whales.

Blue, Sei, and Sperm Whales

The limited surveys that were conducted in the Northeast Region (CeTAP surveys in 1979-81, and NMFS summer ship and aerial surveys conducted from 1990-98) did not record significant sightings of blue whales over shelf waters. Sei whales are seen more commonly along the northern and eastern flanks of Georges Bank, and are observed occasionally in near shore shelf waters as well. The known feeding behavior of blue and Sei whales suggest they focus on plankton/zooplankton resources that are found in the upper water column. Sperm whales are frequently found foraging along the shelf edge at the outer edge of the known multispecies fishing areas and forage in the deeper waters where trawl gear does not operate.

Although the sink gillnet gear operations that catch multispecies may affect the blue, sei, and sperm whales, there appears to be significant separation between the known feeding range of these species and the primary multispecies fishing areas. This is borne out by the marine mammal stock assessment report statements that the level of interaction for these species is insignificant and approaching a zero mortality and serious injury rate (Waring et al. 2001). As stated above, Amendment 13 will reduce by some degree the existing adverse impacts of multispecies fishing activities to all large whales including the blue, sei, and sperm whales. Therefore, the gear used in the multispecies fishery is not likely to adversely affect the blue, sei, or sperm whales.

Other Marine Mammals

Several other marine mammal species (such as seals, dolphins, and small whales) are known to frequent the continental shelf regions where multispecies fisheries activities occur. Although it is unlikely that the bottom-tending trawl gear used by the bulk of the multispecies vessels will affect these species, interactions with the sink gillnet component of the fishery are well documented. Assessments of the impacts of fishing activities on these species can be found in the annual marine mammal stock assessment reports published by NMFS (Waring et al. 2001) and are described further in Section 9.2.2. Interactions between sink gillnet gear used in the multispecies fishery and these marine mammal species are not expected to increase under the Amendment 13 measures due to the general decrease in fishing effort expected as a result of these measures.

Sea Turtles

Multispecies fishing effort is concentrated primarily in the Gulf of Maine and Georges Bank areas. Sea turtle distribution in the Northeast Region is focused along the Mid-Atlantic and Southern New England shelf region during the summer and early fall. Therefore, with the exception of cold-tolerant leatherbacks that are able to forage into the middle of the Gulf of Maine, the overlap between the multispecies fishery and sea turtles does not appear to be great.

The multispecies gears most likely to affect sea turtles are otter trawls and sink gillnets. NMFS assessed the potential impact of these two gear types on all sea turtle species in the Biological Opinion issued for the Multispecies FMP and concluded that the takes would not jeopardize the continued existence of the ridley, green, leatherback, or loggerhead sea turtles. As stated above, Amendment 13 to the Multispecies FMP will decrease the overall effort for trawl and gillnet gear. Therefore, the potential impacts to sea turtles will not increase with its implementation, and are likely to decrease.

Fish
The existing multispecies fisheries activities were determined to have no affect on the endangered shortnose sturgeon and Atlantic salmon. The new measures imposed under Amendment 13 will not change the basis for this determination.

The barndoor skate is a candidate species that is often caught as a bycatch species in the offshore trawl and sink gillnet fisheries that target multispecies. Possession of barndoor skate has been prohibited under the Skate FMP. In addition, the bulk of the measures to be implemented under Amendment 13 are designed to achieve specific fishing mortality reductions for cod, haddock and yellowtail flounder. The tools selected by the Council include effort reduction in all components of the fleet through DAS restrictions and closed areas. Many of these measures are likely to reduce the bycatch of barndoor skate as well. Therefore, barndoor skate should not be further depleted by management actions taken under the Amendment 13.

Right Whale Critical Habitat
NMFS evaluated the potential effects of the multispecies fisheries on the two critical habitats that have been designated in the Great South Channel and Cape Cod Bay in a Biological Opinion issued on June 14, 2001. NMFS evaluated the potential effects of the proposed fisheries operations on both prey availability and quality and nursery protection in the critical habitat. There was concern that the operation of these fisheries could diminish the value of the habitat by altering trophic dynamics that could reduce the availability of right whale prey within the critical habitat areas. However, right whales feed primarily on copepods that live in the mid-water zone, making it highly unlikely that bottom-tending multispecies gear will have any adverse effect on microscopic copepods believed to be unaffected by the use of gear that catch larger fish such as multispecies. Amendment 13 does not change the way in which the fishing gear will operate. Therefore, the Council does not believe the multispecies fishery, as operated under Amendment 13, will affect right whale critical habitat.

Impacts of the Amendment 13 Alternatives
The basic goals of the proposed Amendment 13 to the Multispecies FMP are to achieve specific fishing mortality reductions for cod, haddock and yellowtail flounder, and to bring the FMP into compliance with the recent court order. The alternatives that were considered by the Council for the Amendment 13 are described in Section 3 of this document. Provided below are assessments of the relative impacts of both the selected an non-selected measures on the protected species described in Section 9.2.2 of this document.

5.2.9.2 Fishery Administration

Fishing Year
The fishing year options that were considered are; May 1 – April 30 (Status Quo – Selected), January 1 – December 31, October 1 – September 30, and July 1 – June 30.

Protected species benefits occur when the beginning of the fishing year does not start during a high use period for large whales and small odontocetes, thus avoiding the surge of effort that often occurs at the beginning of a season. The No Action starting date of May 1 occurs during the spring migration of large whales and small odontocetes such as harbor porpoise into the Gulf of Maine. Compared to May 1, the July 1 – June 30 fishing year would have been the best option for protected species, followed by October 1 – September 30, and then January 1 – December 31.

DAS Pro-Ration (Not Selected)
Since DAS are based on the fishing year, a system was proposed to prorate DAS to accommodate for any change in fishing year. Three options were offered. Option 1 is a straightforward pro-ration scheme that could result in a short-term increase in DAS. Option 2 would cap any increase in DAS during the first year, and Option 3 would delay any change to the next fishing year. Depending on at what point in the calendar year the increase described in Option 1 would have occurred, it may have been less beneficial to protected species than the other two options. Option 2 would have been favored over Option 3 as the increased DAS would have been capped and not just deferred to the next year. There was no need for a DAS pro-ration scheme under the selected No Action alternative.

Periodic Adjustment Process (Selected)
Several alternative processes for periodic adjustment of the Multispecies FMP measures were proposed. These alternatives are administrative in nature and have little effect to protected species. In addition, protected species impacts are assessed independently on a regular basis under the NEPA and the ESA. Therefore, protected species impacts are not changed by the adjustment process used for FMP measures.

United States/Canada Resource Sharing Understanding (Selected)
This alternative will set up a comprehensive program by which transboundary stocks would be co-managed by the two countries. The program involves entry requirements for vessels, observer and VMS requirements, as well as significant reporting requirements designed to provide adequate management controls. Special TACs will be established with appropriate gear and other harvesting controls implemented to assure adherence to TACs.

The transboundary stocks are generally found on the eastern edges of Georges Bank or along the Hague Line in the center of the Gulf of Maine. Large whales and small odontocetes such as harbor porpoise are found in these areas during certain specific seasons.

Although this alternative is administrative in nature, the means by which the specific requirements of the ALWTRP and HPTRP are incorporated into the program is not addressed in this alternative. This is important both in terms of applicability to Canadian participants that are fishing in US waters as well as US vessels in Canadian waters. There is no U.S./ Canada resource sharing agreement for transboundary stocks under the No Action alternative, thus any attempt at international management of these stocks, and the associated incorporation of protected species protection measures on an international basis would be a benefit to transboundary protected species such as large whales and harbor porpoise.

Administration of Certified Bycatch/Exempted Fisheries (Selected)
This alternative is administrative in nature and has little effect to protected species. An assessment of the effects of an exempted fishery on protected species in closed areas would be conducted prior to approval of the exempted fishery. Therefore, administration of the exempted fishery program will always involve its own protected assessment process.

Special Access Programs (Selected)
This alternative will establish a Special Access Program (SAP) that would allow access to certain fish stocks that are partially rebuilt. The SAPs will define the how participants may utilize the Category B – DAS under the selected rebuilding alternative. Incentives would also be offered to vessels using gear or techniques that avoid or significantly reduce the catch of stocks of concern. Stocks that may be considered for this program include those whose previous year's catch fell short of the target or hard TAC. SAPs must be approved by either Framework or Amendment action. Therefore, each SAP will undergo complete protected species review before it can be approved.

SAPs are not available under the No Action alternative, thus any additional fishing effort that may result under the No Action alternative must be implemented by either a framework action, further amendment, or under an exempted fishery. Each of these actions requires individual protected species assessment. Therefore, in regard to protected species, the SAP process is identical to the No Action alternative.

The following SAPs are included in the Amendment 13 document.

Georges Bank Yellowtail Flounder Special Access Program (Selected)
During June through December, fishing vessels may make two trips per month into a portion of Closed Area 2 that was opened for scallops in order to fish for yellowtail flounder (30,000 lb trip limit). This option is expected to involve 320 trips.

This option will not affect protected species, as Closed Area 2 is not a high use area for either marine mammal or sea turtle species.

Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program (Selected)
Vessels fishing for fluke west of 72-30W would be allowed to retain and land up to 200 lbs of winter flounder.

The fluke fishery generally occurs in the early spring months before sea turtles move into the Southern New England/Mid-Atlantic region thus limiting the potential effect to those species.

US/CA Resource Sharing Understanding SAP (Selected)
Limitations will be place on the number of trips vessels may take into the US/CA area. Further, vessels participating in this SAP will not be charged for DAS for steaming time.

Large whales and small odontocetes such as harbor porpoise are found in these areas during certain specific seasons. Vessels utilizing this SAP are likely to be transferring their fishing effort from an area of higher use by large whales and harbor porpoise. Thus the net impact to these species may be less.

Hook Gear Closed Area I SAP (Selected)
Vessels using hook gear may participate in a program to access haddock in Closed Area I. Closed Area I is not available to any multispecies permit holder under the No Action alternative. Hook vessels would be limited to a maximum of 3,600 hooks to be used from September 16 to December 31, and must have observers on all trips.

Hook gear used in Closed Area I in the fall is generally not a serious threat to the large whale species that frequent Closed Area I in the spring. However, the presence of any fixed gear in this area may be problematic to these species.

Sea turtles and seals are not known to frequent Closed Area I. Small odontocetes are known to become entangled in gillnet gear, although the Closed Area I region is not a high use area for those species. In any case, the complete closure of Closed Area I under No Action alternative is more protective for protected species.

Gillnet Gear Closed Area I SAP (Not selected)
Vessels using gillnet gear could have participated in a program to access haddock in Closed Area I. Closed Area I is not available to any multispecies permit holder under the No Action alternative. Gillnet vessels would have been limited to 50 gillnets to be used from July 1 through March 31. Observers would have been required on all trips, and vessels would have been equipped with a VMS.

Much of Closed Area I is closed to gillnet gear from April 1 to June 30 under the ALWTRP. The timing of this SAP would have avoided the spring large whale concentrations in Closed Area I. This would have protected the large whales during the critical spring period. Although gillnet gear is a problem for large whales throughout their summer foraging range, allowing gillnet gear into the area during late summer through winter might have actually moved the gear away from more highly utilized areas in the GOM.

Sea turtles and seals do not frequent Closed Area I. Small odontocetes are known to become entangled in gillnet gear, although the Closed Area I region is not a high use area for those species in the summer and fall. In any case, the complete closure of Closed Area I under No Action alternative would have been more protective for protected species.

Closed Areas Administration (Not Selected)
Year round closed areas have been established for a variety of reasons over an extended period. The No Action alternative does not allow exempted fisheries to operate in the year-round closed areas. This option would provide a detailed rationale for existing closed areas and would review the issue of access to those areas. Five options were considered. No specific option was selected, however, the intent, specific purpose, duration, and who can or cannot fish in a closed area will be part of the decision process for future closure and/or closure access discussions.

Option 1 – All Exempted Fisheries are Allowed in a Closed Area
Closed Area 1 is part of Right Whale Critical Habitat that is closed to sink gillnet gear from April 1 to June 30 under the SAM provisions of the ALWTRP. Allowing exempted fisheries utilizing sink gillnet gear in that area during the spring migration period could have been a problem for large whales. However, as mentioned above, each exempted fishery undergoes its own review under the ESA and NEPA. Any large whale or other protected species issue will be handled at that time.

Option 2 – Certain Exempted Fisheries Allowed in Closed areas 1 & 2
See the response above. Large whales would have been subject to potential threats if gillnet and pot/trap gear were allowed in Closed Area 1 at certain times. However, a separate ESA consultation and NEPA review would have addressed these concerns.

Option 3 – Certain Exempted Fisheries Allowed in the Nantucket Lightship Closed Area
Since the Nantucket Lightship Closed Area is not a high use area for protected species, no adverse effect on protected species was anticipated. However, as mentioned above, a separate ESA consultation and NEPA review is conducted when any exempted fishery is being considered. Any new information regarding possible protected species concerns will be addressed at that time.

Option 4 – Certain Exempted Fisheries Allowed in the Western GOM
The western GOM is a seasonal high use area for large whales (spring and summer), harbor porpoise (spring and fall), and seals (winter). However, pelagic gillnet gear was the only gear identified under this alternative. Any potential threat to these species would have been assessed at the time of issuance for the exempted fishery.

Option 5 – No Commercial Exempted Fisheries are Allowed
A complete ban on exempted fisheries in closed areas would have been the best situation for protected species, as it would have excluded all commercial fishing gear from closed areas. Since this option was identical to the No Action alternative, no additional effort shifts to avoid a new closure would have occurred.

Flexible Area Action System (Selected)
The FAAS is available under the No Action alternative, but has never been successfully implemented in the Northeast. Therefore, eliminating the FAAS will not change the impacts of Amendment 13 on protected species.

Leasing of DAS (Selected)
This alternative will allow vessels to lease active DAS (Category A) from other vessels, which was not allowed under the No Action alternative.

Leasing DAS represents a consolidation of effort to fewer vessels utilizing the same amount of effort. This could have either a beneficial or adverse impact to protected species with respect to interactions with gillnet gear. If gillnet vessels lease only to gillnet vessels, then there would be less gear in the water, although the remaining gear could be fished longer. This may be beneficial to protected species. However, if trawl vessels are allowed to lease to gillnet vessels it would result in an increase in overall gillnet effort thus raising the probability of interactions with large whales, harbor porpoise, and seals. In addition, increased trawl effort in the southern New England area frequented by sea turtles and small pelagic odontocetes may be a problem for those species.

Recreational Fishing Permit (Not Selected)
No recreational fishing permit is required under the No Action alternative. Although recreational fishing gear is known to interact with protected species, the size and relative low strength of the gear make it unlikely to cause serious injury to whales, dolphins, or sea turtles. Therefore, requiring recreational fishermen to obtain a permit would have had no adverse effect on protected species. Requiring permits would have offered a means of providing education to permit holders on avoiding interactions with protected species.

"Running Clock" Alternatives (Not Selected)
Several "running clock " alternatives were proposed to accommodate overages in daily trip limits and/or DAS that were not a part of the No Action alternative. The method by which DAS and/or trip limits are tallied would not have had a direct effect on protected species as the at sea effort per DAS or trip length will be the same in the long run.

Observer Coverage (Selected)
Two alternatives that would increase observer coverage over what occurs under the No Action alternative were proposed. The Council desires 10 per cent coverage in all gear sectors. Any increase in observer

coverage will be a benefit to protected species, as better data will be collected on protected species bycatch in all gear sectors.

Vessel Monitoring System Requirements (Selected)
A mechanism to allow vessels to drop out of the program for a one-month period was selected under this alternative, as long as the vessel does not participate in any monkfish or groundfish fishery. No such mechanism existed under the No Action alternative. The VMS requirements have no direct or indirect impact on protected species.

Day Gillnet Out of the Fishery (Not Selected)
This alternative would have eliminated the current requirement for day gillnet vessels to be out of the fishery for a 21-day period between June and September. Retaining the 21 days for a day gillnet vessel to be out of the fishery between June and September (Option 1) is a benefit to large whales, harbor porpoise, and small odontocetes, as those months are high use periods for those species and any reduction in gillnet effort would maintain a lower probability of interaction during that period.

DAS Counting (Not Selected)
This alternative contained three options for counting partial DAS. The method by which DAS are counted has no affect on protected species, since effort reduction will remain the same under each option.

Reporting Requirements (Selected)
Three options for linking dealer reports with vessel trip reports were considered in this alternative. The method by which dealers and vessels provide required reports has no effect on protected species, as the data received will remain the same.

Hand Gear-Only Permit Alternatives (Selected)
An open access hand gear permit exists under the No Action alternative. An option to create a second limited access hand gear-only permit was selected to set a 250 hook limit, while allowing 300 pounds of cod to be caught. Open access permits are limited to 75 pounds of cod. Although this gear type is known to interact with protected species, the size and relative low strength of the gear make it unlikely to cause serious injury to the large whales, dolphins, or sea turtles. Therefore, this gear allocation program will not affect protected species.

Sector Allocation Alternatives (Selected)
A sector allocation system will apportion part or all of groundfish fishery resources to various industry sectors. Sectors will be formed voluntarily based on gear used, permit category, vessel size, homeport, area fished, or some other grouping. Vessels not in a sector will remain in a common pool under normal Council management. A detailed sector management plan must be developed and approved by NMFS, following which the Council will impose restrictions to allocate resources and establish fishing mortality controls.

We are unable to assess the protected species impacts of the sector allocation system until each sector plan is developed for approval. However, the following comments can be made on the sector allocation that was discussed in this alternative.

Georges Bank Hook Sector
Participation in this sector will be open to vessels with a history of using jig, demersal longline, open access hand gear, to harvest Georges Bank cod.

Although the hook gear types are known to interact with protected species, they are unlikely to cause serious injury to the large marine mammals or sea turtles. The transfer of multispecies effort from traditional gear types (trawl and gillnet) used under the No Action alternative to hook gear will be an overall benefit to most protected species except seals who may be attracted to the baited hook method.

While the Council considered establishing a gillnet sector, it was not selected. It is not clear whether the gillnet restrictions are individual or cumulative for day and trip boats. If adopted in the future, the cumulative number of 500 nets is high for gillnet vessels and would not be a benefit to large whales, harbor porpoise, and seals over the No Action alternative levels of 80 stand-up nets and 160 tie-down nets. Sea turtles and small pelagic odontocetes do not frequent Georges Bank and thus would be unaffected by this measure.

Gulf of Maine Inshore Conservation and Management Stewardship Plan (Not selected)
Three distinct regulatory areas would have been created in the GOM. Effort was frozen at DAS levels used by each vessel as of August 1, 2002. The Amendment 13 DAS level chosen would have been set for each vessel and the amount left over would have been established as the frozen amount available to each vessel under the rebuilding program. Gillnet gear restrictions were set at 50 nets for all vessels.

The 50 gillnet restriction would have provided benefits for large whales, harbor porpoise, seals, and the cold-tolerant leatherback sea turtle in the GOM, as it was more restrictive than the 80 net restriction under the No Action alternative. The DAS structure would have provided no additional benefit to protected species, although when combined with the gillnet restrictions, it would have assured an overall reduction in gillnet effort in the GOM. This alternative would not have affected other sea turtles or small odontocetes, as they do not frequent the Gulf of Maine.

5.2.9.3 Alternatives To Control Capacity

Alternative 1 - Permit Absorption (Not Selected)
A permit holder could have transferred all permits held to another vessel under this alternative. This alternative also would have allowed permit holders to combine scallop and multispecies limited access permits with some restrictions. The transferee would have had to retire from fishing. A transfer tax would have been applied that would have reduced the active DAS by 10%, 20%, or 50%. Transferred DAS would not have been available immediately, but could only have been used on a graduated scale (20% in year 1, 40% in year 2, and 60% in year 3).

Reactivation of latent effort could have caused a problem to protected species. Transfer to scallop fishing would not have been a problem unless it increased scallop effort in sea turtle high use areas. Transfer of trawl DAS to the sink gillnet component of the fleet would have represented an increase in overall gillnet effort, thus increasing the potential threat to large whales, harbor porpoise, seals, and other marine mammal species. However, the heavy layer of restrictions placed on the use of gillnet in the Gulf of Maine under the ALWTRP and HPTRP would have made transfer to that gear type less attractive than trawl gear.

The No Action alternative does not contain strong measures to control capacity, thus avoiding the potential for latent effort shifting to a more harmful gear type. However, the eventual rebuilding of stocks will bring that latent effort back into the fishery without any control mechanism to reduce overall effort such as the phasing in of effort under the permit absorption alternative. Therefore, this alternative would have represented a more favorable capacity controlling scheme than the No Action alternative.

Alternative 2 - Permit Transfer (Not Selected)
This alternative would have allowed limited access permit holders to transfer their multispecies permits to another vessel, provided they retire from fishing. A transfer tax similar to above would have been assessed, and the reactivation schedule would have been the same as well.

As mentioned above permit transfer and reactivation of latent effort may be a problem to large whales, harbor porpoise, seals, and other marine mammal species due to the potential for transfer from trawl gear to gillnet gear. However, it is not clear how much sink gillnet effort would have been changed by this alternative. The comparison of this alternative to the No Action alternative was the same as above.

Alternative 3 - Days-at-Sea (DAS) Transfer (Selected)
Multispecies limited access permit holders will be allowed to permanently transfer DAS to other multispecies limited access permit holders. Transferring vessels must be of similar size and horsepower, and the selling vessel must retire. Only 60% of active DAS and 10% of inactive DAS may be transferred.

Since DAS are a major limiting factor in total effort, the overall impact to protected species may not be significant. The restriction on use of inactive DAS and the same size and horsepower restriction will mitigate the effect of latent effort transferring to gillnet vessels. This alternative will have less of an impact to large whales, harbor porpoise, seals, and other marine mammal species than the permit absorption or transfer alternatives discussed above.

The comparison of this alternative with the No Action alternative is similar to the above alternatives. However, DAS transfer does represent a more beneficial capacity reducing program for protected species than Alternatives 1 and 2 above.

Alternative 4 - Freeze on Unused Days-at-Sea (Not Selected)
This alternative would have reduced the latent effort in the groundfish fishery by allowing vessels to voluntarily "freeze" their DAS during a specified period ("freeze period") while incrementally reducing the number of "unfrozen" DAS at an annual rate for the duration of the freeze period. Unused DAS would have been reduced by 5% for each year of the freeze period. Vessels could have reentered the fishery after the freeze period with their reduced DAS. Freeze period options would have included; five years, when 75% of the rebuilding target for all species is reached, and when 75% of the rebuilding target for cod, haddock and yellowtail flounder is reached.

Although this alternative would have kept latent effort out of the fishery until the fish stocks are rebuilt, there would have been no assurance that the protected species stocks would have been able to take the increased effort once fish stocks are rebuilt. It is also not clear how many gillnet vessels would have participated in this program. Since the overall potential reduction in frozen DAS would have been less than in Alternatives 1 through 3 above, this alternative did not provide the same effort reduction unless the freeze lasts nearly a decade in length.

Comparison with the No Action alternative is similar in that having some capacity controlling mechanism would have been better than none.

Alternative 5 - Days-at-Sea Reserve (Selected)

This alternative was incorporated in the proposed action for addressing rebuilding requirements discussed below. DAS allocated to each vessel will be divided into three categories A, B, and C. The DAS baseline will be the maximum DAS used in a year that there were 5,000 pounds of groundfish landings for that permit during the period from 1996 through 2001 (estimated total of 68,700 DAS). Category A will be DAS (estimated 41,280 DAS) available under the selected rebuilding alternative, Category B will be DAS available under SAPs and Sector Allocation programs developed by the Council, and Category C will be DAS not used (latent effort) by the vessel. As rebuilding occurs, Category B and then Category C DAS will be available for use. This alternative assures that previously active vessels will regain access to the fishery first.

This alternative will apply to all vessels, a potential added benefit over the voluntary programs above. The influx of latent effort (Category C - DAS) will be delayed under this alternative until after all potential effort now available to the fleet has been restored. Under the NSC Alternative some of the Category B - DAS will be available for use in 2004 under the SAPs and Sector Allocations selected in the above measures.

As in all the Alternatives above, this alternative will provide more capacity controlling benefits than the No Action Alternative.

Alternative 6 - Mandatory Latent Effort Categorization with Voluntary Flexibility Options (Not Selected)
This alternative combines the elements of DAS Reserve with the tools of permit transfer, permit absorption, and DAS transfer. All vessels would have had their DAS categorized in A, B, and C categories as described above. Any permit transfer, absorption or DAS transfer would have carried with it the categories of the seller's DAS. A formula was derived for reactivation of these DAS based on the response of fish stocks to the management program, and a cap would have been placed on the number of permits or DAS an individual is allowed to hold.

As in the DAS Reserve alternative discussed above, there was unlikely to be any direct effect to large whales, harbor porpoise, and seals unless gillnet vessels were favored by the program. This alternative was favored over Alternative 5 above as it allowed permit absorption/transfer or DAS transfer to occur so that the number of participating vessels would be reduced, as well as the overall fleet fishing capacity.

The comparison to the No Action alternative was similar to Alternative 5 above.

5.2.9.4 Management Alternatives to Address Rebuilding Requirements

The Council developed several management measures designed to achieve specific fishing mortality reductions shown in the previous sections. These fishing mortality reductions were based on a constant fishing mortality rate that will achieve rebuilding and/or end overfishing.

Proposed Action
During the comment period for the DSEIS for Amendment 13 the Council received a new alternative to address rebuilding requirements. During deliberations at their November 2003 meeting, the Council selected this alternative for Amendment 13.

The use of DAS will be restricted as follows: (1) 60 percent (estimated to be 41,000) can be used as Category A DAS to fish for any species of groundfish; (2) the remaining 40 percent can only be used as Category B DAS under specific programs that can only catch stocks that have reduced fishing mortality; (3) Category C DAS days will not be available until significant rebuilding has occurred and the latent DAS are unfrozen. Vessels will declare the types of DAS to be used on a trip-by-trip basis. A limited call-in system will be developed to allow vessels to switch from a Category B DAS trip to a Category A DAS trip under certain conditions. The Council will be working to develop the programs similar to the existing SAPs and sector allocation fisheries under which B DAS may be used. Changes were made to the trip limits for GOM cod (to 800/4,000), GB cod (a seasonal limit for hooks, 1,000/10,000 for others), a month was added to the current SNE/MA yellowtail flounder trip limit, and a CC/GOM yellowtail flounder trip limit was adopted. Minor changes were made to various gillnet restrictions regarding the mesh size and number of nets that may be used in certain areas. The gillnet restrictions will serve to cap the total number of nets that may be used.

The total effective effort is estimated to be 68,700 DAS, which is less than the 71,000 DAS level under the Court Ordered baseline. The Category A DAS level is estimated to be between 41,000 which represents almost a 40% reduction over existing levels. However, this alternative will allow vessels to fish under B - DAS for stocks that are not overfished. Several SAPs were approved that could be available for a limited number of vessels to use Category B DAS in 2004. The Council will also be considering other SAPs that may be implemented in the future. This means that overall fishing effort will not be reduced as much as in a pure DAS reduction program such as Alternative 1 below. However, this alternative will provide more protected species benefits than the No Action alternative, and the TAC related measures in Alternatives 3 and 4 since DAS reduction equate to a direct reduction in effort.

No Action Alternative (Not Selected)
This alternative would have left in place the management measures implemented during fishing year 2001. DAS allocations would have returned to levels implemented under Amendment 7. Area closures, gear restrictions and trip limits would have reverted to those in place under Amendment 7 and Frameworks 27, 31, and 33.

The protected species impacts of the management measures in place under Amendment 7 were reviewed by NMFS in a Biological Opinion dated June 14, 2001. The extant Biological Opinion concluded that although jeopardy to right whales was likely, it could be relieved by implementation of certain RPAs. The RPAs are currently in place under the ALWTRP (see details at the beginning of this section). The Opinion also determined that the adverse effects of the existing fishery on sea turtles were not likely to jeopardize the continued existence of those stocks. In addition, the HPTRP measures have reduced the take of harbor porpoise to the point that would allow the stocks to achieve optimum levels. The level of take for the remaining odontocetes and seals that are affected by this fishery are low enough, in relation to the size of their populations, that the stocks would be allowed to achieve optimum levels.

Alternative 1 – Up to 65% Reduction in Used DAS (Not Selected)
In general, a direct reduction in effort by the appropriate components of the fleet would have been beneficial to protected species, and was favored over the other four alternatives proposed. This alternative represents a decrease in DAS over the No Action alternative that would have translated to a direct proportional benefit to all protected species.

This alternative would have phased-in a 65% reduction in used DAS over several years. It was designed to implement the phased-reduction fishing mortality rebuilding strategy. This option used an annually increasing reduction in unused DAS from the 2000-2001 season applied across the fleet DAS allocation, to achieve the individual species mortality reductions in the amendment. The 35% reduction called for in 2004 would have allowed 41,050 DAS. It would then have been ramped down to only 22,100 DAS that could be fished by 2007 at the full 65% reduction level. Depending on the capacity options chosen, this alternative required an additional effort reduction of between 34% and 67% for each permit in 2004.

The effort reduction in the sink gillnet component of the fleet would have been greater than the selected option, and thus would have been of greater overall benefit to large whales, harbor porpoise and seals. Similarly, reductions in trawl effort would have provided more benefit to the sea turtle and small odontocete species that are found in the southern New England region of the Multispecies FMP management area. This option did not provide the immediate effort reduction of Option 1, although its eventual reduction level (65%) was lower than Option 1 (55%) and 5.

Alternative 2 - Reduction in Allocated DAS/Gear Modifications (Not Selected)
This alternative was a combination of additional gear restrictions and reduction in allocated (not used) DAS. The complex matrix of effort controls, closed areas, possession limits and gear restrictions proposed in this alternative were difficult to compare to the more direct approaches offered by Alternative 1 above, and for this reason was not favored over that Alternative. However, this alternative would have provided more protected species benefits than the No Action alternative, and the TAC related measures in Alternatives 3 and 4 since DAS reduction and gear restrictions would have equated to a direct reduction in effort..

Effort Controls – Option 1
Allocated DAS would have been reduced by 20%. Vessels fishing in the Gulf of Maine would have had to sign into that area and would have received a 30% reduction in DAS for that area. In addition, they could only use 25% of their allocated DAS during the May to July period.

The reduced DAS in the GOM for the May to July period would have been a benefit to large whales, but would have been of little added benefit to harbor porpoise and seals as they also concentrate in the area in the fall months. Sea turtles and the pelagic small odontocetes are found outside the GOM and would have received no added benefit from this alternative.

Effort Controls – Option 2
Allocated DAS would have been reduced by 20%. Vessels could only use 70% of their allocated DAS in the GOM regulated mesh area.

The reduced DAS in the GOM regulated mesh area would have reduced effort in the general high use area for marine mammals, thus providing some benefit to large whales, harbor porpoise, seals, and leatherback sea turtles but of no additional benefit to other sea turtles and small odontocetes as they do not forage in the GOM waters.

Closed Areas
In addition to the current closed areas and the seasonal closed areas implemented on August 1, 2002, the area north of 44^0N would have been closed from October to November.

The additional closed area was located to the north of most marine mammal and sea turtle habitats. In addition, leatherback sea turtle and other marine mammal species that are found in the northern GOM and Lower Bay of Fundy have left that area by October. Therefore, this alternative would have provided no additional benefit to protected species except seals.

Possession Limits
Possession limits would have been set at 500 lb/day and 4,000 lb/trip for GOM and GB cod, and 50 lb for yellowtail flounder in areas 514 and 521.

Possession limits may have curtailed trips and/or caused movement in areas fished. To the degree that gillnet vessels would have been affected, it might have benefited large whales, harbor porpoise, and seals unless the area to which the vessels moved was of higher use by protected species. Since current area closures have covered most of the protected species high use areas, this option was not expected to provide any measurable benefit to protected species.

Gear Restrictions
On Georges Bank, trip gillnet vessels would have been capped at 100 to 150 nets, and day gillnet vessels would have been restricted to 50 nets. In the GOM, gillnets set inshore of 70^{0}W would have been restricted to 50 nets, and no tie-down nets could be used in certain areas around Cape Cod.

Net restrictions in the GOM areas would have been a benefit to large whales, harbor porpoise, and seals, although the No Action alternative contains an 80 net cap that was not significantly different than were proposed in this alternative. In addition, a ban on tie-down nets would have provided no additional benefit to protected species, and may have been an adverse effect if the species are more susceptible to the stand-up nets that may have replaced tie-down nets.

Alternative 3 - Area Management (Not Selected)
Six areas were defined that represent the traditional areas fished by certain gear types operating out of specific ports, and targeting similar species. Species-specific TACs would have been defined for each area. Calculation of TAC would have been based either on VTR data, landings from fishing years 1996 to 1998, landings from 1996 to 2000, or the last three years average survey data. A system was set up for assuring adherence to TACs, with subsequent year consequences for exceeding the TAC. Movement was allowed between areas under certain controls and restrictions.

TAC allocation does not by itself reduce impacts to protected species, since vessels can spend the same amount of effort to catch different TAC levels. Although, if the TACs were set low enough to assure a reduction in effort, then an indirect benefit to protected species may have occurred. Separate TACs for each stock would have allowed gear to stay in the water longer as vessels move from stock to stock. Therefore, this alternative would have provided minimal additional benefit to protected species unless the TAC chosen for the high use protected species areas was low enough to reduce effort in those areas. This alternative would have offered less protection to protected species than Alternatives 1 and 2, and the No Action alternative that provided more effort control through DAS restrictions, gear restrictions and closed areas. This alternative was the same as Alternative 4 as far as protected species benefit.

Alternative 4 - "Hard" Total Allowable Catch (TAC) (Not Selected)
TACs would have been applied to all stocks in the multispecies FMP on a single or multi-stock basis. Three options were developed for applying TACs to the multispecies fishery. They included; a separate

TAC for each stock, aggregate TACs for stocks not overfished, hard TACs for directed the groundfish fishery, and target TACs for incidental catch fisheries.

TAC allocation does not by itself reduce impacts to protected species, since vessels can spend the same amount of effort to catch different TAC levels. Although, if the TACs were set low enough to assure a reduction in effort, then a benefit to protected species would occur. Separate TACs for each stock may have allowed gear to stay in the water longer as vessels moved from stock to stock. DAS reductions provide a more direct reduction in impact to protected species than reduced TACs. As stated above, this alternative offered less protection to protected species than Alternatives 1 and 2, and the No Action alternative, and was identical to Alternative 3 as far as protected species benefit.

Recreational Fishing Measures (Selected)
This alternative sets recreational bag and size limits on cod and haddock. Although recreational fishing gear is known to interact with protected species, the size and relative low strength of the gear make it unlikely to cause serious injury to the large whales, dolphins, and sea turtles. Therefore, any measures designed for recreational fishing vessels will not affect protected species, thus providing no added benefit or adverse effect to protected species over the other rebuilding alternatives, including the No Action alternative.

5.2.9.5 Alternatives to Minimize the Adverse Effects of Fishing on Habitat

The following alternatives represent several varying actions, many of which contain closed areas that were proposed to protect the adverse effects of fishing on habitat. Four levels of habitat closure were considered for those alternatives that contain closed areas. The levels of habitat closure selected will make a significant difference in the degree of protection that will be provided to protected species. The four habitat closure levels and their relative benefit to protected species are discussed below.

Level 1 – The area will be closed indefinitely on a year round basis to all fishing gear.
This level will clearly provide the highest level of protection for protected species within the area to which it is applied, as all fishing gear types are prohibited.

Level 2 – Areas will be closed indefinitely on a year round basis to all bottom tending gear (static and mobile)
This level will provide the next highest level of protection, as it will prohibit the major gear types that are known to affect protected species. The gear types that will be allowed would be mid-water and surface gears that generally interact with small odontocetes and sea turtles.

Level 3 – The area would be closed indefinitely to all bottom tending mobile gear.
This level would provide very limited protection to protected species, as only sea turtles are known to be captured in bottom tending mobile gear.

Level 4 – Areas would be open indefinitely on a year round basis to "reduced impact" gear as defined by the Habitat Technical Team.
This level could provide as much protection to protected species as level 1 or 2, or could have no beneficial impact depending on how the "reduced impact" gear is defined.

Alternative 1 - No Action (Not Selected)
This alternative would have used the measures implemented under Amendment 7 and associated Framework measures in place during the 2001 fishing year as adequate habitat protection. See Section 5.2.11.4 above for protected species impacts assessed for the No Action alternative.

Alternative 2 - Incidental Benefit of Other Amendment 13 Measures (Selected)
This alternative uses the other non-habitat-specific measures to be implemented under Amendment 13 as adequate habitat protection. The protection afforded protected species under the alternatives selected by the Council for Amendment 13 are discussed for each alternative in this section. The overall perspective is that the reduction in fishing effort through DAS restrictions will be beneficial to protected species.

Alternatives 3 and 4 – Closed Areas to Protect Hard-Bottom Habitats (Not Selected)
A series of options were proposed to modify existing multispecies closed areas to better protect EFH. The proposed areas were generally adjacent to existing closed areas implemented under MFCMA, MMPA or ESA. As discussed above, the protected species impacts vary according to what Habitat Closure level would have been applied. If areas were to be closed to all gear, then the impacts are generally beneficial to protected species. However, gear specific restrictions to protect EFH generally target mobile gear, and may have encouraged fixed gear such as gillnet or pot gear to move into the area. The impact to large whales and harbor porpoise depends on whether the seasonal restrictions that are in place under the ALWTRP or HPTRP overlay the proposed EFH area. Only one or two habitat closed areas located in the SNE or shelf-edge areas would have protected sea turtles and pelagic odontocetes.

Alternative 5 - Closed Areas Designed to Protect Important EFH and Balance Fishery Productivity (Not Selected)
Under this alternative, EFH areas would have been drawn based on relative productivity of areas for several fish and mollusk species. The impacts to protected species would have been similar to those above. However, this alternative did contain areas off Marthas Vineyard, Nantucket and the New York Bight that would have included sea turtle and pelagic odontocete high use areas.

Alternative 6 - Closed Area Consistent with FW 13 Scallop Closed Areas Access Program (Not Selected)
This alternative would have included areas off Marthas Vineyard, and the offshore New York Bight where sea turtles and pelagic odontocetes are found. Depending on the way in which the EFH areas would have been protected (see discussion above on Habitat Closure level), this alternative may have provided some benefit for sea turtle and pelagic odontocete species.

Alternative 7 - Expand List of Gears Prohibited in Closed Areas (Selected)
The proposed list of expanded gear types that will be prohibited is limited to hydraulic clam dredges. Therefore, the potential impact to large whales, harbor porpoise, and seals is only somewhat beneficial under this alternative.

Alternative 8 - Prohibit Rockhopper and/or Roller Trawl Gear (Not Selected)
Rockhopper and/or roller gear refer to modifications to the footrope of trawl gear that, if prohibited, would have been replaced by some other footrope configuration. Therefore, the use of trawl gear would continue, and the potential impacts to the sea turtle and pelagic odontocetes species that may have been affected by trawl gear would not change.

Alternative 9 - VMS Requirement for all Multispecies Vessels (Selected)

A VMS requirement will not provide any direct beneficial advantage to protected species. However, there are several indirect advantages including providing accurate data on gear use by area, and identifying where fishing effort overlaps protected species high use areas.

Alternative 10 - Closed Areas that are Modifications of Existing Mortality Closures (Selected)
Certain habitat subsets of the existing or proposed multispecies closed areas are identified to provide increased EFH protection. The areas selected will be afforded Level 3 protection, which means that they will be closed indefinitely to all bottom-tending mobile gear. This would provide very limited protection to protected species, as only sea turtles and some dolphins are known to be captured in bottom tending mobile gear. The new areas that are not overlapped by ALWTRP and HPTRP closed areas are an area immediately to the north of the NLSCA and an area to the south of Penobscot Bay in the GOM. Level 3 protection for the area to the north of the NLSCA will benefit sea turtles and some dolphins that may inhabit that area in the summer. However, Level 3 protection in the area south of Penobscot Bay in the GOM will not benefit the large whales, harbor porpoise and seals that frequent the central GOM.

5.2.9.6 Other Issues

Northern Shrimp Fishery Exemption Area (Selected)
The small mesh Northern Shrimp Fishery Exemption Area extends from Cape Cod to the US-Canada border along the near shore waters. Northern shrimp fishing efforts had been restricted to that area. This alternative will remove the area restriction for northern shrimp fishing.

The trawl or mobile bottom gear that is used in the northern shrimp fishery poses no threat to large whales, harbor porpoise, seals and leatherback sea turtles, as it is dragged slowly along the bottom where these mobile species can easily avoid it's slow movement. Therefore, extension of the fishing area will have no affect on protected species since sea turtles (except leatherbacks) and small pelagic odontocetes do not frequent this area.

Tuna Purse Seine Vessel Access to Groundfish Closed Areas (Selected)
Small odontocetes, large whales and sea turtles are occasionally captured in tuna purse seine gear. However, the animals are easily released from the open nets by backing down the gear or otherwise lowering the edge of the seine to provide the animals access to open water. Therefore, although this gear may capture these species, it rarely results in injury to them. Allowing these vessels access to Groundfish Closed Areas is not likely to adversely affect protected species.

SNE General Category Scallop Vessel Exemption Program (Selected)
Scallop dredge gear does not pose a threat to large whales, harbor porpoise, small odontocetes, or seals. Sea turtles are occasionally taken in this gear, and the impacts have been analyzed by the NMFS under the Scallop FMP. The conclusion of a recent Biological Opinion was that the scallop fishery may affect sea turtles, but will not result in jeopardy to the populations involved. This alternative will not increase the scallop fishing effort in the SNE area such that the threat of sea turtle capture would increase.

5.2.9.7 MMPA Conclusions

It is recognized that the multispecies fishery will be prosecuted in the continental shelf waters frequented by several species of offshore odontocetes including Risso's, coastal bottlenose, spotted and striped dolphins. These species generally inhabit the offshore waters off southern New England and the Mid-Atlantic region. Due to their pelagic tendencies, it is unlikely that the bottom-tending trawl gear used by the multispecies fishery will affect these odontocetes. The levels of take of these species in the sink gillnet fisheries has been well documented by long-term NMFS observer effort in Northeast fisheries. The mortality and serious injury suffered by these species has been assessed relative to the PBR allowed under the MMPA for each species and have been found to be below those levels. Amendment 13 will reduce effort providing additional protection to these species.

Pilot whales, Atlantic white-sided, common, and offshore bottlenose dolphins are found entangled in both sink gillnet gear as well as bottom trawl gear. However, their pelagic prey species suggest they do not forage near the bottom, making it unlikely that they would frequently encounter the bottom tending gear used in the multispecies fishery. Therefore, it is unlikely that the small number of animals that are taken in this fishery will be at levels that compromise their ability to maintain optimum sustainable population levels, or result in serious injury and mortality levels that exceed the PBR levels allowed for commercial fisheries under the MMPA. Amendment 13 will reduce effort providing additional protection to these species.

Harbor, gray, and harp seals, as well as minke whales are often entangled in sink gillnet gear used to catch multispecies, although the populations of these species are high relative to the estimated total take. Therefore, the general reduction in effort afforded by Amendment 13 measures will not further inhibit the ability of the seal populations to achieve their optimum sustainable population levels, or result in serious injury and mortality levels that exceed the PBR levels allowed for commercial fisheries under the MMPA.

Harbor porpoise are taken in sink gillnet gear used to catch multispecies as noted in Table 110 that depicts harbor porpoise takes in gillnet fisheries from 1994 to 2001. Although they are found primarily in the northern Gulf of Maine in the summer months, they migrate seasonally through regions where multispecies are caught. For example, they move through the southern New England area where sink gillnet fishing operations occur in the spring (March and April). Harbor porpoise also move through the Massachusetts Bay and Jeffrey's Ledge region in the spring (April and May) and the fall (October November).

Amendment 13 to the Multispecies FMP will decrease effort among all gear components of the fishery. Thus sink gillnet effort in the Northeast Region is likely to be decreasing and will not affect the ability of the HPTRP to maintain the serious injury and mortality levels of harbor porpoise below the PBR levels allowed for commercial fisheries under the MMPA. In summary, the Multispecies FMP will continue to allow harbor porpoise to achieve its optimum sustainable population level.

5.2.9.8 ESA Conclusions

The extant Biological Opinion for the Multispecies FMP concluded that the existing FMP measures in, have been found by NMFS to affect, but not likely to jeopardize the continued existence of the large whales (humpback, fin, blue, sei, and sperm whales). Implementation of the Opinion's RPAs is intended to relieve the initial jeopardy conclusion for the right whale. A no jeopardy conclusion has also been found by NMFS for the green, Kemp's ridley, leatherback, and loggerhead and sea turtles. Furthermore, the NMFS has determined that the multispecies fishery will not affect the endangered shortnose sturgeon, Atlantic salmon, hawksbill sea turtle, roseate tern, piping plover, or the two right whale critical habitat areas found in the Northeast Region.

Given the current critical status of the right whale population and the aggregate effects of human-caused mortality that have led to the species current status, the Council understands that the right whale population cannot sustain additional incidental mortality. The Council also understands that the multispecies fishery uses sink gillnet gear that has caused serious injury and mortality to right whales. All vessels that utilize sink gillnet gear will be operating under the Multispecies FMP due to the requirement that any gear capable of catching multispecies must obtain a multispecies permit. Since a sink gillnet cannot be deployed in the Northeast waters without the possibility of catching a species covered under the Multispecies FMP, they will be included in the effort control measures that have been developed under Amendment 13 to the Multispecies FMP. As described above, these measures will affect significant reductions in effort largely through a DAS reduction plan. Therefore, it is reasonable to assume that Amendment 13 is not likely to increase sink gillnet effort in the Northeast Region, and that the current assessment of jeopardy to right whales could be revaluated. This is based primarily on the understanding stated above, that Amendment 13 to the Multispecies FMP will provide an adequate mechanism to control and reduce fishing effort, and that the restrictive measures implemented under the ALWTRP will continue to provide specific protection to the right whale as well as other large whale species.

5.3 Impacts to Essential Fish Habitat

5.3.1 Clarification of Status Determination Criteria

Status determination criteria (overfishing definitions) were previously adopted in Amendment 9. Alternatives are presented that will clarify and revise the status determination criteria (overfishing definitions). Criteria for most stocks will be based on fully-recruited fishing mortality and spawning stock biomass. In addition, minimum biomass thresholds may be changed to comply with National Standards guidelines. The Amendment also considered three options for revising numerical estimates of these parameters.

Habitat Impacts

The implementation of this measure would result in minimal or no habitat impacts.

5.3.2 Proposed Rebuilding Periods

For stocks that require a formal rebuilding program, the Council considered two different rebuilding periods:

(1) Rebuilding most stocks by 2009
(2) Rebuilding most stocks by 2014 **(selected for most stocks)**

Habitat Impacts

In so far as the 2009 rebuilding timeframe would reduce effort in the groundfish fishery more severely than the 2014 timeframe, rebuilding most stocks by 2009 would have a positive effect on essential fish habitat protection.

5.3.3 Proposed Rebuilding Programs

Three strategies to rebuild overfished stocks were considered in Amendment 13:

(1) A constant fishing mortality during the rebuilding period;
(2) A phased fishing mortality reduction.

(3) An adaptive fishing mortality strategy

The Council selected a combination of a phased and adaptive mortality reduction strategy. The three strategies differ with respect to the timing of reductions in fishing mortality (catch) necessary to rebuild the stocks. The constant fishing mortality strategy would mean more severe reductions in catch during the beginning of the rebuilding period (10 year rebuilding period for most stocks). The phased fishing mortality reduction strategy would not require as severe reductions in the initial years, but larger reductions in fishing mortality would be needed in later years. The adaptive strategy would fish at F_{MSY} through fishing year 2008, and then adjust mortality in order to rebuild most stocks by 2014.

Although the impact of a constant fishing mortality strategy would be immediately beneficial to habitat as compared to the other options, it is not possible at this time to say which types of habitat and essential fish habitat for vulnerable species would be positively or negative impacted more or less under the different strategies. It is likely that under any of the strategies, protection of essential fish habitat will be strengthened as compared to the No Action Alternative.

5.3.4 Fishery Program Administration

5.3.4.1 Fishing Year Change (No Action)

This alternative would change the start of the fishing year, which is currently May, to one of the following options: January 1, October 1, or July 1. The Council selected the No Action Alterative (start of May 1). The fishing year changes considered would have some or all of the following advantages over the current fishing year: minimizes the time lag between new scientific information and incorporation into the FMP, resolves the current mismatch between the stock assessments (based on a calendar year) and the fishing year, facilitates management of trans-boundary stocks (those shared with Canada), and reduces the likelihood of a derby fishery.

The implementation of this measure would result in minimal or no habitat impacts because it doesn't directly affect the frequency or intensity with which the fishery is prosecuted.

5.3.4.2 Periodic Adjustment Process (Selected)

This alternative would combine two existing management committees - the Multispecies Monitoring Committee (MSMC) and the Plan Development Team (PDT) - in order to streamline the management process.

The implementation of this measure would result in minimal or no habitat impacts.

5.3.4.3 Biennial Adjustment (Selected)

This alternative would decrease the frequency of framework adjustments to existing fishery regulations. Compared with the current annual adjustment, the proposed biennial adjustment (every two years) would provide more time for management measures to take effect and allow more time to evaluate the relevant scientific information on the status of the stocks and the effectiveness of the regulations. If necessary, the Council could choose to initiate an adjustment at other times.

The implementation of this measure would result in minimal or no habitat impacts. However, this will allow the effect of regulations on essential fish habitat to be better assessed.

5.3.4.4 Administration of Certified Bycatch/Exempted Fisheries (No Action)

The Council selected the No Action alternative for this measure. As in Amendment 7, the incidental catch of regulated multispecies must be less than 5% of total catch by weight. The other alternative considered proposed alterations to the current rules to provide increased flexibility to administer the exempted fisheries program, and requires periodic review of the current exempted fisheries.

The implementation of this measure would result in minimal or no habitat impacts. However, this may impact habitat negatively if the exempted fisheries programs allow non-habitat friendly gear into areas currently prohibited. Conversely, this may impact habitat positively if the exempted fisheries program under application includes testing gear in areas that may result in reduced habitat impacts.

5.3.4.5 Special Access Program (Selected)

Because management measures are generally applied over a wide geographic area and across many sectors of the fishing industry, access to stocks in good condition is sometimes overly restricted. This alternative addresses this problem by implementing a system to expedite the implementation of regulations that allow access to multispecies stocks that are in good condition, or to non-multispecies stocks that can be harvested without compromising the goals of this amendment. These measures reduce fishing mortality on stocks that are overfished, but also are likely to reduce fishing mortality on stocks that could support an increase in catch.

Three specific special access program are proposed: a program to access GB yellowtail flounder in Closed Area II, a program to allow small incidental catches of winter flounder in the fluke fishery in Southern New England, and a program to facilitate catching the U.S. share of eastern GB cod, haddock, and GB yellowtail flounder under the U.S./CA resource sharing understanding.

5.3.4.5.1 Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program

Allowing fluke vessels fishing west of 72º 30' W to retain small quantities of winter flounder without using a DAS may slightly increase DAS use, since it may free a small number of DAS for directed groundfish fishing that were previously used to retain winter flounder caught on fluke trips. Habitat effects would be negligible.

5.3.4.5.2 Georges Bank Yellowtail Flounder Special Access Program

There is a provision in this alternative allowing for limited fishing (two trips per month during June-December) of yellowtail flounder inside the southern portion of Closed Area II. The area specified is the same as that used in the scallop CAII access program. As this area is primarily of sandy bottom composition, it is less susceptible to the adverse effects of fishing than the gravel bottom area in the northern portion of the closed area. Also, the fact that this area was heavily fished during the CAII access program during 1999-2001 means that any additional habitat impacts associated with trawling for yellowtail are likely to be minimal.

5.3.4.5.3 US/Canada Resource Sharing Understanding (Selected)

This alternative would incorporate the US/Canada Resource Sharing Understanding into the FMP. The informal agreement specifies an allocation of cod, haddock and yellowtail flounder on eastern Georges Bank for each country. Total catches by U.S. vessels from specific areas may not exceed designated quota. U.S. vessels in trans-boundary area would be required to use an approved Vessel Monitoring System. There are a range of measures to ensure the U.S. does not exceed its share.

The DAS adjustment, or tradeoff for vessels that participate in this access program is undefined in the proposal. Therefore, it is impossible to analyze the potential benefit of reduced bottom time in other areas, because the DAS differential rate could be 1:1. In general, if DAS are counted more than on a 1:1 ratio for this program, then it is likely that the amount of time available for fishing is reduced, producing some habitat benefits. The Council selected to give vessels credit for steaming time, so there will not be habitat benefits from reductions in bottom contact time for the amount of time it takes a vessel to get to the access area. In addition, the adjustment downward in mesh size permitted in this access program is not expected to have any additional impacts on habitat.

The length of time that access is granted into Closed Area II is an issue for habitat. The access length of time was not specified, but can be for a period of time between 1 and 10 months. At the extreme, this would reduce Closed Area II from a year round closure to a seasonal two (2) month closure. Year-round closures are believed to generate greater habitat benefits then seasonal closures; therefore, any access will decrease the habitat benefits generated from that area. If the area is open one month versus ten months, the habitat impacts may not vary that much, because most of the negative impacts generated from bottom tending gear is believed to occur from the first pass.

Habitat benefits are reduced when an area is opened to bottom-tending mobile gear as substantiated by the NRC Report and the Gear Effects Workshop Report conclusions about the effect of these gears on the benthic environment. Seasonal closures will reduce gear impacts on habitat, but only for short periods of time. The habitat benefits of seasonal closed areas, as for year-round closures, partially depend upon the types of gear permitted inside them (Table 127). Seasonal closures in the Gulf of Maine eliminate fishing effects on benthic habitats for short periods of time, but probably not long enough to provide any significant habitat benefits. The redistribution of effort (both geographically and amongst other fisheries and gear types) caused by these closures, combined with potential short-term increases in fishing effort inside these areas when they are open, may in fact increase the adverse effects of seasonal area closures on EFH. In addition, because of their intermittent protection, seasonal closures offer less opportunity than year-round closures for growth and recovery of benthic communities that may have been altered by fishing activity. The longer the duration of a closure, the more protection it will afford to fish stocks and habitat in that area. The rolling closures currently in existence afford the greatest degree of protection to benthic habitat in inshore regions of the Gulf of Maine, particularly in the waters north of Cape Cod to Cape Ann.

Nantucket Lightship Closed Area	Closed Areas I and II	Western Gulf of Maine Closed Area	Cashes Ledge Closed Area
Lobster and hagfish traps	Lobster and hagfish traps	Multispecies exempted gear	Multispecies exempted gear
Pelagic longline, hook and line and/or harpoon gear	Pelagic longline, hook and line and/or harpoon gear	Charter, party or recreational vessels	Charter, party or recreational vessels
Pelagic mid-water trawl gear	Pelagic mid-water trawl gear	Lobster and hagfish traps	Lobster and hagfish traps
Surf clam/ocean quahog dredge gear			
Charter, party or recreational vessels			

Table 127- Gears currently authorized for use inside the year-round closed areas.

The Council selected to give the Regional Administrator the authority to authorize the number of trips into the area. It is difficult to predict whether the limitations on number of trips to the area will have an impact on habitat. Option 1 could cause more frequent disturbance if a significant amount of vessels participate in the program, while Option 2 could spread the effort out over a longer period of time.

The habitat analysis below describes the original area that was proposed in the DSEIS, the sediment types and EFH contained in each area based on descriptive environmental analysis. (Methodology of this analysis can be found in Appendix XI). Note, that the access area the Council selected for the final US/Canada SAP is significantly smaller that the northern portion of Closed Area II described in these analyses. The access area is the northern tip of Closed Area II, north of the cod HAPC. Overall, the southern portion of Closed Area II is larger than the northern area proposed for access (Table 128). Both areas are primarily sandy bottom, with some gravelly sand (Table 129). The northern portion of closed area II contains more EFH for species with EFH vulnerable to bottom tending gear, especially juvenile cod, barndoor skate, winter flounder, and winter skate. The southern portion of Closed Area II contains about 3% of scallop (J), haddock (A and J), and yellowtail flounder (A and J) EFH. Overall, neither portion of Closed Area II contain more than 3% of total EFH for any of the species with EFH vulnerable to bottom tending gear (Table 130). Furthermore, it is important to note that the southern area has been exposed to scallop dredge effort through FW11 and FW13 to the Scallop FMP, so this area has been disturbed in the recent past.

	AREA (nm^2)	Percent of Closed Area II
Portion of CAII North of 41° 30	871	44%
Portion of CAII South of 41° 30	1127	56%

There are numerous reasons why the Council selected not to include access into the cod HAPC for this access program. The following paragraphs provide some background on the importance of an area that has been designated as an HAPC, and summarizes some of the research that has been done on the habitat of that area. Following a review of the scientific literature for information on areas deserving special attention or species with particular habitat associations, the Council has designated an area on Georges Bank as an HAPC for juvenile Atlantic cod. The Council may consider designating additional habitat areas of particular concern in the future. Additional designations may be based on existing or developing knowledge of species-habitat associations, the unique characteristics of a particular habitat type, the threats to sensitive habitats, or the importance of an area to multiple species.

Several sources document the importance of gravel/cobble substrate to the survival of newly settled juvenile cod (Lough *et al.* 1989; Valentine and Lough 1991; Gotceitas and Brown 1993; Tupper and Boutilier 1995; Valentine and Schmuck 1995). A substrate of gravel or cobble allows sufficient space for newly settled juvenile cod to find shelter and avoid predation (Lough *et al.* 1989; Valentine and Lough 1991; Gotceitas and Brown 1993; Tupper and Boutilier 1995; Valentine and Schmuck 1995). Particular life history stages or transitions are sometimes considered "ecological bottlenecks" if there are extremely high levels of mortality associated with the life history stage or transition. Extremely high mortality rates attendant to post-settlement juvenile cod are attributed to high levels of predation (Tupper and Boutilier 1995). Increasing the availability of suitable habitat for post-settlement juvenile cod could ease the bottleneck, increasing juvenile survivorship and recruitment into the fishery. For these reasons, areas with a gravel/cobble substrate meet the first criterion for habitat areas of particular concern.

Specific areas on the northern edge of Georges Bank have been extensively studied and identified as important areas for the survival of juvenile cod (Lough *et al.* 1989; Valentine and Lough 1991; Valentine and Schmuck 1995). These studies provide reliable information on the location of the areas most important to juvenile cod and the type of substrate found in those areas. These areas have also been studied to determine the effects of bottom fishing on the benthic megafauna (Collie *et al.* 1996; Collie *et al.* 1997). Gravel/cobble substrates not subject to fishing pressure support thick colonies of emergent epifauna, but bottom fishing, especially scallop dredging, reduces habitat complexity and removes much of the emergent epifauna (Collie *et al.* 1996; Collie *et al.* 1997). Acknowledging that a single tow of a dredge across pristine habitat will have few long-term effects, Collie *et al.* (1997) focus on the cumulative effects and intensity of trawling and dredging as responsible for potential long-term changes in benthic communities. For these reasons, the identified area on the northern edge of Georges Bank meets the second criterion, as well as the cumulative effects consideration, for designation as a habitat area of particular concern.

Collie *et al.* (1997) also describe the relative abundance of several other species such as shrimps, polychaetes, brittle stars, and mussels in the undisturbed sites. These species are found in association with the emergent epifauna (bryozoans, hydroids, worm tubes) prevalent in the undisturbed areas. Several studies of the food habits of several demersal species (including juvenile cod) identify these associated species as important prey items (Hacunda 1981; Lilly and Parsons 1991; Witman and Sebens 1992; Casas and Paz 1994; NEFSC 1998). These areas provide two important ecological functions for post-settlement juvenile gadids relative to other areas: increased survivability and readily available prey. Scientists are still not certain if these higher survivability rates ultimately translate into population effects. These areas are also particularly vulnerable to adverse impacts from mobile fishing gear.

Collie et al. (2000), in a follow-up publication, analyzed video images and still photographs recorded at five of the six study sites surveyed in the two 1994 research cruises to George Bank. In the videotapes, the U sites at both depths had slightly coarser sediments (higher frequency of pebble-gravel than sand-gravel); in the still photos, there was a higher frequency of sand and cobble in U sites and a lower frequency of pebbles. Bottom photos showed a high percent cover of colonial hydroids and bryozoans at one of the deep U sites and of the rock-encrusting polychaete, *Filograna implexa*, at both deep U sites. In contrast, at the D sites the gravel was free of epifaunal cover and few animals were visible. Statistical analysis confirmed that the U sites had a significantly higher percent cover of *Filograna implexa*.. However, cover provided by this species was also significantly greater in deeper water than in shallow water. Emergent hydroids and bryozoans were significantly more abundant in the deep U sites, but less abundant at the shallow U site. Significant differences between the disturbed and undisturbed sites were noted. However, overall, the percent cover of all emergent epifauna was significantly higher at the deep sites, but there was no significant disturbance effect. It was clear from this study that depth appeared to be just as important as disturbance.

5.3.4.6 Closed Area Administration (Not Selected)

This alternative contained various options for a policy for access to closed areas and the review of current closed areas.

This alternative could have negative impacts on EFH if the administration of closed area access is not tightly reviewed by the Essential Fish Habitat Technical Team as well as the Council's Habitat Committee. If increased access is provided, this may allow access to Habitat Areas of Particular Concern; some areas of current year round closed areas for groundfish have been identified as Habitat Areas of Particular Concern. Additionally, other areas not under the HAPC designation that are currently part of year round closed areas house complex and possible rare habitats. Future research may show that these areas have an impact on fisheries productivity and ecosystem ecology. Under Option 5, however, access by any commercial vessel would be prohibited in any year-round closures. This option would greatly benefit habitat as compared to the NAA as it provides the current year-round closed areas 100% habitat protection from commercial fishing gear.

There are five potential levels of closure addressed in the Closed Area Administration Section. Any level of closure that permits bottom-tending mobile fishing gear is likely to have negative impacts on the EFH found in that area. Table 131 summarizes the impacts of these five options on EFH (specific closed areas affected are noted in the column heading). A score of "-1" indicates a reduction from the levels of habitat protection afforded by the groundfish management measures that were in place during the 2001 fishing year (the No Action Alternative). A score of "0" indicates no change, and a score of "+1" indicates an increased level of protection.

	Option 1 (All Closed Areas)	**Option 2** (CA I and CA II)	**Option 3** (NLCA)	**Option 4** (WGOM)	**Option 5** (All Closed Areas)
Qualitative Analysis	-1	-1	-1	-1	+1

Table 131 - Qualitative summary of Closed Area Administration Options considered in Amendment 13 (none were selected).

Flexible Area Action System (Selected)
The FAAS is available under the No Action alternative, but has never been successfully implemented in the Northeast. Therefore, eliminating the FAAS will not change the impacts of Amendment 13 on habitat.

5.3.4.7 Leasing Days-at-Sea (Selected)

This alternative proposes a DAS leasing program for the fishery in order to enhance economic viability through increased flexibility. Under this alternative, DAS can be leased one at a time, there is no conservation tax on leased DAS, DAS may be leased for a one-year period, leased DAS must be used during the period of the lease, leasing to more than one vessel is allowed, and only Category A DAS may be leased (see Capacity Alternative 5 for a description). Lease agreements would need to be registered with the NMFS. Additional options within this alternative address administrative and conservation issues related to DAS leasing.

If the conservation issues outlined under this alternative are implemented, it would appear that this alternative will have minimal or no effect on habitat.

5.3.4.8 Recreational Fishing Permit (Not selected)

Amendment 13 considered three permit options for a permit for recreational vessels fishing for multispecies in federal waters, and one No Action option (no permit required in federal waters). The Council selected the No Action alternative.

As most recreational fishing is prosecuted by gears other than those determined to have an adverse effect on EFH (otter trawl, scallop dredge and hydraulic clam dredge), recreational fishing of groundfish in general does not negatively impact habitat. However, a recreational fishing permit requirement would allow managers access to data that will enable them to better understand the impacts, if any, of recreational fishing on EFH.

5.3.4.9 "Running clock" alternatives (Not Selected)

Amendment 13 considered three options for modifying the "running clock" used to calculate trip/possession limits, and selected not to implement any of them.

The considered alternatives will not likely increase effort beyond the NAA, thus the running clock alternatives considered would have minimal or no impact to habitat.

5.3.4.10 Observer coverage (Selected)

This alternative contained two options pertaining to the level of observer coverage in the multispecies fishery. Both options represent an increase in observer coverage over past levels. The Council requested 10% observer coverage and NMFS will determine by 2006 if this level is appropriate.

In so far as observers are able to collect data of interest to EFH management (targeted species, non-targeted and non-regulated species and substrate), increased observer coverage in the multispecies fisheries will indirectly benefit the protection of EFH through a better understanding of the habitats that are fished.

5.3.4.11 Vessel Monitoring System Requirements (Selected)

This measure allows vessels to sign-out of the multispecies fishery and stop VMS messaging for a period of at least 30 days.

This alternative will not impact EFH as it is an administrative issue.

5.3.4.12 Days-at-Sea Counting (No Action)

The Council considered three options for counting DAS: Option 1 maintains the current system. Option 2 counts all trips between 3 and 24 hours in length as 24 hours. Option 3 counts all trips between 3 and 24 hours in length as 24 hours with no partial DAS counted (all days would be in 24 hour increments; for example a trip of 26 hours would count as 2 DAS). They selected the No Action alternative.

Options 2 and 3 will result in the reduction of fishing effort during the transition period as compared to Option 1 or the NAA. This would benefit EFH protection.

5.3.4.13 Handgear Permit (Selected)

The Council considered three options for this measure and selected Alternative 3. Alternative 1 maintains the limits on open access permits that were implemented August 1, 2002. It includes a 200 lb trip limit on cod, and no trip limit on other species. Alternative 2 includes a 300 lb trip limit on cod, haddock and yellowtail combined, with a 200 lb maximum on cod. Permits would be open access. Alternative 3 establishes one limited access permit category and one open access permit category. To be eligible for a limited access permit, a vessel would need to have landed 500 lbs. of cod, haddock, or yellowtail flounder in any one fishing year from fishing years 1997 through 2001 when fishing under the handgear category. The trip limits for this new category would be either a 150 lb or 300 lb trip limit for cod. Open access permits are limited to 75 lbs. of cod.

There are no significant habitat impacts associated with these alternatives.

5.3.4.14 Reporting Requirements (Selected)

The Council considered several alternatives for reporting requirements for vessels and dealers – including the possibility of a VMS requirement for all vessels – to improve monitoring of catches. Many of these options are designed to facilitate monitoring of a hard TAC. The Council selected No Action for vessels with addition of trip identifier paper, and daily electronic dealer reporting within 24 hours of all transactions.

Option 1 would not benefit habitat as it allows the current system to remain. Very little habitat information can be derived from the current VMS system in the groundfish fishery. Options 3 and 4 would improve the knowledge of fishing intensity by area and habitat type. This will benefit EFH protection indirectly.

5.3.4.15 Sector allocation (Selected)

This alternative creates a system for approval of voluntary, co-operative sectors within the multispecies fishery. An organized sector would receive a share of the TAC or available DAS, based on prior history in the case of the TAC or current DAS allocations. The sector would form a plan that when approved by NMFS would control fishing by that sector. This may provide a way for sectors to adapt to the management regulations proposed.

One specific sector is proposed – the GB hook sector. This would implement a sector allocation for Georges Bank cod to the hook sector and allocates a portion of the Georges Bank cod total allowable catch.

The habitat impacts of this alternative will be directly tied to the over-arching alternative chosen. Sectors are not geographically constrained; it is unlikely that they, as a management measure, will have any significant habitat impacts.

5.3.4.16 Gulf of Maine Inshore Conservation and Management Stewardship Plan (Not Selected)

This plan was not selected by the Council. It proposed specific management measures that would control fishing in the Gulf of Maine. It is based on an understanding of cod distribution in and migration in this area. Because it does not address fishing in all areas, it is not a stand-alone alternative and would have to be combined with other measures in other areas. It could, for example, be used as the measures for the GOM under an area management proposal. The provisions of this alternative include:

--Creates two inshore Gulf of Maine areas and one offshore area
--Prohibits night trawling
--Begins the fishing year July 1
--Increases the Gulf of Maine cod trip limit slightly
--Recreational fishing limits would be similar to those currently in place
--Each area subject to a 'hard' TAC (see discussion above for a description of 'hard' TAC).
--DAS allocations will be the number of DAS implemented August 1, 2002, with the exception that vessels with less than 25 DAS would be allocated a minimum of 25 DAS.
--Unused permits could be purchased by State management agencies and converted into state permits to allow small-scale groundfish fishing with traps, hooks, or jigging machines.
--20% observer coverage for groundfish trips, and recommends 100% coverage of mid-water trawl trips.
--Rolling closures and year round closures would be similar to those currently in effect.
--Gear restrictions include 6.5 inch mesh, 10" maximum rockhopper size, limitation on groundcable length, 50 gillnet maximum, and 2,000 hook maximum.

This alternative does not meet the biological objectives for stocks outside of the Gulf of Maine and would have to be adopted in conjunction with another rebuilding alternative. It employs three separate management areas within the Gulf of Maine, similar in concept to Rebuilding Alternative 3. It uses possession limits and effort controls (vice hard TACs) to control mortality in these management areas.

The possession limit for this plan is 600 lbs/day / 6,000 lbs/trip on cod for all three GOM management areas. The impacts of this trip/possession limit are likely to be similar to those discussed in Rebuilding Alternative 1.

To reduce overall fishing effort this alternative employs DAS reductions, equal in amount to the maximum number of DAS utilized in any single year and not to exceed the allocation of FY 2001. All vessels under 50 ft possessing a multispecies permit are allocated 25 DAS minimum.

The difference between the total DAS allocated under this plan and the DAS allocated in FY 2001 are to be "frozen." There is a provision for "thawing" these DAS for use by vessels "diversifying" their fishing habits by targeting groundfish part-time. Such vessels would be permitted to utilize fish traps or hooks only. Anticipated DAS reductions are not quantified in this document; it is therefore impossible to assess potential impacts to habitat. The concept of re-introducing "thawed" DAS to low-impact gears, though, may have positive habitat impacts beyond the direct benefits of reduced effort if the amount of DAS "frozen" is large. If vessels in the "diversification" program shift their fishing effort from higher-impact fisheries (inshore scalloping, shrimp trawling, etc) to groundfish fishing with hooks or fish traps, there may be an overall reduction in the amount of bottom contact by trawl nets.

Several gear restrictions with potential habitat impacts are proposed under this alternative. For trawl gear operating in the two inshore areas, a maximum limit of 10 inches is imposed for roller/rockhopper gear. See Habitat Alternative 8 for more details on the potential habitat benefits associated with reducing the size of roller/rockhopper gear.

There is a provision for annually decreasing the maximum legal length of cables deployed (defined as distance between the wind and the doors). Decreasing this distance may have an impact on areas targeted by otter trawl gear. As a result of these restrictions, vessels may be limited in the depths of water they can effectively fish in. This is presumed to be a benefit for specific geographic areas, as deeper (and potentially "low energy"—see Physical Environment Section) areas become de-facto off-limits to mobile bottom-tending gear.

There are provisions for increasing the minimum mesh size for trawl nets and reducing the number of gillnets and longline hooks. There are no habitat implications for the increases in mesh size for gillnet gear. The limitation imposed on longline vessels may result in less gear deployed, which may have a corresponding benefit to habitat. Seasonal closures similar to those discussed in Rebuilding Alternative 2 are also proposed here.

5.3.5 Alternatives to Control Fishing Capacity

Since the implementation of the DAS program under Amendment 5, a large portion of the total number of allocated DAS has not been used. Such unused DAS (also known as 'latent effort') represent potential future fishing effort. Without some type of control on this latent effort, the use of DAS could increase and thus make it more difficult to rebuild stocks. The following alternatives were designed to reduce unused DAS and provide additional flexibility to the industry by allowing, for example, transfer of permits or DAS. The Council selected **two** of these strategies to reduce capacity.

--Permit absorption proposal
--Permit transfer proposal
--DAS transfer proposal **(Selected)**

--Freeze on unused DAS
--DAS reserve proposal (Groundfish PDT proposal) **(Selected)**
--Combined voluntary/mandatory alternative

Many of the measures discussed in this section address capacity issues affecting latent (unused) effort. Such measures have significant impacts on future effort levels, which may expand dramatically as fish stocks rebound and anticipated revenues from the groundfish fishery increase. If latent effort re-enters the groundfish fishery, there will be an adverse impact on EFH; the magnitude of this impact is likely to be similar to overall DAS allocation increases.
Six alternatives for reducing capacity in the groundfish fishery were considered in the Amendment 13 draft document.

Any measures aimed at reducing the amount of time spent fishing by mobile gear vessels will likely have benefits to EFH, but the degree of this benefit varies considerably based on fishery entry/exit decisions, geographic areas targeted by affected fisheries and the impacts of other regulatory requirements. Many of the measures discussed in this section address capacity issues affecting latent (unused) effort. Such measures have significant impacts on future effort levels, which may expand dramatically as fish stocks rebound and anticipated revenues from the groundfish fishery increase. If latent effort re-enters the groundfish fishery, there will be an adverse impact on EFH; the magnitude of this impact is likely to be similar to overall DAS allocation increases.

All four alternatives include options that would reduce DAS by as much as 50%/90% for active/inactive permit holders. This will reduce the amount of latent effort re-entering the fishery as the resource condition improves.

5.3.6 Alternatives to Address Rebuilding Requirements

The Council developed several management measures designed to achieve specific fishing mortality reductions shown in the previous sections. These fishing mortality reductions were based on a constant fishing mortality rate that will achieve rebuilding and/or end overfishing. During the comment period for the DSEIS for Amendment 13 the Council received a new alternative to address rebuilding requirements. During deliberations at their November 2003 meeting, the Council selected this alternative for Amendment 13. The proposed action is described in detail in Section 3.6.

5.3.6.1 Habitat Impacts of Commonly Used Management Tools

A suite of seven management tools is utilized in various combinations within the alternatives designed to meet rebuilding objectives. The impact of each of these tools upon EFH, in general terms, is summarized below. The impacts from these general tools will be utilized in the evaluation of management alternatives to follow.

5.3.6.1.1 Days-At-Sea Reductions

There are a number of factors that will affect the speed and degree of habitat recovery in areas where bottom tending mobile gear use is reduced. These include: 1) the degree, duration, and extent of fishing in the area; 2) any other anthropogenic sources of habitat disturbance (e.g., contamination of bottom sediments in coastal waters); 3) the natural disturbance regime (e.g., frequency and intensity of storms, bottom currents, etc.); 4) the type of substrate or sediment; 5) depth; 6) the type of benthic organisms that inhabit the area; and 7) the length of time that the area remains undisturbed by fishing. Improvements in habitat quality would most likely occur in areas where trawling and dredging activity was minimal to begin with and is totally eliminated, or substantially reduced; in deeper, low-energy locations not exposed to storm events or strong bottom currents; in hard-bottom areas (in shallow or deep water) that support prolific growth of large, attached epifauna, or in other bottom habitat types that provide food and cover for demersal fish; and in areas populated by benthic organisms that grow faster and reproduce quickly. For some benthic environments that have been altered by fishing activity, complete recovery could take years. For others, recovery might only take a few months. If reductions in bottom trawling activity in marginal areas are temporary and increase after a year or two as stock abundance increases, habitat recovery in certain areas may never be complete.

A useful conceptual model for understanding the relationship between changes in fishing effort and the degree of habitat modification described in the National Research Council report on trawling and dredging effects (NRC 2002). Starting from zero fishing effort with no habitat impact, a change in fishing effort will change the degree of habitat modification, but as effort continues to increase habitat alteration reaches its maximum point and levels off even as effort continues to increase. For heavily modified habitats exposed to high levels of fishing activity, effort must be reduced substantially before any improvement in habitat quality is realized. Although there is much uncertainty regarding the relationship between fishing effort and habitat alteration at low effort levels, it is probably not linear as depicted in NRC 2002. A more realistic relationship, at least for certain habitats exposed to mobile bottom-tending gear, is curvilinear since the first few tows in an undisturbed habitat would be expected to produce the greatest relative change in habitat conditions (e.g. three-dimensional structure), with reduced effects as fishing effort increases to the point of maximum habitat modification. In this scenario, reductions in effort would have to be even more severe (approaching zero effort) in order to achieve, say, a 50% habitat recovery.

Most of the available studies of gear effects for mobile gear types used in the Northeast region examine the effects of single or multiple tows in previously fished or un-fished locations within some defined time period, with control plots in nearby undisturbed locations. There are a few studies that compare benthic communities or physical habitat features in areas exposed historically to different levels of fishing effort. One of them (Frid et al. 1999) compared periods of low, medium, and high otter trawling activity at two sites in the North Sea over a 27-year period. At the heavily-fished, mud-bottom, site, benthic organisms that were predicted to increase as fishing effort did increase in abundance, but organisms that were expected to decrease in abundance did not. At the lightly fished, sand-bottom site, there was a correlation with primary production, but no correlation with fishing effort. In a similar study, Kaiser et al. (2000b) compared benthic communities exposed to high, medium, and low fishing intensity by otter trawls, beam trawls, toothed scallop dredges, and lobster pots in the English Channel (sand substrate) and found no significant effects of increased effort on the numbers of benthic organisms or species, but did find reductions in the abundance of larger, less mobile, emergent epifauna and increased abundance of more mobile invertebrate species, fewer larger organisms, and more smaller organisms in high effort areas. Two factors that complicate this kind of research are the effects of different habitat conditions (e.g., depth, sediment type) that may exist at low and high-effort sites, and temporal changes in environmental conditions (e.g., changes in sediment composition or water temperatures) that occur over the time period being investigated.

More direct evidence of the effects of changes in bottom fishing effort is provided by studies that relate progressive increases in disturbance to changes in benthic community structure and seafloor topography and sediment composition. Jennings et al. (2001) documented effects of increasing beam trawling activity on sand and muddy sand-bottom communities in the North Sea. Thrush et al. (1998) did the same for 18 stations (mud and sand bottom) in Hauraki Gulf, New Zealand, that were fished at varying levels of effort by otter trawls, Danish seines, and toothed scallop dredges. Unfortunately, these studies examine the combined effects of a number of gear types, including toothed scallop dredges and beam trawls that are not used in the Northeast region of the U.S. Nevertheless, a number of significant impacts to benthic communities are identified which can probably, to some extent, be generalized to dredging and otter trawling on similar habitat types in the Northeast region. These included decreased infaunal and epifaunal biomass (North Sea), decreased densities of large epifauna, echinoderms, and long-lived surface dwellers, and increased densities of small, opportunistic species (New Zealand).

There are three experimental studies of the habitat effects of increasing otter trawling effort in commercially un-exploited areas. Two of these were performed in mud-bottom habitats, one in Sweden (Hansson et al. 2000) and the other in Scotland (Tuck et al. 1998). Another (Moran and Stephenson 2000) was conducted in Australia on sandy substrate. In the Swedish study, two tows were made per week for a year in an area closed to fishing for six years. During the last six months of the experiment, 61% of the infaunal species were negatively affected (i.e., they decreased more or increased less in the trawled sites compared to the control sites), and there were significant reductions in brittle stars (compared to a control area), but not in polychaetes, amphipods, or mollusks. In the Scottish study, multiple tows were made during a single day for 16 consecutive months in an area closed to fishing for more than 25 years. Increased bottom trawling produced door tracks, increased bottom roughness, but had no effect on sediment composition. There were significant increases in the number of infaunal species after 16 months of disturbance, but no changes in biomass or total number of individuals; community structure, however, was altered after five months and community diversity declined six months after trawling ceased. Effects on species groups varied: polychaetes increased in abundance while bivalves decreased in abundance five months after trawling began. In the Australian study, four tows made at 2-day intervals on the same area of bottom. Underwater video surveys showed that the first tow reduced the density of large (>20 cm) benthic organisms by 15% and four tows by 50%. Sainsbury et al. (1997), working in the same general area, reported that a single pass of a trawl footrope removed 89% of sponges larger than 15 cm.

Although there is some information (summarized above) that documents habitat modifications that result from <u>increasing</u> fishing effort by mobile bottom-tending gear, there is no corresponding evidence of the effects of progressive <u>reductions</u> in fishing effort on benthic marine habitats. There are, however, a number of studies that document the recovery of benthic habitats following the cessation of bottom fishing. These have been performed in areas that have been closed to various types of fishing activity, mostly by mobile bottom-tending gear. Tuck et al. (1998) monitored the recovery of a mud-bottom benthic habitat for 18 months in a closed area in Scotland after 16 months of bottom trawling and found that door tracks were still visible after 18 months, and that the infaunal community had recovered completely within the same period. This is the only directed study of recovery from simulated commercial trawling activity that has been conducted. Other observations have been made by a number of authors who have monitored the recovery of benthic habitats from single trawl or dredge tows, or following multiple tows in a single day (see section 9.3.2). Kenchington et al. (2001) did note that infaunal organisms that were reduced in abundance during one of three years of experimental fishing in a closed area on the Grand Banks had recovered by the time experimental fishing resumed a year later and Schwinghamer et al. (1998), working on the same project, noted that door tracks lasted up to a year and seafloor topography recovered within a year's time. Sainsbury et al. (1997) compared historical survey data – collected before and after commercial fishing started – to data collected in an area in Australia that remained open to trawling and another area that was closed for five years and reported increased catch rates of fish associated with large epifauna and small benthic epifaunal organisms (but not large ones) within the five-year period.

5.3.6.1.2 Year-round Closed Areas

The benefits of year-round closed areas are dependent upon the types of habitat within the closed area and the sensitivity of that habitat to disturbances. Sensitive habitats that require long periods of time for recovery from disturbances (e.g. complex habitats with biogenic structure) would accrue greater benefits from long-term closure. Less sensitive habitats that have rapid recovery rates (e.g. high energy sand environments) may not accrue additional benefits from long-term closures.

Furthermore, long term area closures provide levels of protection to EFH that are commensurate with the habitat impacts of the gear that they prohibit. For example, the Nantucket Lightship Closed Area likely provides less habitat protection than do Closed Area I and Closed Area II based on the inclusion of surf clam/ocean quahog dredge fishing vessels as permitted gear inside this area (see Table 132). (See Gear Effects Evaluation Section) for more details on the impacts of specific gears on EFH).

Nantucket Lightship Closed Area	Closed Areas I and II	Western Gulf of Maine Closed Area	Cashes Ledge Closed Area
Lobster and hagfish traps	Lobster and hagfish traps	Multispecies exempted gear	Multispecies exempted gear
Pelagic longline, hook and line and/or harpoon gear	Pelagic longline, hook and line and/or harpoon gear	Charter, party or recreational vessels	Charter, party or recreational vessels
Pelagic mid-water trawl gear	Pelagic mid-water trawl gear		
Surf clam/ocean quahog dredge gear			
Charter, party or recreational vessels			

Table 132- Gears currently authorized for use inside the year-round closed areas.

Year-round closed areas that are fished periodically or seasonally by bottom tending mobile gear (e.g. scallop access to NLCA, CAI and CAII) offer significantly less protection for habitat than those that are not fished by mobile bottom gear. In such cases, the affect on habitat is similar to the effects of seasonal closures. Here again the impact is greater for complex habitats than "high-energy" sand habitats, which may be able to sustain periodic fishing by mobile gears.

Year-round closed areas have a very serious distributional affect, which can be a potential cause of adverse impacts upon EFH. This impact may be even more severe than anticipated in areas where little information about bottom type exists. Kaiser et al. (2002) note "the inappropriate use of closed areas may displace fishing activities into habitats that are more vulnerable to disturbance than those currently trawled by fishers. Management actions that force [fisherman] to redistribute their effort may be more damaging in the longer term." While much is known about the habitats of the northwest Atlantic, much is also unknown. The impacts of year-round closed areas on EFH outside areas closed cannot be quantified at this time.

Additionally, the impacts of closure cannot be quantified for areas contained within the closure. There is no published literature detailing the specific habitat benefits from the long-term year-round closed areas on Georges Bank. However, there is growing literature on the benefits of long-term closures to fisheries productivity and habitat complexity related to Marine Protected Areas and Marine Reserves in other marine ecosystems (Woods Hole Oceanographic Institution 2001).

Additionally, year-round, long-term closed areas are most suitable as locations for many types of habitat research. In order for scientists to invest time and money into habitat research, including gear effects research and habitat recovery experiments there is a need for the scientific community to be assured that experiments will not be compromised by fishing gear or other controllable disturbances.

Collie et al. (1997) sampled two shallow (42-47 m) and four deep (80-90 m) gravel sites in U.S. and Canadian waters on eastern Georges Bank during two cruises in 1994 that were classified as disturbed (D) or undisturbed (U) by bottom-tending mobile gear based on the number of dredge and trawl tracks in side-scan sonar images, the presence or absence of large boulders and epifauna in bottom photographs, and 1993 records of scallop dredging effort in ten minute squares of latitude and longitude in U.S. waters on the bank. There were three U sites and one D site in deep water and one U and one D site in shallow water. Bottom substrates were predominantly pebble/cobble with or without encrusting organisms, with some overlying sand. Quantitative samples of epibenthic organisms (>10 mm) were collected with a 1 m-wide Naturalists' dredge fitted with a 6.4 mm square mesh liner. Organisms such as colonial sponges, bryozoans, hydroids, and the tube-dwelling polychaete *Filograna implexa* that were not quantitatively sampled by the dredge were excluded from analysis.

There were significant effects of fishing and depth on total density, biomass, and an evenness diversity index based on abundance and some evidence of a gradient in abundance, biomass, and species diversity from deep, undisturbed sites (high values) to shallow, disturbed sites (low values). However, because of the significant depth effects and depth x disturbance interactions, fishing disturbance alone was not a significant factor. Cluster analysis identified a group of six species that were abundant at U sites and rare or absent at D sites and were not affected by depth: this group included two species of shrimp, a tube-dwelling polychaete, a nemertean, horse mussels, and a bloodstar. Six other species groups were defined either by depth or some combination of depth and disturbance level, or included species that were ubiquitous.

Collie et al. (2000), in a follow-up publication, analyzed video images and still photographs recorded at five of the six study sites surveyed in the two 1994 research cruises to George Bank (see above). In the videotapes, the U sites at both depths had slightly coarser sediments (higher frequency of pebble-gravel than sand-gravel); in the still photos, there was a higher frequency of sand and cobble in U sites and a lower frequency of pebbles. Bottom photos showed a high percent cover of colonial hydroids and bryozoans at one of the deep U sites and of the rock-encrusting polychaete, *Filograna implexa,* at both deep U sites. In contrast, at the D sites the gravel was free of epifaunal cover and few animals were visible. Statistical analysis confirmed that the U sites had a significantly higherhigh percent cover of *Filograna implexa*.. However, cover provided by this species was also significantly greater in deeper water than in shallow water. Emergent hydroids and bryozoans were significantly more abundant in the deep U sites, but less abundant at the shallow U site. Overall, the percent cover of all emergent epifauna was significantly higher at the deep sites, but there was no significant disturbance effect.

5.3.6.1.2.1 Fishing Activity in Closed Areas

Year-round closed areas that are fished periodically or seasonally by bottom tending mobile gear (e.g. scallop access to NLCA, CAI and CAII) offer significantly less protection for habitat than those that are not tended by mobile bottom gear. In such cases, the effect on habitat is similar to the effects of seasonal closures. Here again, the impact is greater for structurally complex hard-bottom habitats than "high-energy" sand habitats, which may be able to sustain periodic fishing by mobile gears. Deep-water mud bottom habitats in the WGOM closed area may also be susceptible to the adverse impacts of mobile, bottom-tending gear which are used there (shrimp trawls).

An analysis of fishing activity by trawl, handline and trap vessels from 1998 to 2001 within year-round closed areas revealed that the greatest number of trips was made within the Western Gulf of Maine closure. Trawls operating in closed areas are either in a class of gears that are exempted from the regulations in the NEFMC Multi-Species FMP or are associated with an exempted fishery. The majority of trips made by trawl vessels in closed areas were clustered in the northwest corner of the WGOM closed area (**Figure 146**). These vessels are predominantly shrimp trawlers operating in the Northern Shrimp Fishery Exemption Area and midwater trawlers targeting herring. Activity by handline vessels was concentrated in the southwest corner of the WGOM closure and the northwest corner of Closed Area I (**Figure 147**). Very few trips were made in the NLCA and CAII. The majority of handline vessels were targeting tuna and other high value species. Trap activity by vessels primarily targeting lobster was concentrated in the WGOM particularly at the southern end of the closure (**Figure 148**). A dense strip of activity by these vessels is evident in the central region of Closed Area II. More trap vessels operated in CA I, CA II and NLCA than vessels using other gears. Overall, limited fishing activity takes place within year-round closures by vessels using gears of any type.

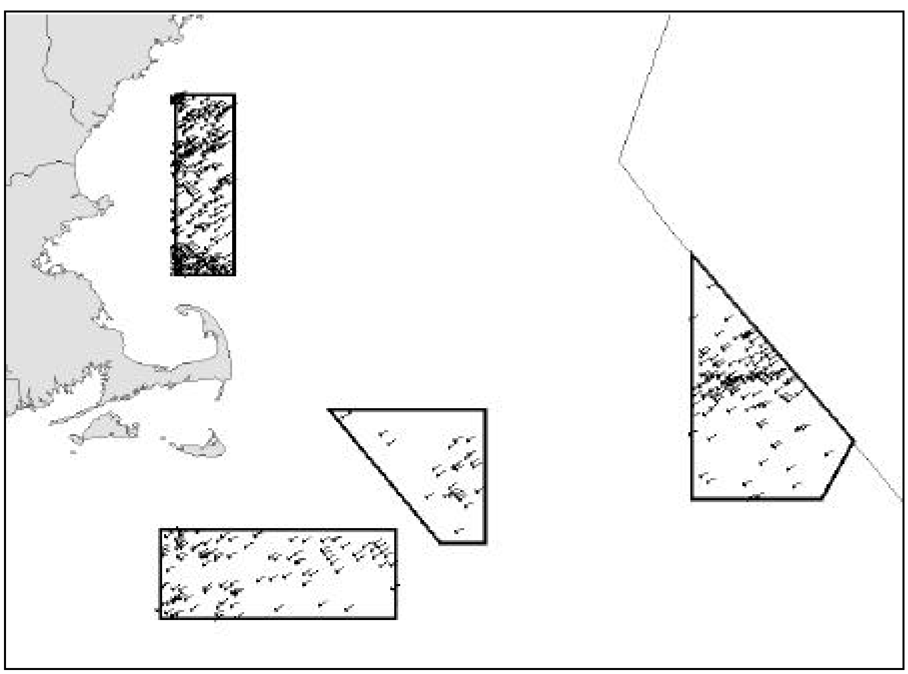

Figure 148 - 1998-2001 trap vessel reported activity inside the year-round CAs (targeted species is primarily lobster)
Source: VTR database. Each symbol represents a single trip.

A scallop access program, established in CAII in June 1999 and in CAI in June 2000, also generated fishing activity in the closed areas by scallop vessels operating under certain gear restrictions (**Figure 149**). Most trips by scallop vessels fishing in closed areas were made in the southern half of Closed Area II, the central region of Closed Area I, and the northeast corner of NLCA. **Figure 150** shows that fishing activity by surf clam/ocean quahog vessels was limited in 2001, with most of the reported trips located in the northwest corner of NLCA.

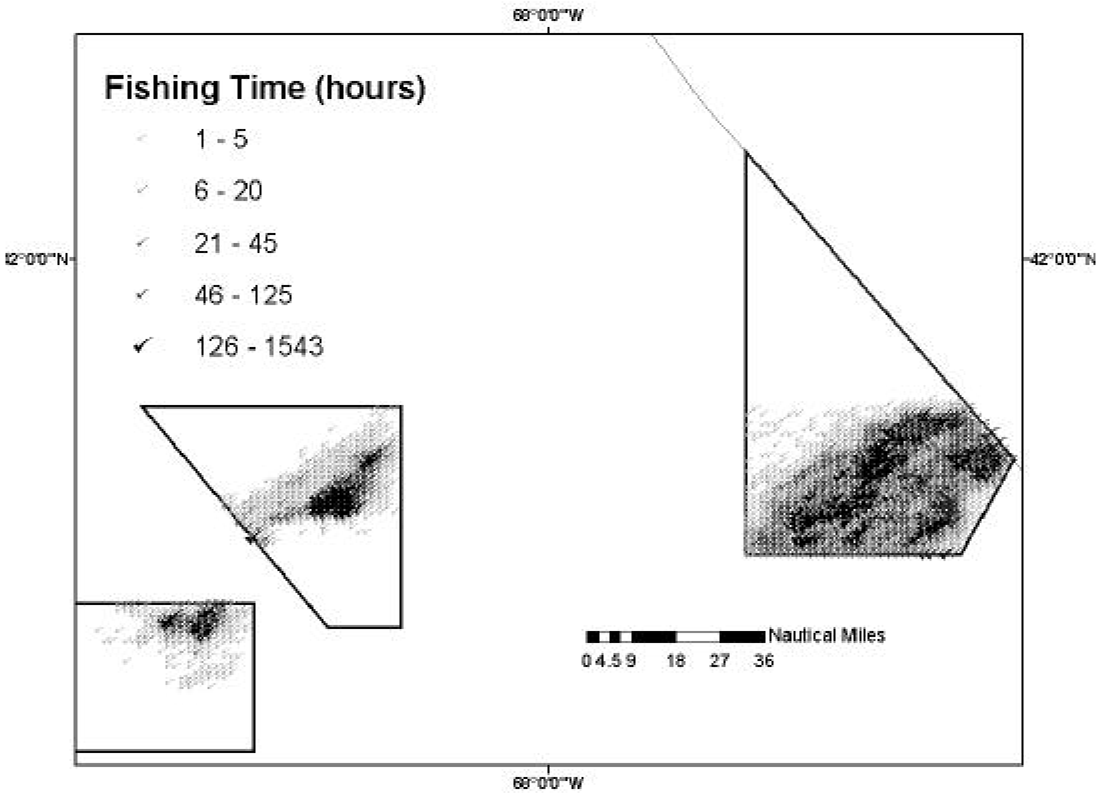

Figure 149 – Scallop vessel activity during the scallop Framework 13 Access Program
Source: NMFS VMS Data

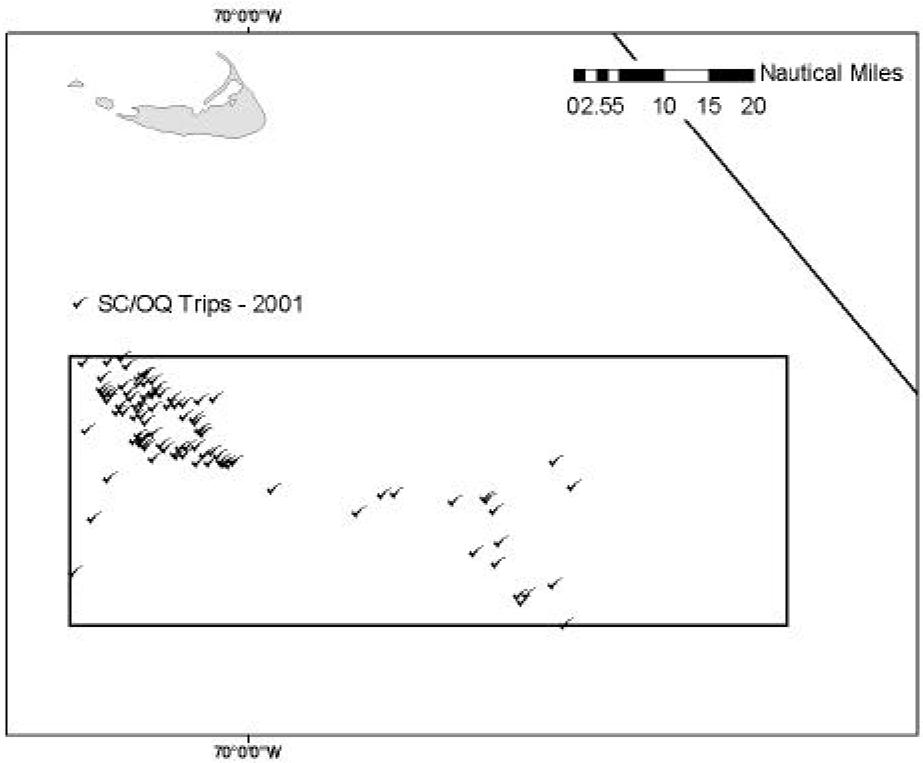

Figure 150 – Surf Clam/Ocean Quahog activity, 2001 (only)
Source: VTR data

Figure 150 shows that limited fishing activity by surf clam/ocean quahog vessels occurred in 2001, with all documented trips located in the northwest corner of NLCA.

All trips made by vessels in closed areas from 1998 to 2001 are represented in **Figure 151**, each symbol representing a single trip, with trip duration indicated for scallop/ocean quahog activity. Fishing activity by all gear types was concentrated throughout the WGOM closure, in the central region of CA I, and at the southern end of CA II. Fishing effort was patchy throughout NLCA, with two small areas of greatest trip density occurring at the northwest and northeast corners. Without more specific information on the intensity of fishing effort on different habitat types in the closed areas, it is difficult to evaluate the degree to which benthic habitats in the year-round closed areas have been affected. As long as these same exempted gears continue to be used in the groundfish closed areas, it is expected that any future impacts on habitat resulting from these activities would be the same as they have been during the last few years. Despite the fishing activity that occurs within groundfish year-round closed areas, they still provide important habitat protection benefits.

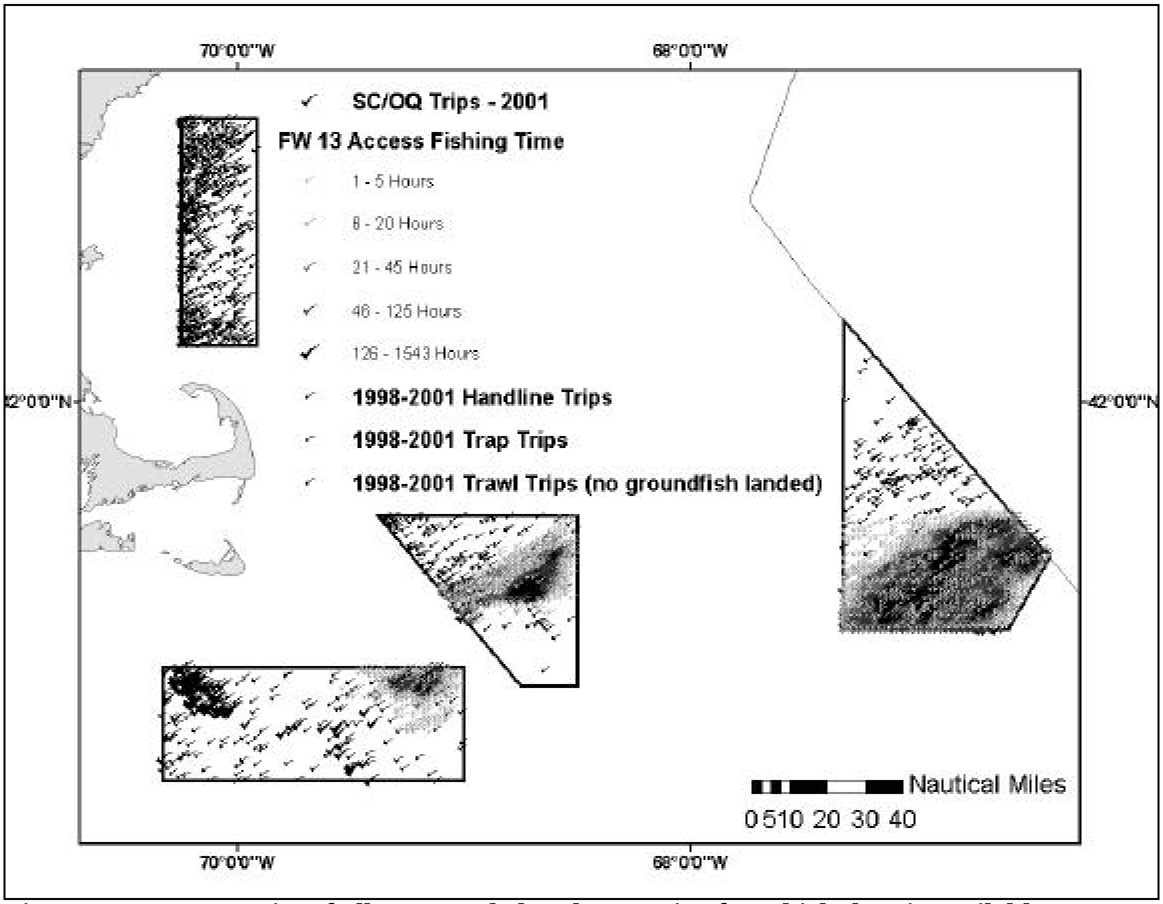

Figure 151 – Composite of all exempted closed area trips for which data is available
Source: NMFS VTR data, NMFS VMS data

The impacts of year-round closed areas on EFH outside the closed areas during the last 5-8 years cannot be quantified at this time, but it is clear that the area closures on George Bank have resulted in a concentration of fishing effort just outside the perimeters of the closed areas. This can be seen by comparing the distribution of scallop dredge fishing activity in 1998, the year before portions of the closed areas were opened up to scallop dredging, with scallop fishing activity in subsequent years (see Figure 152 - Figure 154)**.** Bottom trawling activity during the seven years following the establishment of the Georges Bank closures (1995-2001) has been concentrated in certain more or less discrete areas (see Gear Effects Evaluation/Distribution of fishing activity by gear type section of SEIS). A comparison of more recent, post-closure, fishing activity with pre-closure 1991-1993 bottom trawling activity (NRC, 2002) indicates that, as trawling effort has been displaced of out of the three closed areas on Georges Bank, there has been an increase in activity in deeper water along the edge of the shelf and in southern New England. Other areas, such as the Gulf of Maine and the Great South Channel, were fished heavily during both time periods.

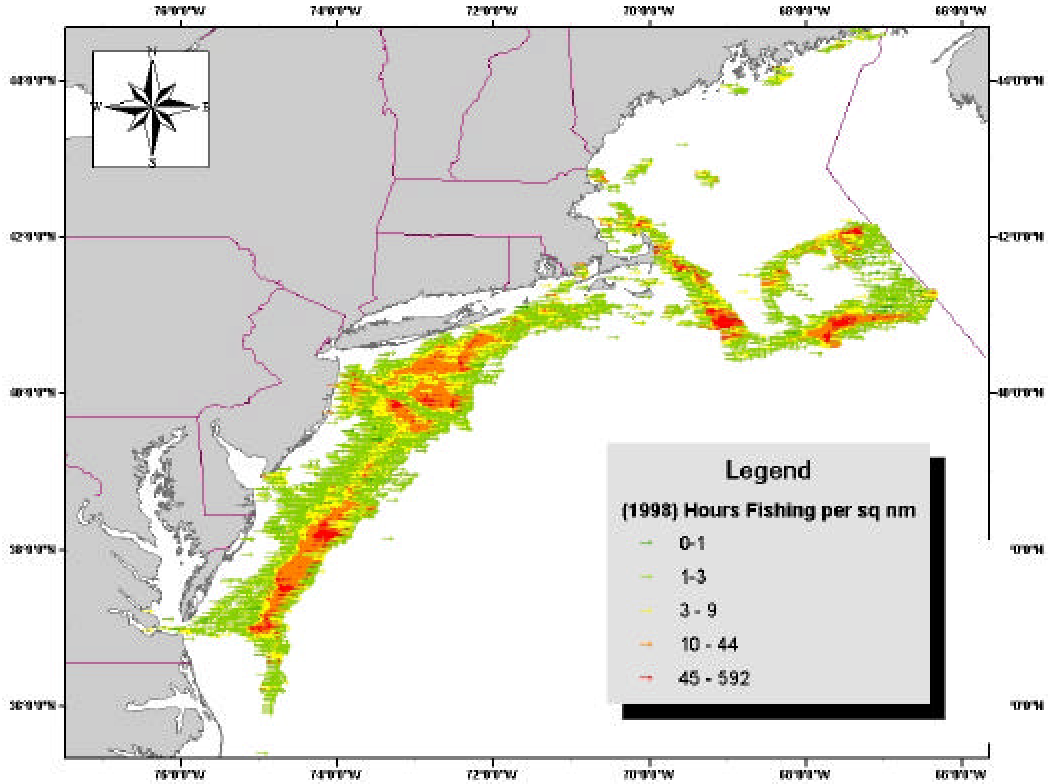

Figure 152 – 1998 Vessel Monitoring System Data for Scallop Fishery.

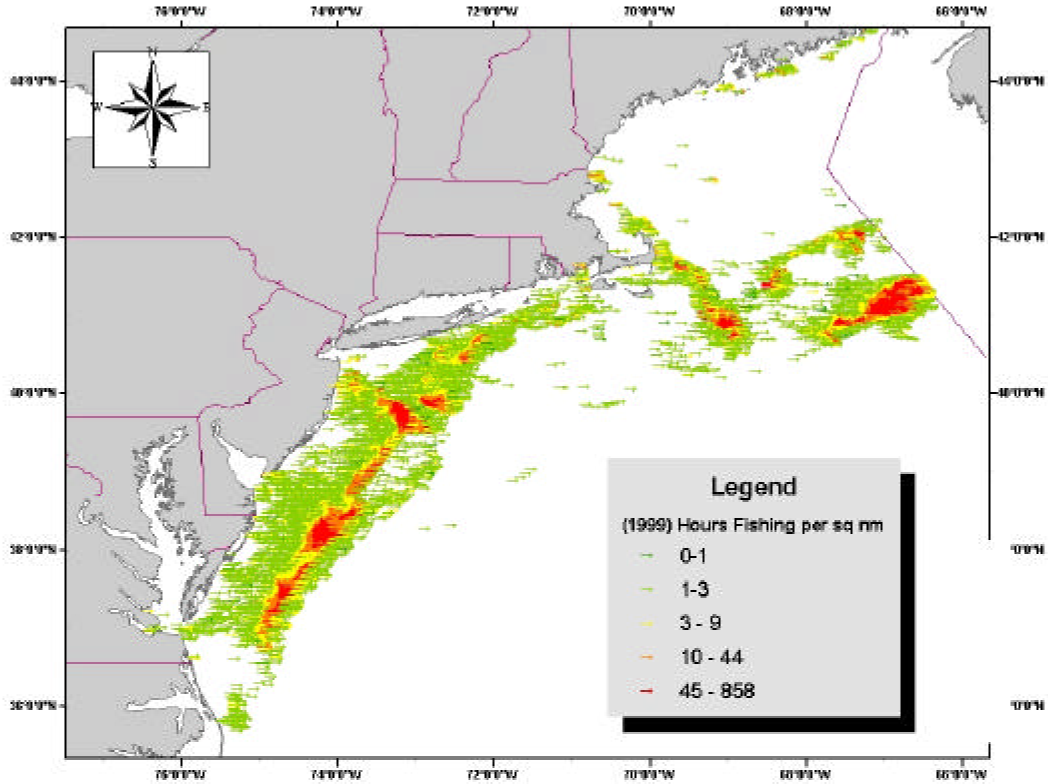

Figure 153 - 1999 Vessel Monitoring System Data for Scallop Fishery.

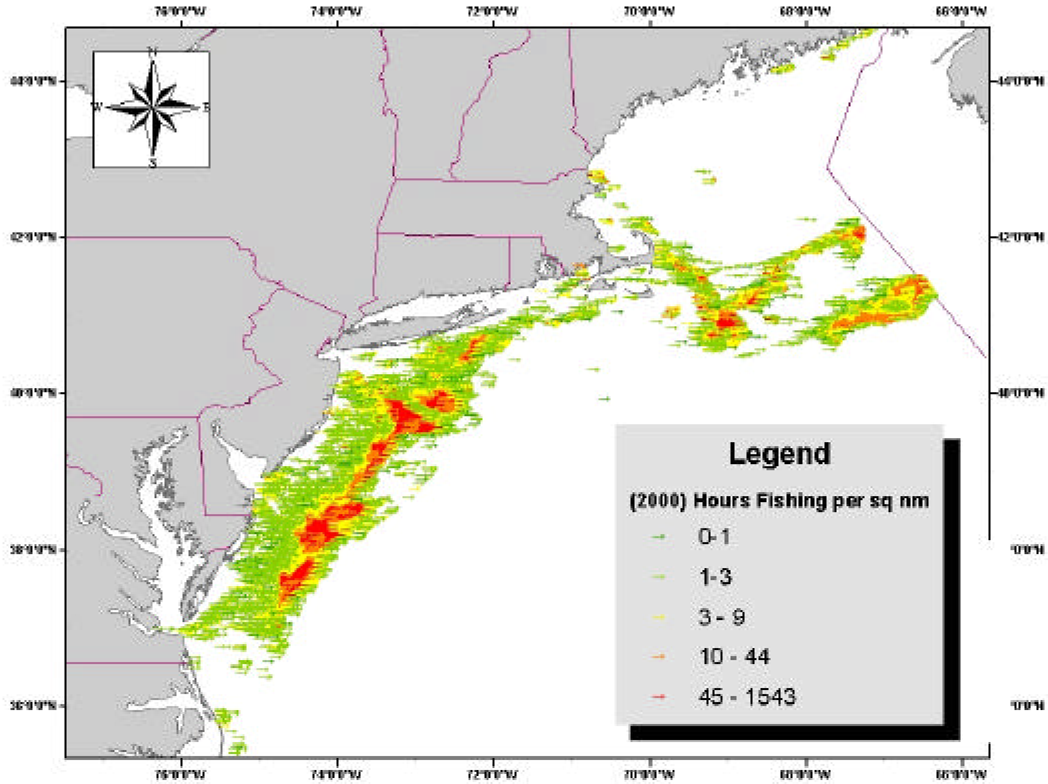

Figure 154 - 2000 Vessel Monitoring System Data for Scallop Fishery

There is some un-published information characterizing habitat conditions inside the year-round closed areas on Georges Bank. There is also growing literature on the benefits of long-term closures to fisheries productivity and habitat complexity related to Marine Protected Areas and Marine Reserves in other marine ecosystems (Woods Hole Oceanographic Institution 2001).

5.3.6.1.3 Seasonal Closed Areas

Like year-round closed areas, the habitat benefits of seasonal closed areas are partially dependent upon the types of gear permitted inside them. Seasonal closed area may offer habitat protection by decreasing the intensity of fishing effort over a longer-term time horizon. However, there is no evidence to suggest that this approach is substantially better for EFH than the habitat impacts faced in the absence of seasonal area closures. The redistribution of effort (both geographically and amongst other fisheries and gear types) combined with potentially greater short-term levels of intensity inside these areas may in fact serve to increase the adverse effects of seasonal area closures on EFH.

Seasonal closures will reduce gear impacts on habitat, but only for short periods of time. The habitat benefits of seasonal closed areas, as for year-round closures, partially depend upon the types of gear permitted inside them (Table 127)**.** Seasonal closures in the Gulf of Maine eliminate fishing effects on benthic habitats for short periods of time, but probably not long enough to provide any significant habitat benefits. The redistribution of effort (both geographically and amongst other fisheries and gear types) caused by these closures, combined with potential short-term increases in fishing effort inside these areas when they are open, may in fact increase the adverse effects of seasonal area closures on EFH. In addition, because of their intermittent protection, seasonal closures offer less opportunity than year-round closures for growth and recovery of benthic communities that may have been altered by fishing activity. The longer the duration of a closure, the more protection it will afford to fish stocks and habitat in that area. The rolling closures currently in existence afford the greatest degree of protection to benthic habitat in inshore regions of the Gulf of Maine, particularly in the waters north of Cape Cod to Cape Ann.

5.3.6.1.4 Total Allowable Catch (TAC)

In a macro sense, the positive impacts of TACs on habitat are mitigated somewhat by the likelihood that once the TAC is achieved, fishing will occur on other (non-TAC) species, or that effort will shift into other fisheries. These changes may or may not have impacts upon EFH similar to the impacts of fishing for the species regulated by the TAC. The impacts upon EFH of targeting different geographic areas or different fisheries as a result of reaching a TAC are unknown.
TACs impact EFH by controlling effort on specific fish stocks. Because these stocks are often found in specific geographic locations or habitats, the benefits to EFH are dependent upon the species being regulated. For example, cod are typically found in areas of proportionally higher bottom complexity, while yellowtail flounder are typically caught in regions with sandy sediments (see Volume II, Affected Environment). Consequently, TACs for cod may protect habitats in geographic regions containing complex bottom-types, while TACs for yellowtail flounder may protect habitats in areas containing sandy sediments.

Potential habitat benefits provided by TACs – like DAS reductions - are derived from reductions in fishing effort. While these benefits are not quantifiable at this time, the single-species nature of the TAC is likely to provide benefits to specific bottom types or geographic areas, as opposed to the more general EFH protection afforded by DAS reductions.

If there are habitat benefits of TACs, they would be somewhat reduced by the likelihood that once the TAC is achieved, fishing will shift to other (non-TAC) species, or into other fisheries. These negative impacts may or may not be equivalent to the positive impacts associated with limiting fishing for the species regulated by the TAC. There is no way of predicting which geographic areas or fisheries might be affected by shifts in fishing effort as species or area-specific TACs are reached.

5.3.6.1.5 Trip and Possession limits

Trip and possession limits have similar impacts on EFH as TACs, in that they limit fishing effort on particular stocks and, consequently, in particular geographic areas or areas of specific bottom sediments. Like TACs, the benefits of possession limits on EFH are directly related to the species being regulated. Trip and possession limits differ subtly, as possession limits prohibit front-loading of the affected species. As costs associated with a fishing trip are relatively unchanged by this management measure, trip limits, in particular, are not likely to reduce bottom contact time for mobile fishing gears as a whole, but rather re-distribute the bottom contact time as fishermen shift from one species to another, during a given trip, once possession limits are reached. For example, while fishing under the expanded Framework 25 haddock trip limit, vessels fishing in the sandy, gravelly areas along the northern border of Closed Area II would often catch their maximum allocation (30,000 lbs of haddock) in the first two or three days of fishing. In order to comply with the 10,000 pounds/day trip limit, these vessels would simply moved north onto the muddier sediments of the Gulf of Maine and target American plaice/witch flounder for the remainder of their 10 day trip.

Possession limits may reduce bottom time in certain geographic areas or on certain sediment types while increasing bottom time on others. The magnitude and direction of this effect depends upon the species being regulated and, more specifically, the characteristics of that species' essential habitats. The aggregate impact of trip/possession limits on habitat is likely to be minimal.

5.3.6.1.6 Gear restrictions/alterations

Gear modifications could refer to any mandated changes to fishing gear . They commonly take the form of minimum mesh size increases, mesh type requirements (i.e. diamond or square mesh), or requirements to include a specific mesh or size in a particular area of the net. Such changes are nearly always made to influence the selectivity and efficiency of the gear, which, by decreasing total catch, may increase fishing time (unless, of course, fishing time is also limited). Other gear modifications (*e.g.*, a raised footrope trawl) can reduce habitat impacts. Modifications that tend to increase bottom contact time for mobile, bottom-tending gear will have negative habitat impacts. Modifications that reduce bottom contact, either by increasing catch efficiency or actually reducing physical contact or disturbance to the sea floor, will have positive habitat impacts.

5.3.6.1.7 Minimum fish sizes

Changes in minimum fish sizes may increase bottom time for mobile fishing gear by increasing the number of tows necessary for a vessel to catch a sufficient quantity of groundfish. The habitat implications of this are not quantifiable, but may be similar to the consequences of small increases in DAS (or any similar measure that increases fishing effort). Simultaneous increases in both minimum fish size and minimum mesh size may increase fishing time and intensity, as it becomes increasingly difficult to reach a trip limit on a target species while avoiding large amounts of bycatch. Any increase in the time gear is in contact with the seafloor will further disturb benthic habitats. It is unlikely, however, that minimum fish sizes will have a direct effect on habitat.

5.3.6.1.8 Summary of Habitat Impacts of Commonly Used Management Tools

Management measures that reduce fishing effort and contact of gear on the bottom will most certainly provide the greatest protection to habitat. Of the measures in place in FY 2001, those most beneficial for habitat protection are limitations on DAS and year-round closed areas. The inshore Gulf of Maine restricted roller gear area is also believed to have had a positive effect on EFH of that region by decreasing effort on high relief bottom types. The four year-round groundfish closures – Closed Area I, Closed Area II, Western Gulf of Maine Closed Area, and Nantucket Lightship Closed Area – most directly benefit benthic habitats by prohibiting the use of most mobile, bottom-tending gear types. Year-round closures also allow for regeneration of benthic communities that are adversely impacted by fishing, as well as the natural recovery of seafloor structure. Seasonal closures may also be beneficial, depending on the time of year when they are in effect, their duration, and the nature of the habitats and the organisms that exist in the closed areas. DAS requirements also limit fishing activity by restricting fishing effort and bottom contact time over the course of each fishing year. However, with the potential for increased utilization of allocated DAS in the fishery, DAS restrictions may provide only limited or negligible benefits to habitat. The benefits of TACs and trip limits on habitat are less clear. While these management tools may reduce fishing in specific areas in which species with TACs or trip limits are commonly caught, they could increase effort in other areas. Mesh restrictions and minimum fish sizes, while improving selectivity of gear and reducing the catch of juveniles and small fish, may prolong fishing time and intensity needed to harvest the TAC/trip limit by decreasing efficiency. Overall, TACs, trip limits, mesh restrictions and minimum fish sizes will likely have little effect, positive or negative, on habitat.

5.3.6.2 No Action Alternative (Not Selected)

Under this alternative, all of the commercial and recreational restrictions that were in place during fishing year 2001 (prior to the *CLF v. Evans* Court order/Settlement agreement) would continue. These measures do not meet the objectives of the M-S Act and are not a reasonable alternative for consideration.

Under this alternative, the management measures in place during fishing year 2001 are maintained. DAS allocations will return to the levels that resulted from the DAS reduction schedule adopted in Amendment 7. Area closures remain the same as contained in Frameworks 27, 31, and 33. The Western GOM Closed Area will be extended until changed by future Council action.

The No Action measures would not be expected to have a direct effect on the habitat of the Gulf of Maine and Georges Bank, with the exception of continuing the protections to habitat incidental to these existing measures. For example, under this alternative the Western Gulf of Maine Closed Area will remain closed until changed by some future Council action. The Western Gulf of Maine Closed Area, although not closed specifically to protect fish habitat, does serve to protect some essential fish habitat (EFH) from potential adverse impacts associated with some types of fishing activities. The indefinite extension of this closed area will ensure that these incidental protections continue until such time that the area closure is changed by a future action.

The No Action Alternative (NAA) is the continuation of measures in place during the 2001 fishing year. The existing management measures, although not implemented specifically to protect habitat, do provide some habitat benefits. This section will assess those benefits. In the multispecies fishery, a suite of seven management tools is utilized in various combinations within the alternatives designed to meet rebuilding objectives. The impacts of these tools on EFH are discussed both in general terms and as they relate specifically to management measures in place during FY 2001.

5.3.6.2.1 Year-Round Closures Under the No Action Alternative

Under the NAA, Closed Area I (CA I), Closed Area II (CA II), Nantucket Lightship Closed Area (NLCA) and the Western Gulf of Maine closed area (WGOM) will remain year-round closures, unless, or until, they are modified for resource management purposes. The three closures on Georges Bank and in southern New England were established in December 1994. The WGOM closure was established in May 1998. About 20% of the Georges Bank closed areas were temporarily opened to scallop dredging in 1999 and 2000.

These areas add up to 5,847 nmi², and are made up primarily of sandy substrates, but also contain fairly high proportions of the gravel and gravelly sand substrates in the Northwest Atlantic Analysis Area (NWA). It is reasonable to assume that these closures have increased the quality of benthic habitats within the closures during the last 5-8 years.

5.3.6.2.2 Seasonal Closures Under the No Action Alternative

Existing groundfish management measures also include rolling seasonal closures, which close a series of fairly large areas in the Gulf of Maine for a month or two at time. These closures are designed to reduce fishing mortality on cod by prohibiting trawling on spawning and pre-spawning aggregations. The Council will continue the backstop provision that additional closures will be implemented if 50% of the GOM cod target TAC (based on the average between the $F_{0.1}$ target TAC and the F_{max} target TAC) is landed by July 31 (with a fishing year beginning May 1). If the contingency is met and the backstop measures are triggered, the Cashes Ledge Closed Area will remain closed for one additional month

(November) and Blocks 124 and 125 (inshore Gulf of Maine between Cape Ann and Cape Cod) will close in January.

5.3.6.2.3 Day-at-Sea Usage Under the No Action Alternative

The NAA will maintain the annual day-at-sea allocations initiated in Amendment 7 (1996). The Amendment 7 effort reduction program resulted in the allocation of 88 DAS per fishing year to Fleet DAS vessels. Table 133 provides a complete summary of DAS usage by multispecies vessels from 1995 to 2001 (2002 data is reported but incomplete). DAS allocations increased steeply from 1995 to 1996 because of the implementation of new limited access permit categories in Amendment 7 (1996) which increased the number of vessels requiring the use of a day-at-sea to fish for groundfish. From 1996 to 1997, the number of allocated DAS in the groundfish fishery decreased substantially as a result of the effort reduction program established in Amendment 7. From 1997 to 2001, the number of total DAS allocated to permitted multispecies vessels and the fraction of the total allocation afforded to active vessels with documented DAS use (according to call-in records) remained relatively stable. The number of DAS used by multispecies vessels, however, has increased steadily since 1997 (Figure 155). With so many unused groundfish DAS allocated to groundfish vessels and evidence that a smaller fraction of the total allocated DAS are remaining latent, there is great potential for expansion of effort in the groundfish fishery. An allocation of 88 days per vessel accompanied by no additional effort reduction measures will most likely lead to increased fishing effort. Expansions in fishing activity will have consequences for the benthic habitat depending on how effort is increased and where it is concentrated.

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Year	Total Number of Permitted Vessels with Allocated DAS	Total Days-at-Sea Allocated	Number of Permitted Vessels that Called In	DAS Allocated to Vessels that Called In	Total DAS Used by Vessels that Called In	% of total allocated DAS Used by Permitted Vessels that called in ((5)/(2)*100)	% of allocated DAS (to vessels that called in) Used by Permitted Vessels that Called In ((5)/(4)*100)

5.3.6.2.4 TACs Under the No Action Alternative

Target TACs for groundfish species will remain as they were in FY 2001.

5.3.6.2.5 Trip and Possession Limits Under the No Action Alternative

Trip limits remain the same as in Framework 33: 400 lbs./day with a maximum possession limit equal to ten times the daily limit (i.e. 4,000 pounds) for GOM cod. Vessels may land a limited overage of cod as follows:

Vessels not enrolled in the Gulf of Maine Cod Trip Limit Exemption Program are limited to 400 pounds for each day or part of a day on the trip. On trips under 24 hours a vessel may not land more than 400 pounds of cod, and may not land cod again until 24 hours have elapsed from the start of the trip, although the vessel may call-out of the DAS program before 24 hours have elapsed. On trips longer than 24 hours, a vessel may land 400 pounds of cod for each full day (24 hours) of the trip and 400 pounds for any part of a 24-hour period, provided it does not call out of the DAS program until the remainder of that 24-hour period has elapsed. A vessel on a trip longer than 24 hours and landing up to 400 pounds of cod for any part of a (24-hour) day may not leave port or call out of the DAS program for the remaining part of the 24 hours.

A vessel may not land more than 4,000 pounds, even if the trip duration exceeds ten days.

Trip limits for GB cod remain the same as implemented through Framework 33: 2,000 pounds per DAS, or part of a DAS, with a maximum possession limit equal to ten times the daily limit (20,000 pounds). There are no trip limits for other key stocks.

5.3.6.2.6 Gear Restrictions Under the No Action Alternative

Under the NAA, there are no revisions to gear requirements adopted in Amendment 7 and subsequent frameworks. Few of these gear restrictions or modifications have had a direct effect on habitat since they have focused to a great extent on improving mesh selectivity and minimizing the catch of juveniles and non-target species. Vessels in the GOM/GB regulated mesh area must use either 6 inch diamond or 6.5 inch square mesh trawl cod ends, and 6 inch or 6.5 inch gillnets. Gillnet vessels are restricted to 80 stand-up nets or 160 tie-down nets; day gillnet vessels must tag nets. Trawl vessels are limited to 12-inch roller gear in the inshore GOM.

5.3.6.2.7 Minimum Fish Sizes Under the No Action Alternative

The minimum sizes for commercially caught groundfish species are:

Cod	19 (48.3 cm)
Haddock	19 (48.3 cm)
Pollock	19 (48.3 cm)
Witch flounder (grey sole)	14 (35.6 cm)
Yellowtail flounder	13 (33.0 cm)
Atlantic halibut	36 (91.4 cm)
American plaice (dab)	14 (35.6 cm)
Winter flounder (blackback)	12 (30.5 cm)
Redfish	9 (22.9 cm)

5.3.6.3 Alternative 1 – Up to a 65% reduction in used days-at-sea (Not Selected)

Commercial Measures

--Reduces used DAS by up to 65% (from the average number of days used in the 2000 and 2001 fishing year), and controls unused DAS. The exact reduction depends in part on the choice of rebuilding strategy.

--Vessels fishing in the Southern New England or Mid-Atlantic Regulated Mesh Areas from December through April would be charged DAS at a rate of 1.5 days for each day fished. Southern New England yellowtail flounder and Cape Cod/Gulf of Maine yellowtail flounder would be under a seasonal trip limit.

--Current rolling closures, year-round closures, trip limits other than yellowtail flounder, minimum fish sizes, implemented August 1, 2002 are continued. Additional gear restrictions would be adopted.

Habitat Impacts

This alternative adopts all of the management measures put in place as a result of a settlement agreement among certain parties in *Conservation Law Foundation et al. v. Donald Evans et al.* (hereafter referred to as the Settlement Agreement). Included is a 20% reduction in DAS, the elimination of unused (latent) DAS, an increase in the minimum size for cod from 19 to 22 inches, and the closing of Cashes Ledge Closure Area year-round.

Alternative 1 focuses on a reduction in total DAS to 21,700 days. By comparison, 53,500 DAS were utilized in FY 1999. This substantial reduction in DAS will reduce bottom contact time by mobile groundfish gears significantly. The impacts of DAS reductions discussed previously are likely to be mitigated somewhat more substantially with such large reductions in available groundfish fishing DAS—fishermen will be forced to make up for the lost revenue in other fisheries, which may or may not have equivalent impacts on habitat. It is possible that the overall time spent fishing with mobile, bottom tending gears may increase as vessels switch to other fisheries, fish inside state waters, etc.

Closing the Cashes Ledge area year-round to all gear capable of catching groundfish imparts the same level of habitat protection to this area as is afforded to the western Gulf of Maine Closed Area. Cashes Ledge Closed Area includes a complex substrate consisting of mud, gravelly sand, and bedrock. This area contains EFH for 19 species in their juvenile life stage and 21 species in the adult life stages.

The benefits of this addition to the year-round closed areas are summarized in the tables below. Note that because no sediment categorized as bedrock was protected under the No Action alternative, it is not possible to calculate the percentage increase of bedrock under the new year-round closed areas. The total amount of bedrock in the Northwest Atlantic analysis area is 27.2 sq nautical miles; none of it is protected under the No Action alternative, but 15.2 sq nautical miles would be protected under Rebuilding Alternative 1.

Table 134 - Rebuilding Alternative 1: Change in total amount of designated EFH encompassed by year-round closed areas.

See Affected Biological Environment for further details on EFH.

Mesh size increases for trawl net cod ends/gillnets and limits on the number of hooks allowed for longline vessels, put in place by the Settlement Agreement, are continued under this alternative. See Gear Restrictions, above, for potential impacts. There are no significant impacts from these seasonal closures.

A possession limit of 500 lbs/day / 4,000 lbs/trip for both GOM and GB cod is proposed. This limit is much more stringent for cod caught on Georges Bank than the No Action Alternative or the Settlement Agreement. This possession limit may reduce fishing effort on the gravel, gravelly sand and muddy sand substrates found in the northern portions of Georges Bank and along Nantucket Shoals where cod are typically found (see Figure 156).

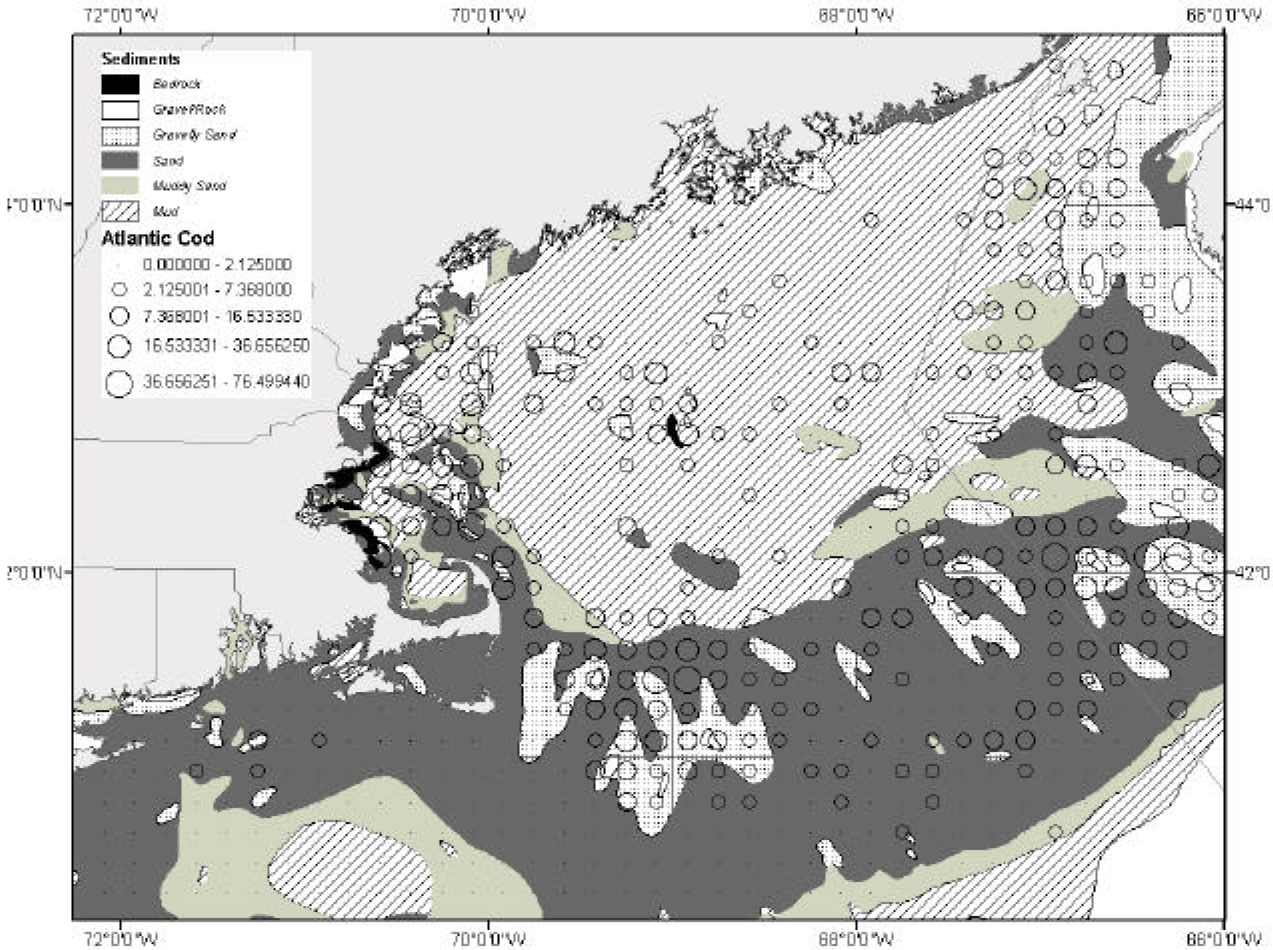

Figure 156 - Mean weight per tow of Atlantic Cod (1995-2001 trawl surveys) with sediment types of the Northwest Atlantic (modified from original map by Poppe *et al.* 1989).

5.3.6.4 Alternative 2 - Reduction of allocated DAS/gear modifications (Not Selected)

Commercial Measures

--Maintain the DAS allocations adopted August 1, 2002, except in the Gulf of Maine, where additional DAS restrictions would apply.

--Maintain rolling closures and year round closures implemented August 1, 2002.

--Maintain the GOM cod trip limit adopted August 1, 2002, and the Georges Bank cod trip limit would be reduced to match the current Gulf of Maine cod trip limit.

--Cape Cod yellowtail flounder would be under a low trip limit in the southern portion of the inshore Gulf of Maine and east of Cape Cod.

--Southern New England yellowtail flounder and Cape Cod/Gulf of Maine yellowtail flounder would be under a seasonal trip limit.

--Additional gear restrictions (the use of flounder net, separator trawl, or raised footrope required in many portions of the Gulf of Maine and Georges Bank).

Habitat Impacts

This alternative utilizes the same year-round closed areas and minimum fish sizes as the No Action Alternative. There are provisions for increased Seasonal Closed Area coverage in the northern sections of the Gulf of Maine. Gear restriction provisions call for the mandatory use of haddock separator nets and/or a flounder net for trawl vessels fishing in the Georges Bank RMA or inshore of 70 degrees west longitude.

There is an important provision for a raised footrope trawl in 30-minute square blocks 114, 115, 123, 124 and 125. A raised footrope trawl reduces the adverse impacts of otter trawl gear on the sea floor (see Gear Effects Evaluation). The area covered by this provision consists primarily of sandy, muddy sand and mud substrate, with small amounts of gravelly sand and bedrock (Figure 157). This area contains designated EFH for 31 juvenile species and 30 adult species.

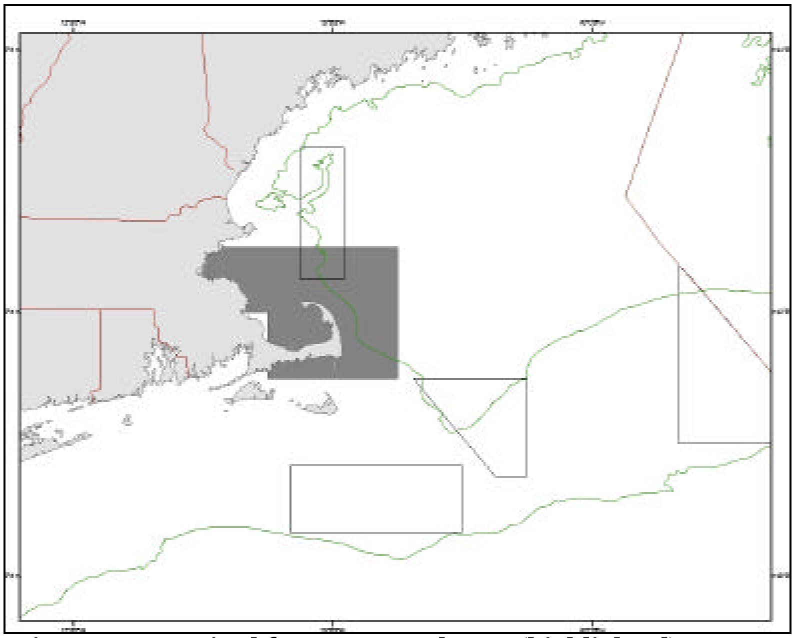

Figure 157 - Raised footrope trawl area (highlighted).

A Georges Bank Yellowtail Flounder Access Program is included in this alternative.

5.3.6.5 Alternative 3 - Area management (Not Selected)

Commercial Measures

--Establishes structure to develop rules for particular geographic areas that are consistent with the type of fishing that occurs in a particular area. This alternative is meant to encourage a sense of stewardship by vessels fishing in a particular area by increasing their involvement in the development of management measures.

--Measures implemented August 1, 2002 will remain in effect until area-specific commercial and recreational measures are developed through a series of meetings and implemented by NMFS.

--Proposes the following 5 management areas: inshore Gulf of Maine (divided into east and west), offshore Gulf of Maine, western Georges Bank, eastern Georges Bank, and Southern New England/Mid Atlantic.
--Establishes total allowable catch (TAC) for each species in each area. There are three options for how the fishery would operate:
--Implement a "hard" TAC. A 'hard' TAC means that when the amount of fish equal to the specified TAC has been caught, the fishery for that particular species closes. Only gears types that have been approved by the NMFS would be allowed to continue fishing for other available groundfish stocks (those stocks where the harvest had not yet reached an amount equal to the TAC).
--Implement a "soft" TAC. A 'soft' TAC means that if the amount of fish caught equals the TAC, the fishery does not automatically shut down. However, under this option, when 80% of the TAC is caught other management measures go into place to slow down the catch rate.
--Allocate up to 60% of the TAC to the directed fishery for a stock, and reserve the remainder of the catch for fisheries that targeted another species. If the amount of fish caught in a particular year exceeded the TAC, the TAC the following year would be reduced.
--Options on where a particular vessel may fish. One option restricts a vessel to fishing in only one management area over the course of a fishing year. Another option allows a vessel to fish in any area on a trip, but for all areas fished the vessel would have to abide by the most restrictive rules (among the areas fished).

Habitat Impacts
This alternative divides species-specific TACs amongst different management areas that divide varying portions of the GB/GOM RMA into management areas. Six options, each comprised of five management areas, are considered. The primary difference among these six options is the boundaries for areas on Georges Bank.

Like Rebuilding Alternative 1, all management measures put in place by the Settlement Agreement, including the year-round closed areas and DAS reductions, are employed here as well. No further changes to these measures (beyond the TACs) are proposed.

The various options for controlling movement of fishing vessels between management areas (there are five such options) may have unpredictable effects on the geographic stability of the fleet. For example, vessels may chose to fish certain areas more exclusively than they had under other management regimes. Two options require vessels to declare at the beginning of the fishing year those management areas they intend to fish in. This requirement may lead to unanticipated (and undesired) increases in geographically specific fishing efforts as aggregations of vessels to continue fishing in areas that they would not otherwise target. It is impossible to quantify the habitat impacts of such situations; they depend largely on the bottom composition and species richness of the affected area, and on the specific gears utilized.

5.3.6.6 Alternative 4 - 'Hard' total allowable catch (Not Selected)

Commercial Measures
--Implements a 'hard' TAC system. A 'hard' total allowable catch means that when the amount of fish equal to the TAC (catch quota) has been caught, the fishery for that particular species shuts down – either by prohibiting fishing in a stock area with gear capable of catching that species, or by prohibiting possession of that species. A separate total allowable catch may be set for each of the stocks managed under the fishery management plan, or for stocks that are in relatively good condition, an aggregate total allowable catch may be set (one quota set for several stocks of fish combined).

--If the recreational fishery represents a significant portion of the total catch, then a recreational total allowable catch may be specified.
--An option under this alternative is to set only 'target' total allowable catches for incidental fisheries. In other words, a maximum amount that may be caught incidentally would be specified, but when the actual incidental catch equals the total allowable incidental catch, the fishery does not automatically shut down. The total allowable catch may be divided into 4 month allotments, or up to 60% of the total allowable catch would be allocated to the directed fishery for a stock, and the remainder of the catch would be reserved for fisheries that target another species.
--As the TAC is approached, a restrictive trip limit is imposed to slow the catch rate. These trip limits may be implemented at either 70 percent or 90 percent of the TAC.

Habitat Impacts
TACs will be applied to all stocks in the multispecies FMP on a single or multi-stock basis. All management measures resulting from the Settlement Agreement, including area closures and DAS restrictions, will remain in place.

Without quantitative predictions of TAC levels and species affected, it is not possible to expand on the habitat impacts of this alternative at this time. The impacts of other management measures are described in the analysis of Rebuilding Alternative 1.

5.3.6.7 Proposed Action

See Section 3.6.1 for the details of the proposed measures for the commercial fishery, and Section 3.6.2 for the details of the proposed measures for the recreational fishery. In general, this proposal adopts management measures to achieve a mix of adaptive and phased reduction rebuilding strategies. In addition, it develops opportunities for fishing on stocks that do not need reductions in fishing mortality. The table below highlights the habitat impacts of this proposed action.

Amendment 13 contains a wide variety of management measures and it the largest and most comprehensive amendment to the Northeast Multispecies FMP since Amendment 9. As such, the changes to the FMP are widespread. The proposed measure has varying impacts on essential fish habitat (EFH) (Table 135). Many of these changes are benign for Essential Fish Habitat (e.g. clarifications of stock status, status determination criteria, and MSY control rules), some new management measures have additional negative impacts on EFH (e.g. US/Canada Resource Sharing Program) while still others perpetuate the negative impacts on EFH under the Status Quo. An example of this can be found under the Closed Area Administration program that allows bottom tending mobile gears to continue to operate in complex habitats (e.g. shrimp trawls in the Western Gulf of Maine Closure). With this in mind, however, the overall or net impact to EFH is positive. This results from the substantial positive impacts from the management measures to address the FMP's management unit's rebuilding requirements through significant effort reductions (DAS), the elimination or restriction of latent effort as potential adverse effects and the retention of the current groundfish closed areas. Habitat Alternative 2 was intended to capture these positive benefits to EFH through the use of the fishery's own need to reduce effort, modify gears and close important areas to groundfish fishing. The net result of these measures to EFH is positive. Additionally, Amendment 13 also proposes other measures developed to directly benefit EFH by minimizing, to the extent practicable, the adverse effects of fishing on EFH (Table 136).

Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
Clarification of Stock Status, Status Determination Criteria and MSY Control Rules	Neutral Impact (O)	Includes definitions of when a stock is overfished, when overfishing is occurring, status determination criteria, and MSY control rules	No Impact
Proposed Rebuilding Programs for Overfished Stocks	Neutral Impact (0)	Defines the rebuilding timelines and trajectories	No direct impact, but a shorter time frame would reduce effort, thus having positive impacts on adversely effected EFH.
Ending Overfishing	Neutral Impact (0)	Defines the management plan for overfished stocks.	No Impact.
Fishery Program Administration	Negative Impact (-)		Negative overall EFH impact because of closed area access by bottom tending mobile gear.
Fishing Year	Neutral Impact (0)	No Action-Fishing year starts on May 1	Neutral habitat impacts because it doesn't directly affect the frequency or intensity with which the fishery is prosecuted.
Periodic Adjustment Process	Neutral Impact (0)	Biennial adjustment	Neutral impact, but this will allow the effect of regulations on EFH to be better assessed.
US/Canada Resource Sharing Agreement	Negative Impact (-)	Specifies an allocation of cod, haddock, and yellowtail flounder for each country in area 5Zjm (eastern Georges Bank) with incentives for participation and subject to catch limits	A small area at the top of CAII will be opened to bottom trawling for 10 months a year: habitat impacts in this area will be negative.
Bycatch/Exempted Fisheries	Neutral Impact (0)	Allows changes to standards for certified bycatch/exempted fisheries	The impact is neutral, however, it could be negative if bottom tending mobile gear are permitted in closed areas or positive if additional gears that adversely impact benthic habitats are prohibited.

Table 135 - Potential habitat impacts of non-habitat Amendment 13 management alternatives

Note: Seasonal (rolling) closures, possession limits, and hard TACs that are included in a number of proposed management measures are not considered to provide any significant habitat benefits. Habitat benefits identified above apply primarily to bottom trawls, not to fixed gear such as hooks and gill nets.

Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
Special Access Programs	Neutral for GB yellowtail. Neutral for SNE winter flounder. Negative for US/Canada SAP.	Provides access to limited, specific regulated fisheries; four SAPs approved for GB Yellowtail, GB haddock, SNE Winter flounder, and US/Canada Sharing Agreement	Neutral impact for GB program because this area is primarily composed of sandy bottom and is less susceptible to the adverse effects of fishing than the gravel bottom area in the northern portion of the closed area. Also, the fact that this area was heavily fished during the CAII access program during 1999-2001 means that any additional habitat impacts associated with trawling for yellowtail are likely to be minimal. Neutral impact from SNE winter flounder access program. CA I program limited to hook gear, with no impact on bottom habitat See above for impacts of US/Canada Sharing Agreement.
Closed Area Administration	Negative Impact (-)	Various options would allow access of currently exempted gear into Georges Bank closed areas, provided no retention of multispecies	There will be negative impact on adversely effected EFH by allowing access for gears such as shrimp trawls (in NLCA, CAI, and CAII) and clam dredges (in NLCA).
DAS Leasing	Neutral Impact (0)		This alternative enhances the economic viability for the fishery and is not expected to have impacts on EFH.
Recreational Fishing Permit	Neutral Impact (0)	No Action-no permit required	Most recreational fishing gear does not have an adverse effect on EFH.
Running Clock	Neutral Impact (0)	No Action-modified running clock will remain in effect	This measure will not likely increase effort beyond the No Action.
Observer Coverage	Indirect benefits (+)	10% requested by 2006 for each gear type, unless NMFS determines other level	If observers are able to collect data of interest to EFH management, increased coverage could indirectly benefit habitat.
VMS Requirements	Neutral Impact (0)	Vessel can sign out of VMS program when not fishing	This is an administrative measure and will not impact EFH.
Day Gillnet Block		No Action-gillnet vessels must take 21-day block out btwn. June and September	

Table 135 - Potential habitat impacts of non-habitat Amendment 13 management alternatives

Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
DAS Counting	Neutral Impact (0)	No Action-DAS counted by hour and minute; gillnet charged min of 15 hours.	DAS is counted the same as under the No Action, so this measure will not impact EFH.
Reporting Requirements	Neutral Impact (0)	Daily electronic dealer reporting and use of trip identifier to link vessel and dealer reports	Same as No Action. Increased VMS would provide more knowledge of fishing intensity by area and habitat type.
Sector Allocation	Neutral Impact (0)	Approval of sector allocation proposal brought to NMFS through Council. Sector decides about movement between sectors. Allocation based on documented catch. Hard TACs by species.	As a management measure, sector allocation is not expected to have any significant habitat impacts.
GB hook/gillnet sector	Neutral Impact (0)	Approval of hook sector	This sector allocation program is not expected to have any significant habitat impacts, especially since hook gear has been deemed not to have adverse impacts on EFH.
Alternatives to Control Capacity	Positive Impact (+)	DAS can be transferred with restrictions and new measures for "reserve days"	Any measure that is intended to reduce the amount of time fishing by bottom-tending mobile gear will likely have benefits to EFH. These measures reduce amount of latent effort as well.
Management Measures to Address Rebuilding Requirements	Overall Positive Impact (+)	Mix of adaptive and phased reduction strategies. Provides opportunity to fish on stocks that do not need rebuilding	The effort reductions, year-round closed areas, and existing gear modifications are likely to have large positive impacts on EFH.
Effort Controls	Positive Impact (+)	A days (60% of effective effort) B days (40% of effective effort) C days (FY01 allocation)	Reducing DAS will benefit EFH by reducing the amount of time vessels can fish. Benefits will vary by area, gear, and habitat type, and will be higher in sensitive habitat areas (e.g., hard bottom) where bottom trawls and scallop dredges are currently being used.
Re-classification of DAS	Neutral Impact (0)	B days can becomes A days if stocks recover	Effort can shift to stocks that can support additional fishing, but overall fishing effort allocated does not change, so habitat impacts are neutral.

Table 135 - Potential habitat impacts of non-habitat Amendment 13 management alternatives (cont.)

Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
Management Measures	Positive (+)	Same as settlement agreement unless specified	Overall the measures are beneficial to EFH, especially the extensive effort reduction measure applicable largely to bottom tending mobile gear.
Closed Areas	Positive Impact (+)	Maintains existing groundfish closures and add Cashes Ledge as a year round closure.	Year-round closures provide habitat benefits to the areas within the closures. The addition of Cashes Ledge as a year-round closure will benefit the EFH and rare kelp beds found in that area.
Possession Limits	Neutral Impact (0)		Possession limits may reduce bottom time in certain geographic areas or on certain sediment types while increasing bottom time on others. The magnitude and direction of this effect depend upon the species being regulated and, more specifically, the characteristics of that species' essential habitats.
Gear Restrictions	Neutral Impact (0)	Additional changes and restrictions on gillnets	Neutral impacts on EFH because these modifications are specific to gillnet gear, which does not have adverse impacts on EFH.
Minimum fish sizes	Neutral Impact (0)	Same as settlement agreement	Overall, neutral impact on EFH, but increases in minimum fish sizes may indirectly cause bottom contact time to increase by increasing the number of tows necessary for a vessel to catch a sufficient quantity of groundfish. Any increase in the time that gear is in contact with the seafloor will further disturb benthic habitats.
Other Issues			
Area Restriction of the Northern Shrimp fishery	Neutral Impact (0)	Eliminate area restriction	Little impact on essential fish habitat is expected, as otter trawling for groundfish is common in areas commonly fished for shrimp outside the Exemption Area. Furthermore, shrimp gear is more limited in the type of bottom it can be towed over as it is generally smaller with lighter ground gear.

Table 135 - Potential habitat impacts of non-habitat Amendment 13 management alternatives (cont.)

Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
Tuna Purse Seine Access	Neutral Impact (0)	Permits access in all groundfish closed areas	This gear type has not been identified as a gear type that has adverse impacts on EFH.
SNE General Category Scallop Exemption Program	Neutral Impact (0)	Allow access to an exemption area in southern New England for vessels that are declared out of the DAS program.	Based on the relatively small amounts of scallops available inside the exempted area and this area's sedimentary makeup (mostly sand), no significant negative impacts to EFH are anticipated. Additionally, bottom habitats in this area are currently subject to disturbance by bottom trawls.

Table 135 - Potential habitat impacts of non-habitat Amendment 13 management alternatives (cont.)

Habitat Alternative	Overall Habitat Impact	Feature	Description of Essential Fish Habitat Impact
Alternative 2	Positive Impact (+)	Benefits of other measures implemented in A13	Several measures that are being implemented in A13 were not intended to minimize adverse effect of fishing on EFH, but they will have complementary habitat benefits.
Alternative 7	Positive Impact (+)	Prohibition of clam dredges in year round closed areas	Hydraulic clam dredges have been demonstrated to cause an adverse impact to EFH (see Gear Effects Evaluation section). Prohibiting this gear will benefit the EFH of species found within the section of the NLCA (NW corner) where this fishery is prosecuted.
Alternative 10b	Positive Impact (+)	Closed areas to minimize impacts on EFH	Year round closures have beneficial impacts on adversely effected EFH, and many of these areas are considered important habitat areas with complex bottom or high EFH value.

Table 136 - Description of alternatives to minimize the adverse effects of fishing on essential fish habitat as proposed in Amendment 13.

5.3.6.8 Recreational Measures

Three were three options considered for the recreational sector (private recreational and charter/party). These options apply to any of the Alternatives that address rebuilding requirements. The Council proposes to implement a minimum fish size requirements, possession limits and all other measures in place during FY2001. See Section 3.6.2 for a complete description of the measures being proposed for the recreations sector.

Habitat Impacts

Recreational fishin g, primarily through hook and line or harpoon, has no significant impact on habitat.

5.3.6.9 Summary of Habitat Impacts of Measures to Achieve Rebuilding Objectives

Table 137 summarizes anticipated impacts of the stand-alone Amendment 13 Stock Rebuilding Alternatives. A score of "-1" indicates a reduction from the levels of protection afforded by the No Action Alternative. A score of "0" indicates no change, a score of "+1" indicates an increased level of protection commensurate with the Settlement Agreement and a score of "+2" indicates a level of protection beyond that of the Settlement Agreement. The No Action Alternative would receive scores of "0" in all rows. Anticipated habitat impacts in some cases depend on which option is selected for an alternative.

	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Proposed Action
Days-at-sea reductions	+2	+2	+1	+1	+2
Year-round closed areas	+1	+1	+1	+1	+1

Trip/possession limits	+2	+1	+1	+1	+2
Gear restrictions	+2	+2	+1	+1	+2
Minimum fish sizes	0	0	0	0	0
Closed area access plan	0	0	0	0	0
SUM	7	6	4	4	7
RANK	1*	2	3*	3*	1*

Table 137 - Qualitative summary of habitat impacts of stand-alone rebuilding objective alternatives
** indicates tied ranking*

5.3.7 Other Issues

5.3.7.1 Northern Shrimp Fishery Exemption Area (Selected)

The Council selected to expand the geographic area of the Northern Shrimp Fishery Exemption Area (Option 2).

Habitat Impacts
Option 1
There are no significant habitat impacts associated with this option.

Option 2 - Eliminate Area Restriction for the Northern Shrimp Fishery

Little impact on essential fish habitat is expected, as otter trawling for groundfish is common in areas commonly fished for shrimp outside the Exemption Area. Furthermore, shrimp gear is more limited in the type of bottom it can be towed over as it is generally smaller with lighter ground gear. Shrimp trawls also have shorter legs and are towed at only about 2 knots. Thus with lighter, smaller ground gear, shrimp trawls will impact the bottom less than groundfish gear and will be fished in less varied, less rugged terrain. When concentrations of shrimp occur offshore, they are most likely to be located in the general vicinity of the Cashes Ledge Closure Area.

5.3.7.2 Tuna Purse Seine Access to Closed Areas (Selected)

This alternative proposed to change the current regulations regarding access to closed areas in order to allow the use of tuna purse seines in Nantucket Lightship Closed Area, Closed Area I, and Closed Area II. The options within this alternative vary with respect to the number of restrictions that would be associated with access to these closed areas, the Council selected Option 2.

Habitat Impacts
Option 1 – Status Quo
This option does not propose any changes to the current prohibitions on access of tuna purse seine vessels to the groundfish closed areas. They would continue to be excluded from Closed Areas I and II and the Nantucket Lightship Closed Area and would continue to have access to the Western Gulf of Maine Closed Area, the Cashes Ledge Closed Area and the seasonal rolling closures. Because this option maintains the status quo, there would be no increase or change to the amount or distribution of adverse impacts to habitat associated with the tuna purse seine fishery.

Option 2 -- Access with Restrictions
This option proposes to change the current restrictions on the tuna purse seine fishery to allow access, subject to certain restrictions, to the groundfish closed areas from which the fishery is currently excluded. The restrictions proposed are intended to prevent any potential adverse impacts to habitat that may result from the use of tuna purse seines in areas otherwise closed to most types of fishing activity. The restrictions include a prohibition on the tuna purse seine fishery operating in any area designated as an HAPC. Based on the restrictions proposed, this option would not be expected to have any adverse impacts to the habitat of the region compared to the level of impacts that may currently be associated with this fishery.

Option 3 -- Access without Restrictions
This option proposes to change the current restrictions on the tuna purse seine fishery to allow access, subject to certain restrictions, to the groundfish closed areas from which the fishery is currently excluded. This option proposes less restrictive conditions on the fishery than the previous option (for example, this option prohibits the fishery from operating in the HAPC on Georges Bank within Closed Area II but the previous option would prohibit the fishery from operating in any HAPC). Because the conditions are less restrictive than the previous option, this option could increase the amount of adverse impacts to habitat that may be associated with the tuna purse seine fishery.

5.3.7.3 Southern New England General Category Scallop Exemption Program (Selected)

The Council selected to allow access to an exemption area in southern New England to fish for scallops for the following types of vessels: limited access scallop vessels that are declared out of the DAS program, limited access scallop vessels that have used all their DAS, or general category scallop vessels.

Vessels would be allowed to fish in this area while not under a multispecies day-at-sea as long as they comply with several restrictions.

Habitat Impacts
This alternative allows scallop dredge vessels to fish in a specified area (Figure 158) for scallops outside of the DAS program providing they employ dredges of not longer than 10.5 ft (combined).

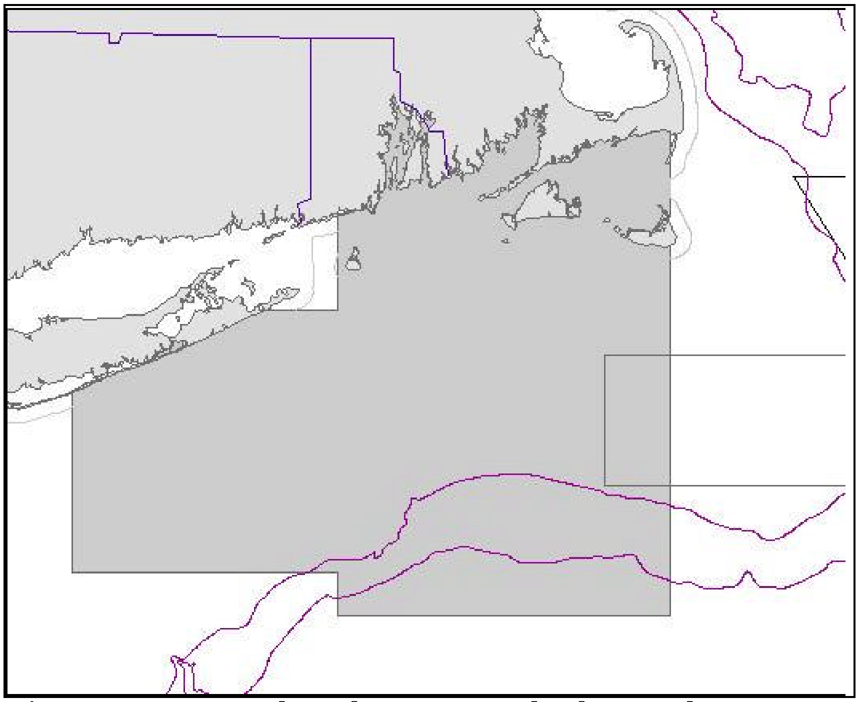

Figure 158 - Proposed Southern New England General Category Scallop Exemption Area.

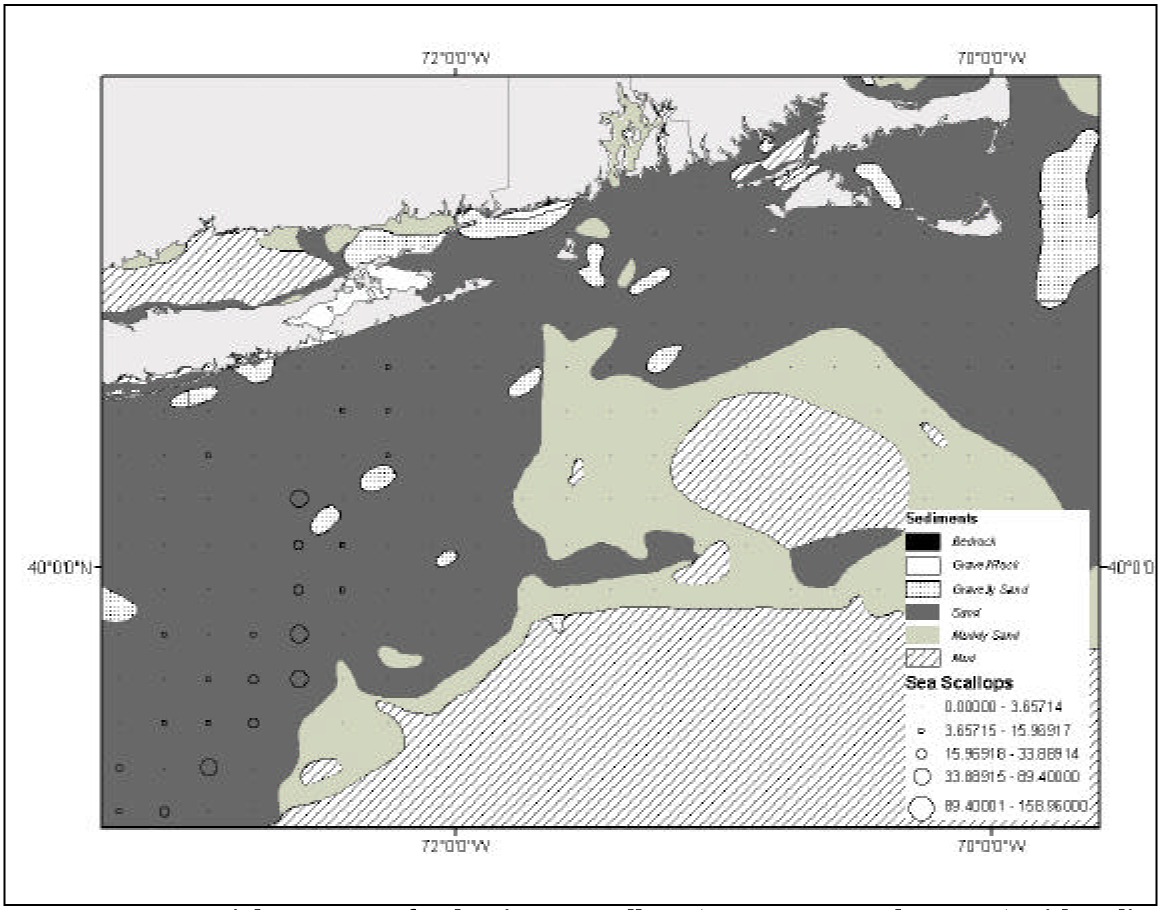

Figure 159 - Mean weight per tow of Atlantic Sea Scallops (1995-2001 trawl surveys) with sediment types of the affected area (modified from original map by Poppe et al. 1989).

The area affected by this alternative consists of primarily sandy, muddy sand and muddy sedimentation, with small patches of gravelly sand near the western boundary of the exemption area. Trawl survey data show scallop populations only along the western boundary of this exemption area. There is no data to indicate an overall increase in expected effort directed at the area covered by this exemption. Based on the relatively small amounts of scallops available inside the exempted area and this area's sedimentary makeup, no significant negative impacts to EFH are anticipated.

5.3.8 Alternatives to Minimize Adverse Effects of Fishing on Essential Fish Habitat

5.3.8.1 No Action Alternative

See analysis of habitat impacts under Section **5.3.6.2**.

5.3.8.2 Alternative 2 – Benefits to Essential Fish Habitat of Other Amendment 13 Measures *(Proposed Measure)*

This section will summarize the potential habitat benefits of the non-habitat Amendment 13 measures. Applying the benefits of these measures to achieve the habitat objectives of the Magnuson-Stevens Act would incur no additional regulatory burden on the fishing community or enforcement/monitoring agencies. However, these measures may not minimize the adverse effects of fishing on EFH at all, or as effectively as the proposed habitat protection alternatives.

The measures being proposed to address rebuilding requirements have the most benefits to habitat because they include significant effort reductions. The proposed action for Amendment 13 will reduce DAS allocations by 60% for A days, and 40% for B days. Long term this effort level may increase when stocks recover, but the habitat impacts from this measure are positive when compared to the No Action level of effort. The habitat impacts of the various rebuilding strategies within the EIS are summarized in Table 137. Furthermore, Cashes Ledge will become a year-round closed area as well, which will increase habitat benefits in that area. The alternatives proposed to address overcapacity will also have positive benefits for EFH by reducing the amount of time that vessels can spend fishing. There are other measures being proposed in Amendment 13 that have neutral or negative impacts on habitat, but overall they are outweighed by the positive impacts of the rebuilding program, thus the net impact of the non-habitat measures proposed in Amendment 13 are positive for habitat impacts.

Alternative	Overall Habitat Impact	Feature	Description of Habitat Impact
Observer Coverage (Fishery Program Admin.)	Indirect benefits (+)	10% requested by 2006 for each gear type, unless NMFS another appropriate level	If observers are able to collect data of interest to EFH management, increased coverage could indirectly benefit habitat.
Alternatives to Control Capacity	Positive Impact (+)	DAS can be transferred with restrictions and new measures for "reserve days"	Any measure that is intended to reduce the amount of time fishing by bottom-tending mobile gear will likely have benefits to EFH. These measures reduce amount of latent effort as well.
Management Measures to Address Rebuilding Requirements	Overall Positive Impact (+)	Mix of adaptive and phased reduction strategies. Provides opportunity to fish on stocks that do not need rebuilding	The effort reductions, year-round closed areas, and existing gear modifications are likely to have large positive impacts on EFH.
Effort Controls	Positive Impact (+)	A days (60% of effective effort) B days (40% of effective effort) C days (FY01 allocation)	Reducing DAS will benefit EFH by reducing the amount of time vessels can fish. Benefits will vary by area, gear, and habitat type, and will be higher in sensitive habitat areas (e.g., hard bottom) where bottom trawls and scallop dredges are currently being used.
Management Measures	Positive (+)	Same as settlement agreement unless specified	Overall measures are beneficial to EFH, especially effort reduction measure applicable largely to bottom tending mobile gear.
Closed Areas	Positive Impact (+)	Maintains existing groundfish closures and add Cashes Ledge as a year round closure.	Year-round closures provide habitat benefits to the areas within the closures. The addition of Cashes Ledge as a year-round closure will benefit the EFH and rare kelp beds found in that area.

Table 138 – Summary of the non-habitat measures proposed in Amendment 13 that have positive impacts on EFH

5.3.8.3 Alternatives 3 – 6, 10a and 10b (Habitat Closed Area Alternatives)

5.3.8.3.1 Environmental Attributes of Proposed Habitat Closed Area Alternatives

The alternatives under consideration include five primary habitat closure alternatives. Three of these include more than one option. In all, there are ten closed area options. The areas potentially impacted by these closures are described here using six metrics to summarize their ecological characteristics and to determine the differences between them. All ten closure options include more than one discrete closed area. The six metrics are:

SIZE and OVERLAP – Size of each proposed closed area option and overlap with year-round closed areas.

SUBSTRATE – Area of each sediment or substrate type contained within each proposed closure.

EFH – The amount of vulnerable species' EFH encompassed by each proposed closure.

TROPHIC GUILD – Biomass encompassed by each closure for five guilds: planktivores, amphipod eaters, shrimp and fish eaters, benthivores, and piscivores.

SPECIES ASSEMBLAGE - Biomass encompassed by each closure for three species aggregations: elasmobranchs, demersal species, and pelagic species.

BENTHIC SPECIES - Biomass encompassed by each closure for six species (longhorn sculpin, sea raven, redfish, ocean pout, jonah crab and American lobster) with high levels of association to benthic habitats.

When assessing the environmental attributes of the proposed closure alternatives, the No Action Alternative (which does not contain areas closed expressly for EFH protection) is included as a point of reference.

5.3.8.3.1.1 Size and Overlap with Groundfish Closed Areas

Methodology

The area (in square nautical miles) of the ten habitat closed area options and of the year-round groundfish closures that were in place during the 2001 fishing year (the No Action Alternative) are shown in Table 139, along with the area and percentage of each proposed habitat closed area that lies inside the boundaries of the existing groundfish closed areas (Type A Closure). Also shown in this table is the degree to which each proposed habitat closed area overlaps with areas that have been off-limits to groundfish and scallop gear on a continuous basis since December, 1994 (Georges Bank) or May 1998 (western Gulf of Maine) (Type B Closure) – when the groundfish closures were first established – and how much of each habitat closed area alternative was exposed to scallop dredging during 1999 and 2000 under the FW 13 Scallop Access Program (Type C Closure). These distinctions are important because the potential added value of continued habitat protection is different for type B and C closures.

	AREA (nm^2)	**PERCENT AREA**

Table 140 – Area (square nautical miles) and percent of each habitat alternative that overlaps with groundfish closed areas, the FW13 scallop access areas, and the portions of the groundfish closed areas that have remained closed since December 1994.

Type A - Area and percentage of proposed habitat closed areas that overlap with existing year-round groundfish closed areas

Type B - Area and percentage of proposed habitat closed areas that overlap with portions of the groundfish closed areas areas that remained closed under the FW 13 Scallop Access program

Type C - Area and percentage of proposed habitat closed areas that overlap with portions of the groundfish closed areas that were opened to scallop dredging in 1999 and 2000 and closed again in 2001

Results of Size and Overlap Analysis

Type A:

The areas that do not overlap with any portion of the existing groundfish closed areas (e.g., 43% of alternative 3a) have been continuously exposed to mobile, bottom-tending gear (see Section 9.3.1: Fishing Gear Effects Evaluation Section/Distribution of Fishing Activities). Closing areas of bottom that have been intensively fished by these gears will provide long-term benefits to habitat and the net gain in habitat quality (improved function and value) will be greater than in portions of habitat closed areas that are located inside the groundfish closed areas. Because alternatives 3, 4, 6 and 10 were designed around existing year-round closed areas, the percentage of overlap is high. Conversely, because all the options under Alternative 5 were designed with closures in five pre-defined eco-regions and were not associated with any of the existing groundfish closed areas, their overlap is very low.

Type B:

These are areas that have been protected from the effects of most mobile, bottom-tending gear since December 1994 on Georges Bank and since May 1998 in the western Gulf of Maine (see Section 4.3.6.1.2.1 for an analysis of bottom fishing activities that took place in the closed areas during 1998-2001). Keeping these areas closed will maintain/continue existing habitat protection and values that have accumulated during the past 5-9 years. However, depending on the substrate types that exist in these areas and recovery times required to restore seafloor features and benthic communities from the effects of bottom fishing that occurred before these areas were closed, any extended habitat protection in these areas will yield minimal additional habitat benefits because recovery may be mostly complete by now. On the other hand, establishment of these areas as habitat closed areas will guarantee that accumulated benefits will not be lost. Consequently, failure to keep these areas closed will have serious consequences for habitat quality, depending on what kind of habitat is contained within them. Alternatives that fall into this category are 3a and b, 4, 6, and 10 a and b. None of the alternative 5 options are strong type B closures.

Type C:
These are areas that benefited from year-round area closures for either four (Closed Area I and the Nantucket Lightship Closed Area) or five years (Closed Area II), and then were exposed to scallop dredging effects for one (CAII) or two (CAI and NLSCA) years under the Framework 13 Scallop Access Program. They were closed again in May of 2001. Figure 149 shows where and how much scallop dredging took place in these areas in 1999/2000. Closing these areas will provide short-term habitat benefits that are intermediate between types A and B since recovery of habitat features was interrupted during 1999/2000. Recovery from the adverse effects of fishing varies according to the type of habitat – faster for sandy areas and slower for hard bottom areas – and will also be affected by the degree of natural disturbance in the area. For instance, the southern portion of CAII is deeper and sandier and therefore less vulnerable than the shallower, northern portion which has more gravel. (Additionally, see Figure 160 and Figure 162 for substrate features of CAI). Failure to keep these areas closed to scallop dredging and bottom trawling would forfeit gains made over the last three years. Small portions of alternatives 3a, 3b, 4, 5b, 10a and 10b overlap with the FW13 scallop access areas.

5.3.8.3.1.2 Substrate

Methodology

Sediment (or substrate) type is a habitat characteristic that is used, in the comparison of habitat closed area alternatives, to represent different types of benthic habitat that are more or less vulnerable to the adverse effects of fishing. Sandy substrates, for example, are considered to be more dynamic (i.e., more subject to alteration by natural events such as bottom currents) and less vulnerable to disturbance by mobile, bottom-tending fishing gear than structurally more complex "hard bottom" (gravel, cobble, pebble and boulder) habitats, especially if they support attached epifaunal organisms (e.g., sponges, corals, bryozoans, anemones) that can be easily damaged or removed from the bottom by bottom trawls and dredges. Seafloor features and benthic communities found in sandy bottom areas also recover more quickly following disturbance than in hard bottom habitats. This approach is supported by conclusions cited in two recent reports (NREFHSC 2002 and NRC 2002) regarding the vulnerability of different substrates to fishing gear effects.

To establish the sedimentary composition of the various closure options, a U.S. Geological Survey dataset was used (for more information, see Appendix XI). This dataset contains sediment data for 975 sampling locations throughout the entire Northeast region (U.S.- Canada border to North Carolina) and was used by Poppe *et al.* (1986, 1989) to map the distribution of nine sediment types, which were reduced to six for the purposes of this analysis (Figure 161). Most of the samples that were analyzed in developing this database were collected using bottom grab samplers. Higher-resolution data sets, such as that based on bottom video work by Stokesbury and Harris (2002), have been made available to the Council but do not cover a sufficiently large geographic area to be useful for a comprehensive evaluation of closure options. These high-resolution data do, however, point out the limitations of the USGS dataset when employed at a small scale. Figure 162 demonstrates that, at small scales, the USGS maps fail to capture the variety of substrates on a scale at which spatial changes in substrates tend to occur. In the absence of similar datasets covering the range of the Northwest Atlantic Analysis Area (NAAA), however, the USGS substrate maps will serve as the best available data for the purposes of description and analysis. Analyses were based on a digitized sediment data set generated from the sediment map shown in Figure 138 and conducted in a GIS format. Table 141 shows the percent that each sediment type makes up of the total area of each sediment type in the NAAA while Table 142 shows the percent sediment composition of each closed area alternative.

The term “gravel,” as used in this analysis, is a collective term that includes granules, pebbles, cobbles, and boulders in order of increasing size. Therefore, the term “gravel” refers to particles larger than sand and generally denotes a variety of “hard bottom” substrates. Granules are slightly coarser than coarse sand and are 2-4 mm in maximum diameter. Pebbles range in size from granules up to 64 mm (2.5 inches) in diameter. Cobbles range in size from pebbles up to 256 mm (10 inches) in diameter. Boulders are larger than cobbles. Common “gravel” bottom types occurring offshore are pebble gravel (pebble pavements); pebble/cobble gravel; and pebble/cobble/boulder mixtures. They all can support attached epifauna and can be vulnerable to disturbance by mobile bottom gear. Pebble gravel and pebble/cobble gravel often overlie sand, and if the gravel has been disturbed, the sand will be visible between pebbles and cobbles.

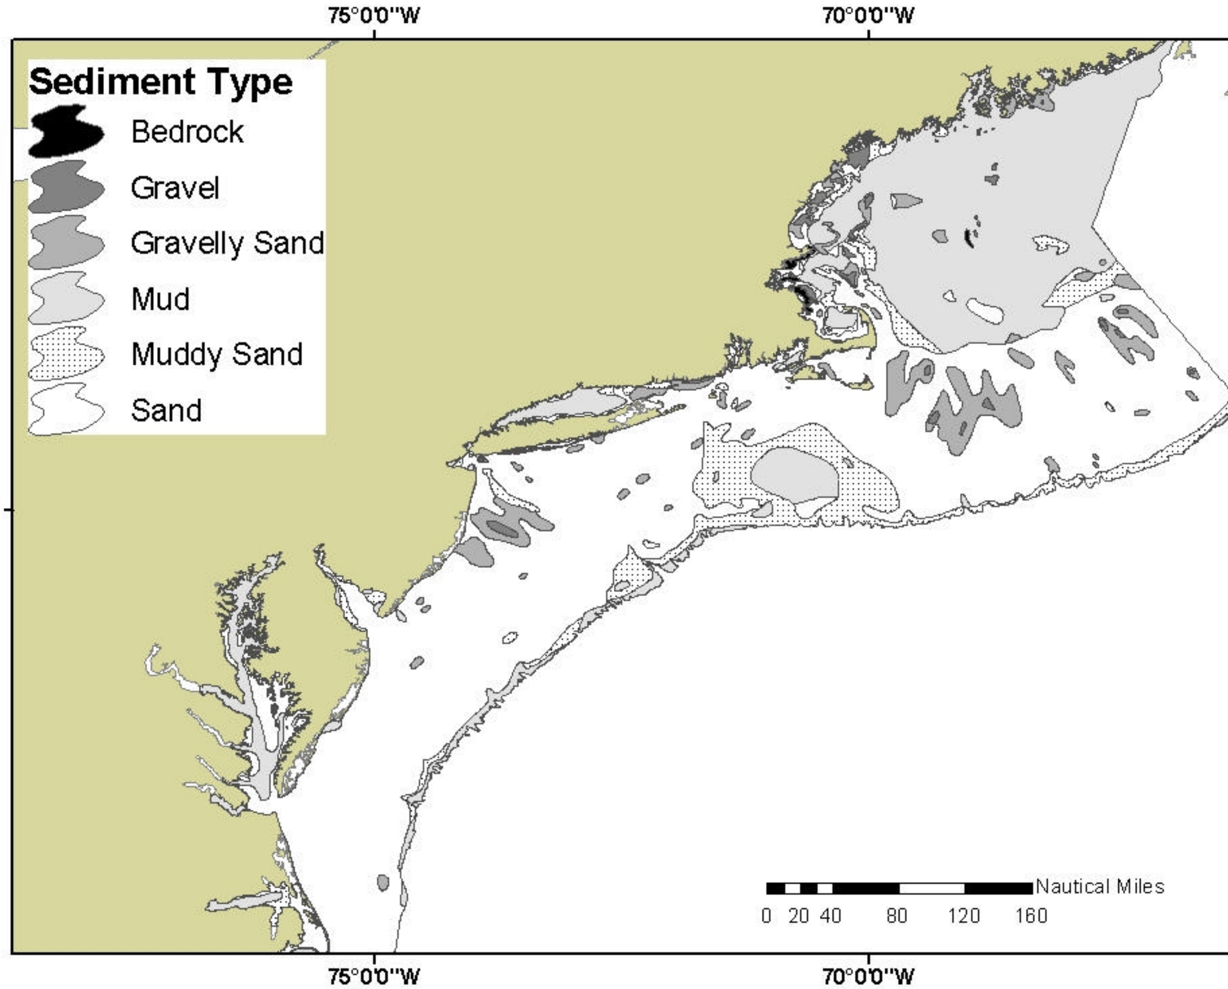

Figure 160 – Sediment map of the Northwest Atlantic Analysis Area based on Poppe *et al.* data (1989)

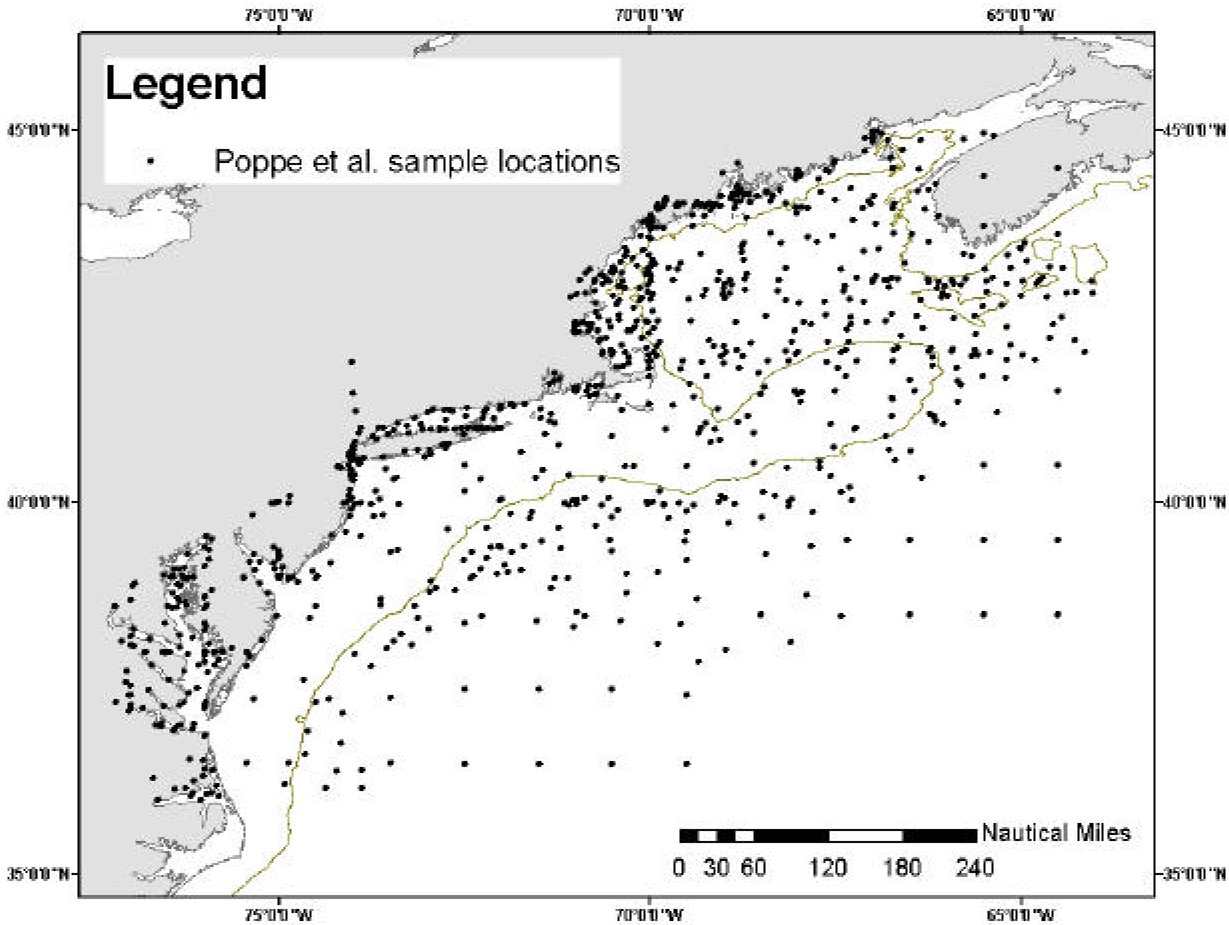

Figure 161 – Poppe *et al.* (1989) sampling locations

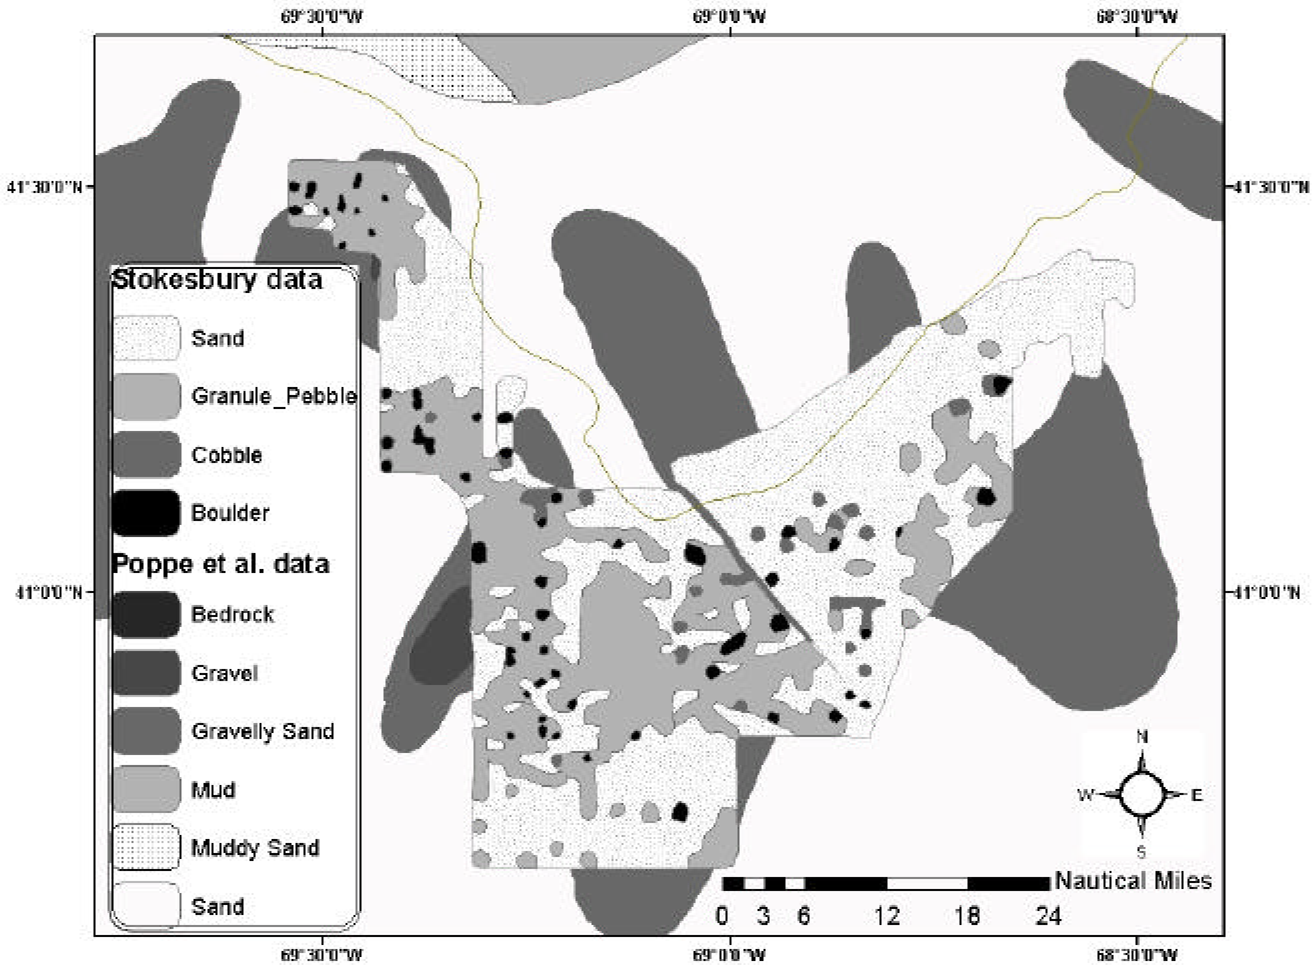

Figure 162 – Stokesbury and Harris (2002) substrate data for areas on Nantucket Shoals from Asia Rip north to Davis Bank and extending west into Closed Area I.

Results of sediment compositions

Alternatives 3 (a), 3(b), 4, 5a, 10a and 10b are the only alternatives to contain areas of bedrock as defined by the Poppe *et al.* data. Alternative 10a and 10b seem to contain a more complex bottom in that area (bedrock and gravel), more than some of the alternatives and less than others. Alternatives 3a, 3b, and 4 contain more gravel and Gravelly sand than the other alternatives, but Alternative 6, 10a, and 10b also contain a significant amount of these sediment types. Alternatives 5(b), 5(c), 6, 10a and 10b are comprised of over 50% sand, and 5(a) contains the highest amount of mud.

5.3.8.3.1.3 Essential Fish Habitat

Methodology

Twenty-three species have been identified as having EFH for at least one life stage moderately or highly vulnerable to the effects of bottom-tending mobile gear (see Section 9.3.1: Gear Effects Evaluation and Adverse Impact Determination Section). Closed areas provide habitat protection for these species and life stages. This analysis can be used to evaluate how the different alternatives rank in terms of EFH protection for the species that are moderately or highly vulnerable to bottom tending gear. The EFH area contained in a closure is calculated by summing the geographic area (in square nautical miles) of the ten minute squares of latitude and longitude (or portions thereof) that are designated as EFH for each species and life stages that is bounded by each proposed closure. Geographic EFH designations are defined in the Omnibus EFH Amendment (NEFMC 1998) and in several species FMPs adopted by the NEFMC and MAFMC. Table 143 summarizes the total and percent-of-total EFH area in the Northwest Atlantic Analysis Area (NAAA) for each of the vulnerable species and life stages (A= Adults, J= Juveniles and E= Eggs) encompassed by each of the closed area alternatives. The total EFH area for each of these species and life stages is shown in the first column. The sum of EFH area values for all species and life stages in each closure alternative and the percent that each closure sum makes up the total EFH in the entire NAAA (sum of column 1) are shown at the bottom of the table.

Table 143 - Total and percent-of-total EFH area for species with EFH identified as vulnerable to bottom-tending mobile gear.

**Values are not scaled for area*

The No action (N.A) alternative is included for comparative purposes only. It is not under consideration as a habitat closure in Amendment 13.

Results of EFH Analysis

Total and percent-of-total EFH area values for all species and life stages with vulnerable EFH range from 41,232 nm^2 (5%) for alternative 4 and 64,701 nm^2 (7.8%) for alternative 6. Alternative 5d also ranked very low while the remaining seven alternatives had intermediate values ranging from 5.9% to 6.6%. Overall, less than 10% of the total EFH for the majority of species and life stages with vulnerable EFH occurs within the habitat closures. Species with high percentages of EFH area are cod (A,J), haddock (A,J), and halibut (A,J). Since the amount of EFH in each alternative varies depending on the size of the closure, the total EFH area values in for each alternative were also divided by the size of each alternative (see Table 153 in Section 4.3.8.3.2). These per-unit-area EFH values measure the relative effectiveness of each proposed habitat closure in protecting EFH for these species. On a per-unit-area basis, alternatives 5d and 6 have low EFH scores (15.2% and 16%), 5c has the highest value (19.7%), and the other seven alternatives have intermediate scores ranging from 17.7% to 18.5%. Per-unit-area EFH values were also calculated for species with highly vulnerable EFH, New England species with highly vulnerable EFH, and for overfished species with highly vulnerable EFH (see Section 4.3.8.3.2).

5.3.8.3.1.4 Trophic Guilds

Methodology

Cluster analysis (based on Garrison 2000) was used to define trophic guilds found in the Northwest Atlantic Analysis Area (NAAA). The general guild structure and levels of dietary overlap are consistent across both temporal and spatial scales. Complimentary analyses to the current study within the Georges Bank region identified similar trophic guilds and general stability in the trophic guild structure over the last three decades. Despite the notable changes in species composition in the Northeast shelf fish community, the patterns of trophic resource use and guild structure have remained remarkably consistent. Five trophic guilds were identified for this analysis: benthivores, amphipod eaters, planktivores, piscivores, and shrimp and fish eaters. The species and size ranges used to define these guilds are identified in Appendix XI. The Biological Environment section of the Amendment 13 SEIS document describes the trophic guilds in greater detail.

Table 149 describes the total and percent-of-total biomass for each guild that is contained within each closure alternative. Biomass is measured as the sum of the mean wt (kg) per tow from the 1995-2001 bottom trawl surveys for each ten-minute square (or fraction thereof) included within each closure area. Table 150 shows the percent composition by closure.

Benthic = benthivore; Ampshr = amphipod/shrimp eater; Plankt = planktivore; Pisc = piscivore; Shrfis = shrimp/fish eater

NAA data are meant for comparison purposes. This NAA is not an alternative under consideration in Amendment 13.

Results of Trophic Guild Analysis

Closed area alternatives 6, 10a and 10b contain the highest biomass values for benthivores and shrimp-and-fish eaters, followed closely by 3a, 3b and 4. Amphipod-eaters biomass is highest in alternative 6 followed by alternatives 5a, 5b, and 5c. Planktivores and piscivores are most abundant in alternatives 5b and 5d. Guild biomass in alternatives 3a, 3b, 4, 6, 10a, and 10b is dominated by benthivores and shrimp/fish-eaters and by benthivores and planktivores in alternatives 5a-5d.

5.3.8.3.1.5 Species Assemblages

Methodology

Cluster analysis (based on Garrison 2000, Gabriel 1992) was used to define spatial-temporal assemblages for major taxonomic aggregates (i.e., principal groundfish, principal pelagics, demersals, pelagics and elasmobranchs) found in the NAAA. Species that were assigned to these assemblages are identified in Table 151. The Biological Environment section of the Amendment 13 SEIS describes the assemblages in greater detail.

Table 152 describes the total and percent-of-total biomass for each species assemblage that is contained within each closure alternative. Biomass is measured as the sum of the mean wt (kg) per tow from the 1995-2001 bottom trawl surveys for each ten minute square (or fraction thereof) included within each closure area. Table 153 shows the percent composition by closure.

NAA data are meant for comparison purposes. This NAA is not an alternative under consideration in Amendment 13.

Results of Species Assemblage Analysis

High elasmobranch biomass values occur in alternatives 5b and 6, with relatively high values in 10a and 10b. High pelagic biomass occurs in all four of the alternative 5 options. Demersal finfish species are most abundant in alternative 6, but high values also occur in alternatives 5b, 10a, and 10b. Biomass of the principal groundfish assemblage is high in alternatives 6, 10a and 10b. The most abundant species assemblage in all ten closed area alternatives is the demersal finfish group.

5.3.8.3.1.6 Benthic Species

Methodology

Six species (longhorn sculpin, sea raven, redfish, ocean pout, jonah crab and American lobster) were chosen for their close association with benthic habitats for both feeding and protection from predators (see Appendix XI for spatial distribution of these species). Table 154 describes the total and percent-of-total biomass for each species that is contained within each closure alternative. Biomass is measured as the sum of the mean wt (kg) per tow from the 1995-2001 bottom trawl surveys for each ten minute square (or fraction there) included within each closure area. Table 155 shows the percent composition by closure.

NAA data are meant for comparison purposes. This NAA is not an alternative under consideration in Amendment 13.

Results of Benthic Species Analysis

Longhorn sculpin biomass is high in 5b and 5c; sea ravens in 3a, 3b, 4, 5b, and 6; redfish in 6, 10a, and 10b; ocean pout in 5a, 5c and 5d; jonah crab in 5a and 5d; and lobsters in 5b and 5c. Alternatives 3a, 3b and 4 are dominated by redfish and longhorn sculpins; 5a by longhorn sculpins, redfish, and ocean pout; 5b by longhorn sculpins; 5c by sculpins and ocean pout; 5d by redfish and ocean pout; and alternatives 6, 10a and 10b by redfish.

5.3.8.3.2 Summary of EFH Benefits of Area Closure Options

5.3.8.3.2.1 Purpose of this section

The M-S Act states that Councils are required to minimize, to the extent practicable, the adverse effects of fishing on EFH. It was concluded in the Gear Effects Evaluation and Adverse Impacts Determination (Section 9.3.2) that mobile bottom-tending gears (otter trawls, scallop dredges and clam dredges) have the potential to adversely impact the essential fish habitat for the benthic life stages of 23 federally-managed species that inhabit the Northeast regional ecosystem. The purpose of this section is to present the results of an EFH-specific analyses for each of the ten area closure alternatives that indicates the degree to which each closure option will protect EFH for these species. It also includes a summary of the substrate, trophic guild, and species assemblage characteristics of these species and life stages in each closed area alternative. The analyses are applied to the moderately and highly vulnerable species, to the highly vulnerable species, the highly vulnerable and overfished species, and the highly vulnerable species that are managed by the New England Fishery Management Council.

5.3.8.3.2.2 EFH-specific analysis: moderately and highly vulnerable species

The following three sections summarize results of habitat metric analyses in more detail for those species that have been defined as adversely impacted by mobile, bottom-tending gears, i.e., in a manner than is more than minimal and not temporary in nature (see Gear Effects Evaluation and Adverse Impact Determination section). This analysis begins with a list of the species and life stages with EFH that has been determined to be either moderately or highly vulnerable to mobile, bottom-tending gears (Table 156). The analysis evaluates the EFH protection afforded by all ten area closure alternatives on a per-unit-area basis (relative effectiveness indices) (see Table 157 through Table 160).

**Values are total EFH area (in square nautical miles) per square nautical mile in each closed area for all moderately and highly vulnerable species and life stages in the Northeast region, and for only the highly vulnerable species and life stages.*

***Proposed measure*

Some of the alternatives are more effective at protecting moderately and highly vulnerable EFH per square nautical mile, notably 4, 5c, and 10b. The only alternatives that do not have a relative effectiveness score over 17 are Alternative 5d and Alternative 6. Alternatives 4, 10a, and 10b score the highest when comparing their effectiveness for protecting species with highly vulnerable EFH, while Alternatives 5d and 6 once again score the lowest (Table 157).

5.3.8.3.2.3 EFH-specific analysis: highly vulnerable New England-managed and overfished species

This analysis highlights area scaled EFH values for species with EFH that is highly vulnerable to mobile bottom-tending gears that are managed by the New England Council, and those that are overfished.

Table 160 - Relative Effectiveness of Amendment 13 Habitat Closed Area Alternatives in Protecting EFH for Two Categories of Species and Life Stages.

**Values are total EFH area (in square nautical miles) per square nautical mile in each closed area, for the highly vulnerable species and life stages in New England, and for highly vulnerable species in the Northeast region.*
*** Proposed measure*

Alternatives 10a and 10b rank the highest in terms of their effectiveness for protecting New England species with highly vulnerable EFH. The only alternative that ranks much lower than the rest for relative effectiveness of protecting these species is Alternative 5d. Alternative 5c ranks the highest for protecting overfished species with highly vulnerable EFH. Alternative 6 ranks the lowest in this category (Table 160).

5.3.8.3.2.4 Analysis of closed area metrics associated with highly vulnerable EFH

Methodology

Table 161 summarizes the habitat and ecological characteristics for benthic life stages of nine species with EFH that is highly vulnerable to disturbance by at least one of the three mobile bottom-tending gears used in the Northeast region (see Table 156), based upon the analysis contained in Section 9.3.2. This information was used to select metric components for an evaluation of environmental features that are associated with these species, which would be protected by each of the ten proposed habitat closures.

Species	Lifestage	Depth (m)	Sediments	Guild	Assemblage
American Plaice	A	45-150	sand or gravel	Benthic	Pringrd, Demersal
Atlantic Cod	J	10-150	rocks, pebble, gravel	Ampshr	Pringrd, Demersal
Black Sea Bass	A	20-50	structures, sand and shell		Demersal
Black Sea Bass	J	1-38	rough bottom, shell and eelgrass beds, structures and offshore clam beds in winter		Demersal

Tilefish	A	76-365	rough, sheltered bottom		Demersal
Tilefish	J	76-365	rough, sheltered bottom		Demersal

Table 161 – Summary of habitat and ecological characteristics of species and life stages with EFH that is highly vulnerable to bottom tending mobile gear

Of the 15 species and life stages listed above with highly vulnerable EFH, 12 are associated with rough, sheltered, hard, pebbled or broken bottom types. The list includes 7 benthivores, 4 shrimp-fish eaters and 2 amphipod eaters. Every species and life stage listed falls under the demersal and, in six cases, also the principle groundfish assemblage. Based on these results, two substrate types, three trophic guilds, and two species assemblages were selected for this analysis. Percent composition data for these habitat metric components are presented in Table 162 through Table 164, along with summed percentages to indicate the overall importance of each habitat characteristic.

Substrates

	Bedrock	Gravel	Sum
3(a)	1%	6%	7%
3(b)	1%	7%	8%
4	1%	6%	7%

**Proposed measure*

Results
Closed area alternatives 3a, 3b, 4, 6, 10a, and 10b rank higher than any of the alternative 5 options for all three habitat metrics. For substrate, alternatives 3a, 3b, and 4 contain a higher percentage of rocky bottom, followed by alternatives 10a and 10b. Alternative 6 has about the same amount of rocky substrate as either of the alternative 10 options, but has a reduced percentage composition due to its larger size. For trophic guilds, alternatives 10a and 10b score slightly higher than alternatives 6, 3a, 3b, or 4. For species assemblages, alternatives 3a, 3b, and 4 score slightly higher due to the higher percentages of principal groundfish species.

5.3.8.3.3 Results of Closed Area Analyses

5.3.8.3.3.1 Alternative 3 - Closed areas designed to protect hard-bottom habitats

Alternative 3 was intended to protect complex hard-bottom and other sensitive and complex benthic habitats. This alternative includes two closed area options: 1) Alternative 3(a), with a larger extension of the WGOM to the west, and 2) Alternative 3(b), which has a smaller extension of the WGOM closure to the west. These extensions were explicitly designed by the EFH Technical Team in 1999 to include additional seafloor habitats inside the closed area. Alternative 3(b) includes two angular extensions from the western boundary to encompass additional gravel habitat on Stellwagen Bank as well as piled boulder features on Tillies Bank to the north. Alternative 3(a) extends the entire southwestern boundary of the closed area to include the previously mentioned features as well as the deep mud basins east, west and north of Tillies Bank. These alternatives originate from an analysis of the USGS multibeam map of the area and observations made using ROVs, submersibles, and video bottom cameras, as well as the accumulated field experience of the EFH Plan Development Team members.

Size and Substrate
Alternative 3(a) is slightly larger than Alternative 3(b), but the substrate compositions of the two alternatives are essentially the same (Table 139, Table 141 and Table 142). Either of these two options is larger than Alternative 4, about the same size as any of the Alternative 5 options and 10a and 10b, and smaller than Alternative 6. Alternatives 3a and 3b overlap 53% and 55% respectively with the existing groundfish closed areas (Table 140). Sand and gravelly sand account for about 70% of the sediment in Alternative 3 and mud for about 20% in these two alternatives (Table 142). The percent composition of rocky substrate (bedrock and gravel) and gravelly sand in Alternatives 3 and 4 is higher than in any of the other proposed habitat closures. Also, relative to the total area of each substrate type in the NAAA, these two options include higher percentages of rocky substrate and gravelly sand than any of the other habitat closed area alternatives (Table 141).

EFH
Because they are intermediate in size, Alternatives 3a and b contain a higher percentage of EFH area for species with the moderately (M) and highly (H) vulnerable EFH than Alternative 4, and a lower percentage than Alternative 6 (Table 143). Compared to the four Alternative 5 closed area options, which are very similar in size to the Alternative 3 options, total EFH area in 3a and b is lower than in options 5a, b, and c, but higher than 5d. On a per unit area basis, the total percent EFH value for the same species and life stages is very similar in Alternatives 3a, 3b, 5a and b (Table 157). The total area scaled M/H vulnerable EFH values are not quite as high as in Alternative 5c, but are notably higher than in Alternatives 5d or 6 and lower than Alternatives 4, 10a and 10b. The results are very similar for most of the alternatives for the H vulnerable

species/life stages, with Alternatives 3a and 3b somewhere in the upper middle (Table 157). For highly vulnerable New England species, total scaled EFH values rank slightly higher in Alternatives 3a, 3b, and 4 than in Alternatives 5a, b, c or d and 6, and slightly less than Alternatives 10a and 10b (Table 160). For overfished and H vulnerable species, Alternatives 3a and b rank lower than most in terms of total EFH per nautical mile (Table 160) because only one of the three species (juvenile cod) in this category is a New England species. Because the footprints of Alternatives 3a and 3b are so similar, the percentages of EFH area inside them are also very similar for virtually all species analyzed (Table 143). Species and life stages with high amounts of vulnerable EFH (over 10 percent) in Alternatives 3a and 3b are cod (A, J), haddock (A,J), halibut (A,J), pollock (A), and smooth skate (A).

Alternatives 3a and b, along with alternatives 4, 6, 10a and 10b, rank high in terms of the environmental characteristics that are associated with the 15 species and life stages with EFH that was determined to be highly vulnerable to the adverse effects of mobile, bottom-tending fishing gear (see Section 5.3.8.3.2.3). This conclusion is based on the high rankings for rocky bottom (Table 162), the benthivore, amphipod-eating, and shrimp and fish-eating trophic guilds (Table 163), and the principal groundfish and demersal finfish species assemblages (Table 164).

Ecosystem Effects: Trophic Guilds, Species Assemblages and Indicator Species
Alternatives 3a and b contain a higher biomass of benthivores than any of the other trophic guilds (Table 149). The percentage composition of benthivores in 3a/b is high (>40%), just as high as in alternatives 4, 10a and 10b (Table 150). Shrimp and fish-eating fish also make up a significant proportion (>20%) of the total biomass of the five trophic guilds in alternatives 3a and b. Alternatives 3a and b contain higher percentages of the benthivore and shrimp and fish-eating guilds than the alternative 5 options, but lower percentages than alternatives 10a and 10b (Table 150). The biomass values and percentages for the other three trophic guilds were fairly low in 3a/b (and 4) compared to the other alternatives. The demersal finfish assemblage, because it includes so many species, dominates the total biomass of all five species assemblages in each closure alternative, accounting for almost 50% of the total biomass in 3a and b (Table 152). Principal groundfish and elasmobranch species assemblages are also important components in Alternatives 3a and b, each accounting for >20% of the biomass. Of the six individual benthic species that were analyzed, redfish accounted for >50% of the total biomass in Alternatives 3a and b, and longhorn sculpins for >20% (Table 155). Redfish biomass is fairly high in Alternatives 3a and b, but not nearly as high as in alternatives 6, 10a and 10b.

Summary
In summary (Table 166), the two alternative 3 options would close five discrete areas on Georges Bank and in the Gulf of Maine with a total area that is intermediate in size (compared to the other eight alternatives). This alternative would offer new habitat protection in open access areas as well as maintain protection to benthic habitats in a considerable portion of the existing groundfish closed areas. There is a higher percentage of higher value rocky bottom in these two areas than in any of the other proposed closures except alternative 4. For species and life stages with EFH that is moderately or highly vulnerable to mobile, bottom-tending fishing gear, the EFH value of Alternative 3 is moderate. Biomass indices for bottom feeding and bottom dwelling fish are high. Summed across eight metrics, alternatives 3a and 3b have slightly higher habitat value than the other eight closed area alternatives.

5.3.8.3.3.2 Alternative 4 - Closed areas designed to protect hard-bottom habitats

Alternative 4 identifies five discrete habitat closed areas within a proposed (but rejected) groundfish rebuilding closed area option in this Amendment (Rebuilding Alternative 1). Much of the area specified in habitat closed area Alternative 3 would be included in this alternative. However, this alternative excludes an area between Closed Area I and the Nantucket Lightship Closed Area that was recommended by the Habitat Technical Team for habitat protection purposes (see Figures 17 and 18). Also, an area in the northern Gulf of Maine (Jefferys Bank) and areas west of the existing Western Gulf of Maine Closed Area that are included in Alternative 3 are not included in Alternative 4. The proposed Cashes Ledge Closed Area is also shaped a little differently.

Size and Substrate

Alternative 4 is the smallest of the ten proposed habitat closed areas (2,241 nmi2) and 69% of the area in this alternative overlaps with the existing year-round groundfish closed areas (Table 140). There is a 55% overlap with portions of the groundfish closures that have remained closed since they were first established and a 14% overlap with areas that were opened to scallop dredging in 1999 and 2000. Because there is a high degree of overlap between alternatives 3 and 4, the substrate composition is very similar in both alternatives. Sand and gravelly sand account for almost 75% of the substrate in Alternative 4 and mud for 15% (Table 142). The percent composition of rocky substrate and gravelly sand in Alternatives 3 and 4 is much higher than in any of the other proposed habitat closures. Because it is smaller, Alternative 4 contains a little less rocky substrate and gravelly sand than Alternatives 3a and b and accounts for lower percentages of the total amount of these substrate types in the NAAA (Table 142).

EFH

Largely because of its small size, Alternative 4 contains a lower percentage of total EFH area for species with moderately (M) and highly (H) vulnerable EFH than any other proposed habitat closure (Table 143). On a per unit area basis, the total EFH value for M/H vulnerable species and life stages is the highest for Alternative 4 , with alternatives 5c and 10b close behind (Table 157). Alternative 4 also ranks high for the relative effectiveness of protecting highly vulnerable species EFH, slightly less than Alternatives 10a and 10b. For highly vulnerable New England species, total scaled EFH values rank slightly higher in Alternatives 3a, 3b, and 4 than in Alternatives 5a, b, c or d and 6, and slightly less than Alternatives 10a and 10b (Table 160). For overfished and H vulnerable species, Alternative 4 ranks somewhere in the middle in terms of total EFH (Table 160) because only one of the three species (juvenile cod) in this category is a New England species. Species and life stages with high amounts of vulnerable EFH (over 10 percent) in this area are cod (A, J), haddock (A,J), halibut (A,J), pollock (A), and smooth skate (A).

Alternatives 3a and 3b and 4 rank high than the in terms of all the environmental characteristics that are associated with the 15 species and life stages with EFH that were determined to be highly (H) vulnerable to the adverse effects of mobile, bottom-tending fishing gear (see Section 5.3.8.3.2.3). This conclusion is based on the high rankings for hard bottom and coarse sediments (Table 162), the benthivore, amphipod-eating, and shrimp and fish-eating trophic guilds (Table 163), and the principal groundfish and demersal finfish species assemblages (Table 164).

Ecosystem Effects: Trophic Guilds, Species Assemblages and Indicator Species

The distribution of biomass among trophic guilds in Alternative 4 is very similar to Alternatives 3a and 3b, i.e., 43% benthivores and 23% shrimp and fish-eating fish and planktivores (Table 150). Alternative 4 contains a slightly lower percentage of total benthivore and shrimp and fish-eaters biomass than Alternatives 3a/b and considerably less than alternatives 6, 10a, and 10b

(Table 149). Percent of total amphipod-eaters biomass is also lower in Alternative 4 than in alternatives 3a, 3b, 6 and 10a, and the same as in 10b. The percentage biomass values for the other two trophic guilds were lower in Alternative 4 than in all the other alternatives. The composition of the five species assemblages in Alternative 4 is also very similar to what it is in Alternatives 3a and b. The demersal finfish assemblage accounts for almost 50% of the total assemblage biomass in Alternative 4, with principal groundfish and elasmobranchs each making up >20% (Table 153). Alternative 4 accounts for a lower percentage of the total biomass of principal groundfish in the NAAA than Alternatives 6, 10a and 10b and the two Alternative 3 options, but more than any of the Alternative 5 options (Table 152). As is the case in alternatives 3a and 3b, redfish accounted for >50% of the total individual species biomass in Alternative 4, and longhorn sculpins for >20% (Table 153). The percentage of total redfish biomass in Alternative 4 (and 3a/b) is higher than in any of the Alternative 5 options and lower than in Alternatives 6, 10a and 10b (Table 152).

Summary

In summary (Table 166), Alternative 4 would close five discrete areas on Georges Bank and in the Gulf of Maine with a total area that is smaller in size than any of the other proposed habitat closure alternatives. This alternative would offer new habitat protection in open access areas as well as maintain protection to benthic habitats in a considerable portion of the existing groundfish closed areas. There is a higher percentage of rocky bottom in this area than in any of the other proposed closures except alternatives 3a and 3b. For species and life stages with EFH that is moderately or highly vulnerable to mobile, bottom-tending fishing gear, the total EFH area that is contained within this alternative is low, but after scaling for its small size, its EFH value is intermediate. Biomass indices for bottom feeding and bottom dwelling fish are high. Summed across eight metrics, Alternative 4 has a slightly lower habitat value than alternatives 3a, 3b, 10a, and 10b, but higher than any of the Alternative 5 options.

5.3.8.3.3.3 Alternative 5 - Closed areas designed to protect EFH and balance fishery productivity

Alternative 5A: EFH/Productivity tradeoffs using the original working group species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of 37 other managed species.

Alternative 5B: Total EFH value only, using revised species EFH weights (omitting relative importance to the fishery as a factor), with no productivity tradeoff.

Alternative 5C. EFH/Productivity tradeoffs using the revised species EFH weights with equal emphasis given to scallop productivity and the combined weighted productivity of the other 37 managed species.

Alternative 5D. EFH/Productivity tradeoffs using the revised species EFH weights and productivity for each of the 37 managed species, considered individually.

A distinguishing characteristic of the proposed habitat closed areas in Alternative 5 is the fact that they are empirically derived from 30 years of trawl survey data for a large number of species (37) (see Appendix XI). Each alternative proposes to close five areas of similar size, one in each of five “eco-regions.” The location of the individual closed areas varies among the four options, but the total area that would be closed under each option is very similar. Because these four closure options were developed without any reference to existing closed areas, only a small fraction of the proposed closed areas overlap with the existing groundfish closed areas. All four alternatives include a closed area in southern New England and the Mid-Atlantic Bight: all of the other habitat closed area alternatives are restricted to Georges Bank and the Gulf of Maine.

Size and Substrate
The overall area that would be closed in each alternative is very similar, roughly 3,022 – 3,098 nmi² (Table 139). The options under Alternative 5 overlap very minimally with the existing year round groundfish closed areas, respectively: 5%, 5%, 0% and 6% (Table 140). Alternative 5c is located entirely outside of these closures. Alternative 5b is the only one that overlaps with any of the areas that were opened to scallop dredging during 1999 and 2000. The substrate compositions of each alternative vary considerably (Table 141 and Table 142). For example, Alternative 5(b) will protect significantly more gravelly sand and sand than the other options in Alternative 5, whereas 5(a) and 5(c) will protect more mud than 5(b) and 5(d). Alternatives 5(a) and 5(c) also protect more mud than any of the other alternatives and 5(a) and 5(d) score the highest for muddy sand. The amount and percentage of rocky bottom in these alternatives is very low.

EFH
The un-scaled percent of total EFH area values for Alternatives 5a-c are higher than the EFH values for Alternatives 3a/b and 4 and lower than for Alternative 6 and about the same as 10a and b (Table 143). The un-scaled EFH value for 5(d) is lower than the other Alternative 5 options, but is still higher than Alternative 4. The total scaled EFH value for M/H vulnerable species and life stages in Alternative 5(c) is high and for 5(d) is lower than all the other alternatives (Table 157). Values for 5a/b are intermediate. Alternatives 5a-c rank somewhere in the middle in terms of EFH protection for highly vulnerable species/life stages, and Alternative 5d ranks last . For highly vulnerable New England species, Alternatives 5a-d rank toward the bottom half of the alternatives (Table 160). On the other hand, these alternatives rank high for overfished and H vulnerable species, especially 5(c). Species that exceed 10% of total EFH area in any of the alternative 5 closure options are cod (J) and haddock (J) in 5b, plaice (J) in 5a and 5c, ocean pout (J) in 5a and b, and smooth skate (A) in 5a, b, and c. None of the species with M/H vulnerable EFH reached this EFH value in 5d.

None of the Alternative 5 closed area options rank nearly as high as the other habitat closed area alternatives in terms of the environmental characteristics that are associated with the 15 species and life stages with EFH that is highly (H) vulnerable to the adverse effects of mobile, bottom-tending fishing gear. Alternatives 5b and 5d score slightly below 5a and 5c for guilds and assemblages (Table 163-Table 164). Assemblage scores for all four Alternative 5 options were very similar. The analysis of substrate data revealed very little rocky bottom in any of these proposed closed areas.

Ecosystem Effects: Trophic Guilds, Species Assemblages and Indicator Species
The dominant trophic guilds in the four Alternative 5 options are benthivores and planktivores (Table 150). Planktivore biomass in these four alternatives is higher than in the other closed area options, but absolute biomass indices for the other guilds are low (Table 143). Shrimp and fish-eater biomass is especially low in 5b and c. Benthivore biomass is also lower in all the Alternative 5 options than in any of the other alternatives. The biomass values for amphipod-eaters and piscivores are comparable to the other alternatives. Elasmobranchs and demersal finfish species account for most of the species assemblage biomass in the four Alternative 5 closed area options (Table 153). Principal groundfish species only make up 9-11% of the total assemblage biomass (compared to 21-22% in Alternative 3). Pelagic species are more abundant in

the Alternative 5 area closures. Individual Alternative 5 closures with high percent-of-total biomass values are 5b (elasmobranchs, principal pelagics, and demersal species), and 5d (principal pelagics) (Table 152). Of the six individual benthic species that were analyzed, redfish, ocean pout, and longhorn sculpins account for most of the total biomass in Alternative 5(a), sculpins in 5(b), sculpins, and ocean pout in 5(c), and redfish and ocean pout in 5(d) (Table 154 and Table 155). Lobsters were more abundant in 5b and c than in any of the other alternatives. Relative to total biomass of each species in the NAAA, the biomass of sculpins in 5b and c is higher than in any of the other alternatives. The same is true for sea ravens in 5b, ocean pout in 5d, jonah crabs in 5a and d, and lobsters in 5c.

Summary
These alternatives would almost exclusively new habitat protection in open access areas without continuing any significant continued protection within the existing groundfish closed areas (Table 166). Protection of high value rocky substrate would be negligible. None of the Alternative 5 closed area options rank nearly as high as the other habitat closed area alternatives in terms of the environmental characteristics that are associated with the 15 species and life stages that are highly (H) vulnerable to the adverse effects of mobile, bottom-tending fishing gear (See Gear Effects Evaluation and Adverse Impacts Determination Sections). Alternative 5(b) ranks higher for sediments and slightly less than 5(a) for guilds and assemblages (Table 162-Table 164). Assemblage scores for all four Alternative 5 options were very similar. Biomass indices for bottom feeding and bottom dwelling fish are intermediate for all four options. Summed across eight metrics, none of the Alternative 5 options rank as high as the other six closed area alternatives.

5.3.8.3.3.4 Alternative 6 - Closed Areas consistent with the FW 13 Scallop Closed Area Access Program

This alternative is consistent with the Controlled Area Access Program under Framework 13 to the Scallop FMP. By allowing mobile, bottom-tending gear to operate in the FW 13 scallop access areas, but not in the remaining 80% of the existing groundfish closed areas, the Council will be able to integrate scallop and groundfish habitat management measures more effectively. However, these areas were not originally closed to protect habitat, and were not identified as areas with high habitat value, this alternative may not minimize the habitat effects of fishing as effectively as other habitat closure alternatives that are designed for that purpose.

Size and Substrate
This alternative is larger (4,041 nmi²) than any of the other habitat alternatives and overlaps entirely with all portions of the three existing groundfish closed areas on Georges Bank that have been off-limits to groundfish gear (including scallop dredges) since these closures were established in December 1994, as well as the entire Western Gulf of Maine groundfish closed area, which was established in May 1998 (Table 139 and Table 140). For this reason, all bottom habitats contained within this alternative have been un-disturbed by groundfish trawls and scallop dredges (but not clam dredges and shrimp trawls) for 5-9 years. (See Section 4.3.6.1.2 for a detailed description of fishing activity that occurred within these four areas during 1998-2001 by gears that are exempted from the groundfish closed area regulations). Over 60% of the area is sand, with 16% gravelly sand, 10% muddy sand, and 10% mud (Table 142). Even though only 2% of the area is “gravel” (rocky bottom), it accounts for 17% of all the gravel in the NAAA (Table 141). Thus, in terms of rocky substrate, this alternative ranks below Alternatives 3 and 4, above all the Alternative 5 options, and about the same as Alternatives 10a and 10b.

EFH
Because it larger than the other closure alternatives, total and percent-of-total EFH area designated for all the species and life stages with moderately (M) and highly (H) vulnerable EFH within Alternative 6 is higher than in any of the other closed area alternatives (Table 143). On a per-unit-area-basis, however, the total EFH value for these species and life stages is relatively low (Table 157). Alternative 6 has a low area-scaled EFH value for all species with H vulnerable EFH, for New England species with H vulnerable EFH, and for overfished species with H vulnerable EFH (Table 157 and Table 160). Species with high amounts of vulnerable EFH (>10%) are cod (A, J), haddock (A,J), halibut (A,J), ocean pout (A), barndoor skate (A,J), smooth skate (A), winter flounder (A), and yellowtail flounder (A).

The Alternative 6 closed area option ranks below Alternatives 3a/b and 4 in terms of the substrates that are associated with the 15 species and life stages with EFH that is highly (H) vulnerable to the adverse effects of mobile, bottom-tending fishing gear (Table 162). This alternative ranks fairly high for high priority trophic guilds (Table 163) and species assemblages (Table 164), and although not as high as 10a and 10b.

Ecosystem Effects: Trophic Guilds, Species Assemblages and Indicator Species
The amphipod-eaters, benthivore, and shrimp and fish-eaters guilds are well represented in the proposed Alternative 6 closed area (Table 150). Owing primarily to its large size, this alternative contains higher percent-of-total biomass values for the piscivore, amphipod, and shrimp/fish eaters guilds than any of the other alternatives (Table 149). Elasmobranchs and demersal finfish species account for most of the species assemblage biomass in Alternative 6 (Table 153). Principal groundfish species make up 15% of the total assemblage biomass (compared to 21-22% in Alternatives 3 and 4) and pelagic species are not abundant. Again, due to its large size, this alternative accounts for the highest percent-of-total biomass values for the elasmobranchs, principal groundfish, and demersal finfish species (Table 152). Of the six individual benthic species that were analyzed, redfish account for 66% of the total biomass in Alternative 6 (Table 155). Relative to the total biomass of each species in the NAAA, the biomass values for redfish, longhorn sculpins, and sea ravens are fairly high (Table 154).

Summary
Alternative 6 would close five discrete areas on Georges Bank and in the Gulf of Maine with a total area that is larger than any of the other proposed habitat closure alternatives (Table 166). All of the habitat protection provided by this alternative would be in portions of the existing groundfish closed areas that have remained closed to most forms of mobile, bottom-tending fishing since these closures were first established 5-9 years ago. Most of the bottom in these areas is sandy; rocky bottom is of intermediate extent compared with the other alternatives. For species and life stages with EFH that is moderately or highly vulnerable to mobile, bottom-tending fishing gear, the total EFH area that is contained within this alternative is high, but after scaling for its large size, its EFH value is low. Biomass indices for bottom feeding and bottom dwelling fish are high. Summed across eight metrics, Alternative 6 has a high habitat value.

5.3.8.3.3.5 Alternative 10 – Compromise Habitat Closure Areas (Proposed Measure)

This action identifies several areas as habitat closures. This alternative was developed to incorporate areas that would benefit EFH, but not in the most productive fishing grounds currently available to fishermen. Both existing mortality closures and proposed habitat closures were modified to develop one alternative that closes sensitive habitat. In general, the alternatives suggest changing the eastern boundary of the Western Gulf of Maine closure, and modifying the

Nantucket Lightship closure. In addition, the access areas used in Framework 13 for Closed Area I were modified slightly. Lastly, the habitat closure proposals for Closed Area II, Jeffrey's, Bank, and Cashes Ledge were included in this alternative, with some modifications.

Size and Substrate

Alternatives 10a and 10b are very similar in size to most of the other habitat closed area alternatives (Table 139). Additionally both 10a and 10b overlap considerably (about 80%) with the existing groundfish closed areas, mostly in portions of the closures that were not opened to scallop dredging in 1999 and 2000 (Table 140). For this reason, the majority of bottom area contained within this alternative has been relatively un-disturbed by mobile, bottom-tending gear for 5-9 years. The seven discrete areas that make up these two alternatives are 58-60% sand, but there is a modest amount of mud and gravelly sand as well (Table 142). Even though only 4% of the area is gravel (rocky bottom), 19% of all the gravel in the NAAA is contained within these two alternatives (Table 141). The only alternatives that include more rocky bottom are 3a/b and 4.

EFH

Total percent EFH area values for all the M/H vulnerable species and life stages in these two alternatives are very similar to values in the other alternatives falling between the high value in alternative 6 and the low value in alternative 4 (Table 143). On a per unit area basis, Alternatives 10a and 10b rank higher than 3, 5b,c, and d, and 6 and lower than Alternative 4 for these species (Table 157). The EFH relative effectiveness scores for Alternatives 10a and 10b are the highest for species with highly vulnerable EFH, and New England species with highly vulnerable EFH. Alternatives 10a and 10b rank fairly low in terms of EFH protection for overfished highly vulnerable species (Table 160).

The Alternative 10 closed area option ranks below Alternatives 3 and 4 in terms of the substrates and species assemblages that are associated with the 15 species and life stages that are highly (H) vulnerable to the adverse effects of mobile, bottom-tending fishing gear but not in terms of trophic guilds (Table 162 and Table 163). Both options in Alternative 10 rank higher than any of the other Alternative 5 options for bottom sediments, trophic guilds and species assemblages (Table 162 through Table 164).

Ecosystem Effects: Trophic Guilds, Species Assemblages and Indicator Species

Both the benthic and shrimp/fish eaters guilds are well represented in the proposed Alternative 10 closures (Table 150). The percent-of-total biomass values for these two trophic guilds are considerably higher than for any of the other alternatives with the exception of Alternative 6 (Table 149). Elasmobranchs and demersal finfish species account for most of the species assemblage biomass in the two Alternative 10 options (Table 153). Principal groundfish species make up 17% of the total assemblage biomass (compared to 21-22% in Alternatives 3 and 4) and pelagic species are not abundant. Percent-of-total biomass values for elasmobranchs, principal groundfish, and demersal finfish species are high, but not as high as in Alternative 6 (Table 152). Of the six individual benthic species that were analyzed, redfish account for 74% of the total biomass in Alternative 10, more than in any of the other alternatives (Table 155). Relative to the total biomass of each species in the NAAA, the biomass values for the other five benthic species are low (Table 154).

Summary

These two alternatives are intermediate in size and are located mostly inside the existing groundfish closed areas (Table 166). They would both close approximately 500 nm^2 of open access area to bottom tending mobile gear mostly in an area south of Nantucket Island. These closures include some rocky substrate but not as much as Alternatives 3 and 4. Total and percent of total EFH values are intermediate, but the area scaled values are fairly high. The fish communities are composed primarily of bottom-feeding and bottom-dwelling fish. Overall, these alternatives have a high habitat value.

Habitat Metric	**Explanation**	**Low**	**Moderate**	**High**
Size	Area (nm^2)	2241	2637-3050	4038
Overlap A (Protection of open access areas)	Percent overlap with existing closed areas	>80%	57-69%	<10%
Overlap B (Continue existing closed area protection)	Percent overlap with non-FW 13 portions of closed areas	<10%	45-55%	>75%
Substrate	Percent rocky bottom	1-2%	4%	7-8%
Percent total EFH area[1]	Sum of EFH areas (nm^2) in closed area divided by total EFH area in NW Atlantic analysis area	5-5.4%	6.1-6.6%	7.8%
Per-unit-area EFH[1]	EFH areas (nm^2) in closed area divided by size of area, summed for all species	14.4-16%	17.2-17.7%	18.4%
Bottom feeders[2]	Sum of total biomass (wt/tow) in closed area divided by total biomass in NW Atlantic analysis area	NA	48-58%	76-82%
Bottom dwellers[3]	Sum of total biomass (wt/tow) in closed area divided by total biomass in NW Atlantic analysis area	NA	56-59%	64-71%

Table 165 - Criteria Used to Rank Habitat Metrics for Analysis of Habitat Closed Area Alternatives in Amendment 13

[1]*For species and life stages with moderately or highly vulnerable EFH*
[2]*For benthivore, amphipod-eaters, and shrimp/fish-eaters trophic guilds*
[3]*For principal groundfish and demersal finfish species assemblages*

Overlap B: Continue existing protection (overlap with existing groundfish closed areas)

5.3.9 Results of Non-Closed Area Habitat Analysis

5.3.9.1 Alternative 7 - Expand list of gears prohibited in closed areas

This alternative proposed to expand the list of fishing gears prohibited from use in the *existing year-round groundfish closed* areas to include shrimp trawls, herring mid-water trawls, clam dredges and pots and traps. These gear types are allowed in at least portions of the existing groundfish closed areas and, due to the nature of the gear and the potential for adverse impacts to groundfish habitat, it may be advantageous to prohibit these gears from use in these areas to better protect habitat. The Council selected to only list clam dredges as an additional fishing gear prohibited from use in the groundfish closed areas.

In some cases, when the gears originally considered under this alternative are used properly, no adverse impacts to habitat are expected (e.g. herring midwater trawls). When the gears are used improperly, however, adverse impacts may occur (e.g., herring trawls fishing on the bottom, tuna purse seines in contact with the bottom, etc.). Since it can be difficult to enforce regulations that the gear only be used properly, gear prohibitions may be an alternative to protect the habitat of the closed areas. In other cases, there may be inconclusive information on the nature of the effects some gears considered under this alternative may have on fish habitat.

This alternative could further reduce the potential for adverse impacts on EFH within the closed areas associated with these gear types. It is difficult to quantify any potential reductions, however, due to lack of data. Both the lobster and shrimp fisheries are exempt from the mandatory logbook data reporting and, as such, activity data for these fisheries is sparse (Figure 146 and Figure 148 detail what data is currently available). Very few herring trips occurring inside the closed areas appear in the VTR database; only vessels with limited access groundfish permits would be likely to report their herring landings via this route. Therefore, it is difficult to assess the actual activity levels for these gear types inside the closed areas and any consequent impacts they may have.

The clam trips reported to the VTR database in 2001 are depicted in Figure 164Figure 150. There were a number of clam dredge trips within the boundaries of the Nantucket Lightship closed area, particularly in the northwestern corner. Habitat Alternative 6 can be used as a proxy for the existing year-round groundfish rebuilding closed areas because it covers the same traditional fishing grounds affected by the Council's motion to exclude clam dredges from the groundfish closed areas. Table 299 describes the proportional loss of surf clam/ocean quahog landings (bushels) by state and habitat alternative. According to that table, the areas within Alternative 6 impact the largest percentage of clam/quahog landings (6.8%). It is probable that those vessels would shift outside the closed area, but efficiency may be reduced in those areas. Assuming no displacement, approximately 6.8% of the clam trips (based on fishing activity in 2001) would be impacted from this measure. It is important to note that all the impacts (40%) come from vessels homeported in Massachusetts; none of the other states with surf clam landings would be impacted from this restriction.

The vulnerability analysis (Section 9.3.1.3) concluded a low impact for all gears mentioned in this alternative with the exception of shrimp trawls (type of otter trawl) and hydraulic clam dredges, which have an adverse impact on EFH. Figure 163 and Figure 164 illustrate the discrete use of shrimp trawls and hydraulic clam dredges inside the current year-round groundfish closed areas where use is prevalent.

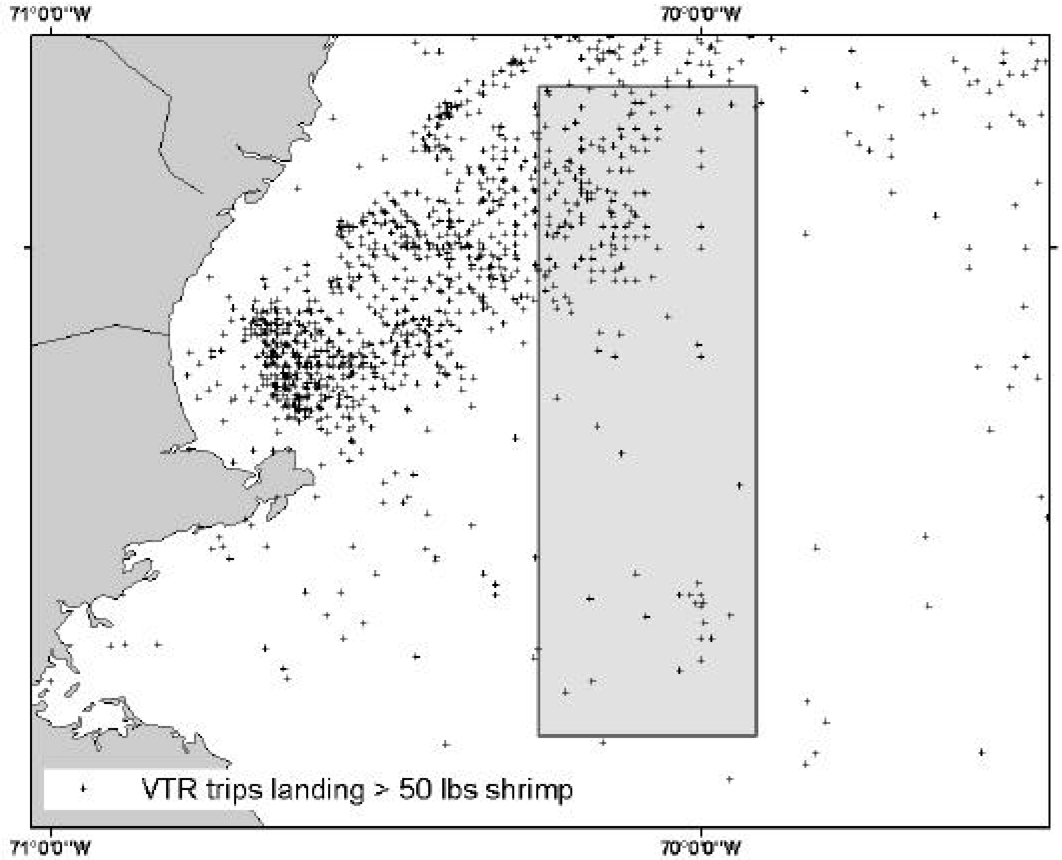

Figure 163 – Spatial distribution of shrimp trawl activity inside the existing year-round groundfish closed areas.

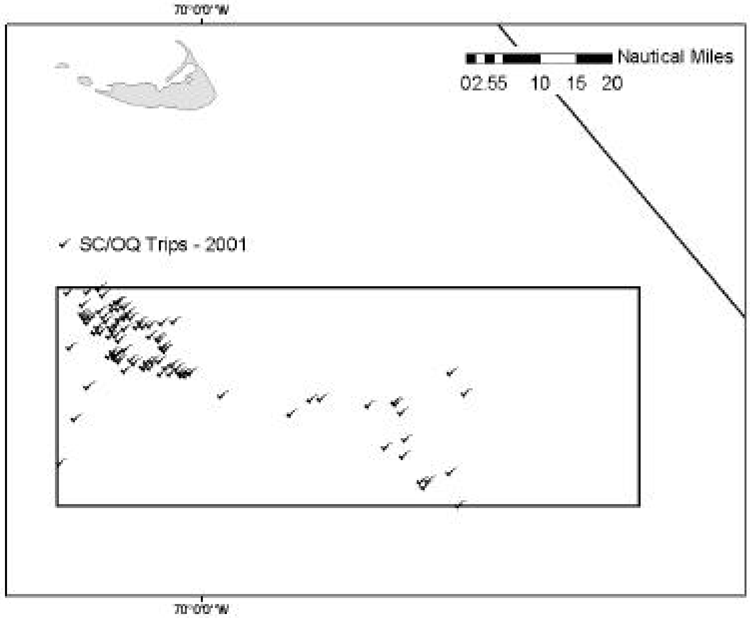

Figure 164 – Spatial distribution of clam dredge activity inside the existing year-round groundfish closed areas

The description of the EFH and environmental attributes within the existing groundfish closed areas (Closed Area I, II, Western Gulf of Maine and the Nantucket Lightship closure) have been evaluated under the No Action Habitat Alternative. Table 167 summarizes the sediment, EFH, and biomass information for these areas from the EFH metric analyses. This table has been extracted from several tables within Section 5.3.8.3.1. Keep in mind that this table summarizes all the closed areas combined, and the clam/quahog fishery only takes place within a portion of the Nantucket Lightship closure.

AREA	5,853 nm2					
SEDIMENT	Bedrock	Gravel	Gravely Sand	Sand	Muddy Sand	Mud
% of total	*0%*	*19%*	*25%*	*8%*	*6%*	*2%*
EFH	Refer to Table 143					
GUILD	Benthic	Ampshr	Plankt	Pisc	Shrifis

% of total	*37*	*30*	*18*	*11*	*9*	*9*

Table 167 – Summary of the environmental attributes of the existing groundfish closed areas (No Action Habitat Alternative) that are consistent with the areas prohibited for Habitat Alternative 7.

5.3.9.2 Alternative 8 – Restrictions on the use of rockhopper and/or roller gear

Scoping comments received by the Council and NMFS suggested the Council should consider restricting the use of both rockhopper and roller trawl gear as a measure to minimize adverse impacts on habitat potentially associated with otter trawl gear. Although rockhopper and roller trawl gear function differently and may interact differently with benthic habitats, we have very little information with which to distinguish the effects of these gears on EFH. For the purposes of this analysis and consideration of management alternatives, these two gear types are considered together. If, as we get additional information on these gear types, we determine that their effects on EFH are different and can be distinguished, the Council would be able to manage rockhopper and roller gear separately.

The inshore restricted roller gear area

Rockhopper and roller gear are currently only managed in an area specified as the Inshore Restricted Roller Gear Area (Figure 165).

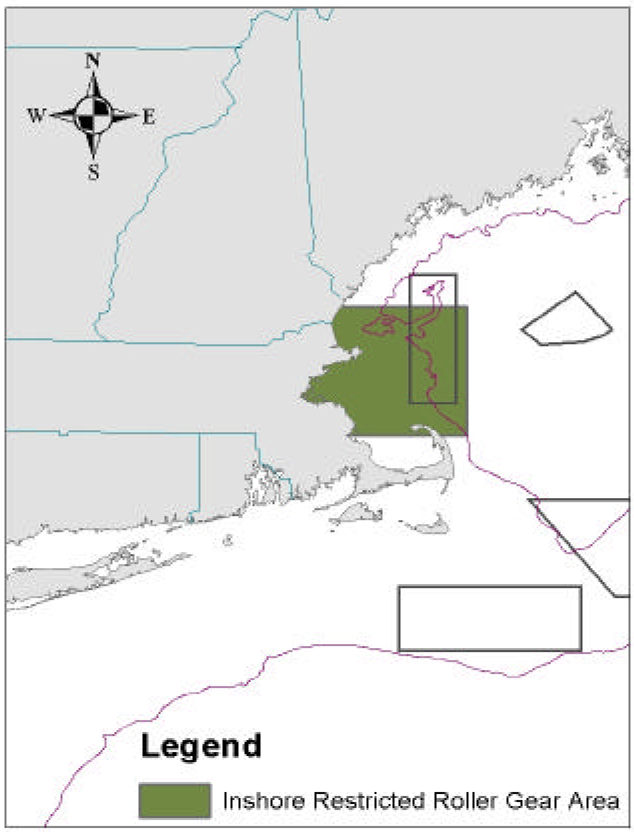

Figure 165 - Inshore restricted roller gear area, which imposes a 12 inch limit on roller gear

In this area, the diameter of any part of the trawl footrope, including discs, rollers, or rockhoppers, must not exceed 12 inches. Anecdotal evidence suggests that this restriction has had an impact on fishing behavior, keeping trawl vessels off of areas of high relief bottom. It has been further suggested that this has led to a reduction in fixed gear conflicts, as gillnet gear has been fished in the very rocky areas that trawlers can no longer access. There is no quantifiable evidence to support the anecdotal evidence, but the anecdotes do strengthen the comments received in scoping which indicate that limiting rockhopper size could have a very positive impact on sensitive high-relief bottom types.

Areas potentially impacted by limits on rockhopper or roller use

To assess the areas potentially affected by a restriction on roller/rockhopper gear, trawl survey data are analyzed. The trawl survey, which uses 16-inch rockhoppers and 4-inch cookies, includes a code for each trawl that indicates if a hang or snag occurred on that tow. Three levels of hang/snag are recorded: minor damage to the gear, requiring repairs; major damage to the gear, requiring extensive repairs; and, significant damage to the gear rendering it unusable for future tows. The position of the haulback from each tow reporting a hang/snag is plotted in the figures below. These data do not indicate or imply the cause of the snag or hang. They are intended instead to show areas of known high relief bottom, and to provide a picture of the general areas where roller gear and rockhoppers *may* be used.

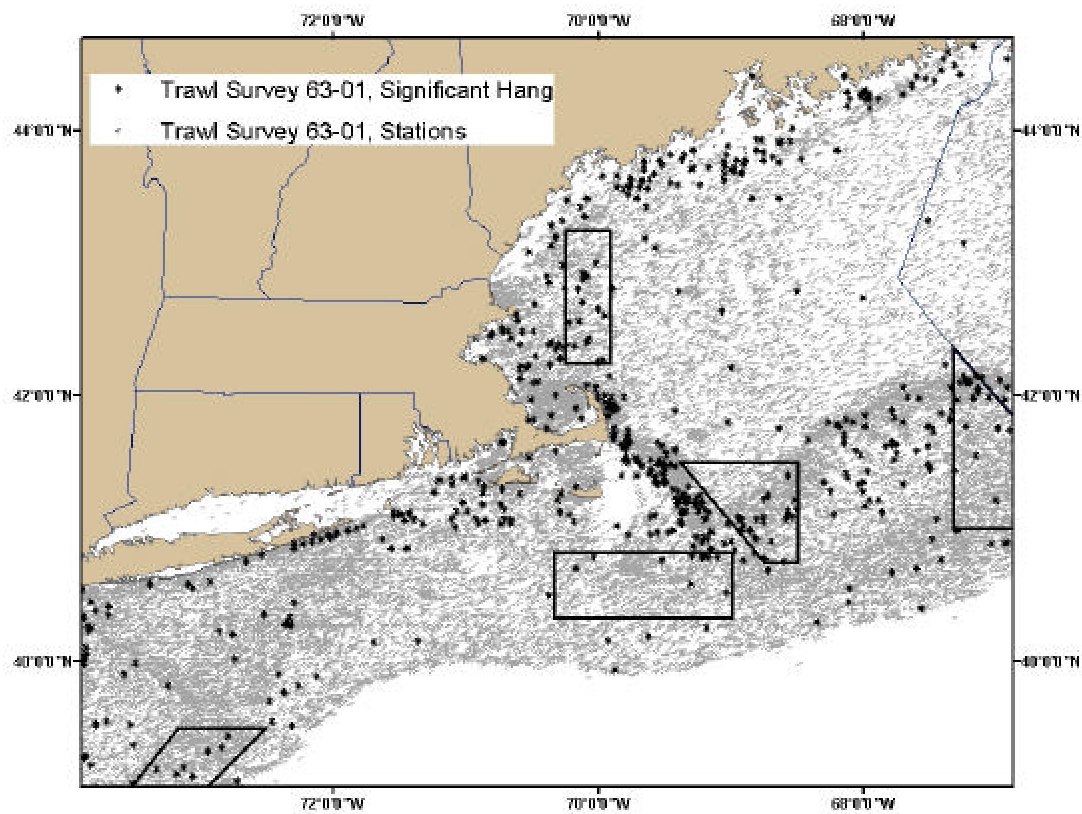

Figure 166 – All trawl survey stations 1963-2001 overlaid with locations of significant gear damage

Figure 166 shows the location and density of known hangs (using 16 inch rockhoppers). The positions in the background are the locations of all trawl surveys (sampling locations); these show the areas that are not sampled and those that are sampled less densely. To correlate these data with known high-resolution substrate data, the hangs were plotted with a two nautical mile buffer around each haul-back location which was then plotted with the Stokesbury and Harris (2002) data on known cobble and boulder locations (Figure 167 and Figure 168).

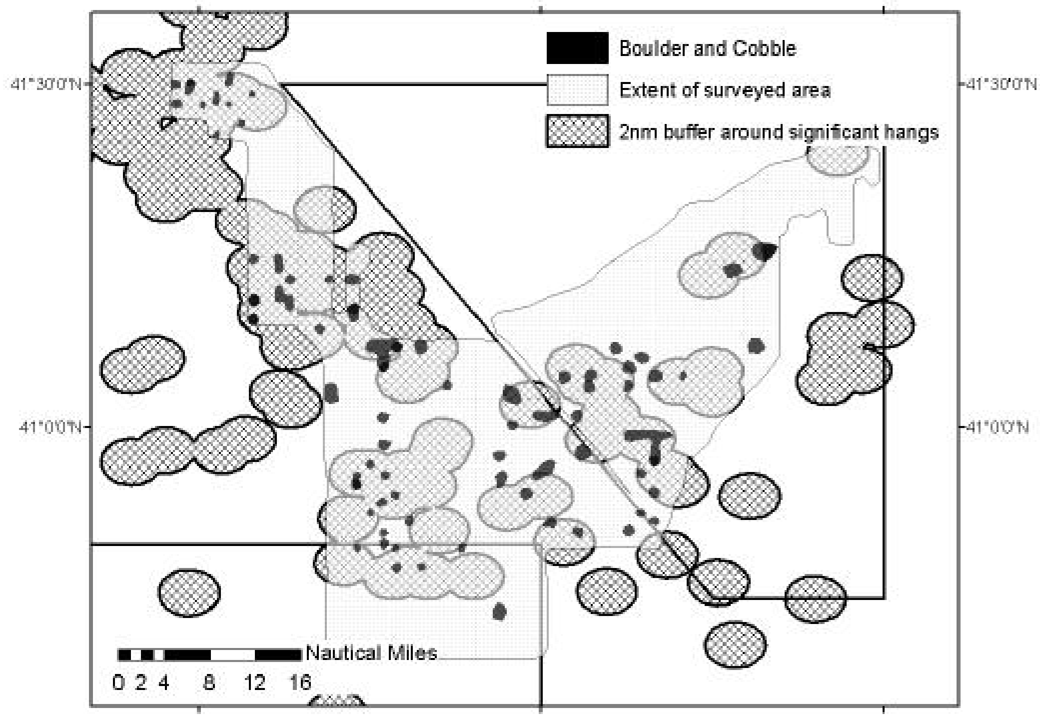

Figure 167 – 2nm buffer around significant hangs with sediment data, Nantucket Shoals area

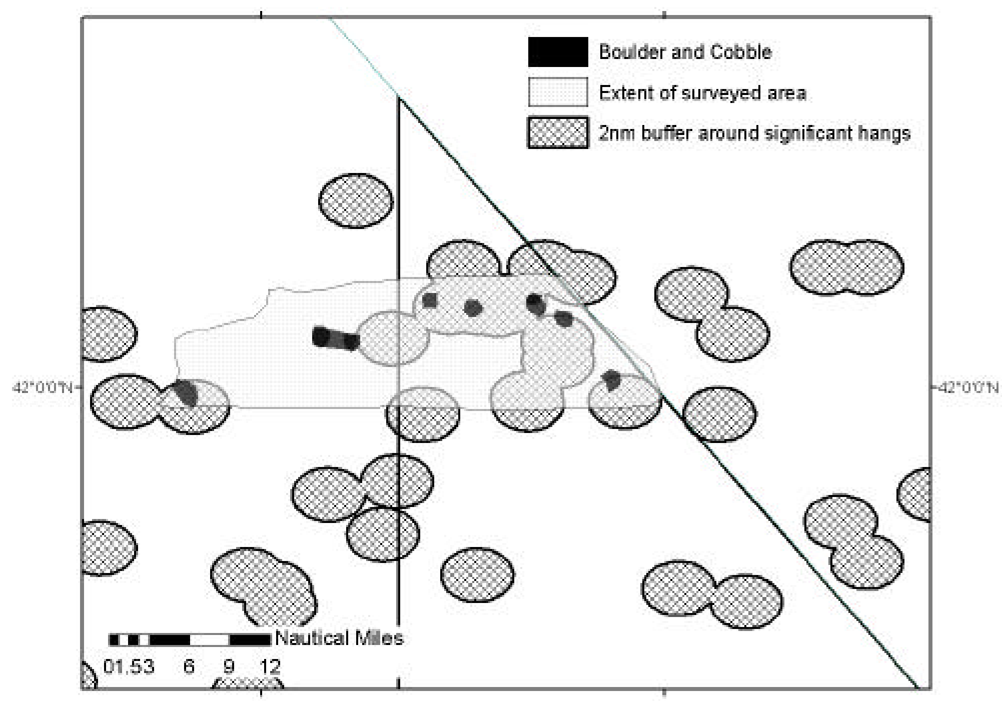

Figure 168 – 2nm buffer around significant hangs with sediment data, Northern Edge area

Visual inspection indicates a slight correlation between the existence of known cobble and boulder patches with the general vicinity in which a known hang occurred. Based on this, it is likely that the presence of clusters of known hangs is indicative of areas where rockhopper gear is employed.

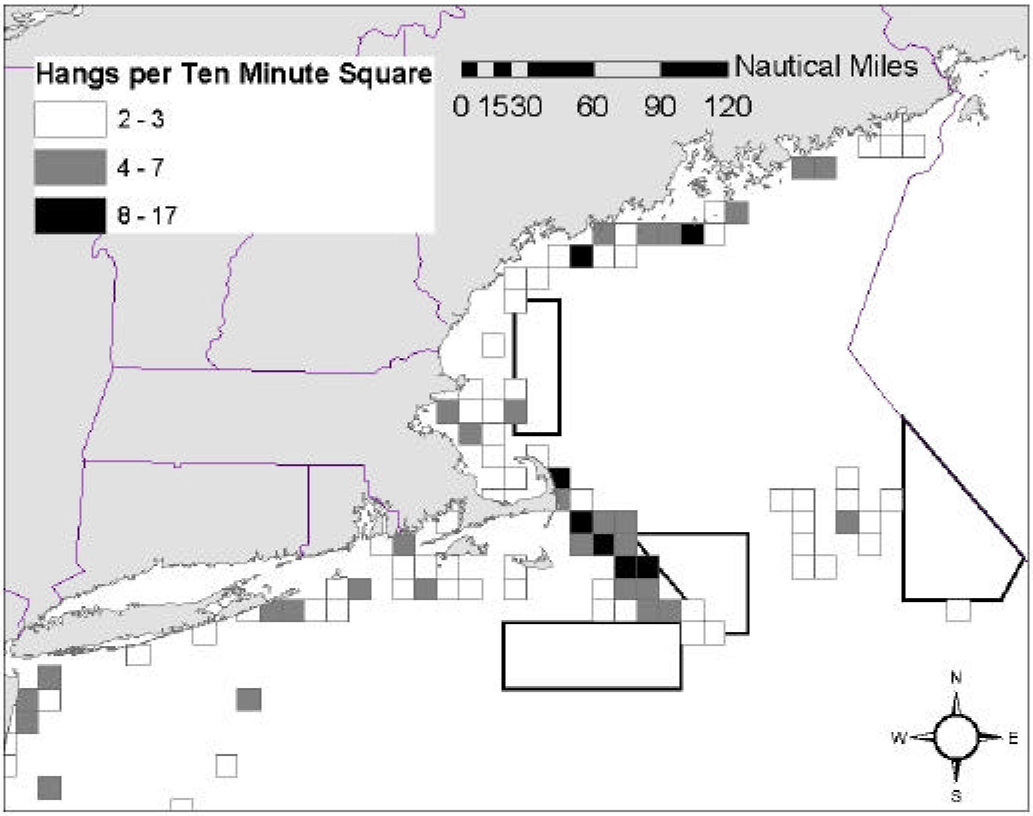

Figure 169 – Hangs per ten minute square

If this is the case, Figure 169 may capture the primary areas for use these gears (though, due to the geographic delineation of the binned data, some important areas are likely not represented). The total area encompassed inside these areas potentially affected by limits on rockhopper/roller gear is just over 4,800 sq nautical miles. *In no way does this imply that any specific amount of area will or may be off limits to fishing based on rockhopper restrictions.* It is simply a way to quantify the amount of area that *could* be impacted if restrictions are enacted.

Given that this area, based on trawl survey hangs (16 inch rockhoppers), is likely to include a large percentage of the high-relief bottom found in the traditional fishing grounds, and coupled with the anecdotal evidence which suggests a move away from high relief bottom in the Inshore Restricted Roller Gear Area (12 inch rollers), a significant habitat benefit may result from restrictions on rockhopper gears below 16 inches.

If the Council determines it is advantageous to implement some form of restrictions on the use of rockhopper and roller trawl gears, the following represent a range of alternatives from least restrictive to most restrictive.

5.3.9.2.1 Alternative 8(a) - Prohibition on the use of any rockhopper and roller trawl gear with a diameter larger than the current maximum size (estimated to be between 31” and 36”).

The intention of this alternative is to freeze the maximum size of rockhopper and roller trawl gear at the maximum size currently in use. It is estimated that the maximum size rockhopper and roller trawl gear currently being used in the New England region is in the range of 31” to 36” in diameter. To determine the actual current maximum size, the Council would contact fishermen and gear distributors in the New England region and assess the largest size rockhopper and roller gear that they currently use or stock and sell. Once the maximum allowable size is capped, the Council and NMFS would be able to direct research and information collection to explore and document the specific effects of various sizes of rockhopper and roller trawl gear on the variety of important groundfish habitats. The Council would use this new information to determine if the maximum allowable size should be further reduced, maintained at current levels, or the size restriction eliminated altogether. This research would also target the differences between rockhopper and roller gear, and whether differential size restrictions would be the most appropriate management tool to minimize the effects of these gear types on EFH.

This alternative would have no effects on current fishing practices, although it would provide time for the Council to collect information and assess the effects of different sizes of rockhoppers and rollers currently in use. This alternative would protect areas not currently accessible with mobile gear from being fished in the future until the Council is able to make a determination on whether further rockhopper and roller gear restrictions are needed. This alternative would not provide any additional habitat protection above current levels. The current maximum size of rockhopper and roller gear in use may be too big to allow for any habitat protection (i.e., there may be no areas currently inaccessible with current rockhopper and roller gear).

5.3.9.2.2 Alternative 8(b) - A prohibition on the use of otter trawl groundgear with a diameter larger than 22”

This alternative prohibits the use of rockhopper and roller trawl gear with a diameter larger than 22”. Cookies or other types of groundgear configurations, including rockhoppers and rollers, 22” in diameter or smaller would be allowed. The implementation of this alternative could be via an immediate prohibition on all gear larger than 22”, or could be done through a step-wise reduction over several years (see 8(e)). This alternative is very similar to Alternatives 8(c), but uses 22” as the maximum allowable size rather than 12”, which would allow some configurations of rockhopper and roller trawl gear to continue to be fished.

Setting limits on the maximum allowable size for rockhopper and roller gear could protect rough bottom habitats from any adverse impacts associated with these gear types by limiting the areas where mobile bottom gear can access. Long-term this could be more economically efficient for the groundfish fishery. As the maximum allowable diameter of the gear decreases, more and more rough bottom habitat would be protected from impacts associated with mobile bottom gear. This alternative would offer more flexibility to the fishing industry than the 12” or 5” options.

There may be short-term costs to the industry from the loss of gear and having to buy new gear to comply with the measures. There may also be short-term production losses (less fish and less revenue) to the industry, although these losses will be mitigated as stocks recover. The smaller the maximum allowable size for this gear, less area and opportunities will remain for the fishing industry. Also, the remaining areas accessible for fishing may be fished harder as more fishermen move into these areas and this could reduce the availability of suitable habitat in open areas. There may be more competition between fishermen for accessible bottom, with the potential for increases in gear conflicts. This alternative would protect less area than the 12", 8", or 5" options.

5.3.9.2.3 Alternative 8(c) - A prohibition on the use of otter trawl groundgear with a diameter larger than 12", consistent with the existing maximum size limit in near shore portions of the Gulf of Maine.

This alternative prohibits the use of rockhopper and roller trawl gear with a diameter larger than 12". Cookies or other types of groundgear configurations, including rockhoppers and rollers, 12" in diameter or smaller would be allowed. The implementation of this alternative could be via an immediate prohibition on all gear larger than 12", or could be done through a step-wise reduction over several years (see 8(e)). This alternative allows some configurations of small rockhopper and roller trawl gear to continue to be fished.

This alternative would be an extension of a limit already in place in the Inshore Restricted Roller Gear Area.

5.3.9.2.4 Alternative 8(d) - A prohibition on the use of all rockhopper and roller trawl gear.

This alternative prohibits the use of all rockhopper and roller trawl gear with a diameter larger than 5". Cookies 5" in diameter or smaller would be allowed. The implementation of this alternative could be via an immediate prohibition on all gear larger than 5", or could be done through a step-wise reduction over several years (see 8(e)). Five inches was identified as an option for the maximum size of cookies based on gear commonly stocked by gear distributors and used by fishermen in New England. Cookie size is reported to be somewhat variable and may vary from 3" to 5" in diameter. A 4" limit or any other limit less than 5" may be smaller than the current size cookie commonly used and may cause economic impacts to the industry that are out of proportion with the expected benefits of the action.

5.3.9.2.5 Alternative 8(e) - A stepwise reduction in the maximum allowable size of otter trawl groundgear.

This could be considered a stand-alone alternative, or it could be incorporated into any of the reductions/prohibitions on rockhopper and roller gear size considered as alternatives above except for alternative 8.1.

This alternative proposes a prohibition on the use of any otter trawl groundgear as follows: From the start of the fishing year (beginning May 1) that begins after the implementation of Amendment 13 to the Groundfish FMP, the maximum allowable diameter of groundgear will be reduced in stages over a period of six years from a maximum of 24 inches to a maximum of 5 inches. For example, if Amendment 13 to the Groundfish FMP is implemented to begin on May 1, 2003, the maximum size of groundgear will be 24 inches from May 1, 2003 until April 30, 2005; it will then be reduced to 12 inches from May 1, 2005 until April 30, 2007, reduced to 8 inches until April 20, 2009. Thereafter, beginning May 1, 2009, the maximum size of groundgear will be 5 inches. The specific dates are examples of a reduction program that could be used. While the May 1 start dates make sense as the beginning of the new fishing years, the program could be compressed over less time, stretched out over a longer timeframe, or the individual time periods that each size limit is in force could be varied. Also, the specific gear size increments could be different (e.g., from a maximum size of 30" to 24", then to 18", and then to 12").

This alternative would decrease fishable area gradually. This may provide increased flexibility to both the fishing industry and management. By delaying implementation of the most stringent gear size restrictions, this alternative should spread out the short-term compliance costs and provide time for the industry to adjust to changing regulations. Setting limits on the maximum allowable size for rockhopper and roller gear could protect rough bottom habitats from any adverse impacts associated with these gear types by limiting the areas where mobile bottom gear can access. Long-term this could be more economically efficient for the fishery. As the maximum allowable diameter of the gear decreases, more and more rough bottom habitat would be protected from impacts associated with mobile bottom gear.

If reducing the maximum allowable size of rockhopper and roller gear is necessary to conserve fish habitat, this alternative would delay much of the anticipated benefits of the measure. There will be short-term costs to the industry from the loss of gear and having to buy new gear to comply with the measures. There may also be short-term production losses (less fish and less revenue) to the industry, although these losses will be mitigated as stocks recover. The smaller the maximum allowable size for this gear, less area and opportunities will remain for the fishing industry. Also, the remaining areas accessible for fishing may be fished harder as more fishermen move into these areas and this could reduce the availability of suitable habitat in open areas. There may be more competition between fishermen for accessible bottom, with potential for increases in conflicts.

5.3.9.3 Alternative 9 – VMS on all groundfish vessels

This would be a critical step in getting high resolution data on the distribution of fishing effort. While there may be issues and problems that need to be resolved before VMS could reasonably be required on all groundfish vessels, addressing these issues and fixing the problems should be a high priority of Amendment 13. The specifications on how best to implement this alternative will be left to the Groundfish Committee and PDT. Ideally, this alternative would be implemented in a way that is not unnecessarily burdensome to groundfish vessels (e.g., eliminate the 24 hour/day operating requirement).

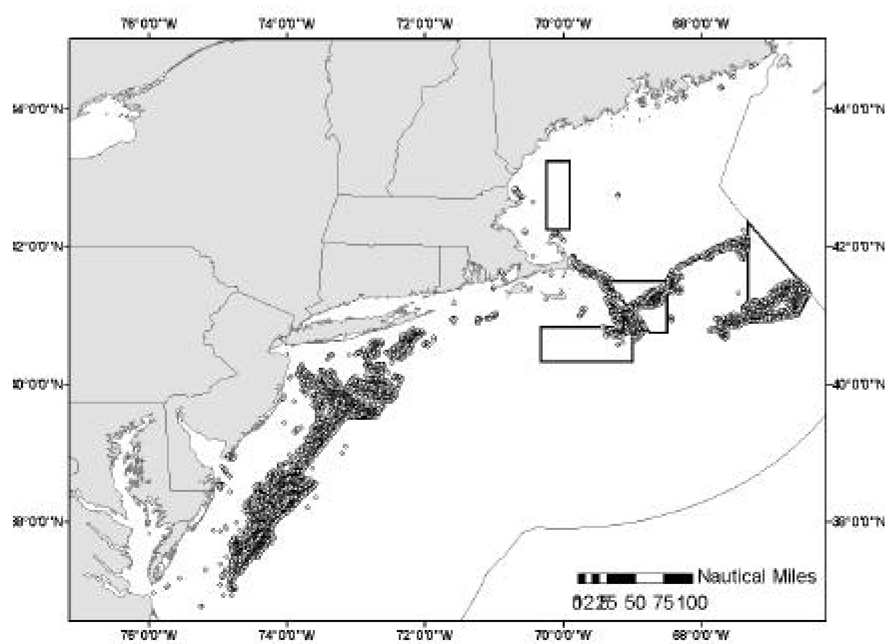

Figure 170 – VMS data from 2000 showing spatial extent of actual scallop fishery

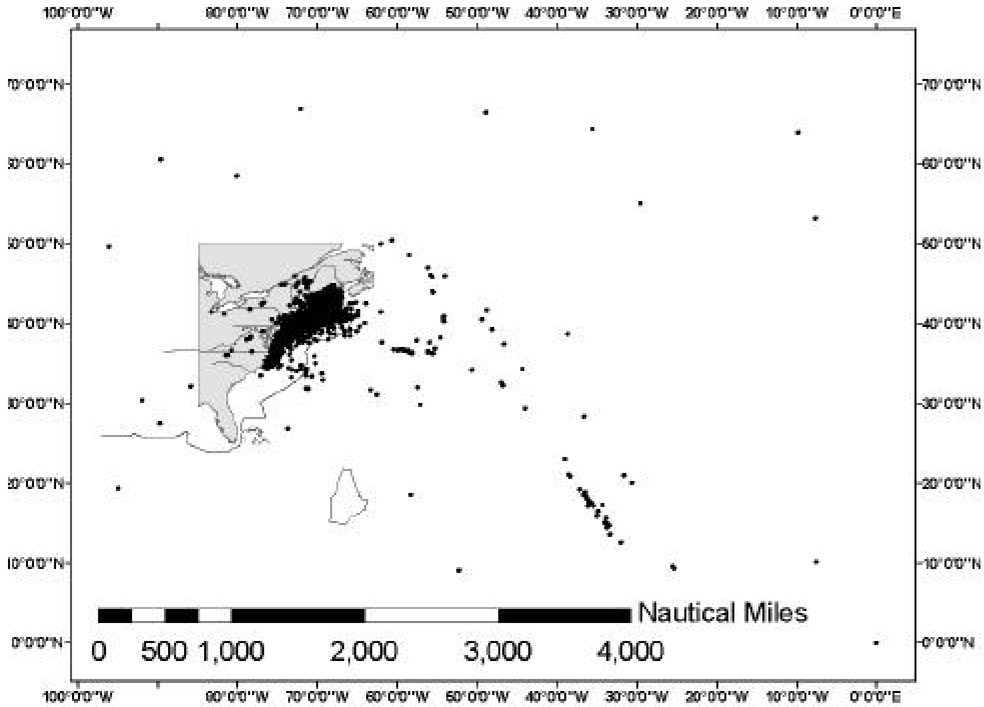

Figure 171 – VTR data (unfiltered) from 2001 showing spatial extent of reported groundfish fishery

The intention of this alternative is not enforcement, but rather much needed and important data collection on the location, frequency and intensity of fishing activities, which has direct application and relevance to understanding potential impacts to habitat. Figure 170 and Figure 171 show the disparity between existing spatial data sets. Implementation of VMS on all groundfish vessels would provide the Council with much needed accurate information on the distribution of fishing effort. Without implementation of the VMS requirement, progress on habitat research and management will be hampered, slowing our ability to answer many habitat-related questions.

5.3.10 Practicability Analysis

The legal EFH provisions state that each FMP shall identify and "minimize to the extent practicable adverse effects on such habitat caused by fishing…" In this context "practicable" was interpreted to man "reasonable and capable of being done in light of available technology and economic considerations."

The EFH regulations at 50 CFR 600.815(a)(2)(iii) provide guidance on evaluating the practicability of management measures:

"In evaluating the practicability of the identified habitat management measures, Council should consider the nature and extent of the adverse effect on EFH and the long and short-term costs and benefits of potential management measures to EFH, associated fisheries and the nation consistent with national standard 7. In determining whether management measures are practicable, Councils are not required to perform a formal cost/benefit analysis."

A practicability analysis of EFH measures in a fisheries management plan is supposed to weigh the economic and social costs (and benefits) against the benefits to habitat of EFH protections. However, the ecological costs and benefits (of taking or not taking action) are substantially harder to evaluate. In essence, the benefits of specific actions to protect or restore habitat are not all readily quantifiable in the same units as the costs (dollars). It is therefore very difficult to make direct quantitative comparisons and hence give specific quantified answers to questions of practicability. This is in part due to uncertainty in the direct effects of fishing gears on habitat function and the lack of information on the relationships between habitat function and the productivity of managed and non-managed species. This uncertainty and lack of information is both a consequence of and exacerbated by the complexities of the ecological relationships and processes involved.

5.3.10.1 Assessing Practicability

There is no preferred methodology for conducting the practicability analysis. Therefore, the Habitat Technical Team and members of the Groundfish PDT have worked together to combine habitat, economic, and social analysis of the habitat alternatives to determine their overall practicability. The habitat closed area alternatives have been analyzed in a more quantitative fashion by incorporating habitat, economic, and social information described in earlier sections of the document. The non-closed area habitat alternatives are analyzed in a more qualitative manner. This analysis synthesizes some of the conclusions from the habitat analysis, the socio-economic impact analysis, the biological and ecological impacts, as well as issues such as compliance with National Standards or MSA in general that are described in other parts of the document.

Specific practicability factors relevant to the EFH Final rule requirements were used to determine if each action is reasonable and capable of being done in light of available technology and economic considerations, and will not impose unreasonable burdens on the fishing industry (Table 168). Four primary components have been extracted from the full analysis to assess the practicability of the habitat management alternatives.

Practicability Factor	Relevance to 50 CFR 600.815(a)(2(iii)	Description
Net economic change to fishery	The long and short-term costs and benefits of potential management measures to associated fisheries and the nation	Industry-level impacts to groundfish, scallop, monkfish and other fisheries
Equity of potential costs among communities	The long and short-term costs and benefits of potential management measures to fishing communities	Short-term impacts on coastal subregions
Differences in EFH Value	The nature and extent of the adverse impact on EFH and the long and short-term costs and benefits of potential management measures to EFH (direct impacts)	Directionality of change in amount and type of area, vulnerable or adversely impacted EFH and complex sediment types
Population effects and ecosystem changes	The long and short-term costs and benefits of potential management measures to EFH (indirect impacts)	Directionality of change in amount and type of important species guilds and species assemblages

Table 168 – Description of four (4) primary analytical components used to determine practicability

5.3.10.2 Assessing Environmental Consequences/Impacts and Practicability with Limited Information

According to information included and evaluated in this document (see Gear Effects Evaluation, Vulnerability of EFH to Bottom-Tending Fishing Gears, and Adverse Impact Determination Sections), there is some understanding in the Northeast U.S. that a relationship exists between the type and intensity of fishing and effects on habitat. For some species, there is also some understanding of the links between exploited populations and habitat in terms of ecological functions. However, there is little or no understanding of how habitat degradation (past, present and future) affects the productivity of managed species populations. According to a provisional framework outlined in Auster (2001), it would seem that the types of management measures needed for preventing, mitigating, or minimizing adverse effects of fishing on EFH are a mixture of preventative and corrective measures and the precautionary approach. The types of actions the author suggests be taken under each of these approaches are as follows:

Preventative approach: restrict effort or gear or use no-take marine protected areas (MPAs) to minimize effects of particular gear types on particular habitats.

Corrective approach: Adjust boundaries or change management measures on the basis of data on habitat recovery and links to population dynamics.

Precautionary approach: Designate no-take MPAs to protect long-lived and sensitive species in areas that do or potentially contain such taxa.

The Council will be considering similar issues and approaches in the upcoming Omnibus Habitat Amendment #2. Additionally, the Council's MPA Committee will be developing a policy and approach to MPAs for the Council's consideration in the near future.

5.3.10.3 Results

5.3.10.3.1 Net economic change to fishery

5.3.10.3.1.1 Potential revenue losses to groundfish, scallop, monkfish and other fisheries

Table 169 compares the short-term annual revenue impacts from lost landings (assuming no displacement of effort to other areas) to all fisheries of each habitat closed area alternative implemented as either a Level 1 closure (total prohibition on all gears) or a Level 3 closure (prohibition on mobile, bottom-tending gear only). Table 170 summarizes the same information by fishery on a percentage basis. Total economic impacts, including lost employment and collateral income losses in the processing sector and in other associated industries and activities (again assuming no displacement of effort), are summarized in Table 171.

Revenue losses would be highest as a result of implementing habitat closed area 5b, nearly reaching $40 million, while either Alternative 6, 10(a) or 10(b) would reduce these impacts by nearly ten-fold. The remaining six alternatives would have impacts ranging from $15 to $25 million. Closing an area to just mobile, bottom-tending gear would reduce total revenue losses by 21-23% for Alternatives 3a, 3b, and 4. For the Alternative 5 variants the revenue losses are reduced by as much as 46% (Alternative 5c). Much of this reduction in revenue impact is associated with savings of monkfish gillnet and lobster trap fishery revenues. A Level 3 habitat closure would have the largest mitigating effect on Alternatives 6, 10A, and 10B.

Alternative	Level 1	Level 3	Reduced Impact ($)	Reduction in Loss (%)
3a	23,237,630	18,098,883	5,138,747	22%
3b	22,042,497	17,498,370	4,544,127	21%
4	15,599,271	11,970,233	3,629,039	23%
5a	20,251,311	11,730,565	8,520,746	42%
5b	38,394,041	24,470,730	13,923,311	36%
5c	25,289,695	13,780,403	11,509,291	46%
5d	16,738,994	9,208,996	7,529,998	45%
6	3,990,045	1,436,544	2,553,501	64%
10A	4,162,998	1,345,937	2,817,060	67%
10B	3,768,834	1,570,002	2,198,832	58%

Table 169-Summary of Revenue Impacts by Alternative and Habitat Closure Level

5.3.10.3.1.2 Potential Revenue loss for groundfish based on fishing year 2001

A "no-displacement" assessment was completed to get a measure of the groundfish landings that were generated from within the closed area alternatives compared to the entire area. The Vessel Trip Report (VTR) database was used to identify trips taken place in fishing year 2001 that reported landings within the geographical area. Reports that did not include a location, or were misreported were excluded from this analysis. Revenues associated with any area inside a proposed closed area were assumed to be lost

(See section Economic Impacts Analysis for EFH Alternatives for a complete description of the methods used in this analysis). Thus, the revenue losses generated from the no-displacement methods are upper bound or worst case estimates. Fishing year 2001 was selected because that is the most current data available (FY 2002 data was not available in time for this analysis).

In general, closing the areas within Alternative 5b would cause the greatest potential loss in revenues, followed by Alternatives 5c, 3a, and 3b (Table 170). Because they include so much of the existing groundfish closed areas, Alternatives 6, 10a and 10b would produce the lowest losses in groundfish revenues.

5.3.10.3.1.3 Potential revenue loss for other fisheries based on fishing year 2001

The same "no-displacement" analysis method described above was also completed for other fisheries in the region. The potential impacts on the surf clam/ocean quahog fishery were evaluated separately because landings in the clam VTR are reported in bushels rather than pounds, so an average price from dealer records was assigned and applied to the bushel amounts.

Scallop Fishery
The losses in revenues for the scallop fishery are the same if the habitat closed areas are implemented as Level 1 or Level 3 closures. Closing the areas within Alternative 5b would cause the greatest potential loss in revenues (assuming no displacement of effort to areas outside the closed areas), followed by Alternatives 3a and 3b. Closing areas identified in Alternatives 5a, 5c, 5d, 6, 10a, and 10b would have very little effect on scallop revenues.

Monkfish Fishery
The monkfish fishery could potentially face a loss of revenues between 2% and 18% under any of the habitat closed areas being considered as Level 1 closures. The potential revenue losses are lower if the habitat closed areas are implemented as Level 3 closures. According to this analysis, alternative 5(a-d) would impact the monkfish fishery more than the other alternatives, assuming no displacement of effort.

Other fisheries
The fisheries included in the "other" category of this analysis include: dogfish, skates, lobster, shrimp, herring, mackerel, tunas, and clams. For the practicability analysis, the relative loss in revenues for squid, whiting, fluke, scup, and black sea bass have also been added to this overall calculation. (Refer to the Economic Impacts of EFH Alternatives Section for a more complete discussion of the impacts on each of these fisheries). The potential loss of revenues for all these fisheries combined is significant. Similar to the results for monkfish, Alternative 5(a-d) effect more revenues, assuming no displacement of effort. These impacts are considerably reduced if the closures are implemented as Level 3 closures.

Alt.	Potential Revenue loss for Groundfish Species		Potential Revenue loss for Other fisheries					
	Percent of revenue contained inside a closed area versus total (based on 2001 VTR data assuming "no displacement")		Scallop		Monkfish		Other fisheries

Table 170 – Summary of benefits and economic costs associated with closure alternatives.
**Proposed measure*

There are three types of economic and social costs that could result from the ten closed area habitat alternatives being considered in Amendment 13. First, if the existing groundfish closed areas, or portions of these areas, remain off limits to gears capable of catching groundfish, then habitat closures inside these areas provide no additional EFH protections in the foreseeable future and no economic or social costs. This situation applies to the No Action alternative (Habitat Alternative 1) and Habitat Alternative 6. Alternative 2, which claims incidental habitat benefits from new measures proposed in Amendment 13, would not result in any EFH-related economic or social costs either.

Second, if groundfish stocks recover to the point that some of the existing closed areas could be opened to the groundfish fleet, but access is denied in portions of the groundfish closures that have been designated as habitat closures, there will be significant negative impacts on affected fisheries and communities, unless the habitat closures increase the productivity of fishery resources in open areas. This situation could pertain to alternatives 3, 4, 6, and 10. Finally, habitat closures that extend beyond current groundfish closed area boundaries will potentially result in negative economic and social impacts whether the groundfish areas are opened to other fisheries or not. This situation would apply primarily to Alternative 5 and less so to alternatives 3, 4, and 10.

Alternative	3a	3b	4	5a	5b	5c	5d	6	10a	10b*
Sales Impacts	102.5	97	68.2	71	150.3	99.3	66.4	15.6	13.7	12.4
Income Impacts	29.8	28.2	20	20.8	43.1	29.6	19.3	4.4	5.4	4.9
Total Economic Losses	132.3	125.2	88.2	91.8	193.4	128.9	85.7	20	19.1	17.3
Employment Losses	1457	1391	982	939	2134	1298	857	211	194	175

Table 171 - Impacts of habitat closed area alternatives on gross sales (millions of dollars), income (millions of dollars), and employment (jobs) in the New England coastal region
** Proposed measure*

The impacts on gross sales, income and employment in the New England coastal region would be greatest for Alternative 5b while either Alternative 6, 10A or 10B would reduce these impacts by nearly ten-fold. The impacts are likely to be upper-bound estimates since the potential impacts of Level 3 versus Level 1 were not estimated. In between these extremes, the remaining alternatives form two clusters, each having similar impacts. Specifically, Alternatives 3a, 3b and 5c form one of these clusters with gross sales impacts of about $100 million, income losses of about $30 million, and employment losses of up to 1,400 jobs. Alternatives 4, 5a, and 5d form a second cluster with lower impacts of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs.

5.3.10.3.2 Equity of potential costs among communities

5.3.10.3.2.1 Short-term impacts on coastal subregions

There are numerous ways to describe the potential social impacts of closed areas on ports and fishing communities. This practicability analysis focuses on the relative distribution of gross sales impacts by sub-region in New England to give an indication of how they would be distributed in different parts of the region. Alternatives which have a disproportionate impact on just a few sub-regions are less practicable than alternatives with impacts that are dispersed across a number of sub-regions (Table 172). Impacts to gross sales measure the total losses associated with a reduction in harvest on all industries impacted by fishing in the region (processing, transportation, etc.). The general patterns of total economic impacts from each proposed alternative are described for each of ten sub-regions (Table 172). (Refer to the Economic Impact and Social Impact Assessment Sections for a more detailed analysis of the losses by port and vessel characteristic classes and expected changes to income and employment).

Most of the gross sales impacts that would result from the proposed habitat closed area alternatives are concentrated in the four Massachusetts sub-regions (Table 172). Sub-regions in Maine, New Hampshire, Rhode Island, and Connecticut would be not be greatly affected. The New Bedford area (all ports within Bristol County, MA but principally the city of New Bedford itself) would be the most impacted, bearing about two-thirds of the gross sales impacts under Alternatives 3a, 3b, and 4, 23-42% under Alternatives 5a, 5c, and 6, and 15-18% under 5d, 10a and 10b. This level of impact is largely due to the importance of New Bedford groundfish, monkfish, and scallop fisheries - fisheries that would be most affected by habitat closures. Note that with the exception of monkfish, both scallops and groundfish would be affected even by a Level 3 closure (Table 170) so that while the magnitude of the impact would be reduced by a Level 3 closure, the proportional impact on the New Bedford sub-region would not be likely to change and may be even greater than the impact in other sub-regions. Other than New Bedford, impacts in the Gloucester area would also be severe (43-45%) for Alternatives 5c and 5d, moderate (27%) for 5a and 5b, and less severe (14-19%) for Alternatives 3a, 6, 10a and 10b. The Boston and Cape and Islands sub-regions would be less severely impacted (<20% for all alternatives).

Sub-Region	Alt 3a	Alt 3b	Alt 4	Alt 5a	Alt 5b	Alt 5c	Alt 5d	Alt 6	Alt 10a	Alt 10b*
Upper Mid-Coast Maine	0.4%	0.4%	0.4%	2.3%	0.6%	1.7%	2.5%	1.8%	2.2%	2.3%
Lower Mid-Coast Maine	2.0%	2.1%	3.1%	2.6%	0.7%	1.6%	1.8%	10.9%	5.5%	6.6%
Southern Maine	0.0%	0.0%	0.1%	1.2%	0.5%	0.1%	0.4%	0.3%	0.6%	0.7%
New Hampshire Seacoast	1.3%	1.3%	1.5%	4.8%	2.6%	0.6%	4.3%	9.6%	11.8%	8.3%
Gloucester Area	14.1%	9.4%	6.5%	27.5%	26.8%	42.9%	45.0%	19.3%	13.7%	14.4%

Table 172- Relative Distribution of Gross Sales Impacts by Sub-Region in New England
**Proposed measure*

5.3.10.3.3 Differences in Habitat Value Between Closure Alternatives

Three primary components have been incorporated in the overall habitat evaluation portion of the practicability analysis: 1) size and percent overlap with groundfish closed areas, 2) EFH value, and 3) amount of rocky substrate. The size/overlap component includes the area of each alternative in square nautical miles, and the percent of each alternative that occurs inside the existing groundfish closed areas. The EFH component includes the percent of total moderately (M) and highly (H) vulnerable adult and juvenile EFH area contained within each proposed closure for the twelve groundfish species managed under the Multispecies FMP, and the percent of total M/H vulnerable adult and juvenile EFH area for all species within the closures. It also includes per-unit-area EFH values for all species with M/H vulnerable and with only H vulnerable EFH. The substrate component of the practicability analysis includes the amount of bedrock and "gravel" (in square nautical miles) contained in each area. These two substrate types best represent "hard-bottom" habitats, which are structurally more complex and support the growth of emergent epifauna. The "gravel" substrate classification includes pebbles, cobbles, and boulders.

The area closure options range from about 2,200 to 4,000 square nautical miles in size (Table 173). The ten alternatives under consideration range from no overlap to 100% overlap with the existing groundfish closures. Alternatives 3a, 3b, and 4 overlap 53-69% and alternatives 10a, and 10b overlap 81-82%. Alternative 6 is the largest proposed closed area and overlaps entirely with the existing closures. The habitat closed area alternatives contain 5.6-8.5%of the total amount of vulnerable EFH area for groundfish in the NWAA. Percent-of-total EFH values for all species with M/H vulnerable EFH range from 5.1% to 7.8%. Alternative 6 contains the highest amount of total EFH for both categories. The substrate component, however, demonstrates a large disparity among the alternatives, with 3(a), 3(b), 4 and 6 containing more rocky substrate than the others, followed by alternatives 10a and 10b.

Table 174 summarizes the effectiveness of the various closure options based upon the amount (summed area) of designated EFH they contain relative to their size. Alternative 5(c) contains the most EFH for species and life stages with medium and highly vulnerable EFH per square nautical mile of closed area. Alternatives 3a-b, 4, 5a-b, and 10b would provide roughly equivalent EFH protection on a per-unit-area basis. Alternatives 5(d), 6 and 10a ranked the lowest on a per square nautical mile basis.

Alt.	Size and Overlap with Groundfish Closures		Vulnerable Groundfish EFH	Vulnerable EFH for All Species	Rocky Substrate
	Area closed in square nautical miles	Percent of closure that overlaps with current groundfish closed areas	Percent of total EFH contained in each area for all Groundfish species with "highly or moderately vulnerable" EFH	Percent of total EFH contained in each area for all species with "highly and moderately vulnerable" EFH	Total amount of Bedrock and "Gravel" enclosed by each alternative (measured in square nm)
3(a)	2913	53%	7.0%	6.1%	196
3(b)	2821	55%	6.7%	5.9%	196
4	2241	69%	5.6%	5.0%	154
5(a)	3032	5%	7.0%	6.3%	21
5(b)	3073	5%	7.0%	6.6%	15
5(c)	3022	0%	7.2%	6.6%	32
5(d)	3098	6%	5.8%	5.4%	38
6	4041	100%	8.5%	7.8%	92
10(a)	3050	82%	7.5%	6.5%	109
10(b)	2810	81%	7.0%	6.2%	109

Table 173 - Summary of benefits and costs associated with the EFH protection of each closure alternative.

Alternatives	Medium/Highly Vulnerable Species	Highly Vulnerable Species Only
	Sum*	Sum*
3a	17.35	5.50
3b	17.25	5.41
4	18.40	5.75

6	16.01	4.67
10a	17.70	5.95
10b**	18.14	6.04

Table 174 - Relative Effectiveness of Amendment 13 Habitat Closed Area Alternatives in Protecting EFH for Two Categories of Species and Life Stages

**Values are total EFH area (in square nautical miles) per square nautical mile in each closed area summed for all moderately and highly vulnerable species and life stages in the Northeast region, and for only the highly vulnerable species and life stages in the region.*

***Proposed measures*

5.3.10.3.4 Population effects and ecosystem values

Distribution of biomass by type of trophic guild and species assemblage

The EFH Final Rule stipulates that fishery management measures be evaluated in terms of their direct and indirect effects on essential fish habitat, or the direct and indirect benefits of proposed habitat protection measures in meeting the provision of the Magnuson-Stevens Act to minimize the effects of fishing on EFH. The previous section of this Practicability Analysis considered the more direct benefits of the ten proposed habitat closure alternatives on EFH. This section evaluates the indirect benefits or ecosystem effects of these closures on EFH by examining the fish communities that occupy them (Table 175).

Alt.	Trophic Guilds*			Species Assemblages *	
	Bottom Feeders	Amphipod Feeders	Shrimp and Fish Feeders	Principal Groundfish	Demersal Finfish
3(a)	42%	11%	24%	22%	49%
3(b)	42%	11%	23%	21%	49%

Table 175 - Percent composition of total biomass (summed mean wt/tow by ten minute squares of latitude and longitude) within each proposed habitat closed area for three trophic guilds and two species assemblages during 1995-2001
(Two guilds and three assemblages not shown).*
*** Proposed measure*

Bottom-feeding fish accounted for most of the total biomass in all the proposed closed areas and would therefore benefit the most from management measures that minimize the adverse impacts of fishing on EFH. This result confirms the importance of habitat closures that protect benthic invertebrate prey populations, which are the food source for benthic-feeding fishes. Fish that feed exclusively on other fish and on plankton were more abundant in the four Alternative 5 options. Species and sizes of fish that feed on shrimp and smaller fish are also important components of the fish fauna in alternatives 3a, 3b, 4, 6, 10a and 10b.

Principal groundfish species (cod, haddock, redfish, pollock, two species of hake, and five species of flounder) accounted for a greater proportion of the finfish biomass in alternatives 3a, 3b, and 4, but were also important components of the fauna in proposed closures 6, 10a, and 10b. These species made up a relatively small percentage of the fish biomass in the Alternative 5 options. A large group (many species) of demersal (bottom-dwelling) finfish species accounted for about 50% of the fish biomass in all the alternatives.

These results indicate that habitat closed areas would be practicable as management measures to protect assemblages of bottom-feeding and bottom-dwelling finfish, especially alternatives 3a, 3b, 4, 6, 10a, and 10b. Fish populations in the four Alternative 5 closures were ecologically more diverse and included pelagic as well as demersal species.

5.3.10.3.4.1 Alternative 1 (No Action)

Net economic change to fishery – Since this alternative would simply maintain the existing groundfish closed areas, there are no new costs associated with it. It also would not impose any additional regulations on the industry since the same measures would be in place as in fishing year 2001.

Equity of potential costs among communities - It is not expected that the industry or fishing dependent communities would be impacted in any additional way from the status quo habitat alternative.

Differences in EFH Value - While this alternative does not close areas solely for habitat protection, it does provide some measure of protection to EFH in the region. This protection is reduced by the impacts of bottom tending mobile gears that are exempted from the groundfish closures (see Alternative 7) and by the fact that these closures will last, in their present configurations, only as long as they are needed to help restore depleted groundfish stocks. This alternative may be practicable in the short term because it will maintain habitat benefits that have accrued inside the closed areas since they were first established, at no cost to the industry, but it will not protect habitats as effectively as other measures that are designed specifically for that purpose and which will remain in place for indefinite periods of time. Continued habitat modification consistent with ongoing trends may occur if this alternative is selected.

Population effects and ecosystem changes – The analysis of fish community composition in the existing groundfish closed areas was not carried forward into the Practicability Analysis because the groundfish closed area do not constitute habitat closed areas and thus would provide no long term protection for fish that reside in these areas.

5.3.10.3.4.2 Alternative 2 (Proposed measure)

Alternative 2 aims to minimize the adverse effects of fishing on EFH through the use of the resource management measures in Amendment 13. Amendment 13 includes a number of proposed management measures that will severely reduce habitat impacts (both long- and short- term) through reductions in fishing effort (days-at-sea), gear modifications, trip/catch limits, time/area restrictions, and capacity reduction alternatives, among other things. The resource management alternatives that provide significant habitat benefits in Amendment 13 may minimize the adverse effects of fishing to the extent practicable even though their economic and social costs are high. Since there are no additional social or economic impacts associated with the use of this alternative as a habitat protection alternative, it is a practicable habitat management alternative.

5.3.10.3.4.3 Alternative 3

Net economic change to fishery - The two options being considered under this alternative would close approximately 1100-1200 square nautical miles of open access ocean bottom on Georges Bank and in the Gulf of Maine to fishing by certain gear types. The potential groundfish revenue loss (assuming no displacement of effort that occurred inside the areas during 2001) that would result from either of these alternatives is high (16-17% Level 1 and 13-14% Level 3). The potential loss in scallop revenues (6.5%) is not as high as in Alternative 5b, but is higher than any of the other alternatives. The potential loss in monkfish revenue is moderate (5-6% Level 1 and 3% Level 3), but much lower than in the Alternative 5 closures. The distribution of impacts in other fisheries is about the same as for monkfish.

Equity of potential costs among communities - These two closure alternatives would heavily impact the New Bedford area, with minor effects on the Gloucester and Cape and Islands sub-regions. No other sub-regions within New England would be significantly impacted.

Differences in EFH Value – Both options under this alternative are about the same size as most of the other proposed habitat closures and overlap nearly 60% with the existing groundfish closures. They would close approximately 1100-1200 square nautical miles of open access ocean bottom on Georges Bank and in the Gulf of Maine to mobile, bottom-tending gear. The amount of rocky substrate in Alternatives 3a and 3b is higher than in any of the other proposed habitat closures except Alternative 4. Percent-of-total EFH values for groundfish species and for all species with EFH that is moderately (M) or highly (H) vulnerable to the adverse effects of fishing in Alternatives 3a and 3b are intermediate between the high values in Alternative 6 and the low values in Alternatives 4 and 5d. On a per-unit-area basis, EFH values for species with M and H vulnerable EFH, and with H vulnerable EFH, are also intermediate. Overall, both alternatives 3a and 3b are beneficial from a habitat standpoint because they add significantly more sensitive habitat protection from relatively small closures. The ability of these closed areas to minimize the adverse impacts of fishing on EFH is high.

Population effects and ecosystem changes – The proportions of bottom feeding fish and principal groundfish species are high in these two alternatives, indicating that they would offer a high degree of protection to these elements of the ecosystem. The proportions of amphipod and shrimp/fish-eaters guilds are moderate. Demersal finfish species account for almost half of the species included in the analysis, as they do in all the other alternatives.

Summary - Overall, owing to their high economic costs and disproportionate community impacts, these two alternatives are not practicable, despite the fact that they would do a relatively good job of protecting EFH, bottom-feeding fish, and principal groundfish species, and contain more high value rocky substrate than most of the other alternatives.

5.3.10.3.4.4 Alternative 4

Net economic change to fishery – The potential revenue losses associated with this habitat closure are slightly less than Alternatives 3a and 3b for all four fishery categories.

Equity of potential costs among communities – This alternative would heavily impact the New Bedford area, with minor effects on the Cape and Islands sub-region. No other sub-regions within New England would be significantly impacted.

Differences in EFH Value – This proposed habitat closed area is smaller than all of the other closure alternatives, but it does overlap fairly significantly (69%) with the existing groundfish closed areas and would therefore only close 700 square nautical miles of open access area to mobile, bottom-tending gear. Because there is a high degree of overlap between alternatives 3a/b and 4, the sediment compositions of the three alternatives are very similar. The amount of rocky substrate in Alternative 4 is high, but not quite as high as in Alternatives 3a and b. Because it is so small, Alternative 4 contains a lower percentage of total EFH area for the 23 species with moderately (M) and highly (H) vulnerable EFH, and for 12 groundfish species with M/H vulnerable EFH, than any other proposed habitat closure. On a per-unit-area basis, however, the total EFH value for all species with M/H vulnerable EFH is higher than in any of the other alternatives. For species with H vulnerable EFH, the area scaled EFH value is moderate. This proposed closure has a high overall EFH value because it would more effectively protect high priority, rocky habitat and vulnerable EFH than larger closures.

Population effects and ecosystem changes – The proportions of bottom feeding fish and principal groundfish species are high in this alternative, indicating that it would offer a high degree of protection to these elements of the ecosystem. The proportions of amphipod and shrimp/fish eaters guilds are moderate.

Summary - The economic costs of closing the areas included in this alternative would be fairly high and, like Alternative 3, it would heavily affect New Bedford. It is a small area, however, has a high per-unit-area EFH value, would protect bottom-feeding fish and principal groundfish species, and contains more high value rocky substrate than most of the other alternatives. It also would close less open access fishing area than Alternative 3. However, due to the disproportionate social and economic cost to one sub-region and the overall high economic cost, it is not a practicable habitat management alternative.

5.3.10.3.4.5 Alternative 5

Net economic change to fishery – The four Alternative closure options would generate significant losses in groundfish revenue, especially if implemented as a Level 1 closure in area 5b. Losses in scallop revenue would be high in Alternative 5b as well, but not in the other Alternative 5 closure options. Losses in monkfish and other fishery revenue would also be high. From a regulatory standpoint, these alternatives are less practicable because they include closed areas in the Mid-Atlantic region, which may not be necessary to protect New England species. Additionally, the Mid-Atlantic Council has determined that it is not necessary to implement year-round closures to protect species managed by the Mid-Atlantic Council. Qualitatively speaking, the costs associated (economic and political) with implementing these closures may outweigh the habitat benefits associated with closing them.

Equity of potential costs among communities – Economic impacts resulting from these four closure alternatives would be more evenly distributed among the four Massachusetts sub-regions than the impacts of alternatives 3 and 4. Alternative 5a would affect Gloucester and New Bedford to the same degree, 5b would primarily affect New Bedford and secondarily affect Gloucester, 5c would affect Gloucester more heavily than New Bedford, and 5d would primarily affect only Gloucester. Boston and the Cape and Islands sub-regions would be affected to a lesser degree (<20%) by all the alternatives.

Differences in EFH Value – All four options under this alternative are intermediate in size and either do not extend into the groundfish closures at all (5c), or only marginally (5a,b and d). For that reason, almost all the area that would be closed for habitat protection purposes is located in open access areas. The amount of rocky bottom in all the Alternative 5 options is very low. Percent-of-total EFH area for groundfish species and all federally-managed species in the Northeast region with M and H vulnerable EFH is low in 5d and intermediate in the other three options. Area scaled EFH values for species with M/H vulnerable EFH are high in 5c, low in 5d, and intermediate in 5a and b. Area scaled EFH values for species with H vulnerable EFH are low in 5d and intermediate in the other three options. Overall, of the four options, Alternative 5d would clearly provide the least amount of EFH protection and 5c the most. As a group, however, none of these alternatives would protect as much rocky substrate or vulnerable EFH as the others. They would also require closing a larger extent of open access fishing area than any of the other alternatives.

Population effects and ecosystem changes – Percent composition biomass indices show that the four closed area options in this alternative are low to moderate for benthivores and shrimp/fish eaters. Alternatives 5a-c include a high proportion of amphipod feeders and 5d a low proportion. Principal groundfish species make up a low percentage of the total species biomass in all four Alternative 5 closed area options.

Summary – None of these closed area alternatives are practicable. They would close over 2,500 square nautical miles of open access fishing area with very little rocky bottom. Economic impacts would be high and each closure option includes a closed area in the Mid-Atlantic, where New England groundfish species do not reside. EFH values are high in one of the proposed closures (5c), but not in the others, and bottom-feeding fish and principal groundfish species are not important components of the fish communities.

5.3.10.3.4.6 Alternative 6

Net economic change to fishery – Habitat Alternative 6 includes the portions of the existing groundfish closed areas that remained closed during the Scallop Framework 13 Controlled Area Access Program. By allowing mobile, bottom-tending gear to operate in the FW13 scallop access areas, but not in the remaining 80% of the existing groundfish closed areas, the Council will be able to integrate scallop and groundfish habitat management measures more effectively. However, these areas were not originally closed to protect habitat, and were not identified as areas with high habitat value, therefore this alternative may not minimize the habitat effects of fishing as effectively as other habitat closure alternatives that are designed specifically for that purpose. This is the only alternative that does not have significant revenue losses for the groundfish, monkfish, scallop, or "other fishery" categories. This is intuitive since most of this area was not accessible to these fisheries in 2001.

Equity of potential costs among communities – This alternative would affect New Bedford more than any other sub-region, but impacts would also be felt in Gloucester, the Cape and the Islands, and less so in New Hampshire and lower mid-coast Maine.

Differences in EFH Value – This is the largest of all the proposed habitat closed areas and coincides completely with portions of the existing groundfish closed areas that have been closed to groundfish and scallop gear for the past 5-9 years. No new habitat protection would be provided in open access areas. Despite its large size, this alternative does not contain very much rocky substrate. Because of its large size, Alternative 6 includes more total and percent total EFH area than the other nine alternatives for groundfish species and for all species with EFH that is M or H vulnerable to the adverse effects of mobile, bottom-tending fishing gear. On a per-unit-area basis, however, EFH values for species with EFH that is M or H vulnerable, or just H vulnerable to fishing, is low. This alternative would do more to extend the habitat benefits that have resulted from the groundfish closures and to protect vulnerable EFH than any other alternative without closing any new areas, but does not contain very much high value, rocky habitat and would not protect EFH as effectively as some of the smaller proposed closed areas that have higher per-unit-area EFH values.

Population effects and ecosystem changes – In terms of biomass, the fish community in Alternative 6 is composed of a lower proportion of benthivores than alternatives 3a/b, 4, and 10a/b, but a higher proportion than any of the Alternative 5 options. The proportion of shrimp/fish eaters is lower than in Alternatives 10a and 10b and higher than the other alternatives. The composition of amphipod feeders is high relative to the other alternatives. Principal groundfish species make up a smaller percentage of the fish community in Alternative 6 than they do in alternatives 3 and 4, more than in any of the Alternative 5 options, and about the same as in alternatives 10a and 10b.

Summary – This alternative is entirely included within the existing groundfish closed areas, thus it would not have any significant short-term economic impacts on the fishing industry. Community impacts are dispersed among several different sub-regions. It does not include as much rocky substrate as Alternatives 3 and 4, but because it so large, total vulnerable EFH area is higher than any of the other alternatives (but low on a per-unit-area basis). The composition of bottom-feeding fish and principal groundfish species is moderate. It is a practicable alternative, particularly considering that it will not close any new area, has little or no economic impact, and will allow for access to areas within the groundfish closures where scallops are abundant. However, the Council determined that Habitat Alternative 10, Option b better minimized the adverse effects of fishing on EFH.

5.3.10.3.4.7 Alternative 7 (Proposed measure)

Habitat Alternative 7 would expand the list of gears prohibited from use in the groundfish closed areas to include clam dredges. While little revenue data is available to analyze specific economic impacts for this alternative, the proportional loss of surf clam/ocean quahog landings by state is described in Table 299 (refer to results for Alternative 6). Based on data from 2001, 6.8% of total landings came from areas within the groundfish closed areas (exclusively in the Nantucket Lightship closed area). Furthermore, the results suggest that vessels from Massachusetts are the only vessels that would be impacted from this measure. The habitat benefits of this alternative are difficult to measure. Table 167 describes the EFH areas that could potentially benefit as a result of this measure, but in reality, this measure will only impact a portion of the Nantucket Lightship closed area where clam dredges are currently used. This measure will not have habitat benefits for the other groundfish closed areas since clam dredges are not used in Closed Area I, II or the Western Gulf of Maine. It is important to note that other gear types are still permitted in these areas which could reduce the overall habitat benefits of prohibiting clam dredges. Mobile, bottom-tending gears (clam dredges and shrimp trawls) can be expected to adversely impact benthic habitats, whereas fixed gear (pots and traps) and pelagic gear (mid-water trawls) have little or no effect on vulnerable benthic habitats. The practicability of prohibiting clam gear from these areas is relatively high because clam/quahog activity only occurs in a relatively small portion of the overall groundfish closed areas. However, 6.8% of the total revenues from 2001 came from within the closed areas, and all of that revenue is from vessels homeported in Massachusetts. This alternative is still considered practicable because it is likely that trips taken within the closures will be able to harvest the same amount of clams in areas outside the closures, however the efficiency of those trips is unknown as compared to the trips inside the closed areas.

5.3.10.3.4.8 Alternative 8

Habitat Alternative 8 includes a series of options that prohibit the use of different sizes of rockhopper and/or roller trawl gear on bottom trawls in New England. Although rockhopper and roller trawl gear function differently and may interact differently with different types of benthic habitats, there is very little information with which to distinguish the habitat effects of these gears, or to evaluate the habitat benefits that would result from limiting the use of different sizes of roller or rockhopper gear. Conclusions from the evaluation of the different options for this alternative vary from “no effects on fishing pressure and no additional habitat protection” to “direct, short-term costs to the industry and more protection for rough and complex bottoms.” This range of conclusions is obviously the result of a series of tradeoffs between the cost to the industry in gear modifications, potential loss of production, and potential habitat benefits. It may be concluded rather generally that the benefits to EFH may outweigh the costs to industry, making this alternative practicable. Furthermore, direct habitat benefits have not been demonstrated. The Council encourages further research into such gear modifications.

5.3.10.3.4.9 Alternative 9

Habitat Alternative 9 proposes the requirement for VMS on all vessels fishing for groundfish with a federal permit. More accurate information on where fishing effort is taking place would be a very beneficial tool for improving our understanding of species distribution and potential impacts on habitat. This alternative may not be practicable in the short term because of the high investment costs, but in the long term it may be a very useful tool for linking fishing effort and potential impacts on habitat.

5.3.10.3.4.10 Alternative 10 (Proposed measure)

Net economic change to fishery – Because 80% of the area included in Alternatives 10a and 10b is included as part of the existing groundfish closed areas (which were closed to groundfish and scallop fishing in 2001), closing them will result in minimal losses to the groundfish, scallop, monkfish, and other fisheries as compared to all the other alternatives under consideration (except Alternative 6). Closure of 10a to all gear (Level 1) will have a greater economic impact than closing it only to mobile, bottom-tending gear (Level 3). The same is true for other fisheries in both alternatives, but not as clearly. These two alternatives would leave various primary fishing grounds open to the industry, as compared to some of the other closure options that close areas in the Great South Channel and on Georges Bank.

Equity of potential costs among communities – Impacts of these two closures would be well distributed across New England. They would primarily affect New Bedford, Boston, and Gloucester with more or less equal impacts (14-18%) in each sub-region. New Hampshire would be less impacted (12%) and there would be minor (<10%) impacts in several other sub-regions.

Differences in EFH Value - Alternatives 10a and 10b are about the same size as most of the other closed area options, larger than Alternative 4 and smaller than Alternative 6. Most of the proposed closure areas (about 80%) fall within the existing groundfish closures, except for the modification to the Nantucket Lightship closed area, as well as the addition of the closures on Cashes Le dge and Jeffreys Bank in the Gulf of Maine. Alternatives 10a and 10b contain roughly the same amount of rocky substrate as Alternative 6, less than Alternatives 3 and 4, and more than any of the Alternative 5 options. EFH values, unsealed for differences in closed area size, are moderate for groundfish and for all species with M/H vulnerable EFH. Area scaled EFH values for species with M/H vulnerable EFH and species with H vulnerable EFH are high. Both of these alternatives would be effective at protecting vulnerable EFH, but would not protect as much rocky bottom as alternatives 3 or 4.

Population effects and ecosystem changes – Both of these alternatives include high proportions of benthic feeding and shrimp/fish eating fish and low proportions of amphipod eaters. The percent composition of principal groundfish species is moderate.

Summary – These two alternatives are mostly enclosed within the existing groundfish closures and thus include very little open access fishing areas. Economic impacts are very low and community impacts are dispersed throughout New England. Total EFH area values are moderate, but area-scaled EFH values are high. The amount of rocky substrate, relative to area, is higher then in Alternative 6 and the proportions of benthic feeding fish is high. Principal groundfish species composition is moderate. Overall, both of these alternatives are practicable. However, Option (a) does not provide the same level of long-term habitat protection to the existing Cod HAPC in Closed Area II as does Option (b). Therefore, Option (b) is the most practicable closed area alternative relative to the others under consideration.

5.3.11 EFH Assessment

5.3.11.1 Description of the Action

For a full description of the proposed action, please refer to Section 3.0.

5.3.11.2 Assessing Potential Adverse Impacts

5.3.11.2.1 Experts Opinion

See Types of Gear Effects in Gear Effects Evaluation and Vulnerability of Benthic EFH to Bottom-Tending Fishing Gears section. To summarize, positive and negative effects of otter trawls, scallop dredges, and hydraulic clam dredges from 32 of these publications are listed by substrate type in Table 176 - Table 179 along with recovery times (when known). Without more information on recovery times, it is difficult to be certain which of the negative effects listed in these tables last for, say, more than a month or two. In fact, it is difficult to conclude in some cases (e.g., furrows produced by trawl doors) whether the habitat effect is positive, negative, or just neutral. Despite these shortcomings in the information, the scientific literature for the NE region does provide some detailed results that confirm the previous determinations of potential adverse impacts of trawls and dredges that were based on the ICES (2001), NRC (2002), and Morgan and Chuenpagdee (2003) reports.

Physical Effects	**Recovery**
Doors produce furrows/berms	2-18 months
Repeated tows increase bottom roughness	
Re-suspension/dispersal of fine sediments	
Rollers compress sediments	
Smoothing of surface features	
Biological Effects	
Reduced infaunal abundance	Within 3 ½ months (1 of 2 studies)
Reduced number of infaunal species	Within 3 ½ months
Reduced abundance of polychaete/bivalve species	Within 3 ½ months (1 of 2 studies)
Increased food value of sediments	
Increased chlorophyll production of surface sediments	
Removal/damage of epifauna	
Reduced abundance of brittlestars	
Increased number of infaunal species	
Increased abundance of polychaetes	
Decreased abundance of bivalves	
Altered community structure	18 months

Table 176. Effects and Recovery Times of Bottom Otter Trawls on Mud Substrate in the Northeast Region as Noted By Authors of Eight Gear Effect Studies.

Physical Effects	**Recovery**
Doors produce furrows/berms	Few days – a year
Smoothing of surface features	Within a year
Re-suspension/dispersal of fine sediments	No lasting effects
Biological Effects	
Mortality of large sedentary and/or immobile epifaunal species	
Reduced density of attached macrobenthos	
Removal/damage of epifauna	
Reduced abundance of polychaetes	
Reduced abundance/biomass of epibenthic organisms	
Reduced biomass/average size of many epibenthic species	
Epifauna (sponges/anemones) less abundant in closed areas	

Table 177. Effects and Recovery Times of Bottom Otter Trawls on Sand Substrate in the Northeast Region as Noted By Authors of Twelve Gear Effect Studies.

Physical Effects	Recovery
Displaced boulders	
Removal of mud covering boulders and rocks	
Groundgear leave furrows	
Biological Effects	
Reduced abundance of attached organisms (sponges, anemones, soft corals)	
Damaged sponges, soft corals, brittle stars	12 months

Table 178. Effects and Recovery Times of Bottom Otter Trawls on Gravel and Rock Substrate in the Northeast Region as Noted By Authors of Three Gear Effect Studies.

Physical Effects	Recovery
Disturbed physical/biogenic structures	
Loss of fine surficial sediments	More than 6 months
Reduced food quality of sediments	Within 6 months
Biological Effects	
Reduction in total number of infaunal individuals	Within 6 months
Reduced abundance of some species (polychaetes/amphipods)	
Decreased densities of two megafaunal species	

Table 179. Effects and Recovery Times of Chain Sweep Scallop Dredges on Sand Substrate in the Northeast Region as Noted By Authors of Three Gear Effect Studies.

The following conclusions can therefore be reached:

1. Adverse and potentially adverse habitat impacts from bottom trawling occur throughout most of the NE region on a variety of substrates;

2. Adverse and potentially adverse habitat impacts from scallop dredging occur primarily in the Mid-Atlantic and secondarily on Georges Bank on sand, gravelly sand, and gravel substrates;

3. Adverse and potentially adverse habitat impacts from hydraulic clam dredging occur primarily in the Mid-Atlantic and secondarily in southern New England on sand substrates.

5.3.11.2.2 Determinations

New Bedford scallop dredges and Otter trawls will have a potential adverse effect on the EFH of species and benthic habitat types listed in Table 180. These species and life stages have been determined to be moderately or highly vulnerable to these gear types. In some cases the adverse effects may be significant (high vulnerability) and are denoted in Table 180 as well. For a detailed look at the full gear effects evaluation and adverse impacts determination, refer to Gear Effects Evaluation section in Volume II of the Amendment 13 FSEIS.

Species	Lifestage	Vulnerability to Otter Trawling	Vulnerability to Scallop Dredging	Depth in meters (EFH Designation)	Substrate (EFH Designation)
American Plaice	A	High	High	45-150	sand or gravel
American Plaice	J	Mod	Mod	45-175	sand or gravel

Table 180 – Summary species and life stage's EFH adversely impacted by otter trawling and scallop dredging (gears that adversely impact EFH used in the Scallop fishery).

5.3.11.3 Minimizing or Mitigating Adverse Impacts

In order to minimize and mitigate the adverse effects of the fishery on EFH the Council will implement Habitat Alternative 2 (Benefits of other Amendment 13 alternatives), Alternative 7 (Expand the list of gears prohibited in year-round closed areas to include clam dredges), and Alternative 10b (Compromise Habitat Closure Areas). Habitat Alternative 10b will prohibit groundfish gear from fishing in vulnerable areas containing the above benthic habitat types. Alternative 7 will prohibit clam dredges from accessing portions of groundfish closed areas they were permitted to access in the past. Additionally, Alternatives 2 will be implemented to further mitigate the adverse effects of the fishery on EFH.

5.3.11.3.1 Habitat Alternative 2

Some of the non-habitat-related management measures in Amendment 13 are likely to provide benefits to essential fish habitat in the region. This alternative will rely on the habitat benefits of other non-habitat management measures that are implemented in Amendment 13 to meet the EFH provisions of the MSA. Depending on which measures are adopted, those benefits may or may not satisfy the EFH provisions of the MSA. summarizes the expected habitat benefits of the proposed non-habitat management measures that are being considered by the Council in Amendment 13.

Alternative	Overall Habitat Impact	Feature	Description of Habitat Impact
Observer Coverage	Indirect benefits (+)	10% requested by 2006 for each gear type	If observers are able to collect data of interest to EFH management, increased coverage could indirectly benefit habitat.
(3.5) Alternatives to Control Capacity	Positive Impact (+)	DAS can be transferred with restrictions and new measures for "reserve days"	Any measure that is intended to reduce the amount of time fishing by mobile gear will likely have benefits to EFH. These measures reduce amount of latent effort as well.
(3.6) Management Measures to Address Rebuilding Requirements	Overall Positive Impact (+)	Mix of adaptive and phased reduction strategies. Provides opportunity to fish on stocks that do not need rebuilding	The effort reductions, year-round closed areas, and existing gear modifications are likely to have positive impacts on EFH.
Effort Controls	Positive Impact (+)	A days (60% of effective effort) B days (40% of effective effort) C days (FY01 allocation)	Reducing DAS will likely benefit EFH by reducing the amount of time vessels can fish. There are studies that document the recovery of benthic habitats following the cessation of bottom fishing.
Closed Areas	Positive Impact (+)	Addition of Cashes as a year round closure	Year-round closures provide habitat benefits to the areas within the closures. The addition of Cashes Ledge as a year-round closure will benefit the EFH and rare kelp beds found in that area.

Table 181 – Summary of the potential habitat benefits of non-habitat measures proposed in Amendment 13.

Note: Seasonal (rolling) closures, possession limits, and hard TACs that are included in a number of proposed management measures are not considered to provide any significant habitat benefits. Habitat benefits identified above apply primarily to bottom trawls, not to fixed gear such as hooks and gill nets

5.3.11.3.2 Habitat Alternative 7

This alternative will expand the list of fishing gears prohibited from use in the year-round closed areas to include clam dredges. This gear is allowed in portions of the existing groundfish closed areas and, due to their impacts, excluding their use will better protect essential fish habitat.

5.3.11.3.3 Habitat Alternative 10b

The Council selected Habitat Alternative 10, Option (b) to implement under Amendment 13 to the Northeast Multispecies FMP to minimize the adverse impacts of fishing as demonstrated in the Adverse Impact Determination section. Refer to 3.7.3 for a complete description of this measure.

This action identifies several areas as habitat closures. These areas are a Level III habitat closure, with one exception This alternative was developed to incorporate areas that would benefit EFH, but not in the most productive fishing grounds. Both existing mortality closures and proposed habitat closures were modified to develop one alternative that closes sensitive habitat. In general, the alternatives suggest changing the eastern boundary of the Western Gulf of Maine closure, and modifying the Nantucket Lightship closure. In addition, the access areas used in Framework 13 for Closed Area I were modified slightly. Lastly, the habitat closure proposals for Closed Area II, Jeffrey's, Bank, and Cashes Ledge were included in this alternative, with some modifications.

5.3.11.3.4 Analysis of Alternatives to Minimize Adverse Effects of Fishing on EFH

For a full analysis of the alternatives selected to minimize or mitigate adverse effects from fishing on EFH in Amendment 13 to the Multispecies FMP, see Section 5.3.8.

5.3.11.4 Conclusion

The management measures, implemented through this action, minimize the adverse effects of fishing on EFH, to the extent practicable pursuant to Section 303(A)(7) of the MSA).

5.3.12 Stellwagen Bank Habitat Research Area

The current WGOM Closed area includes a section of the Stellwagen Bank National Marine Sanctuary (SBNMS), referred to as "the sliver." The SBNMS is making a significant investment in research in the "sliver" and surrounding area that will exceed over $4 million in funding over this decade (Figure 173). This research closure provides an unprecedented opportunity to understand the impacts of fishing gear on habitat, and the recovery of from those impacts.

There are several properties of the WGOM/SBNMS overlap that make it an excellent choice for a habitat research area. These properties include scientific, practical, and political elements.

- The area includes the four major habitat types found in SBNMS and in the Gulf of Maine—boulder, gravel, mud and sand. This will enhance the exportability of any research results to areas outside the reserve. Further, the habitats are distributed on either side of the closed area boundary, making comparative habitat studies possible across the boundary.

- The proximity of the area to the ports of Boston, Gloucester, Scituate, Plymouth and Provincetown make it accessible to researchers for day trips using small and relatively inexpensive vessels, including fishing vessels.

- The area has already been closed to fishing for approximately 3 years. From a scientific perspective, this greatly enhances our ability to study the ecological processes and expedites the timeline on which results of research will be attained.

Several on-going studies are being conducted in the closed area. The SBNMS initiated a Seafloor Habitat Recovery Monitoring Program in 1998 to look at rates of recovery from fishing in the four major habitat types found in the Gulf of Maine. Three years of data now exist for the eight monitoring stations inside and outside of the closed area. A 10-year continuation of this study of seafloor habitat recovery following cessation of anthropogenic disturbance (e.g., fishing and fiber optic cable installation) begins in summer 2001. Other current projects in the closed area include the quantification of fish movement rates relative to seafloor habitat and species-area relationships of multiple taxa. This research is supported by NMFS, NEFMC and SBNMS.

Also, the WGOM/SBNMS seafloor has been mapped in its entirety by the U.S. Geological Survey. One of the key issues for a Gulf of Maine research reserve is the generalized applicability of research conducted there to other sites. The four habitat types in SBNMS and WGOM are essentially the four major habitat types in the Gulf of Maine. Assuming that only one site will be designated as a habitat research area in the near future, the WGOM/SBNMS closed area provides the greatest opportunity to generalize research results to other areas due to the range of habitats it contains. The high resolution mapping completed provides for unprecedented specificity in the selection of research sites for a range of projects, and is a notably invaluable asset.

The area closures being considered in this action will not affect the research stations that are inside the current WGOM closed area. Some of the proposed closures will reduce fishing activity in the vicinity of the stations outside the current WGOM closed area. For example, rebuilding Alternative 1 will either close the area inshore of the WGOM closed area, or will charge DAS at a differential rate. This may lessen the utility of these stations for comparing habitat subject to fishing pressure with that subject to less pressure inside the closed area.

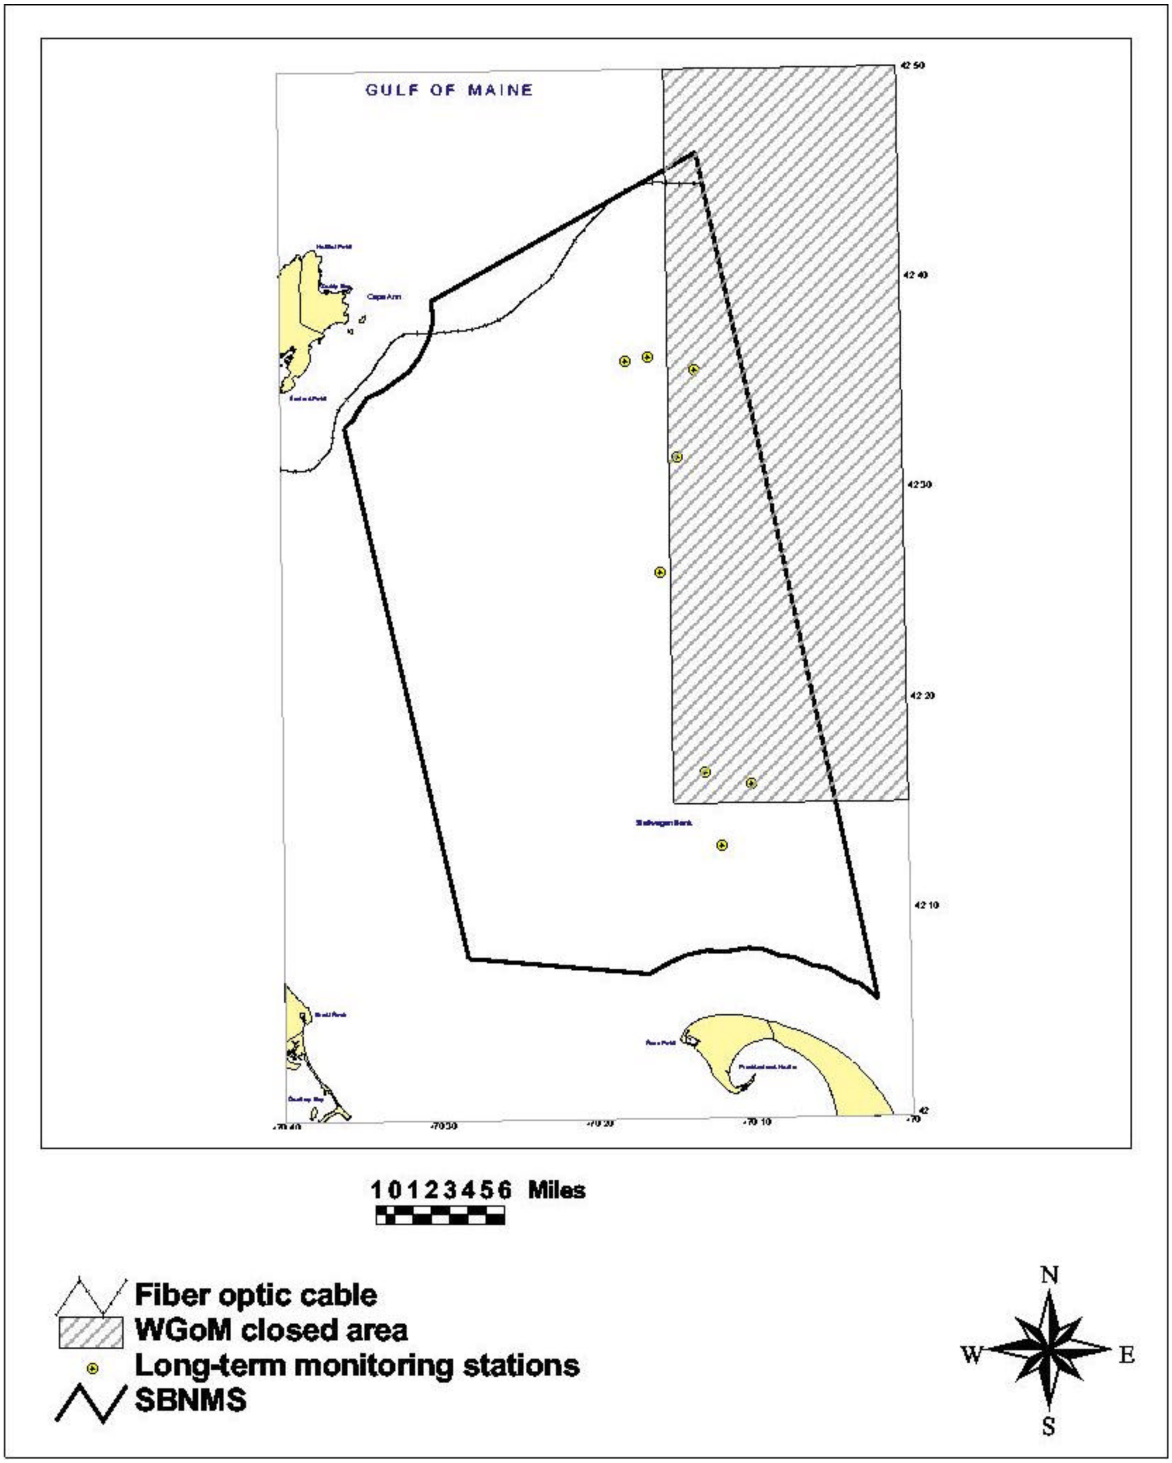

Figure 173 - Map depicting SBNMS boundary, truncated WGOM closure area, fiber optic cable route through SBNMS, and long-term Seafloor Habitat Recovery Monitoring stations.

5.4 Economic Impacts

This section describes potential economic value of the different rebuilding programs. The economic effects of the proposed action are evaluated from both a longer and short-term perspective. This analysis was developed using a national benefit perspective and estimates the present value of consumer and producer surpluses for all stocks. The Council considered two different rebuilding time frames (an end date of 2009 or 2014 for selected stocks) and three different rebuilding strategies (constant fishing mortality at an F-rebuild, phased fishing mortality, and an adaptive approach) in addition to the No Action alternative. In addition, the rebuilding strategies are also compared to the Status Quo – that is, maintaining 2002 fishing mortality rates into the future. The proposed action rebuilds most stocks by 2014, but uses a combined rebuilding strategy approach. Some stocks are rebuilt using the adaptive strategy, and some stocks are rebuilt using a phased reduction strategy.

In this section, the economic value of the proposed action is presented first. The non-selected alternatives are presented next – first for the strategies using a 2009 rebuilding time frame, then followed by an evaluation of the economic value of a 2014 rebuilding time frame. The difference in economic benefit between the two rebuilding time frames is evaluated in a subsequent section. Finally, there is a comparison between the proposed action and the other rebuilding strategies that uses a 2014 ending date for most stocks.

Each of the rebuilding alternatives provide for a specified suite of fishing mortality rates designed to achieve biological objectives for all stocks subject to rebuilding within the selected time frame. Applying these fishing mortality rates in a projection framework results in a set of projected landings and revenues under ideal conditions. That is, the resulting landings projections are what would result with perfect management such that every fishing mortality target for every stock was achieved. Realized landings may be higher, but are more likely to be lower for some key stocks because they coexist with others for which management measures are, by necessity, more restrictive. For this reason, the following should be regarded as an assessment of the longer term benefit of the policy decision to pursue a rebuilding plan, as well as which rebuilding approach yields highest net benefit, as compared to maintaining current management targets. From this perspective, the analysis is illustrative of the potential economic yield that may be derived from a rebuilding strategy but is not necessarily matched with a specific suite of management measures specifically designed to achieve the rebuilding targets over time. The difference between the projected and estimates of realized landings is evaluated in a concluding section. This analysis is based on a comparison between the projected landings for 2004 and the estimated landings from the area closure model used to estimate the short-term biological and distributive economic impacts of the selected management alternatives. Differences between the two estimates of 2004 landings may highlight areas of concern or identify candidate fisheries for special access programs (the proposed Georges Bank yellowtail special access program, for example).

Present Value of Regulatory Action

Net national benefit may be measured by the economic surpluses that accrue to a fishery. These surpluses include consumer and producer surplus. Consumer surplus is associated with the value over and above the purchase price derived from having seafood available for consumption; the difference between what consumers may be willing to pay for fish and what they actually do pay. Producer surplus is a return to seafood harvesters over and above the resource cost of harvesting fish. Measurement of the present value of any given stream of seafood supplies requires a set of projected landings streams, a model to estimate price response to changing market supplies, and an estimate of harvesting costs.

Prices

The price and demand analysis departs somewhat from the traditional approach used in most plans and amendments, including the New England multispecies plan. The NEFSC recently funded a statistical analysis of the relationships among groundfish dockside prices through the CMER (Cooperative Marine Education and Research) Program with the University of Rhode Island. Researchers in the Department of Environmental and Natural Resource Economics found that with the exception of windowpane flounder and redfish, the prices of large mesh groundfish species were co integrated (Roheim in prep). That is, the prices of several species move together over long time periods. Further, the price of Atlantic cod determines the prices of haddock and flounders. These results mean that it is reasonable to aggregate the landings of most species into composite products when modeling dockside demand, and that the dockside price of cod is an exogenous variable in the demands for most other species. The role of cod prices is new for dockside demand analysis, but researchers have long suspected that most groundfish were close substitutes in markets for whitefish (Bockstael 1976).

The dockside demand model (see Appendix 16 for a more detailed discussion of methods) was specified as a system of price equations. The model reflects management's focus on principal stocks, practical considerations having to do with available data, and the co integration results. There are separate price equations for Atlantic cod, haddock, and yellowtail flounder. The price of redfish was also modeled separately because it was neither dependent on cod prices nor co integrated with the other large mesh species. The remaining large mesh species - i.e., haddock, white hake, winter flounder, American plaice, witch flounder, windowpane flounder, and pollock - were aggregated in a single equation.

The resulting price models capture trends in seafood demand as well as the interaction between supply and demand. The latter means that predicted prices decline with increased supplies. However, this effect is counterbalanced by trends in seafood demand that have tended to result in higher prices for a given seafood supply. The combined effects mean that prices may increase gradually over time, but for any given year, the predicted price for one rebuilding alternative that results in higher landings will be lower than another alternative with lower landings. For example, the phased fishing mortality strategy would result in lower predicted prices than a constant fishing mortality strategy in the early years of the program because projected landings would be higher. As the schedule of phased fishing mortality rates falls below the constant F the expected landings would be lower, hence predicted prices would be higher compared to expected landings at a constant fishing mortality rate.

Predicted prices in time t were standardized by multiplying the observed price in 2001 by the ratio of the predicted price in time t to the predicted price in 2001. In this manner predicted prices were converted to real or current 2001 relative prices. Estimates of consumer surplus were obtained by calculating the area under the demand function from zero to the quantity supplied and subtracting total revenues paid to vessels.

Costs
Fishing costs consist of fixed costs (costs that must be paid regardless of output levels) and variable costs. Variable costs consist of vessel operating costs and crew payments. However, since crew payments are based on a share basis that may be adjusted as economic conditions warrant only vessel operating costs were considered herein. Thus, the difference between gross revenues and fishing costs (fixed plus operating) represents a return to labor and owner profit. Note that this return is not producer surplus in the strict economic sense. A theoretically correct estimate of producer surplus would require an estimate of the opportunity cost of labor and capital. Since adequate data are not available on either employment or profitability in the groundfish fishery, returns are based on accounting definitions of "profit" rather than strict adherence to economic concepts. Fixed and operating costs were estimated from the survey data described in section 5.4.5.

Fixed Costs - Because vessels may be active in a number of different fisheries total fixed costs would normally be prorated across these activities rather than be assigned to groundfish alone. Fixed costs were estimated by multiplying the mean fixed cost by vessel gear and size group by the proportion of days absent where groundfish landed to total days absent. This calculation resulted in an estimate of $30.5 million per year in fixed costs (Table 182). Note that this calculation was based on 809 vessels. Since approximately 900-1,000 vessels have landed groundfish in the past, fixed costs may be underestimated but since all scenarios were evaluated in a consistent manner, the ordinal ranking across alternatives would not be affected.

Fixed costs were assumed to be borne throughout the time period of analysis even though the actual number of vessels may change. For example, if additional buyouts or some other capacity rationalization program were implemented, fixed costs would decline. At this time, an industry funded buyout is under discussion but the components of any such plan have yet to be developed.

Gear Group	Number of Vessels	Groundfish Days Absent (VTR)	Total Days Absent (VTR)	Ratio	Mean Fixed Cost per Vessel	Prorated Fixed Cost per Vessel	Total Fixed Cost
Small Hook	43	1,468	2,698	0.54	26,630	14,490	623,051
Large Hook	20	790	1,875	0.42	34,018	14,333	286,658
Small Trawl	181	10,606	18,469	0.57	30,073	17,270	3,125,817
Medium Trawl	216	14,232	23,928	0.59	66,937	39,813	8,599,625
Large Trawl	176	15,214	24,908	0.61	135,092	82,515	14,522,683
Small Gillnet	68	3,035	5,813	0.52	26,630	13,904	945,450
Large Gillnet	105	6,808	10,143	0.67	34,018	22,833	2,397,459
Total	809	52,153	87,834	0.56	50,485	29,308	30,500,744

Table 182 - Estimated Fixed Costs for Groundfish Vessels

Operating Costs - Vessel operating costs are affected by a mixture of expenditures some of which are dependent on output levels (handling and offloading fish) but the majority are associated with a combination of taking a fishing trip (food, bait, supplies) and time spent fishing (fuel). For purposes of analysis, operating costs were assumed to be correlated with annual changes in effort, which in turn were assumed to be linked to annual changes in DAS allocations of time spent fishing. Unfortunately, the management measures described in Section 3.6 do not detail how adjustments to the rebuilding program will be made over time. Nevertheless, since there is an assumed functional relationship between fishing mortality rates and effective effort, changes in operating costs were indexed to annual changes in the average projected fishing mortality rate for all age-based stocks. This approach permits consideration of the difference in operating costs that may be associated with different rebuilding approaches. For example, the constant F approach would require that effective effort be held constant while a phased reduction approach requires continual downward adjustments in effective effort. With an assumed relationship between effective effort and operating costs, fishing costs would remain relatively constant under the former but would decline under the latter rebuilding strategy.

Operating costs were estimated in a manner similar to that of fixed costs. Average operating costs by vessel gear and size groups (Table 232) were multiplied by DAS called-in for FY2001. This product was approximately $29 million (Table 183). Annual projected operating costs were then calculated from this baseline.

Gear Group	DAS Called-In FY2001	Mean Operating Cost	Total Operating Cost
Small Hook	1,145	362	414,505
Large Hook	938	344	322,608
Small Trawl	10,803	268	2,895,146
Medium Trawl	19,893	363	7,221,133
Large Trawl	21,098	814	17,173,772
Small Gillnet	2,691	50	134,572
Large Gillnet	7,852	94	738,088
Total	64,420		28,899,824

Table 183 - Estimated FY2001 Operating Costs

Projection Methods

Projections of annual landings, revenues, costs, consumer surplus, and returns to labor and owner profit were conducted using Monte Carlo simulation (1,000 realizations) procedures using @RISK. In this manner the full range of possible outcomes could be simulated and permits calculation of expected values as well as confidence intervals. In the simulation, the empirical distribution of landings from age-based assessments were replaced by fitted theoretical probability distributions using BestFit software. Adjustments to certain stocks were made to account for expected recreational landings and Canadian shares of landings. Specifically, 20 percent of Gulf of Maine cod was assumed to be landed by recreational anglers while the U.S. share of Georges Bank Yellowtail, Georges Bank cod, and Georges Bank haddock were set to 58%, 82%, and 40%, respectively. These shares were averaged based on reported U.S. and Canadian landings in the Multispecies Monitoring Committee Reports for 1996 - 2001. In the future, the U.S. share of these stocks may be determined by the US/Canada resource sharing understanding (see section 3.4.3) and may differ from these assumed values.

The simulation time period covered a twenty-three year span from 2003 to 2026. This time period is consistent with the prescribed rebuilding period for all stocks (except for redfish). All dollar values were discounted at an interest rate of 7-percent for purposes of calculating present values. Sensitivity analyses to determine the robustness of the ordinal ranking of alternatives was conducted using discount rates from 0 to 20 percent.

5.4.1 Economic Benefits of the Proposed Action

The Proposed Action would implement an overall rebuilding approach that would target Fmsy for stocks that require comparatively less effort reduction while adopting a phased approach for stocks that require larger reductions in effort. The combined rebuilding strategies that are being adopted are closely linked to the proposed management measures. For example, the rebuilding fishing mortality target for GB cod from 2004 through 2008 is based in part on the mortality that is expected to result from the proposed measures. This means that the estimated economic impacts of the proposed combined rebuilding strategy should more closely reflect the future realized landings and revenues under the adopted suite of management measures.

With this mixed approach, projected landings from all 10 large mesh species start out at 130 million pounds in 2003 and increase to 146 million pounds in 2004 (Figure 174). From 2004 onward, projected landings would continue to increase by about 15 million pounds per year through 2008. Based on the assumed fishing mortality rates for 2004 to 2008, for some stocks, adjustments to the management measures will be implemented in 2009. Therefore, fishing mortality rates that would be necessary to rebuild in the remaining time period were estimated and applied through 2014 for all stocks except Georges Bank cod (rebuilding in 2026) and Cape Cod/Gulf of Maine yellowtail flounder (rebuilding in 2023). Based on modeled performance from 2004 to 2008 the effort reduction required in 2009 would result in a one-year reduction of 11 million pounds; down from 206 million pounds in 2008. Projected landings would recover rapidly to 208 million pounds in 2010 and would increase by an average of 12 million pounds each year through 2014. Landings in 2015 would approach 300 million pounds as most stocks would be fished at MSY levels and would continue to increase to about 320 million pounds at the end of the rebuilding period in 2026.

Average projected revenues follow the same general pattern as landings with nominal gross revenues of $128 million in 2003 and increasing to $139 million in 2004 (Figure 175). The relative change in gross revenues is less than that of the change in landings as prices decline due to larger market supplies. For example, revenues decline less than half as much as that of landings in 2009 because the offsetting effect of price increases as market supplies go down. Similarly, revenues in 2015 do not increase as much as landings do, because of the price dampening effect of higher market supplies.

Average returns to crew and captain incomes and vessel owner profits were projected to be $68 million in 2003 and increase to $84 million in 2004 (Figure 176). In 2015, when all stocks except Cape Cod/Gulf of Maine yellowtail flounder are fished at MSY levels returns to crew and captain income and owner profit would be $240 million. The overall change in income and profit from 2003 to 2026 is actually larger than that of either landings or revenues because costs remain relatively constant from 2015 onward. With constant costs and increasing landings the share of revenue going to income and profits continues to get larger over time.

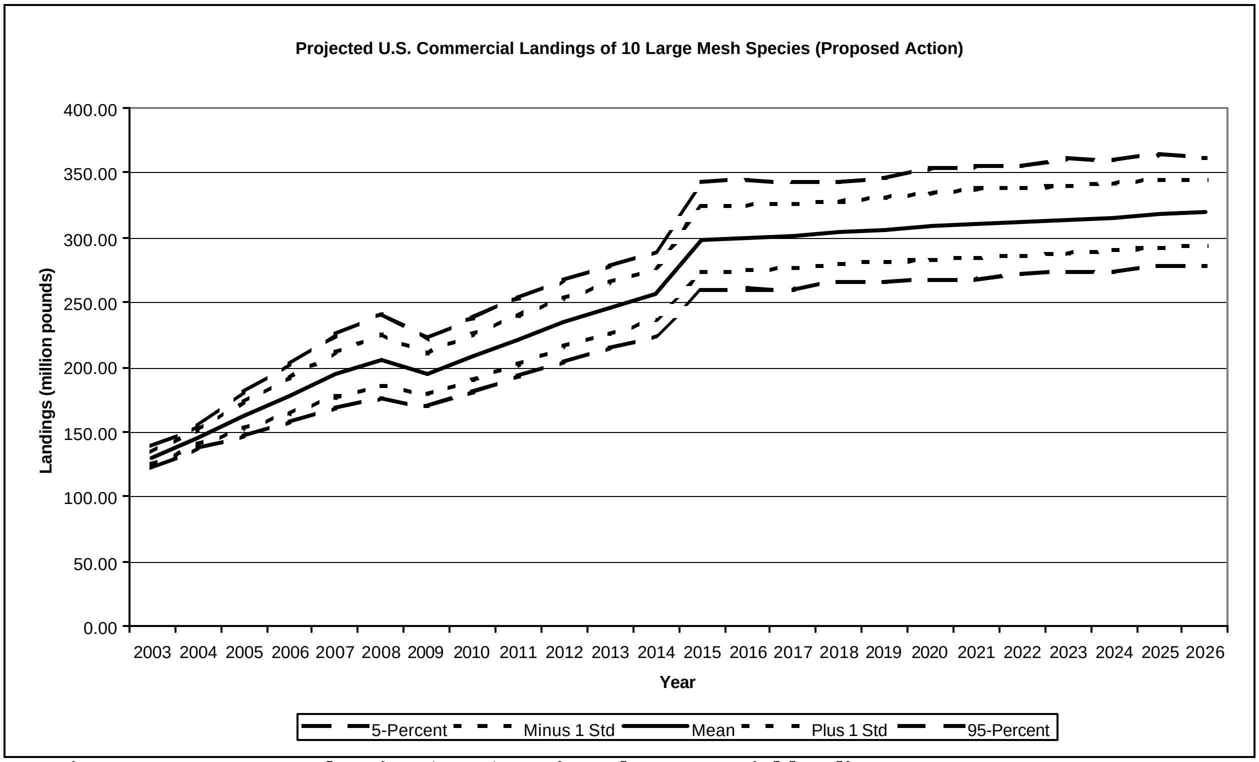

Figure 174 – Proposed action (2014) projected commercial landings

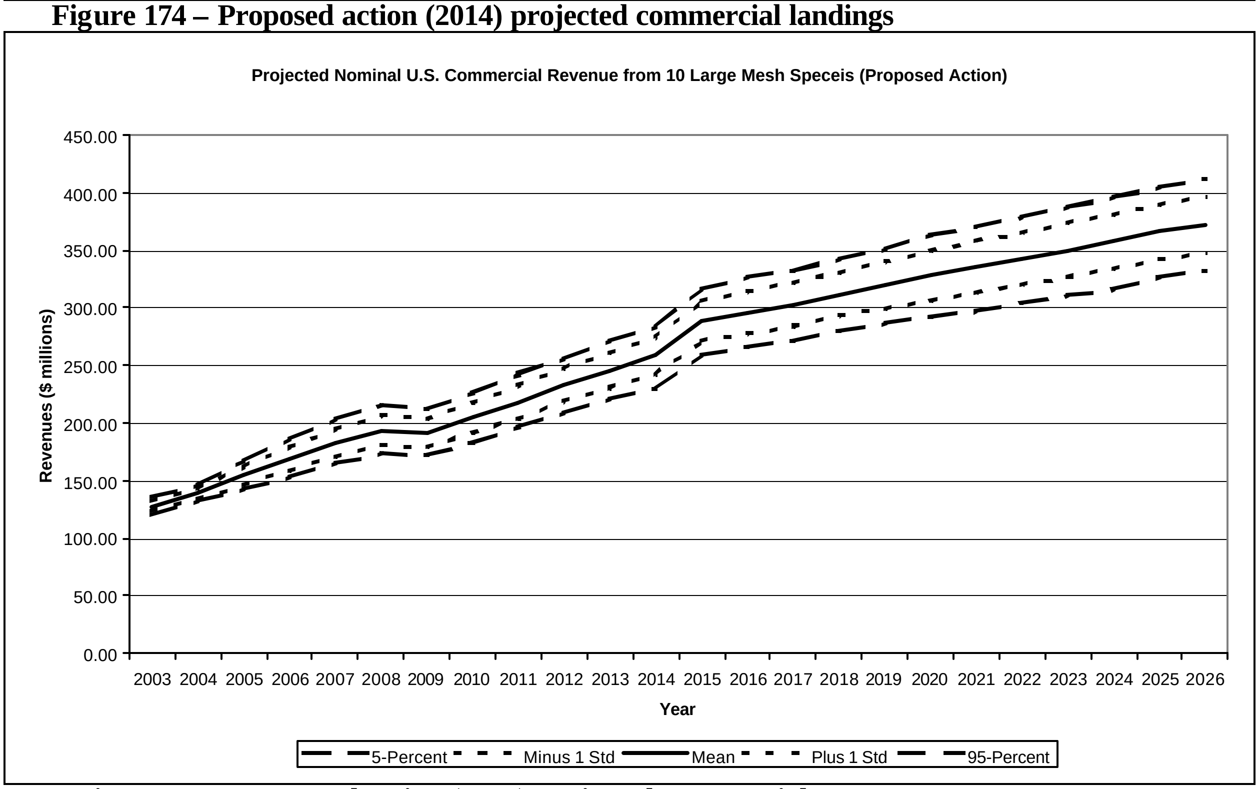

Figure 175 – Proposed action (2014) projected commercial revenues

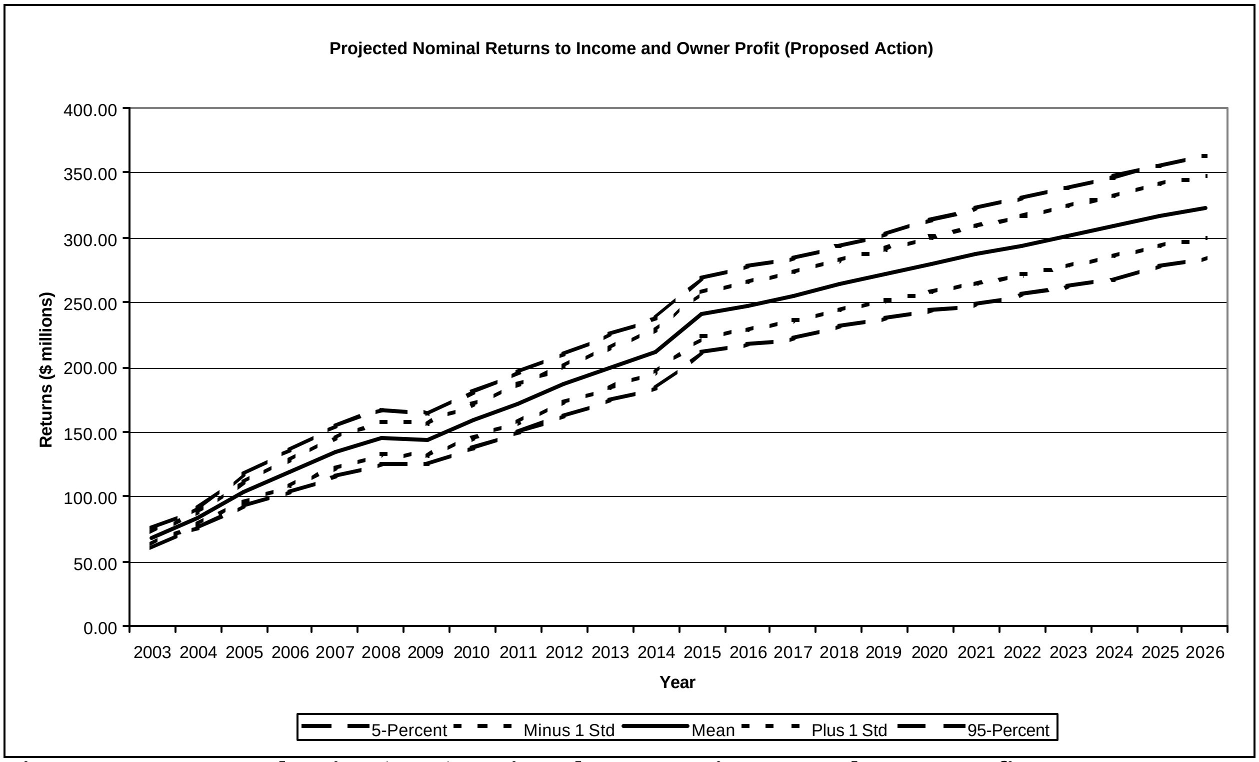

Figure 176 – Proposed action (2014) projected return on income and owner profit

5.4.2 Economic Benefit of Rebuilding Strategies Not Selected

This section summarizes the economic benefits of the alternatives to the proposed action that were considered by the Council. It includes, for reference only, the benefits of the status quo alternative. This alternative was not explicitly considered by the Council because it does not meet requirements to end overfishing and rebuild overfished stocks. Nevertheless, there was considerable interest in this information during the public comment period, so it is included in this document.

Section 3.2.2 describes the stocks that would effectively be managed to achieve rebuilding targets by 2009 with the indicated exceptions. Commensurate with this rebuilding time frame rebuilding fishing mortality rates were determined for both a constant fishing mortality rate strategy (F-Rebuild) and a sequence of phased reductions in fishing mortality rates (Phased-F). Since the rebuilding time frame would be comparatively short (five years from implementation) an adaptive management approach would be impractical so this rebuilding alternative was not developed for the 2009 rebuilding time.

Section 3.2.2 also described stocks that would be managed to achieve rebuilding targets by 2014 with the exception of redfish, Cape Cod/Yellowtail Flounder, and Georges Bank cod. With this rebuilding time frame rebuilding fishing mortality rates were determined for three rebuilding alternatives; a constant fishing mortality rate strategy (F-Rebuild), a phased reductions in fishing mortality rates (Phased-F), and an adaptive approach (Adaptive). The adaptive approach will involve an evaluation of progress toward rebuilding for each stock that would take place during 2008. In the interim all stocks would be fished at levels consistent with Fmsy. To develop an estimate of landings streams for the remaining years of the time frame the constant fishing mortality rate needed to rebuild the stock by the end of the rebuilding period was determined and applied from 2009 to 2014.

5.4.2.1 No Action Alternative

The No Action alternative would return the fishery management regulations back to those in place during fishing year 2001. The projections started with present (2002) stock sizes and 2002 fishing mortality rates but applied the estimated 2001 fishing mortality rates throughout the 2003-2026 projection period to all stocks. Based on these conditions the average value of landings started out at 127 million pounds from the 10 combined large mesh species and increased to 289 million pounds in 2026 (Figure 177). The majority of the increase in landings was projected to occur between 2003 and 2012. Thereafter, landings were projected to continue to increase but by less than 3 million pounds per year. The 95-percent confidence interval also stabilizes in 2012 suggesting that landings could be within the range of about 45 million pounds below the mean or about 55 million pounds above the mean.

Projected average nominal revenue streams begin at approximately $127 million in 2003 and increase to $344 million in 2026 (Figure 178). The estimated revenue streams increase almost linearly with time even though average landings do not increase appreciably after 2012. The linear increase is due to the estimated time trend in the price model. This annual time trend captures shifts in un-modeled factors (principally increases in the demand for seafood) that tend to result in higher prices paid for fish even though market supplies may be relatively constant from one year to the next.

Projected returns above fixed and operating costs were approximately $70 million (about 55% of fishing revenue) in 2003 and increased to $280 million in 2026 (Figure 179). These results suggest that returns to crew and captain payments and owner profit will increase from 55% to 81% of fishing revenue from 2003 to 2026. This projected increase results because while predicted groundfish prices are increasing with time operating costs and fixed costs were assumed to remain constant. The resulting calculated increase in profitability is certain to be overstated although some improvement in financial position may occur. Note that this effect will result in an upward bias in estimated economic benefits but this bias will also be embedded across all alternatives which serves as a reminder that the primary purpose of the analysis is to establish an ordinal ranking of alternatives rather than as providing a refined point estimate of economic benefit.

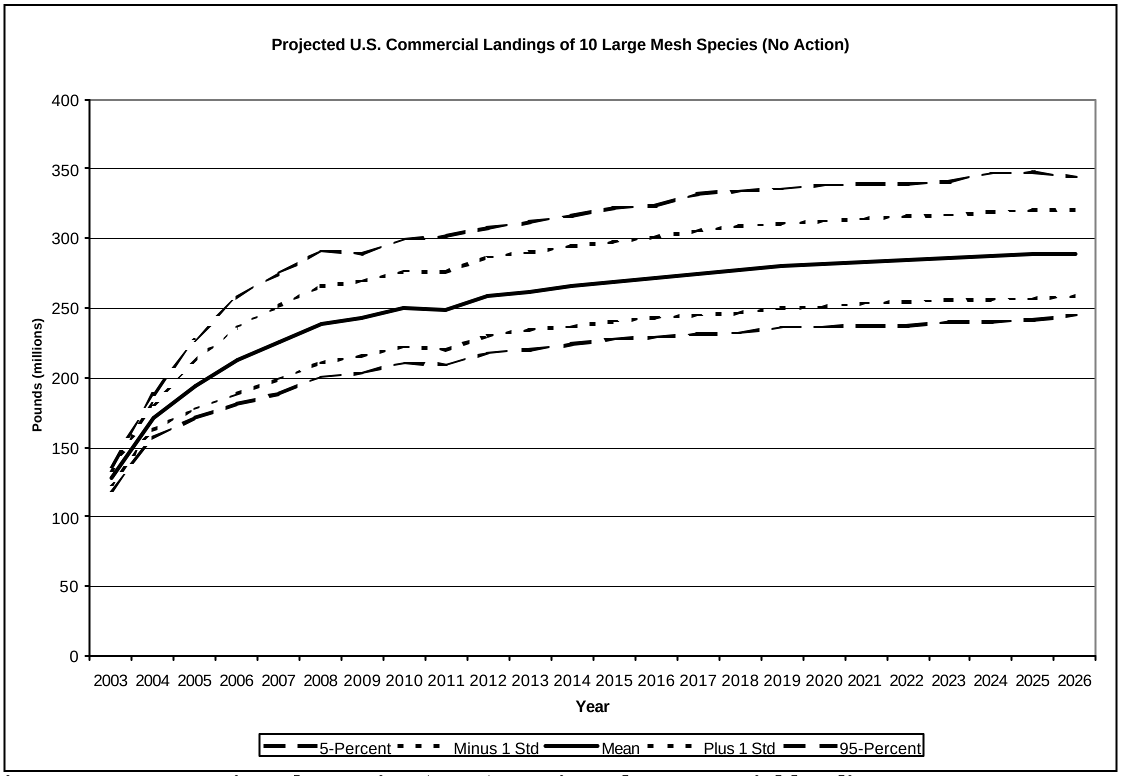

Figure 177 – No action alternative (2009), projected commercial landings

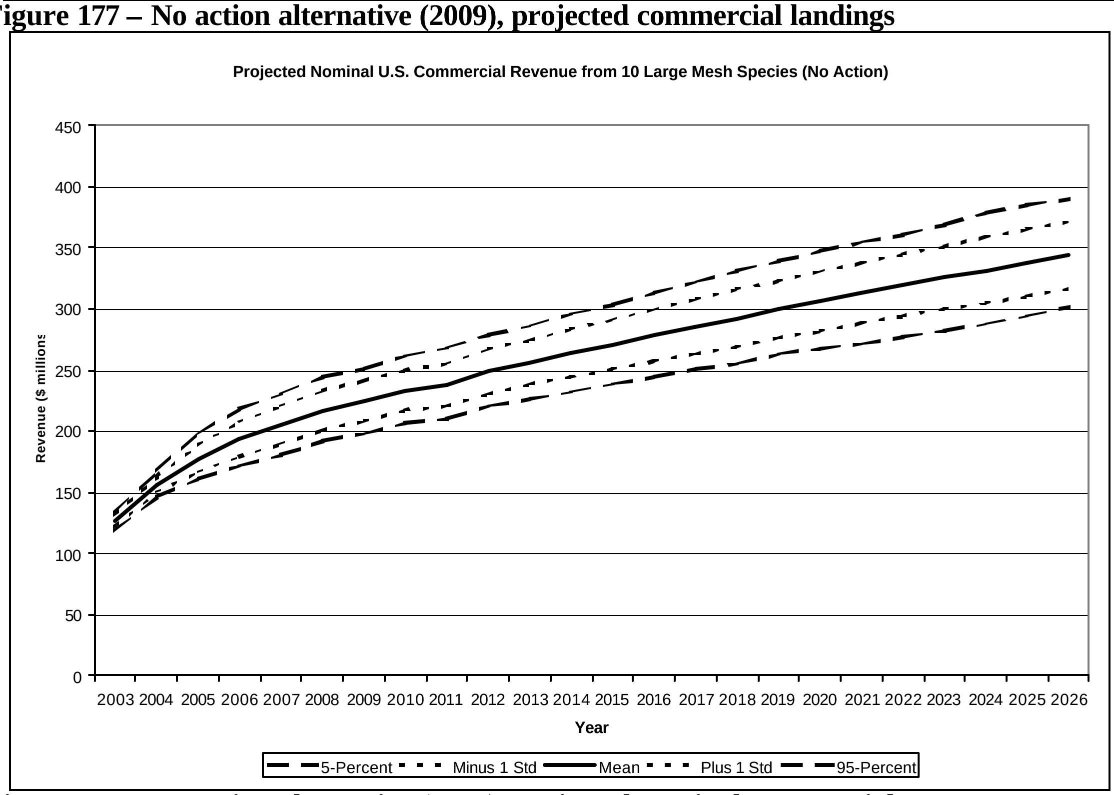

Figure 178 – No action alternative (2009), projected nominal commercial revenues

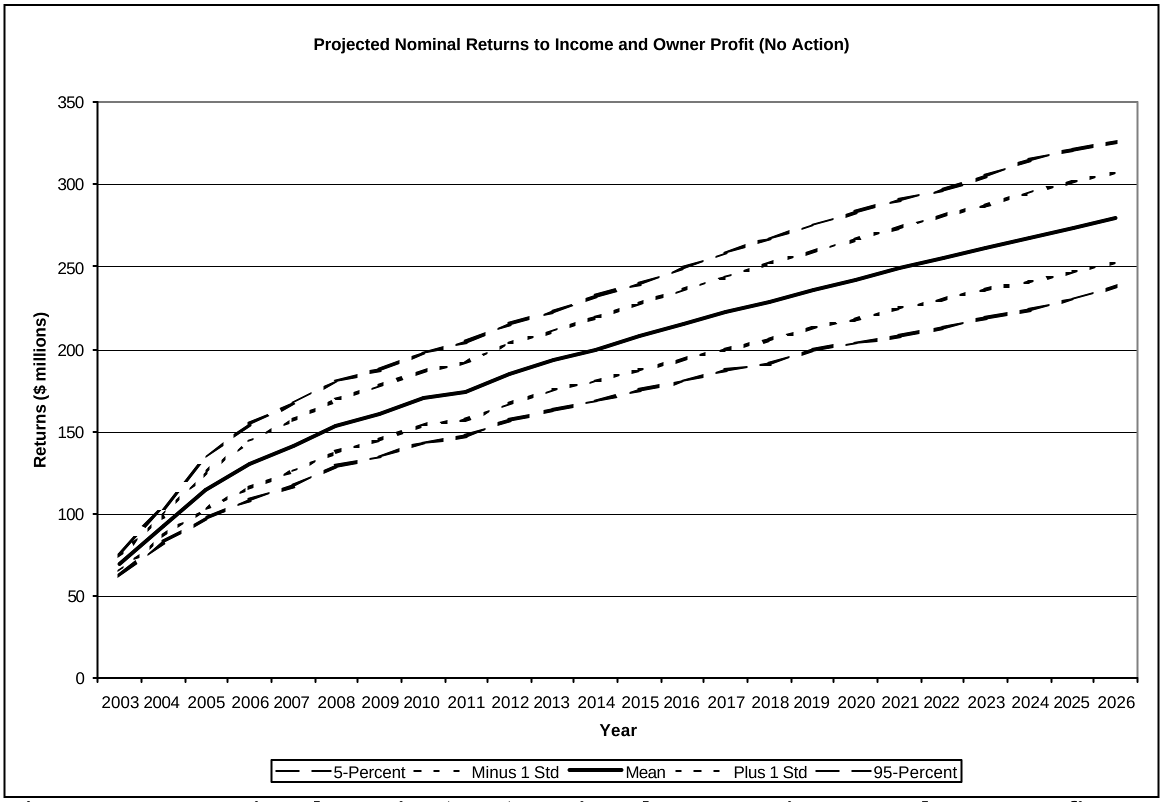

Figure 179 – No action alternative (2009), projected return on income and owner profit

5.4.2.2 Status Quo

The Council did not explicitly considering a Status Quo alternative because the management measures put in place as a result of the FW 33 lawsuit do not meet M-S Act rebuilding requirements. Nevertheless, the expected economic results from such a strategy are provided as a further comparison to the rebuilding strategies. Projections for the Status Quo alternative were conducted by applying estimated 2002 fishing mortality rates to present stock conditions and holding these mortality rates constant from 2003 to 2026. Average projected regulated large mesh groundfish landings were 124 million pounds in 2003 (Figure 180). Projected landings increased to 282 million pounds in 2026, about 7 million pounds less than that of the No Action alternative. In general, Status Quo projected landings followed a similar pattern to that of No Action but were consistently lower because in most cases 2002 fishing mortality rates were lower than that of 2001 given similar stock conditions.

Average projected nominal fishing revenue was $123 million in 2003 and was $335 million in 2026 (Figure 181). Even though predicted groundfish prices were slightly higher (since landings in any given year were lower) for the Status Quo than No Action, the difference in landings between the two alternatives more than offsets the higher predicted prices.

In 2003 average returns to income (payments to crew and captain) were $65 million, about 53% of gross revenues (Figure 182). By the end of the projection period total payments to income and owner profit averaged $277 million. The share of fishing income under the Status Quo is less than that of the No Action for a combination of reasons. First, estimated fixed costs were the same under both alternatives (i.e. fleet size and composition is held constant across all analyses). This means that even if operating costs were the same for any two alternatives the profit margin would be lower for the alternative with lower gross. Projected operating costs for the Status Quo were lower than No Action because of the assumed relationship between fishing mortality rates and operating costs. However, the relative difference in gross revenues between No Action and the Status Quo more than offsets the reduced operating costs resulting in lower income and profit payments after all costs have been paid to distribute to captains, crew and vessel owners.

5.4.2.3 Constant Fishing Mortality Rebuilding Strategy (2009)

Projected landings under a constant fishing mortality rate rebuilding strategy begin in 2003 at the same level as that of the status quo since each of these alternatives start with the same initial conditions and fishing mortality rates in 2003. The constant F rebuilding strategy begins in 2004 with estimated average landings of 120 million pounds (Figure 183). Note that this rebuilding option contains a mixture of stocks that must be rebuilt by 2009, others that have a rebuilding period ending in 2014, others (Georges Bank cod and Cape Cod/Gulf of Maine yellowtail flounder) with longer rebuilding time frames, and other stocks that are not subject to a rebuilding plan. Because of the mixture of rebuilding time frames, the projected landings exhibit several peaks in landings that correspond to a transition to fishing at MSY levels once the rebuilding objective has been attained. The more pronounced peaks occur in 2010 and 2015 as most stocks have entered a maintenance phase. Landings also increase in 2023 as Cape Cod/Gulf of Maine yellowtail is projected to be rebuilt. In 2026 projected landings averaged 322 million pounds; about 40 million pounds greater than the Status Quo and 33 million pounds greater than No Action.

The projected revenue streams follow a similar pattern to that of landings except that the revenue peaks are less pronounced (Figure 184) because of the dampening effect of price reductions that attend a relatively large increase in groundfish supplies. Average nominal revenue falls to $116 million between 2003 and 2004 but recovers to 2003 levels or greater by 2006. Projected nominal revenues increase to $375 million in 2026; $30 million more than the Status Quo and about $32 million more than No Action.

Average projected returns to income payments and owner profit were $71 million in 2004 (Figure 185); about $6 million less than Status Quo and $22 million less than No Action. The pattern of change in income and profit levels is similar to that of the projected revenues with an increase of $56 million occurring in 2010 as rebuilding objectives are met. Nominal returns increase to $327 million n 2026. However, as noted previously this estimate of income and profit is likely to be overstated since ex-vessel changes have been explicitly modeled while changes in fixed or input costs have not.

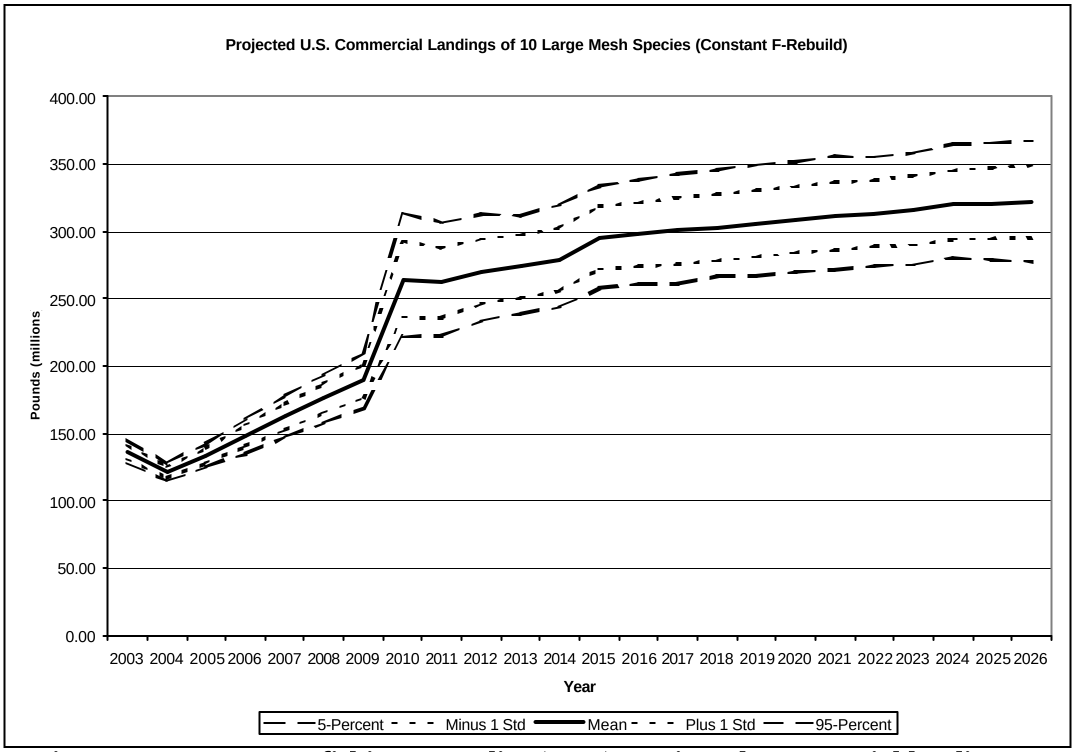

Figure 183 – Constant fishing mortality (2009), projected commercial landings

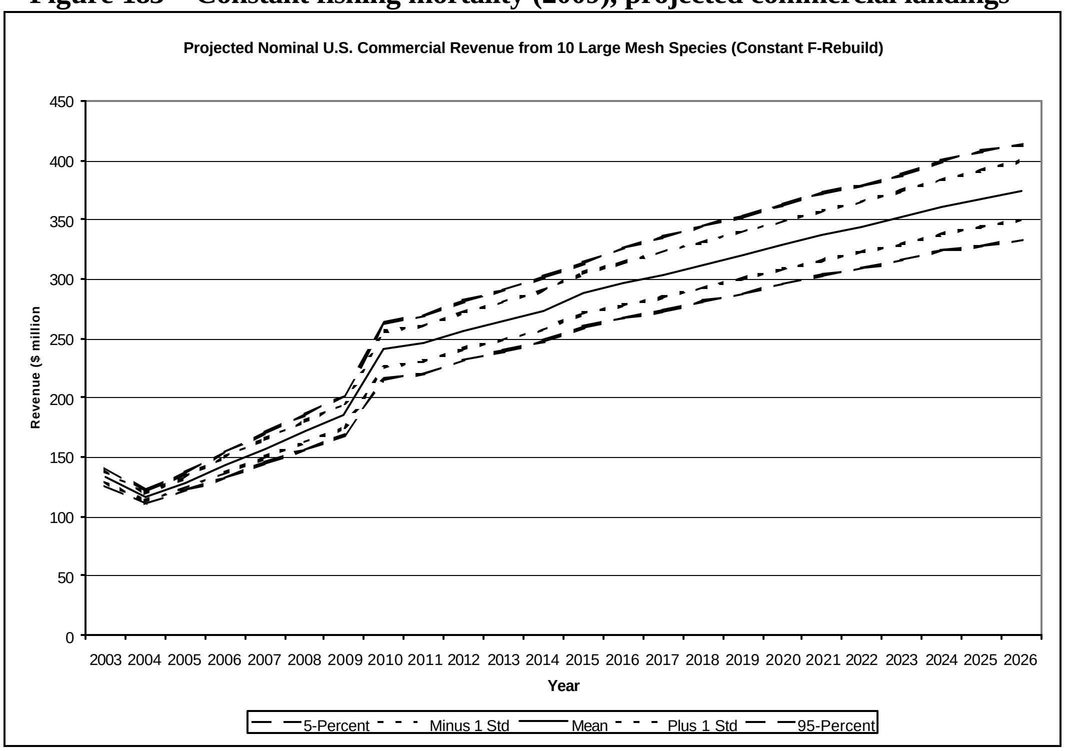

Figure 184 – Constant fishing mortality (2009), projected nominal commercial revenues

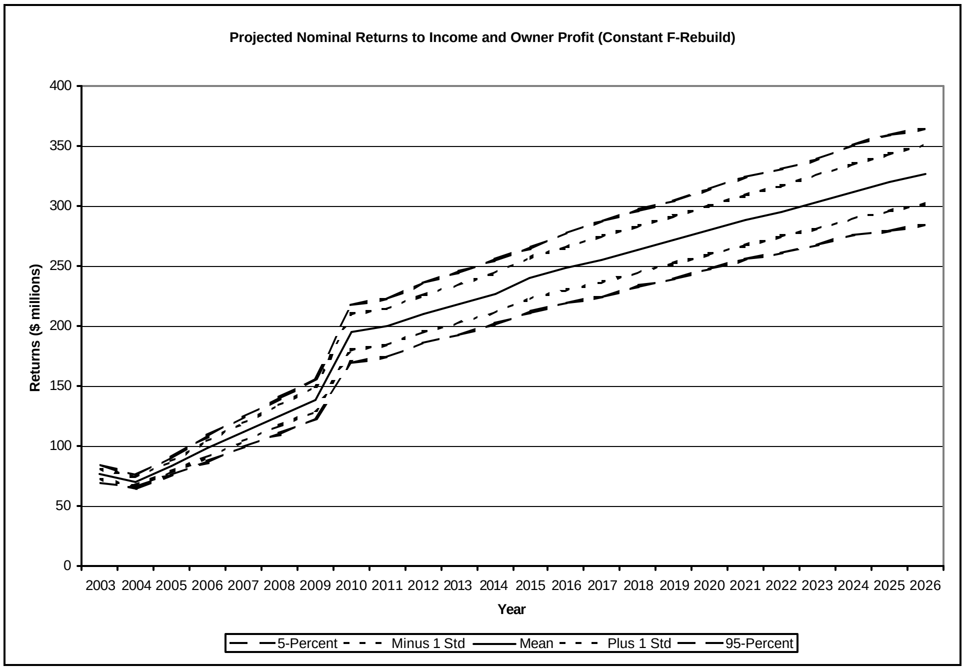

Figure 185 – Constant fishing mortality (2009), projected return on income and owner profit

5.4.2.4 Phased Fishing Mortality Rebuilding Strategy (2009)

The general pattern of landings over time under the phased fishing mortality rate rebuilding strategy is similar to the constant fishing mortality rate strategy in that there are distinct peaks in landings as stocks reach their rebuilding targets (Figure 186). The two strategies differ in that the phased rebuilding strategy does not exhibit the reduction in landings from 2003 to 2004 that occurs in the constant F strategy but that landings tend to be lower particularly for stocks like Georges Bank cod and Cape Cod/Gulf of Maine yellowtail flounder that have a longer rebuilding time as these stocks near completion of the prescribed rebuilding time. However, the difference between the two rebuilding strategies in terms of landings is not large and each result in identical outcomes once all stocks have been rebuilt.

Average gross revenues in 2004 were projected to be $134 million (Figure 187); about $21 million more than the constant fishing mortality alternative. As was the case for landings, the phased rebuilding strategy results in revenue streams that are higher than the constant fishing mortality alternative from 2003 to 2009. However, the phased strategy requires keep fishing mortality rates low throughout much of the remaining rebuilding period so that nominal revenues from 2009 to 2026 lie below that of the constant fishing mortality alternative. In all subsequent years, both alternatives would be expected to produce equivalent revenue streams.

The projected income to captains and crew as well as owner profit follow the same general pattern as that just described for gross revenues (Figure 188). Estimated operating costs would be higher while the phased fishing mortality rates were above those associated with a constant fishing mortality rate strategy but would be lower in later years. However, these later year cost savings are not offset by large enough increases in gross revenues so that nominal income and profit levels for the Phased alternative are less than that of the constant fishing mortality rebuilding strategy from 2010 to 2026. Once all stocks have been rebuilt then both alternatives would yield identical levels of profitability.

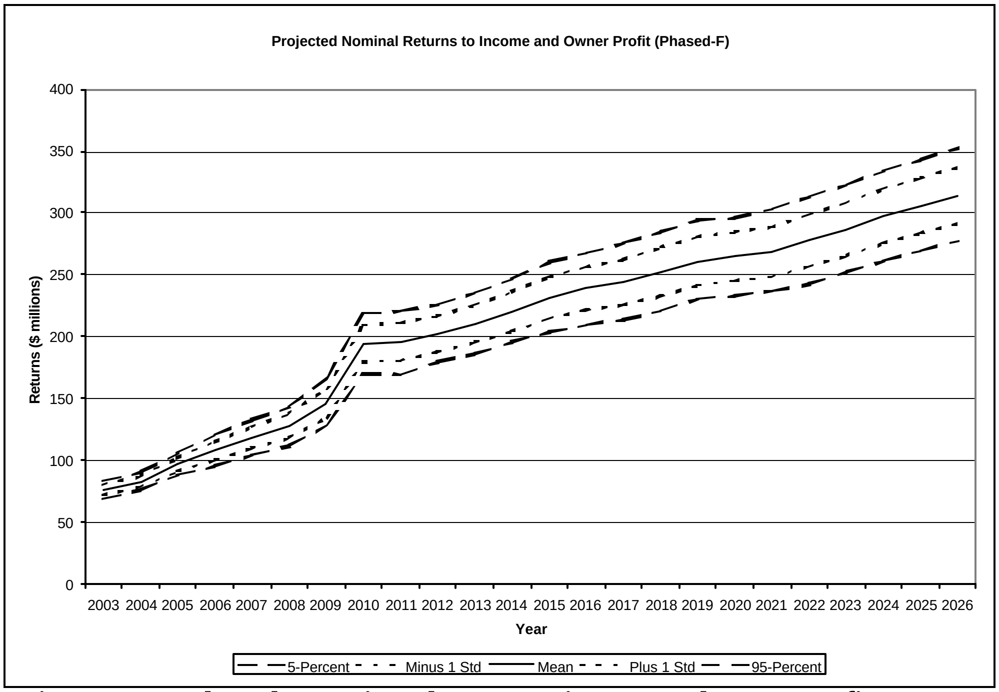

Figure 188 – Phased-F, projected return to income and owner profit

5.4.2.5 Comparison of Rebuilding Strategies for 2009 Rebuilding Time Frame for Most Stocks

While each rebuilding alternative achieves the same conservation objective for all stocks within the same time frame they do result in different time paths for landings and net benefit. To examine the performance of each alternative over time, all alternatives (including the Status Quo) are compared to No Action. In this context negative values indicate that a given rebuilding alternative would not yield higher landings or net benefit while positive values would indicate improvements in economic benefits relative to No Action.

With the exception of 2011 average landings for the Status Quo would not exceed No Action in any year other of the projection period although from 2007 onward the difference is relatively small (Figure 189). Both the Phased and Constant fishing mortality rebuilding strategies result in lower landings through 2009 but exceed No Action in every year thereafter. Compared to the Constant fishing mortality strategy, the Phased approach results in higher average landings 2004 to 2007, nearly equivalent landings from 2008 to 2011, but results in lower average landings from 2012 to 2026. Note that if the projection period were extended beyond 2026 the landings streams from both rebuilding strategies would be equivalent.

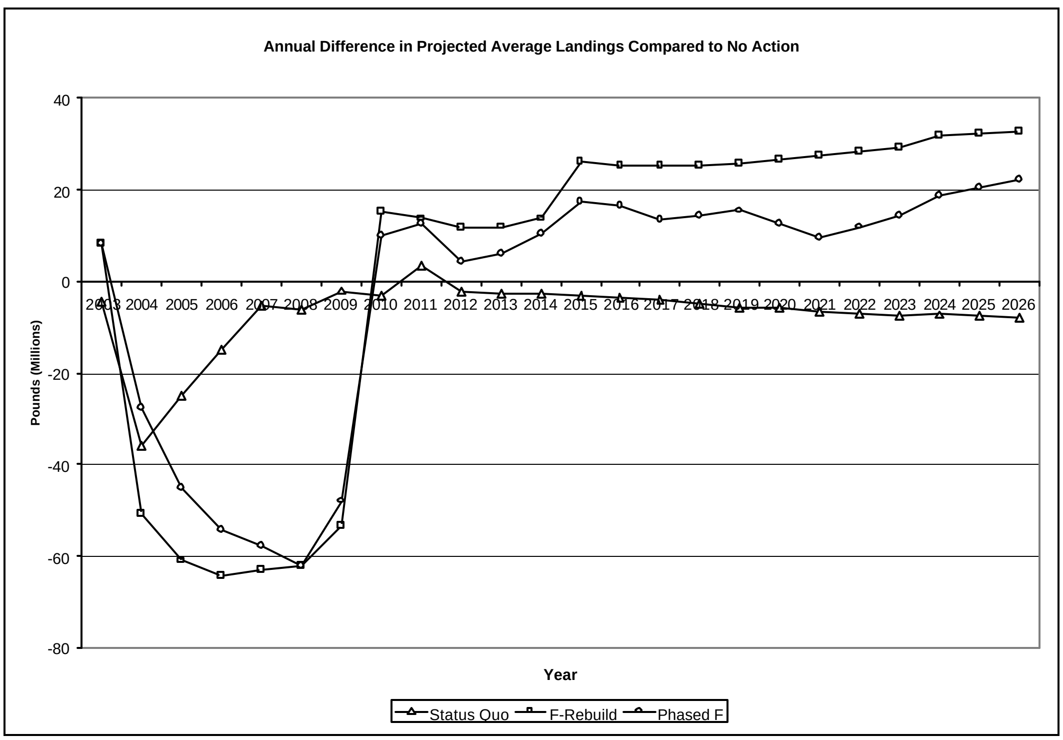

Figure 189 - Difference in projected landings (2009) for rebuilding strategies

Comparison of alternative benefit streams over time requires discounting future benefits to convert all benefit streams to a present value. For this purpose, a discount rate of 7% was selected as recommended by the Office of Management and Budget Circular A-94 and economic benefits were measured as the sum of consumer surplus, crew and captain payments, and vessel owner profit.

The Status Quo would not yield higher discounted net benefit than No Action in any year except 2011 (Figure 190). Neither rebuilding alternative would yield higher discounted net benefit in any year prior to 2010. However, as was the case for landings streams, both rebuilding alternatives would yield higher net benefit than No Action in 2010 and all subsequent years of the projection period and beyond. The relative pattern of average net benefit streams is similar to that of the landings streams with the Phased strategy yielding higher net benefit until 2008 but resulting in lower values of net benefit from 2010 to 2026.

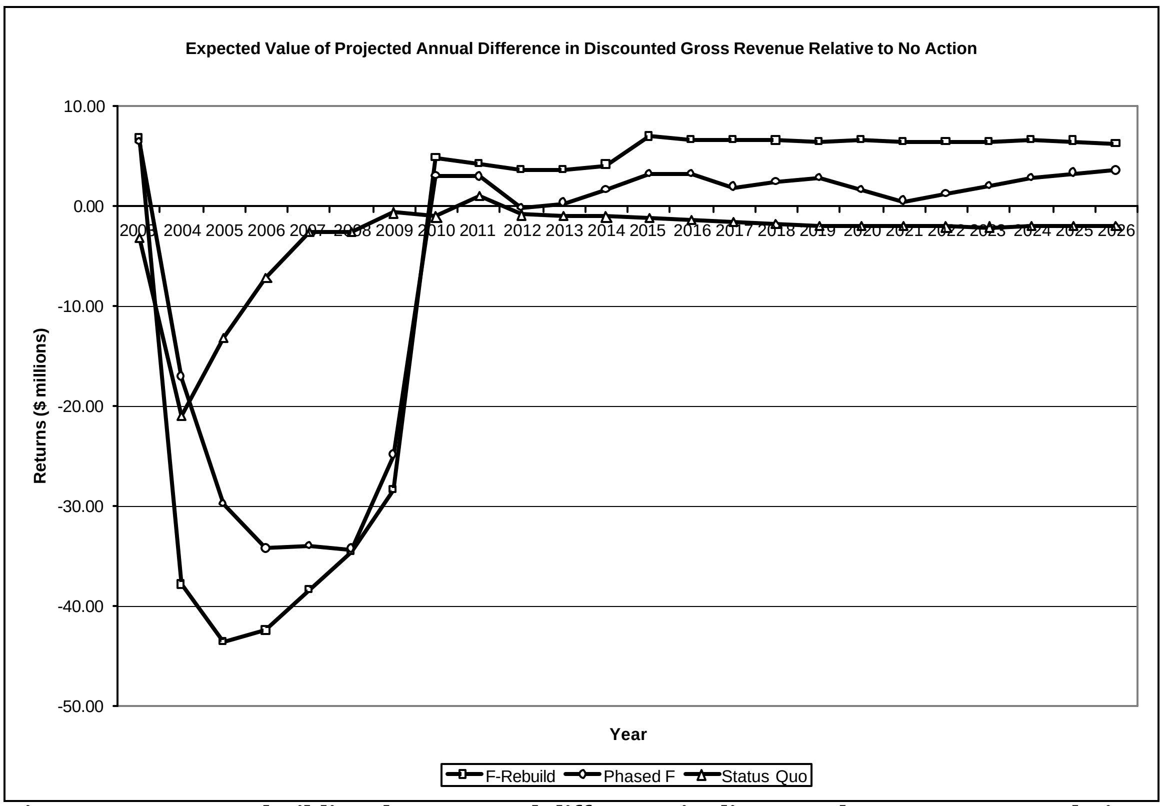

Figure 190 – 2009 rebuilding date - annual difference in discounted gross revenues relative to no action

Since both rebuilding alternatives result in net benefit streams that start out below that of No Action but end up well above No Action the year in which a benefit/cost ratio would exceed 1 (i.e. the present value of net benefit of rebuilding is greater than No Action) can be determined by examining the cumulative net benefit over time. Specifically, the Status Quo would not result in a benefit/cost ratio above 1 in any year of the projection period (Figure 191). The benefit/cost ratio would exceed 1 in 2022 for the Constant fishing mortality rate strategy and would exceed 1 in 2023 for the Phased rebuilding approach. Note that at lower discount rates the benefit/cost ratio would exceed 1 in an earlier year but would exceed 1 in later years at higher discount rates. The cumulative net benefit of the Phased rebuilding strategy is greater than the Constant fishing mortality rate alternative in every year until 2021. This means that the accumulated difference between these rebuilding alternatives over the first four years (2004 to 2007) takes thirteen years to overcome.

Over the entire rebuilding period the present value of net benefit is greatest for the Constant fishing mortality strategy at a discount rate of 7-percent. To test whether this ordinal ranking would be robust to the selected discount rates a range of discount rates from zero to 20-percent was evaluated. For all discount rates below 10-percent the present value of net benefit was positive for both rebuilding alternatives and the ordinal ranking of each alternative was consistent (Figure 192). However, at discount rates at 10-percent and above neither rebuilding alternative yielded positive present value (relative to No Action) and the ordinal ranking of the two alternatives was reversed.

As noted previously the projected landings streams, hence benefit streams, are subject to variability. Taking this variability into account means that there is some probability that any given alternative would result in higher net benefit than No Action after a specified time period. Compared to the Constant fishing mortality strategy (5-percent), the Phased rebuilding strategy would have a slightly higher probability (10-percent) of producing higher net benefit than No Action ten years after implementation (Figure 193). By contrast, the Status Quo would have a 30-percent chance of yielding higher net benefit than No Action. At the end of the rebuilding period the probability that the Status Quo would exceed No Action does not change, but the probability that either rebuilding alternative would produce higher present value of net benefit would increase to at least 70-percent.

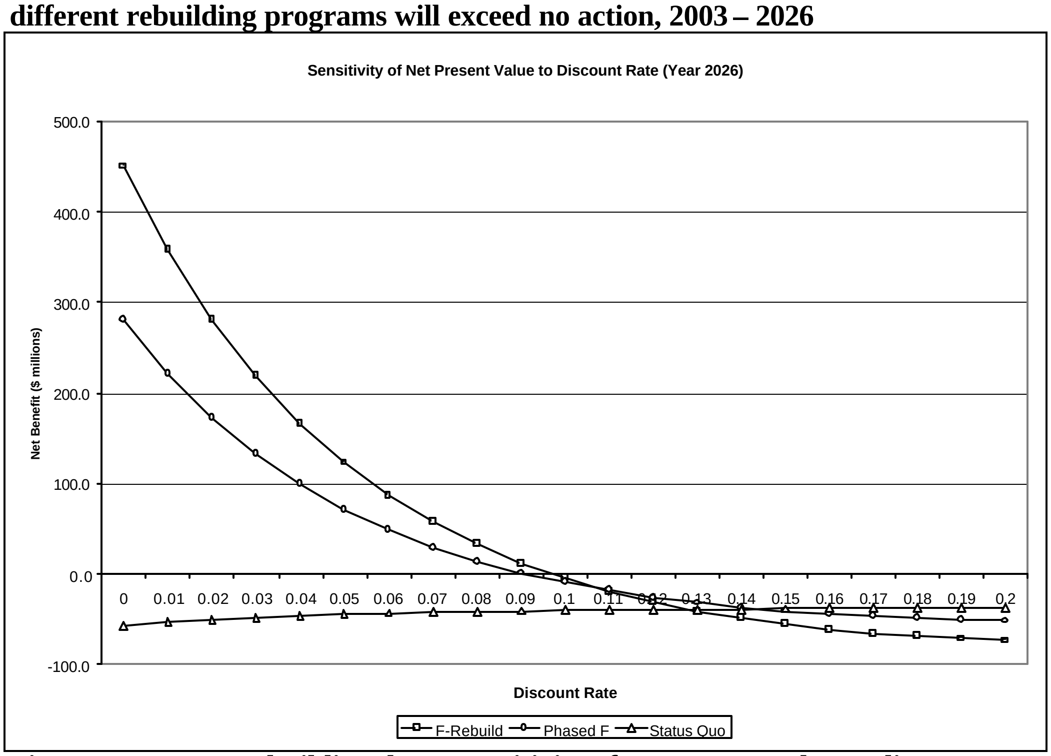

Figure 194 – 2009 rebuilding date – sensitivity of net present value to discount rate

5.4.2.6 Constant Fishing Mortality Rebuilding Strategy (2014)

Projected average landings under a constant fishing mortality strategy start out at 136 million pounds in 2003 but drop only slightly to 135 million pounds upon implementation of Amendment 13 in 2004 (Figure 195). This small reduction is due to the fact that the fishing mortality rates needed to achieve rebuilding in 2014 are higher than that needed to rebuild by 2009 so landings do not drop as much upon implementation. Compared to a mixture of 2009 and 2014 rebuilding times, projected landings exhibit only a single peak because nearly all stocks are on the same rebuilding time. After 2014 all stocks except for Cape Cod/Gulf of Maine yellowtail, Georges Bank Cod, and Acadian redfish are fished at MSY levels so from 2015 onward the projected landings under a 2014 rebuilding schedule are identical to a mixed 2009 and 2014 rebuilding time frame.

Average projected gross revenues follow the same general pattern as that of landings with nominal gross revenues in 2003 of $133 million falling $3 million in 2004 but rising to $375 million in 2026. Projected revenues bump up in 2015 as most stocks are fished a MSY levels but compared to the bump in landings, the magnitude of the bump is dampened by price reductions as market supplies increase. Note also that the revenues increase almost linearly with time even though landings increase at a slower rate. This effect is due to the time trend in the model used to predict prices, which results in a tendency for market prices to increase from one year to the next even though supplies may be relatively stable. This also means that projected revenues streams may be overly optimistic but since this relationship is embedded in all alternatives relative comparisons across alternatives are not likely to be significantly biased unless the time path is dramatically different.

Average returns to crew and captain incomes and vessel owner profit were projected to be $76 million in 2003 and increase to $83 million in 2004 (Figure 197). The increase in returns to labor and profit results because operating costs were projected to decline proportionally more (i.e. changes in operating costs are based on changes in fishing mortality rates; which decline under this alternative) than projected gross revenues. The net result is an increase in profit and income payments even though both landings and gross revenues decline.

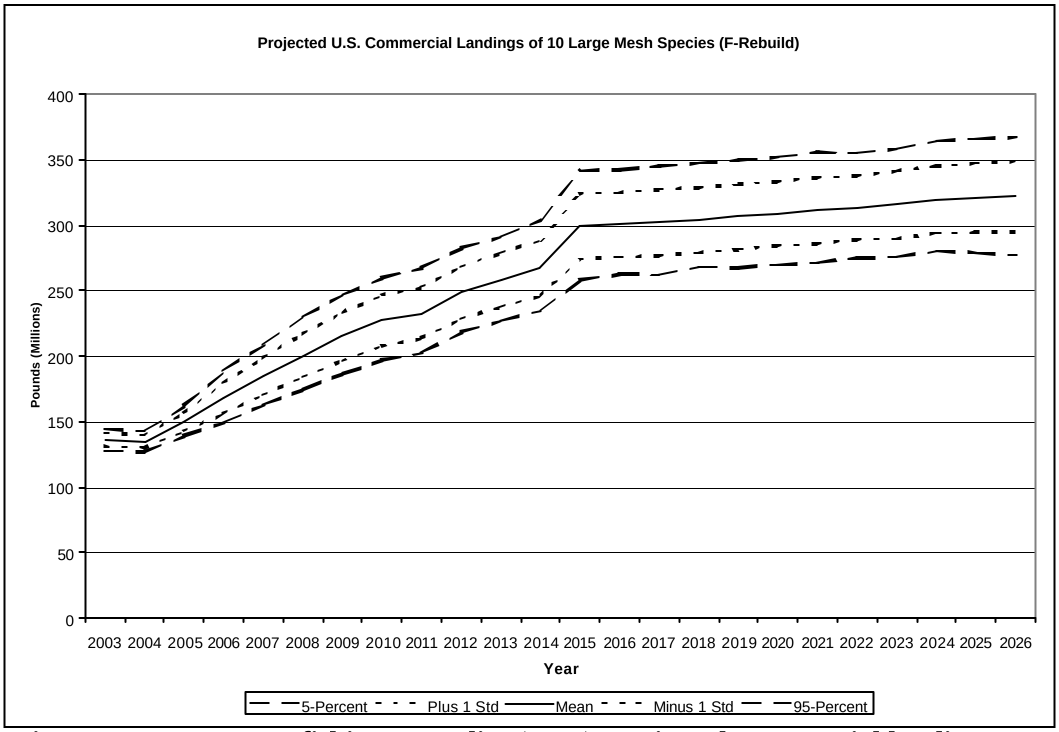

Figure 195 – Constant fishing mortality (2014), projected commercial landings

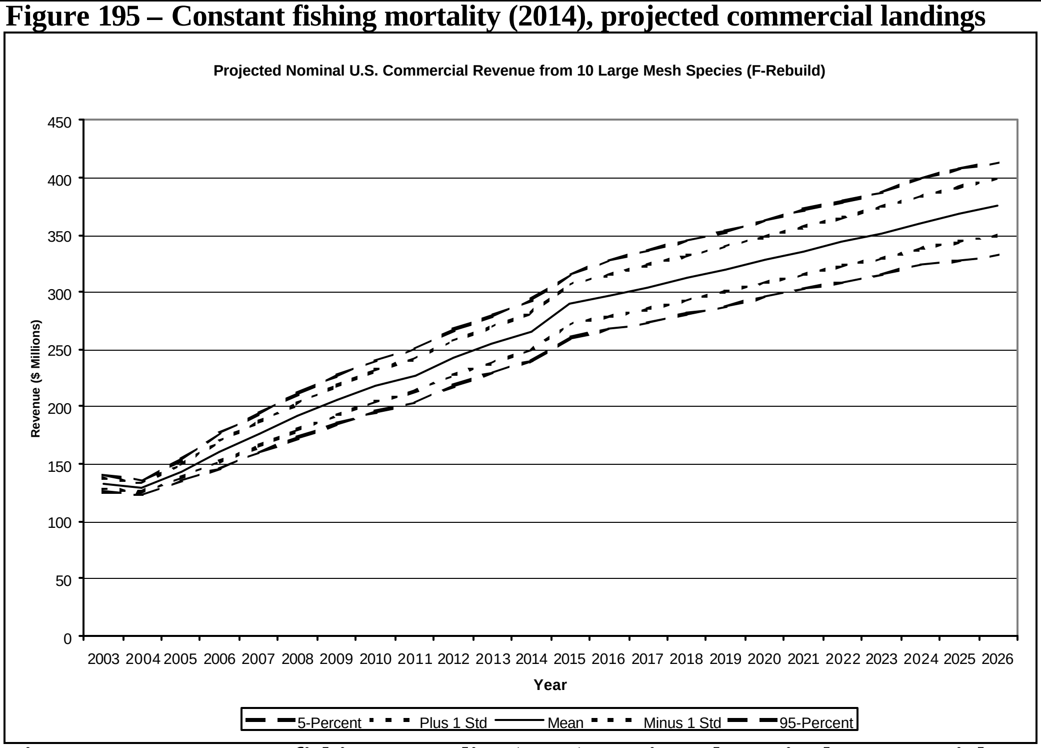

Figure 196 – Constant fishing mortality (2014), projected nominal commercial revenues

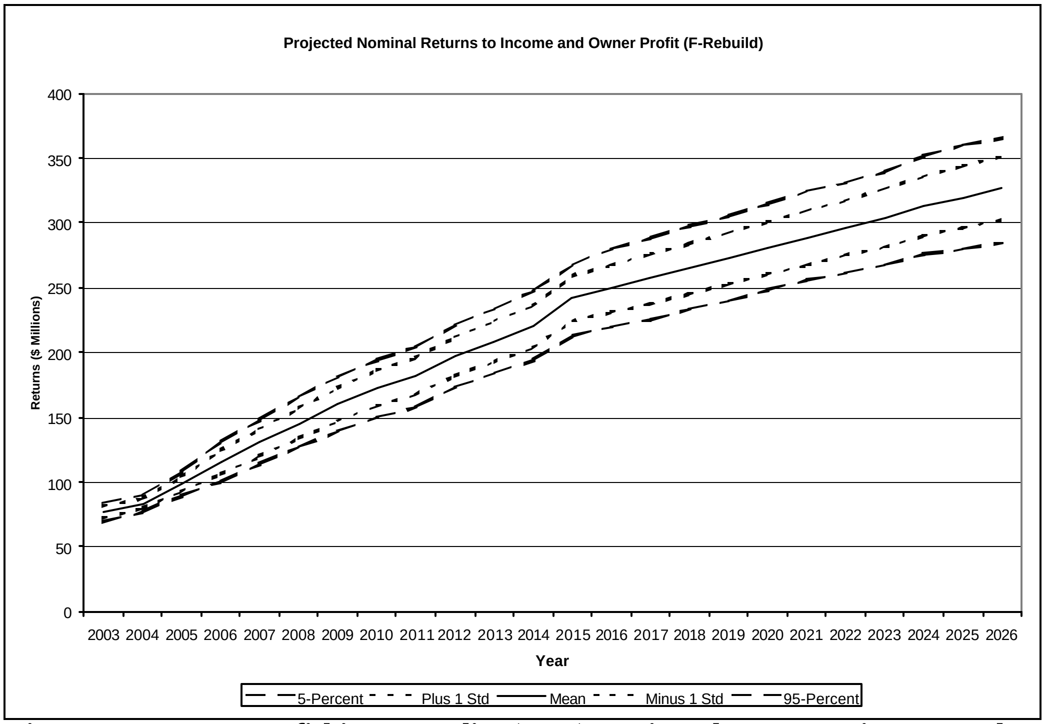

Figure 197 – Constant fishing mortality (2014), projected returns to income and owner profit

5.4.2.7 Phased Fishing Mortality Rebuilding Strategy (2014)

Average commercial U.S. landings of large mesh groundfish species were projected to be 136 million pounds in 2003 and increase to 152 million pounds in 2004 (Figure 198). Compared to the Constant fishing mortality strategy landings increase from 2003 to 2004 because the phased reduction schedule would actually result in increases in fishing mortality rates for a few stocks, but only within the first year of implementation. Compared to the Constant fishing mortality rate strategy the Phased rebuilding approach would result in higher landings until 2008 but would result in lower landings from 2009 onward until the end of the projection period.

Projected revenue streams for the Phased rebuilding strategy were $133 million in 2003 and increase to $146 million in 2004 (Figure 199). As was the case for landings, the revenue streams for the phased approach exceed that of the Constant fishing mortality strategy until 2009. From 2009 onward the Constant fishing mortality approach yields higher nominal revenues through 2026. Note, however that the 95-percent confidence intervals around the average revenue streams for both rebuilding approaches overlap which means that the two revenues from either alternative are virtually indistinguishable from one another.

Average returns to crew and captain incomes and vessel owner profit follow the same general pattern as that of projected revenues. Returns to income and profit were estimated to be $76 million in 2003 and $92 million in 2004 (Figure 200). As noted above, the confidence intervals for the Phased and Constant fishing mortality approaches overlap, but the distinguishing feature of the Phased approach is that neither revenues nor income payments go down in any year of the rebuilding period.

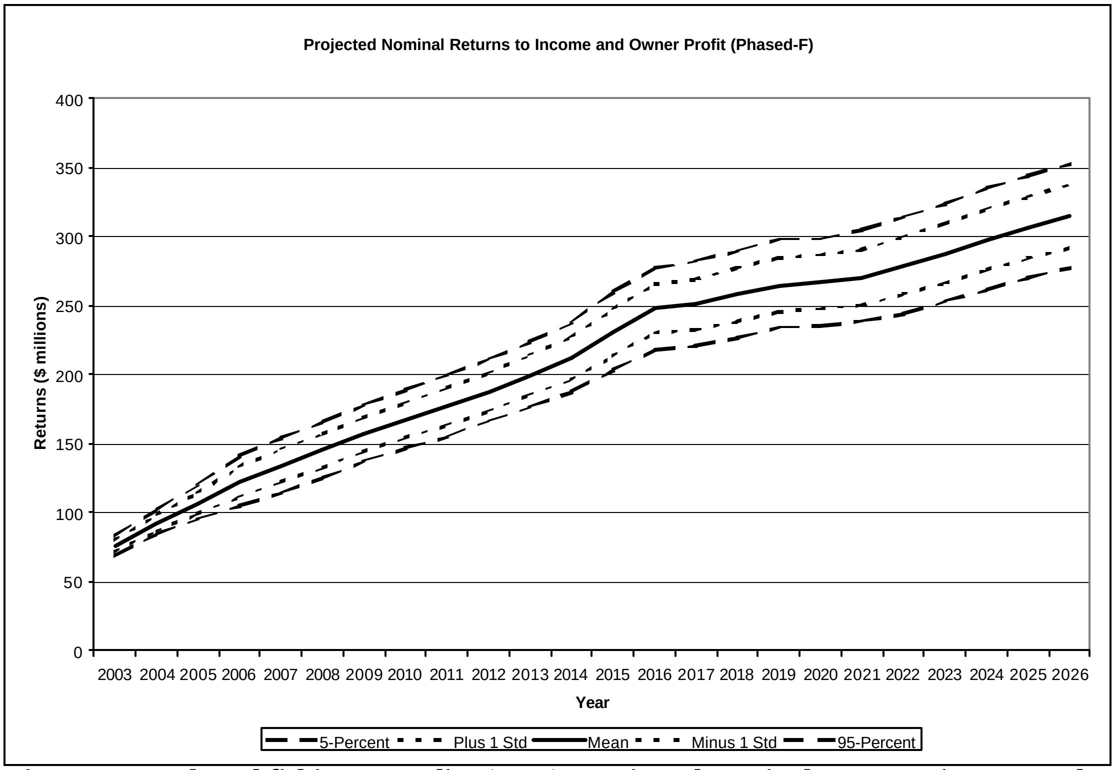

Figure 200 – Phased fishing mortality (2014), projected nominal return to income and owner profit

5.4.2.8 Adaptive Management Rebuilding Strategy (2014)

The landings streams under the Adaptive strategy represent one of many possibilities that could be realized pending the scheduled 2008 review of progress toward rebuilding. The particular projected landings represent the scenario where the management program is determined to meet all Fmsy targets and all biomass reference points remain unchanged. Under this scenario management measures would be implemented in 2009 to achieve constant fishing mortality rates from 2009 until the end of the 2014 rebuilding period. Average landings under this scenario increase slightly from 136 million pounds to 139 million pounds in 2004. (Figure 201). Projected landings increase in each subsequent year through 2008 but decline (about 4 million pounds) in 2009 with implementation of rebuilding fishing mortality rates where required. Note that this reduction in landings is recovered within one year as average 2010 landings were approximately 10 million pounds greater than 2008.

Average projected revenues follow a pattern similar to that of landings with the exception that the reduction in revenues is dampened by changes in predicted prices such that average revenues do not decline from 2008 to 2009 (Figure 202). As noted previously, the 95% confidence intervals around the mean revenues stream overlap for all rebuilding alternatives. This means that the average revenue stream could be obtained under any of the rebuilding alternatives.

Projected nominal returns to captain and crew income and vessel owner profit averaged $76 million in 2003 and $85 million in 2004 (Figure 203). Projected returns follow a pattern similar to that of the revenues streams except that the change in income and profit is slightly greater ($6 million) than the revenue change ($4 million). This difference is due to a reduction in operating costs that accompany the reduction in effort that is required in 2009 to meet all rebuilding targets within the 2014 rebuilding time.

5.4.2.9 Comparison of Rebuilding Strategies for 2014 Rebuilding Time Frame for Most Stocks

Each rebuilding alternative results in the same conservation outcome in 2014 for most stocks and by 2026 for Georges Bank cod and Cape Cod/Gulf of Maine yellowtail flounder but they do so by achieving different fishing mortality rates over time. Figure 204 shows recent calendar year landings of regulated groundfish species and the projected landings under different rebuilding options.

In the draft amendment, the economic impacts of rebuilding strategies were estimated assuming perfect implementation – that is, all mortality rates were assumed to be precisely achieved. The projected landings streams from these analyses represent the yield that could be produced if all fishing mortality rates appropriate to each stock were exactly achieved in each year. As such, these landings streams may not reflect realized yield, since realized fishing mortality rates will be sensitive to the specific management measures to be implemented. While estimates of realized fishing mortality rates have been developed, these forecasts are likely to be valid only over the very short term, leaving considerable uncertainty over the longer-term performance of any given rebuilding strategy. Substituting allowable fishing mortality rates for "realized" fishing mortality rates sharpens the focus of analysis on the fundamental difference among alternative rebuilding strategies which is the magnitude and timing of fishing mortality rate changes over time. The cost of doing so is that a meaningful link between estimates of realized short-term impacts and projected landings streams is difficult to establish. This was one of the criticisms of the analyses raised during the public comment period. The benefit of doing so is that all projections are internally consistent with one another and comparisons across alternatives and over time are also valid.

Analysis of the proposed action, while using the same analytic techniques, has a key difference. The rebuilding strategies in the draft amendment were theoretical constructs; management measures were then developed that tried to meet the target fishing mortality rates. In some cases the proposed measures did so imperfectly. The proposed action, however, has a much closer link between the measures and the rebuilding fishing mortality rate schedule. For healthy stocks, the estimates assume that the special access programs and other measures in the plan will allow harvesting to the appropriate fishing mortality rate. For stocks in poor condition, the proposed combined rebuilding strategy mortality rates are closely linked to the expected impacts of the proposed management measures. Thus, the estimated impacts should more accurately reflect the realized landings and revenues from the proposed action. This approach addresses to some extent the criticism that the draft amendment did not accurately reflect revenues that could be expected as a result of the management program. It also narrows the perceived difference between the short and long term analyses of the proposed action.

The fact that projected landings streams represent somewhat idealized conditions complicates interpretation of Figure 204 at least over the short term. While the projected landings in 2004 indicate an increase in landings, the management measures may prevent these projected levels from being realized. Nevertheless, the longer term projections indicate that rebuilding the groundfish resource would ultimately result in levels of landings more than four times as great as the 75 million pounds experienced from 1994 to 1999 and would be three times that landed in 2001, the highest recorded landings since 1993.

Average performance of each of these rebuilding alternatives is measured against No Action by subtracting the No Action projection from the rebuilding projection (the Status Quo included). In this manner, a negative value means that No Action produces higher yield while a positive value means that

No Action produces lower yield than a given rebuilding alternative. Note that No Action only serves as a common benchmark against which all rebuilding alternatives may be compared; not as a rebuilding alternative itself.

The Status Quo produces lower landings than No Action in every year except 2011 (Figure 204). Every rebuilding alternative produced lower projected landings from 2004 to 2013. Only the Constant fishing mortality alternative produces higher landings than No Action in 2014. All rebuilding alternatives result in higher projected landings in all years from 2015 onward. Specifically, projected landings would be more than twice (119%) what the 2003 projected level and would be 136% higher than 2003 levels in 2026.

Across rebuilding alternatives, the Proposed Action produces higher landings in each year from 2004 through 2007 and produces second highest yield in 2008. Over these years the Proposed Action benefits from the higher fishing mortality rates under the early years of both the phased and the adaptive approach. However, from 2010 to 2014 the fishing mortality rates under the Proposed Action must be lower than under any other alternative to make up for the higher rates of the first four years. From 2015 onward the Proposed Action landings follow a pattern similar to the Adaptive and the Constant fishing mortality rate strategies since all stocks except Cape Cod Yellowtail Flounder will be fished at approximately the same level.

The range of the difference between No Action revenue streams (Figure 205) and any rebuilding alternative is somewhat less than that of the landings streams (plus 35 million or minus 45 million pounds). Further note that the gap in projected revenues between any given rebuilding alternative is even narrower, which means that the time path for revenues streams is not substantially different across rebuilding alternatives. Across rebuilding alternatives the largest difference in projected revenues occurs within the first four years of the rebuilding time where the Proposed Action results in roughly equivalent or slightly higher revenue streams from 2004 to 2008. As noted above, the Proposed Action produces lowest revenue streams in every year from 2009 to 2014. From 2015 onward, the Proposed Action, Adaptive, and Constant F approaches all produce nearly identical revenues.

The cumulative annual difference in present value of net benefit (consumers surplus plus income and profit) between No Action and any give alternative indicates in which year a benefit/cost ratio (relative to No Action) would be greater than one (Figure 206). The cumulative difference in net present value for the Status Quo is not positive for any year of the projection period suggesting that the Status Quo would never producer higher economic benefit than No Action (Figure 207). At a 7-Percent discount rate the Adaptive approach would yield positive present value of economic benefit in fourteen years (2018) while the Proposed Action and the Constant fishing mortality strategy would produce positive economic benefit net, of No Action, in fifteen years (2019). Relative to No Action, the pure Phased approach would yield positive present value of economic benefit in sixteen years (2020). At lower discount rates, the number of years to reach positive cumulative present value would be lower but the ordinal ranking across alternatives would not change.

The sensitivity of the ordinal ranking across rebuilding alternatives was examined by selecting discount rates from zero to twenty-percent (Figure 208). Over the entire rebuilding period the ordinal ranking of all alternatives was robust for all discount rates up to seven percent. At discount rates above seven, the Proposed Action would produce lowest net present value among all alternatives except for the Status Quo. All alternatives would at least produce positive net benefits net of No Action at any discount rate up to and including ten-percent. At higher discount rates benefits net of No Action would be less than zero (eleven-percent for the Proposed Action; twelve-percent for the pure phased approach; fourteen-percent for Constant fishing mortality; and fifteen-percent for the Adaptive approach).

Projected landings streams, hence estimates of present value of net benefit are subject to uncertainty. Taking the full range of simulated realizations into account, the probability that the present value of net benefit will exceed No Action from 2003 to 2014 is approximately fifteen-percent for the Adaptive, pure Phased, and Constant fishing mortality rate strategies but is only about five-percent for the Proposed Action (Figure 209). Conversely, there is an Eighty-five-percent chance that No Action would produce higher present value of net benefit than any one of the three rebuilding alternatives.

Over the entire rebuilding period (2003 to 2026) there is at least an eighty-percent probability that any one of the rebuilding alternatives would yield higher present value of net benefit than No Action (Figure 210). Unlike the shorter time period, the cumulative probability distributions across all rebuilding alternatives do not overlap. Specifically, the cumulative probability distribution for the Adaptive approach lies everywhere rightward of all other alternatives. This means that for any given value of economic benefit net of No Action the Adaptive approach has the highest probability of being larger than No Action. By contrast, the Phased approach would have the lowest probability of being greater than No Action for any given value of present value of net benefit. The probability that the Proposed Action would be greater than No Action was estimated to be only slightly less than 80% and would be nearly equivalent to that of the pure Phased approach.

5.4.3 Comparison of Economic Benefit of Alternative Rebuilding Times

The distinction between the two alternatives for rebuilding time frame is predictable. The 2009 rebuilding time would result in lower landings than 2014 until 2009, higher landings from 2010 to 2014, and roughly equivalent landings from 2015 onward as most stocks would be on a similar schedule of fishing mortality objectives after 2014 regardless of rebuilding time frame. Subtracting projected landings and related economic benefits of the 2014 rebuilding time frame from landings from the 2009 rebuilding alternative and summing these annual differences provides an estimate of the net gain from selecting the 2014 rebuilding time.

Over the projection period, the Constant fishing mortality rebuilding alternative would result in a net gain of 19 million pounds for a 2014 rebuilding time frame for most stocks (Figure 211). That, is the sum of the accumulated gains from 2003 to 2009 (denoted as area A) plus gains from 2015 to 2026 (area B) less accumulated losses from 2010 to 2014 (area C) is 19 million pounds. The Phased rebuilding alternative results in a small net loss of 1.4 million pounds. The relative difference between rebuilding alternatives is related to the fact that the phased fishing mortality rate alternative must resort to low fishing mortality rates in order the achieve rebuilding objectives within the prescribed time frame.

As noted previously price effects tend to moderate the relative magnitude of impact as compared to projected landings. This is why even though the Phased approach results in slightly less landings there is an overall net gain of $12 million in gross revenue. (Figure 212). Specifically, over the period where the phased alternative results in lower landings predicted prices increase which offsets the relative difference on landings. Where projected landings are higher predicted prices are lower but the difference in landings more than offsets the price change so the net effect is an increase in total revenue. The Constant fishing mortality rebuilding alternative also results in a net revenue gain, but at $35 million is higher than that of the Phased rebuilding alternative.

The accumulated difference in discounted economic benefit (the sum of consumer surplus and captain and crew income and vessel owner profit) between rebuilding time frames (2014 minus 2009) is a gain of $40 and $12 million respectively for the Constant fishing mortality and Phased rebuilding alternatives (Figure 213). This means that net economic benefit would be improved by selecting a 2014 rebuilding time frame for most stocks for either a Constant fishing mortality or a Phased rebuilding strategy. Note that this result is robust with respect to the choice of discount rate.

At discount rates from zero to twenty-percent the Constant fishing mortality strategy always results in higher net present value under a 2014 as compared to a 2009 rebuilding time for most stocks (Figure 214). The Phased approach for a 2014 rebuilding time does yield positive benefits at all discount rates above two-percent compared to a 2009 rebuilding time for most stocks. Even at discount rates of two-percent or less the difference between the 2009 and 2014 rebuilding times for the phased approach was small (no more than $11 million over a 23 year projection period).

5.4.4 Relative Impacts on Commercial Fishing Gross Revenues

Quantitative analysis of the biological effectiveness of the proposed alternatives was accomplished primarily by using an area closure model described in section 5.1.1. This model provided a relative measure of the change in exploitation of each of the primary groundfish stocks that would be impacted, as well as a relative measure of gross revenue changes. The data embedded in this model include gear type, landings, value, effort, and monthly average CPUEs of the 10 regulated groundfish species, by area block, for the Northeast region. To reflect the most current economic and resource conditions the effort data were updated to calendar years 1998-2001 by averaging a combination of VTR activity records and dealer price data for trips that had a valid latitude-longitude coordinate. This means that the area closure model excludes two types of information for vessels that land some quantity of regulated groundfish: landings and value of groundfish with no valid lat-long coordinates and landings and value of all other species. While the former is implicitly included in the gross revenue changes predicted by the area-closure model by assuming that the revenue impacts for groundfish landings that do not have valid location information will be proportional to the revenue impacts for data that is included in the model, exclusion of the latter will tend to result in an upward bias in the magnitude of impact on a vessel's total annual income. Note that the magnitude of this bias will be greater/lesser for vessels the lesser/greater their dependence on regulated groundfish for fishing income. The procedures used to correct for this estimation bias are described below.

There are two major differences between this analysis and that used to compare rebuilding strategies. First, this analysis reflects the fishing mortality that is expected to be realized from a suite of management measures. In many instances, that mortality is different than the mortality that is targeted. Often the proposed management measures reduce mortality on stocks that are in good condition far lower than necessary. Second, this analysis is short-term in nature and does not reflect the revenue streams expected over the entire rebuilding program. Both of these issues are discussed in detail in a later section.

The proposed action relies on effort controls to achieve the biological objectives, but includes opportunities to mitigate economic impacts through the use of different categories of DAS. Alternative 1 relies on effort controls (primarily DAS reductions and area closures) to achieve the biological objectives. Alternative 2 also contains a variety of effort controls but would also implement a hard TAC as a back-stop measure to assure that conservation objectives are met. Alternatives 4 and 4A include a hard TAC as the primary measure while Alternative 3 would also include a hard TAC but would also have a variety of other effort controls as yet to be determined. Alternatives that include a hard TAC were modeled as if each vessel had a share of the TAC. In effect, each vessel makes fishing decisions based on the total available quota to that vessel. Once a vessel's quota for a given species has been exceeded that vessel is assumed to make fishing decisions with no bycatch of that species. This assumption introduces two potentially counter balancing biases. First, vessels are likely to be either unable or unwilling to cease fishing in times or areas to avoid bycatch of a species where the TAC has been met. To the extent that vessels do continue to fish while discarding, the actual losses in fishing revenues will be less than that estimated herein. Second, this assumption does not take into account the derby effects that are likely to arise with quota-based management without specification of quota sharing arrangements either to individuals or recognized groups. Thus, the economic impacts of Alternatives 2, 3, 4, and 4A may not capture the full distributive impacts should derby fisheries result, which will tend to favor those that can catch earliest and fastest.

Most of the alternatives are designed to achieve the mortality reductions necessary to rebuild stocks by 2014 or later. Alternative 4, the hard TAC alternatives, could also be used to rebuild stocks by 2009. Larger reductions in mortality are necessary to achieve a faster rebuilding rate, and the short-term economic impacts would be different than for a later rebuilding date. The impacts for a 2009 rebuilding date are shown separately from those for the 2014 rebuilding dates.

Data
Data for this analysis included landings data from the VTR, price data from dealer records, and NMFS Northeast Regional Office permit data. The permit data for fishing year 2001 were queried to obtain homeport state and vessel length for all vessels (exclusive of vessels removed through the permit buyback) that were included in the area closure model[1]. VTR data for calendar years 1998-2001 were used to estimate total landings of all species by trip and by year for each vessel. The VTR data were used to maintain consistency with the data used in the area closure model and because it was the only way to maintain individual vessel information for vessels that may have landed in the states of Connecticut or Delaware. Total trip value was estimated by applying monthly average price, by species, to each trip record.

Data for groundfish revenues and all other species revenues for trips where groundfish were landed and trips where no groundfish were landed were then summed by vessel and aggregated into total annual income from trips where groundfish were landed and total income from trips where no groundfish were landed. Note that income from groundfish and income from all other species on trips where groundfish were landed were summed separately. In this manner, the dollar value of other species income per dollar of groundfish revenue can be calculated and used to estimate changes in other species revenue on affected groundfish trips. Total income by vessel for calendar years 1998-2001 were then averaged to construct a final data set that included the vessel permit number, gear sector (consistent with that included in the area-closure model), home port state, vessel length, 4-year average annual income from groundfish trips, and 4-year average income from all other trips.

Procedures
The area closure model was designed to provide a relative measure of change in the exploitation of species included in the model. As such, a status quo or baseline is constructed by imposing a set of constraints on where and when vessels may fish, to observed fishing location data, where the constraints represent the selected management measures in place. By changing these constraints, an estimate of how effort may be redistributed and the resulting revenue and landings is produced. The percent change in exploitation and regulated groundfish revenue is then estimated relative to the status quo.

Given that the area closure model produces a relative measure of change, and that the status quo is dependent on the specified constraints, there is no direct mapping between the modeled status quo and landings data tabulated from either dealer or VTR records. However, in concept, the area closure status quo is designed to approximate the specified suite of management measures. For purposes of analysis these measures include DAS, trip limits, and combinations of year-round and rolling closures that had been implemented in FY2001. The economic effects of the proposed alternatives were then estimated relative to this simulated Status Quo in the following manner. For purposes of illustration a sample vessel with a total baseline income of $77,500 is used.

Step 1. For a given option, the area closure model was used to estimate the expected change in large-mesh groundfish revenues by vessel.

1Even though the area closure model may not have included 100 percent of any given vessels activity, all vessels that did record landing of one or more pounds of regulated groundfish were included. Therefore, the area closure model should be a reasonable census of vessels that have landed regulated groundfish during calendar years 1998-2001 and that currently hold a valid multispecies permit.

Step 2. The change from Step 1 was then applied to baseline (i.e., the 1998-2001 average) groundfish revenues to estimate expected groundfish revenue under that option. Assuming, for example, that the illustration vessel's baseline groundfish revenue were $50,000 and the change from Step 1 was -20%, the estimated Amendment 13 revenue would be (50,000)*(0.8) = $40,000.

Step 3. Changes in other species revenues on groundfish trips was estimated by multiplying the calculated average other species revenues per dollar of groundfish revenue by the resulting estimated groundfish revenue from Step 2. For the example vessel, assume that this average revenue rate were 0.25 (i.e. $0.25 in revenue from non-regulated groundfish per dollar of regulated groundfish). The change in other species revenues on groundfish trips would be (40,000)*(0.25) = $10,000.

Step 4. Assuming revenues from trips where no groundfish were landed would not be affected, the revenue from these trips was added to the estimated revenue from Steps 2 and 3 to calculate a new level of total fishing income. Assuming $15,000 in revenue from trips where no groundfish were landed the total income under the option would be ($40,000 + $10,000 + $15,000) = $65,000.

Step 5. The estimated proportional changes in total fishing income was then calculated as estimated income minus baseline income divided by baseline income or (65,000 - 77,500)/77,500 = -16.1%.

There are likely to be several potential sources of bias associated with the method described above. One source of bias is associated with the treatment of revenue from species other than regulated groundfish. This potential bias has two sources. First, applying a constant ratio of other species revenue to groundfish revenue may not be appropriate. Since the applied other species revenue rate was based on 1998-2001 data this rate could change (may increase for some vessels and decrease for others) as vessels change fishing strategies in response to changes in DAS, trip limits, or area closures.

The assumption that revenues earned on trips that do not land any groundfish would remain unchanged is the second source of bias. The extent that vessels adapt to any one or more of the proposed measures by increased targeting of species other than regulated groundfish, assuming no change in other species' revenues will result in an upward bias in the estimated economic impacts.

In addition to the aforementioned, there is a potential bias associated with the inability to account for possible improvements in catch rates with changing stock sizes. This bias will be more severe for stocks that respond quickly to management changes than for stocks that respond relatively slowly. In the former case, the estimated impacts will tend to be biased upward, while in the latter the economic impact estimates would not be affected. Note also that the extent of the bias will be greater the longer the time period associated with the projected impacts.

The introduction of bias in the estimated impacts would be a more significant problem if the primary purpose were to calculate the absolute magnitude of economic impacts. This is not the case. The primary purpose of the analysis is to provide a comparative assessment of economic impacts across alternatives, as well as an assessment of the distributive effects by gear sector, state, and vessel size class. Thus, even though some bias is likely, as long as each alternative is assessed in a consistent manner, the ordinal ranking of alternatives and the relative impacts across gears, sizes, and states should be preserved.

5.4.4.1 Impacts of the Proposed Action on Vessel Fishing Revenue

The Proposed Action would implement a large number of management measures some of which are quantifiable using the area closure model while many are not. The quantifiable measures include the impact of DAS reductions, area closures, and trip limits. Based on an evaluation of the proposed new baseline DAS allocations it was determined that the estimated DAS reduction would be approximately 45% from the 2000-2001 baseline. This reduction was combined with the proposed area closures and trip limits for Gulf of Maine cod, Georges Bank cod, Cape Cod/Gulf of Maine yellowtail and Southern New England yellowtail flounder to produce an estimate of relative revenue changes compared to 1998-2001 average conditions.

The estimated DAS reduction was based only on final allocations of category A DAS coupled with an assumed leasing of 3,000 DAS. This means that several key provisions of the Proposed Action that would provide opportunities for some vessels to increase fishing income could not be included. The potential use of category B DAS would provide fishing opportunities in Special Access Programs (Reserve B DAS) and other fisheries with low incidental catches of stocks of concern (Regular B DAS). The impacts of these opportunities could not be quantified because either type of B day could only be used under proscribed conditions that may not be typical of fishing activity that took place during the baseline period of 1998-2001. This means that observed CPUE data would not adequately capture revenue opportunities for either Regular or Reserve B DAS.

The Proposed Action would implement a sector allocation for Georges Bank cod hook and gillnet sectors. However, the actual number of participating vessels, how much quota they will receive and the manner in which the quota will be fished has yet to be determined. While hook and gillnet effort are included in the area closure model the resulting economic impacts for these sectors may not reflect realized impacts.

Last, while the total DAS reduction does include an estimate of 3,000 leased DAS it was not possible to determine exchanges between vessels. Instead, the leased DAS was treated as being equivalent to a DAS reduction offset to every vessel that would not have been available without DAS leasing. Specifically, using the estimated use rate (without DAS leasing) of 78% the expected DAS use would have been about 32,000 DAS; a 49% reduction from the baseline DAS use of 63,100 DAS (FY2000-2001 average). The 4% difference between the DAS reduction with and without leasing was spread across all vessels even though leasing would really mean that some vessels fish less while others would fish more.

The inability to capture the potential beneficial use of Category B DAS means that estimated revenue losses will be overestimated for vessels that will be able to participate in SAPs or will be able to use Regular B DAS. The potential affect of the Georges Bank cod hook and gillnet sector allocations on estimated revenue impacts are difficult to assess. Having a sector allocation does not mean that the sector participants will be able to take any more Georges Bank cod than they would otherwise. This means that the impact on the sector as a whole may be reasonably estimated but that individual vessel impacts may not be adequately captured. Thus, while hook sector impacts are reported herein, it is hard to predict the direction of error or bias in these estimates.

A final consideration relates to the interpretation of the results to follow for the Proposed Action as well as that of the non-selected alternatives. As noted in section 5.4.4 the area closure model itself produces a set of revenue estimates for a baseline condition. This baseline condition is formulated by modeling fishing time and area decisions subject to FY2001 regulatory constraints and 1998-2001 average resource conditions. All revenue impacts are based on a comparison of the estimated revenues associated with the Proposed Action management measures applied to the same 1998-2001 resource conditions. Interpretation of these results must be tempered by the fact that they are relative to a baseline resource condition and that they represent a change from average 1998-2001 revenues. The former means that estimated revenue impacts do not take into account improved productivity due to changes in stock size (i.e. realized revenue impacts are likely to be lower than predicted) while the latter means that the resulting revenue changes should be thought of as cumulative (i.e. they include the effect of the interim FY2002-2003 measures as well as anticipated FY2004 impacts) and not a marginal change from current (FY2003) conditions.

The Proposed Action would have an estimated $40 million reduction in total fishing revenues from groundfish trips compared to the 1998-2001 average. Since regulated groundfish account for approximately 60% of total groundfish trip income, losses in groundfish revenue alone would be about $24 million and revenue losses from all species other than regulated groundf ish would be $16 million. Due to differences in dependence on groundfish and normal fishing patterns, these total revenue losses are not equally distributed across all vessels. In fact, revenue changes were found to be quite skewed which means that reporting average or even median vessel impacts fails to identify the full range of revenue losses across the groundfish fleet. For this reason, revenue impacts are reported for the 10th, 25th, 50th (median), 75th and 90th percentile of the distribution of impacted vessels sorted in ascending order from most negatively to least impacted vessel (Table 184). Each percentile forms an interval that represents a specific number of vessels as well as the lower and upper range of impact on vessels between percentiles. For example, since there are 848 vessels included in the analysis, there are 85 (rounding to the nearest whole number) vessels at or below the 10th percentile. Gross revenues losses for these vessels would be 40.4% or greater for the Proposed Action. Revenue loss for the 127 vessels between the 10th and 25th percentile would range from 40.4 to 34.3%. Note that the values reported in the column labeled "Upper" represent the revenue change at the specified percentile while the values in the column labeled "Lower" represent the revenue change at the next lower percentile. For example, the revenue loss for the median (50th percentile) vessel was 19.60% and the revenue loss at the 25th percentile was 34.3%.

Note that at the 90th percentile revenue loss was estimated to be zero or no change from 1998-2001 average conditions. Even with a 45% reduction in DAS some vessels could experience no change or an improvement in revenues under a variety of different circumstances. For example, a doubling of the GOM cod trip limit (compared to FY2001) would offset the DAS reduction if the vessel had a very high dependence on Gulf of Maine cod. The area closures under the Proposed Action also differ from that of FY2001. Vessels with a high affinity for a specific area or of limited range may be highly sensitive to specific closures. In these cases, changes in area closures may offset DAS reductions. This highlights the relationship between efficiency and regulatory design. That is, economic impacts may be reduced by identifying measures that permit vessel's to operate as efficiently as possible within available effort allocations. The trip limit is one such example; the tradeoff between DAS and area closures is another. For example, for vessels with limited range a larger DAS reduction with fewer area closures may yield higher revenues as compared to a lower DAS reduction with more area closures.

Impact by Dependence on Groundfish

The impact on individual vessels depends on a variety of factors. Vessels that have a relatively high dependence on groundfish would be more affected by a given reduction in groundfish trip income than another vessel that is engaged in other fisheries. For example, if vessel A earned

80% and vessel B earned 20% of annual revenue from groundfish trips, a 20% reduction in groundfish revenue for both vessels would result in 16% reduction in total fishing income for a vessel A, but would be only a 4% reduction in total annual fishing revenue for vessel B.

For the Proposed Action, gross fishing revenue losses increase with higher dependence on groundfish trip income (Table 185). The median revenue loss for vessels that depend on groundfish for 25% or less of fishing revenue was estimated to be 2.5% while the median loss for vessels with 75% or greater dependence on groundfish was 35.0%. This difference between vessels from lower to higher levels of dependence on groundfish trip income is consistent for all percentiles.

	Number of Vessels	Lower	Upper
10th Percentile and Below	85	Minimum	-40.4%
10th to 25th Percentile	127	-40.4%	-34.3%
25th to 50th Percentile	212	-34.3%	-19.6%
50th to 75th Percentile	212	-19.6%	-5.4%
75th to 90th Percentile	127	-5.4%	0.0%
Above 90th Percentile	85	0.0%	Maximum

Table 185 - Revenue Impacts by Dependency on Groundfish for Proposed Action

Impact by Entity Size in Terms of Gross Sales

Dependence on groundfish is defined as the proportion of groundfish trip income of total fishing income. This measure does not take into account the level of total fishing income since a vessel with $5,000 in total fishing income could have the same level of dependence on groundfish as a vessel with $500,000 in total fishing income. In relative terms the impact on these two vessels may be the same but the total impact may be very different since the former may have income from other non-fishing sources while for the latter fishing may be the sole source of income and may support a larger number of people. To examine the relative impact on vessels with differing levels of groundfish revenues the estimated distribution of Status Quo revenues was divided into approximate quartiles resulting in the following revenue classes; $35,000 or less, $35,001 to $100,000, $100,001 to $250,000, and $250,001 or more.

As was the case for groundfish dependence, the relative impact on vessels with higher gross sales was estimated to be greater at all percentiles, although the relative impact for the most affected vessels (the 10th percentile) was not markedly different (-38 to 43%) for all sales categories from $35,001 and above (Table 186). Note that the fact that estimated relative revenue losses were generally higher for vessels with higher gross sales also means that the revenue losses in absolute terms would also be greater.

The relative impact on vessels with gross groundfish sales of $35,000 or less was substantially lower than vessels with higher gross sales. In fact, 25% of these vessels were estimated to earn higher fishing income under the Proposed Action as compared to 1998-2001 average revenue. Vessels with increased revenue tended to be smaller vessels using gillnet or hook gear; vessels that would benefit relatively more from the increased GOM cod trip limit and whose revenue would be more sensitive to differences in area closures.

Impact by Gear Groups
Median revenue losses for hook and gillnet gear were similar (7.7 and 9.7% respectively) but were much lower than that of median trawl vessel impacts (-22.7%) (Table 187). However, the relative revenue impact among the most impacted vessels was similar across all gear groups (40 to 44% at the 10th percentile). At all percentiles above the median trawl vessels were estimated to incur revenue losses while revenue changes are positive for gillnet and hook gear. In fact, both gillnet and hook gear groups appear to be split between vessels that may experience significant revenue losses and vessels that may experience revenue gains. This disparity is likely due to differences in dependence on Georges Bank cod and Gulf of Maine cod. Because cod tends to represent such a high proportion of total fishing income for these two gear groups revenue are very sensitive to changes in cod trip limits. Thus, while the Gulf of Maine cod trip limit would be double that of FY2001 the Georges Bank cod trip limit is more restrictive. This means that even with a 45% DAS reduction, hook and gillnet vessels with a high dependence on Gulf of Maine cod can increase total fishing income while vessels with high dependence on Georges Bank cod experience revenue losses.

Gross Groundfish Sales Intervals	Number of Vessels	Lower	Upper
$35,000 or less (n = 209)			
10th Percentile and Below	21	Minimum	-27.1%
10th to 25th Percentile	31	-27.1%	-9.8%

Table 187 - Proportional Change in Gross Annual Revenues by Gear Group for Proposed Action

Impact by Vessel Length Class
The Proposed Action revenue impacts on both medium and large trawls were estimated to be similar at all percentiles for both large and medium sized vessels with median revenue loss of at least 22.5 and 24.3% respectively (Table 188). For small vessels, the most impacted vessels would experience potential revenue losses of at least 38% at the 10th percentile and 21.7% at the 25th percentile. However, median revenue losses would be less than 5% and vessels at and above the 75th percentile would experience revenue gains. The upper half of the distribution of small vessel revenue impact is likely to be dominated by the same hook or gillnet vessels that comprised the group of vessels with positive revenue impacts shown in Table 187.

Impact by Gear/Length Groups
Impacts among hook vessels of different size indicate that the Proposed Action would have a similar pattern of impact regardless of size although small hook vessels would experience revenues losses of about 10-percentage points greater for the median vessel and at all percentiles below the median (Table 189). By contrast, the Proposed Action would have larger revenue impacts on large as compared to small gillnet vessels.

Compared to either medium or large vessels, small trawl vessels were estimated to incur lower revenue reductions at all percentiles. Among medium and large trawl vessels the estimated revenue losses were similar although up to the median vessel revenue losses were higher for trawl than they were for medium vessels. However, at percentiles above the median, medium vessel revenue losses were higher than that of large trawlers.

Large (n=190)	Number of Vessels	Lower	Upper

Impacts by Home Port State

The Proposed Action would result in a revenue loss of at least one-third for 25% of all vessels with a Maine, New Hampshire or a Massachusetts homeport (Table 190). Across all states revenue impacts would be lowest for New Jersey vessels. Revenue impacts on Rhode Island would be quite similar to that of Connecticut/New York vessels. Among states that border the Gulf of Maine the revenue impacts for Massachusetts and Maine vessels were similar at all percentiles while revenue impacts on New Hampshire vessels were lower for the median vessel and for all other percentiles above the median.

Impacts by Port Groups

Median revenue impacts were at least -30% in the Boston, Chatham/Harwich, New Bedford, Portland, and Upper Mid-Coast Maine port groups (Table 191). Median revenue losses were between 20 and 29% in the port groups of Gloucester, Portsmouth and Provincetown. Among the remaining port groups median revenue losses were about 16% in Point Judith and South Shore Massachusetts while median impacts were -11% or less everywhere else.

Table 191 - Proportional Change in Gross Annual Revenues by Port Group for Proposed Action (cont.)

5.4.4.2 Impacts on Vessel Fishing Revenue of Alternative 1

Alternative 1 contains two different proposed DAS use levels and two different trip limit alternatives for Georges Bank Cod. Alternative 1A has a DAS use of 28,400 days and a Georges Bank cod trip limit of 2,000 pounds per DAS up to 20,000 pounds per trip. Alternative 1B has the same Georges Bank cod trip limit but would reduce DAS use to 41,050 in the first year, with used DAS declining to 22,100 DAS in the fourth year after implementation. Alternative 1C would have the same DAS use as 1A but would implement a Georges Bank cod trip limit that would vary by gear and season. Similarly, Alternative 1D would implement the same Georges Bank cod trip limit as 1C but would reduce DAS use to the same level as 1B. Alternative 1A would result in an estimated reduction of $45.6 million in total fishing income while Alternative 1B would have a lower impact ($28.3 million) in the first year. Due to a more restrictive Georges Bank cod trip limit, Alternative 1C would result in an estimated reduction in total fishing revenues of $49.1 million and Alternative 1D would result in a reduction of $33 million.

Vessel-level impacts are not uniformly distributed with some vessels being much more impacted than others. Because of the tendency for revenue impacts to be skewed, revenue impacts are reported for the 10th, 25th, 50th (median), 75th and 90th percentile of the distribution of impacted vessels sorted in ascending order from most negatively to least impacted vessel (Table 192). Each percentile forms an interval that represents a specific number of vessels as well as the lower and upper range of impact on vessels between percentiles. For example, since there are 848 vessels included in the analysis, there are 85 (rounding to the nearest whole number) vessels at or below the 10th percentile. Gross revenues for these vessels would decline 46.3% or greater for Alternative 1A but would decline 29.8% or more for Alternative 1B. Similarly, the revenue loss for the 127 vessels between the 10th and 25th percentile would range from 46.3 to 40.1% for Alternative 1A and from 29.8 to 25.4% for Alternative 1B. Note that the values reported in the column labeled "Upper" represent the revenue change at the specified percentile while the values in the column labeled "Lower" represent the revenue change at the next lower percentile. For example, the revenue loss for the median (50th percentile) vessel was 24.0% and the revenue loss at the 25th percentile was 40.1%. Since 1A and 1B differ only in their DAS reduction, the option with the least DAS reduction results in lower revenue impacts for all vessels. It should be remembered, however, that in Alternatives 1B and 1D, by year four the DAS reductions are lower than those under Alternatives 1A and 1C.

At the upper end of the distribution of impacted vessels are some vessels that may realize an increase in fishing revenues in spite of the DAS reductions proposed under Alternative 1. For example, the 85 vessels above the 90th percentile would realize either no change or some modest improvement in fishing income because of the increase in the GOM cod trip limit from 400 under No Action to 800 pounds per day as well as differences in the suite of closures between what had been in place in FY2001 and that proposed under Alternative 1. That is, compared to No Action, Alternative 1 measures permit a small number of vessels (about 10%) to be more efficient. For these vessels, the gain in efficiency is sufficient to more than offset the DAS losses resulting in a net increase in fishing income relative to No Action. This highlights the relationship between efficiency and regulatory design. That is, economic impacts may be reduced by identifying measures that permit vessels to operate as efficiently as possible within available effort allocations. The trip limit is one such example; the tradeoff between DAS and area closures is another. For example, for vessels with limited range a larger DAS reduction with fewer area closures may yield higher revenues as compared to a lower DAS reduction with more area closures.

At a fleet-wide level, Alternatives 1C and 1D have similar predicted revenue losses to that of Alternatives 1A and 1B. However, because of the comparatively more restrictive Georges Bank cod trip limit, the Alternative 1C and 1D revenue impacts at each percentile are higher by 2-3 percentage points.

		Alternative 1A		Alternative 1B		Alternative 1C		Alternative 1D

Table 192 - Fleet-Wide Impacts of Alternatives 1A, 1B, 1C and 1D

Impact by Dependence on Groundfish

The impact on individual vessels depends on a variety of factors. Vessels that have a relatively high dependence on groundfish would be more affected by a given reduction in groundfish trip income than another vessel that is engaged in other fisheries. For example, if vessel A earned 80% and vessel B earned 20% of annual revenue from groundfish trips, a 20% reduction in groundfish revenue for both vessels would result in 16% reduction in total fishing income for a vessel A, but would be only a 4% reduction in total annual fishing revenue for vessel B.

For Alternative 1A and 1B the impact on gross fishing revenue increases with higher dependence on groundfish trip income (Table 193). For Alternative 1A, the median revenue loss for vessels that depend on groundfish for 25% or less of fishing revenue was estimated to be 3.2% while the median loss for vessels with 75% or greater dependence on groundfish was 41.1%. This difference between vessels from lower to higher levels of dependence on groundfish trip income is consistent for all percentiles. As noted above, the revenue impacts for Alternative 1B are lower across all dependence categories.

Alternative 1C and 1D revenue impacts are higher, but not appreciably so, for vessels with groundfish dependence below 75%. Among vessels that are most dependent on groundfish, the revenue impacts for Alternative 1C are 3 to 5 percentage points higher as compared to Alternative 1A with the same used DAS. Similarly, the impacts of Alternative 1D exceed that of 1B particularly among vessels at or below the 10^{th} percentile (i.e. the most affected vessels).

Table 193 - Revenue Impacts by Dependency on Groundfish for Alternatives 1A, 1B, 1C and 1D

Impact by Entity Size in Terms of Gross Sales

Dependence on groundfish is defined as the proportion of groundfish trip income of total fishing income. This measure does not take into account the level of total fishing income since a vessel with $5,000 in total fishing income could have the same level of dependence on groundfish as a vessel with $500,000 in total fishing income. In relative terms the impact on these two vessels may be the same but the total impact may be very different since the former may have income from other non-fishing sources while for the latter fishing may be the sole source of income and may support a larger number of people. To examine the relative impact on vessels with differing levels of groundfish revenues the estimated distribution of No Action revenues was divided into approximate quartiles resulting in the following revenue classes; $35,000 or less, $35,001 to $100,000, $100,001 to $250,000, and $250,001 or more.

As was the case for groundfish dependence, the relative impact on vessels with higher gross sales was estimated to be greater at all percentiles, although the relative impact for the most affected vessels (the 10th percentile) was approximately the same (-47%) for all sales categories from $35,001 and above (Table 194). Note that the fact that estimated relative revenue losses were generally higher for vessels with higher gross sales also means that the revenue losses in absolute terms would also be greater.

The relative impact on vessels with gross groundfish sales of $35,000 or less was substantially lower than vessels with higher gross sales. In fact, 25% of these vessels were estimated to earn higher fishing income under either Alternative 1A or 1B as compared to No Action. Vessels with increased revenue tended to be smaller vessels using gillnet or hook gear; vessels that would benefit relatively more from the increased GOM cod trip limit and whose revenue would be more sensitive to differences in area closures between No Action and Alternative 1.

Estimated impacts on gross revenues were higher for Alternative 1C and 1D as compared to 1A and 1B but the relative distribution of impacts among sales intervals was similar; with revenue impacts tending to increase with sales.

		Alternative 1A		**Alternative 1B**		**Alternative 1C**		**Alternative 1D**

Table 194 - Revenue Impacts by Size of Gross Groundfish Sales for Alternatives 1A, 1B, 1C and 1D (cont.)

Impact by Gear Groups

The relative revenue impact was lower for hook gear than for either gillnet or trawl gears for both Alternative 1A and 1B (Table 195). Since cod represents a higher proportion of trip income for hook gear than for gillnet or trawl gear, revenue impacts associated with DAS reductions are offset by the higher GOM cod trip limit that for some vessels is enough to result in a net increase in fishing revenue.

Estimated revenue impacts were similar among the most impacted gillnet and trawl vessels but estimated revenue changes tended to be less severe for gillnet vessels above the 25th percentile as compared to the trawl vessels. For example, the revenue impact on the median gillnet vessel was 12.0% as compared to 29.5% for the median trawl vessel. Gillnet impacts tended to be lower than trawl impacts, because like hook gear, cod represents a higher proportion of trip income so gillnet gear tends to benefit proportionally more from a change in cod trip limits than trawl gear. Note that total impact on trawl vessels is not only greater in relative terms but would also be greater in absolute terms since there are more than twice as many trawl vessels than either gillnet or hook vessels.

The more restrictive Georges Bank cod trip limit for Alternative 1C and 1D has only a small impact on trawl vessels compared to Alternatives 1A and 1B but would have a larger impact on both gillnet and hook gears. However, this impact is not uniform for all hook and gillnet vessels. That is, vessels that rely on Gulf of Main stocks would not be affected by a change in Georges Bank cod trip limits whereas, vessels that fish primarily on Georges Bank are more affected.

Table 195 - Proportional Change in Gross Annual Revenues by Gear Group for Alternatives 1A, 1B, 1C and 1D

Impact by Vessel Length Class

The estimated relative impact of total annual fishing revenue was lower for vessels under 50-feet for either Alternative 1A or 1B, although the Alternative 1A impact on the most affected small vessels was not substantially less (40.3%) than either medium (46.6%) or large (46.3%) vessels (Table 196). The distribution of revenue impact was similar for both medium and large vessels indicating that neither vessel size class would be disproportionately affected relative to each other under either Alternative 1A or 1B. Since hook and gillnet vessels tend to be small, the economic impacts on small vessels of Alternatives 1C and 1D was proportionally greater than Alternatives 1A and 1B.

Table 196 - Proportional Change in Gross Annual Revenues by Vessel Size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternatives 1A, 1B, 1C, and 1D

Impact by Gear/Length Groups

The relative revenue impact for small hook vessels was less than that of larger hook vessels, although not substantially so (Table 197). Unlike hook gear, small gillnet vessels were less affected than larger gillnet vessels but there was a greater difference in revenue impact with larger gillnet vessels being substantially more impacted at all percentiles than small gillnet vessels. For trawl gear, the distribution of revenue impacts was similar across all size classes at least up to the 50^{th} percentile. Above the 50^{th} percentile small vessels tended to be proportionally less affected than either medium or large vessels and large vessels tended to be less impacted than medium vessels. As noted previously, due to the lower DAS reductions the revenue impacts for Alternative 1B were lower across all gear and size groupings than that of Alternative 1A.

Table 197 - Proportional Change in Gross Annual Revenues by Gear Group and Vessel Size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternatives 1A, 1B, 1C, and 1D

Impacts by Home Port State

Alternative 1A would have greatest revenue impact on vessels from Maine home ports as compared to other states (Table 198). The distribution of revenue impacts was similar across all states except for New Jersey at the 10^{th} percentile ranging from a loss of 42.8% in Rhode Island to 47.8% in Massachusetts. At the 25^{th} percentile, Maine and Massachusetts's vessel revenue reductions were higher than all other states at 42.5% and 42.4% respectively. However, at higher percentiles Maine vessels were estimated to experience higher revenue impacts than any other state at both the 50^{th} and 75^{th} percentiles.

Across all states, only New Jersey and Rhode Island (and quite likely New York vessels) did not have any vessels with unchanged or increased fishing revenues under Alternative 1A. Vessels from these states are most likely to fish on Georges Bank or Southern New England and so would not be likely to benefit from an increase in the GOM cod trip limit.

Home Port State	Number of Vessels	Alternative 1A		Alternative 1B		Alternative 1C		Alternative 1D

Table 198 - Proportional Change in Gross Revenue by Home Port State for Alternatives 1A, 1B, 1C, and 1D

Impacts by Port Groups

Across port groups the relative distribution of estimated revenue impacts was similar at and below the 25th percentile for the port groups of Boston, Gloucester, New Bedford, Portland, Portsmouth, and Upper Mid-Coast, Maine (Table 199). For these ports and port groups, the revenue impact on the most affected vessels ranged from -43.0% in Boston to -45.9% in Portland. Revenue losses at the 50th percentile ranged from nearly 30% in Portsmouth to 43.6% in Portland. Overall, Portland, Maine had the highest revenue reduction at the 25th, 50th, and 75th percentile. However, even though Portland vessels would be disproportionately affected, the total impact on the ports of New Bedford and Gloucester would likely be greater because the number of vessels operating out of these ports is greater. Among other ports the groups including Point Judith, Provincetown, and South Shore Massachusetts all had roughly equivalent revenue impacts across all percentiles.

Revenue impacts on home port vessels in states with proportionally more vessels that rely on Georges Bank cod would be comparatively more affected under Alternative 1C and 1D as compared to 1A and 1B than vessels from states that have greater reliance on Gulf of Maine stocks.

As noted previously, revenue impacts of Alternatives 1C and 1D are larger for vessels that fish predominantly on Georges Bank and Georges Bank cod in particular. This is particularly notable for the Chatham/Harwich port group that is home to a concentration of hook and gillnet vessels.

Table 199 - Proportional Change in Gross Annual Revenues by Port Group for Alternatives 1A, 1B, 1C, and 1D (cont.)

5.4.4.3 Impacts on Vessel Fishing Revenue of Alternative 2

Alternative 2 would implement a suite of measures that would require a number of gear changes over and above what current regulations require. Alternative 2 would also implement a set of area closures that differ from no action and differ from that of Alternative 1. The DAS would be similar to current regulations (under the FW 33 court order) except that under Alternative 2A vessels that fished in the GOM would take a 30% reduction in DAS instead of 20% while Alternative 2B would result in the same proportional DAS reduction for all vessels but would restrict the total number of DAS that could be fished in the GOM to 70% of allocated DAS. In all other respects there are no differences between 2A and 2B.

In addition to DAS and area controls Alternative 2 has a number of proposed gear restrictions that have been designed to reduce fishing mortality to desired levels. Alternative 2 also includes a hard TAC as a backstop measure in case any one of the other effort reduction measures are not as effective as anticipated. The analysis presented below reports the impacts of fishing revenues for Alternative 2 with and without the TAC backstop. In this manner, the economic impact of the management measures modeled in the Closed Area Model can be contrasted with that of the TAC backstop. The Closed Area Model, however, does not include the impacts of some of the gear changes (haddock separator trawl, raised footrope trawl, mesh changes, etc). If these measures are as effective as expected, the revenue impacts would be more severe than those shown here for the alternative without the hard TAC. Nevertheless, removing the hard TAC from Alternative 2A and 2B and showing the economic impacts does demonstrate that these two alternatives may have slightly different distributive economic impacts.

Alternative 2B provides some flexibility to vessels to fish outside the GOM rather than be subject to a different DAS reduction. Because of this flexibility, the estimated gross revenue loss (Table 200) for Alternative 2B ($30.2 million) was slightly less than that of 2A ($31.6 million). This difference may be underestimated because the area closure model imposes constraints on fishing location decisions that are consistent with recent fishing history. This means that a vessel that never fished outside the GOM under the no action would not choose to do so under Amendment 13 even though it may be advantageous. Given this limitation, the revenue impacts of Alternative 2B may be overestimated relative to Alternative 2A which would tend to obscure the difference in relative economic effect between the two ways of administering DAS controls in the GOM.

As modeled, Alternative 2 does not meet conservation objectives without the hard TAC backstop. With a hard TAC, the added flexibility offered by the different DAS management options under Alternative 2A and 2B is eliminated because the hard TAC becomes more constraining than DAS allocations. This means that the estimated economic effects of the hard TAC backstop were the same regardless of the proposed DAS administration under Alternative 2A or 2B. The total impact on gross revenues was estimated to be $64.2 million. Note that this impact may be overestimated because the effectiveness of the gear changes could not be quantified. Should the gear changes be as effective as anticipated, or more so, then the hard TAC may not be constraining or would at least not be as constraining as predicted. Nevertheless, even though the economic impact would likely be lower it would probably still be greater than that estimated for Alternative 2A and 2B without the hard TAC backstop since that analysis underestimates revenue impacts because assumed catch rates, hence fishing revenue, would be overestimated.

At the vessel-level the estimated revenue impacts of Alternative 2 with the hard TAC were higher by about 30% at the 10th and 25th percentile. The difference in impact at the median was not quite as high but was still higher by 23% (-37.1% for Alternative 2 with a hard TAC as compared to -13.8% for Alternative 2 without a TAC backstop).

		Alternative 2A		Alternative 2B		Alternative 2A & 2B With Hard TAC	
	Number of Vessels	Lower	Upper	Lower	Upper	Lower	Upper
10th Percentile and Below	85	Minimum	-38.8%	Minimum	-40.9%	Minimum	-69.4%
10th to 25th Percentile	127	-38.8%	-26.1%	-40.9%	-26.0%	-69.4%	-55.2%

Table 200 - Fleet-wide Impacts of Alternative 2A and 2B, both with and without hard TAC

Impact by Dependence on Groundfish
Without the TAC backstop the impact on annual estimated gross fishing revenue increased as dependence on groundfish revenue increased (Table 201). The median loss for vessels that rely on groundfish was less than 1% but was almost 25% for vessels with 75% or greater reliance on groundfish. Among those most dependent on groundfish, estimated revenue loss was 63% or more for 37 of 371 vessels.

For some vessels the estimated revenue change was positive suggesting some vessels would see modest improvements in total fishing revenues under Alternative 2. Such an increase in gross revenue results relative to the Status Quo because of the increase in the GOM cod trip limit as well as some differences in area closures. Note that positive changes in revenues tend to be associated with vessels that are less dependent on groundfish.

With the hard TAC backstop the estimated revenue impacts for vessels least dependent on groundfish would be higher but not by more than 6% at any given percentile. However, for vessels with greater dependence on groundfish for total fishing revenue the estimated impact of the hard TAC backstop was much greater particularly among the most affected vessels (i.e. at the 10^{th} percentile). For example, the impact on gross revenues for vessels that depend on groundfish for 25 to 50% of revenue would be almost -33% with a hard TAC as compared to about -20% without a TAC backstop.

		Alternative 2A		Alternative 2B		Alternative 2A & 2B With Hard TAC

Table 201 - Revenue impacts by dependency on groundfish for Alternative 2A and 2B

Impact by Entity Size in Terms of Gross Sales

The estimated impact of Alternative 2 without the TAC backstop was generally less for vessels with gross sales of $35,000 or less (Table 202). Across all categories of gross sales the largest reduction in gross revenue was 50.9% or greater for vessels with gross sales between $100 and $250 thousand. However, at the 25th and 50th percentile revenue impacts within this sales category were similar to that of vessels with sales of between $35 and $100 thousand and to vessels with sales in excess of $250 thousand. Above the 50th percentile the proportional change in revenue impacts was greatest for vessels with gross sales above $250 thousand.

With a hard TAC backstop the estimated revenue impacts were larger across all categories of gross sales at all percentiles with revenue reductions at the 10th percentile of 70% or more for vessels with gross sales of $35 thousand to $250,000. Estimated impact on the median vessel was highest (-49.9%) for vessels with gross sales of more than $250 thousand and lowest (-12.9%) for vessels with $35 thousand or less in gross sales.

Table 202 - Revenue impacts by gross sales of groundfish for Alternative 2A and 2B

5.4.4.3.1 Impact by Gear Groups

Alternative 2 contains a modest increase in the GOM cod trip limit compared to what had been implemented during FY2001. However, Alternative 2 has a trip limit on GB cod that is much lower than that of the Status Quo which means that vessels that depend on GB cod for the majority of fishing revenue would be significantly affected under this particular Alternative. The difference in cod trip limits between GOM and GB is evident in the estimated revenue impacts of both gillnet and hook gear. Without a hard TAC backstop the revenue impacts for these two sectors show markedly different effects depending upon whether a vessel might fish in the GOM or GB as estimated revenue losses for gillnet vessels ranged from -56.9% at the 10th percentile to a gain of 0.7% at the 90th percentile (Table 203). The range of impact on hook gear was even greater with 8 vessels experiencing a loss of 73.7% or more with the same number of vessels experiencing revenue increases of 6.3% at the 90th percentile. Revenue impacts on trawl gear ranged between -33.4% and no change in revenue at the 10th percentile and 90th percentiles respectively. The disproportionate loss in revenue for hook and gillnet vessels operating on Georges Bank is due to the greater reliance on cod for fishing revenue as compared to trawl gear.

With the hard TAC backstop the disparity across gear groups does not disappear altogether but it is lessened. Specifically, at the 10th percentile gillnet and hook gear impacts were estimated to be -75.9% and -78.5% respectively. The impact on trawl gear was still lower, but was nearly 67%; a much smaller difference than estimated impacts without the hard TAC. The median vessel impact across gear groups was similar ranging between -34 and -38.1%.

Table 203 - Proportional change in gross annual revenues by gear group for Alternative 2A and 2B

Impact by Vessel Length Class

Without a hard TAC backstop, the relative impacts of Alternative 2 on vessels of different sizes were similar for Alternatives 2A and 2B (Table 204). Across size classes the impacts on medium and large vessels were similar as there were only modest differences in revenue change at any percentile from the 10th to the 90th. By contrast, small vessels were substantially more affected at the 10th percentile (58.8% loss) than either medium (36.1%) or large (33.3%) vessels.

With a hard TAC backstop the impact was still proportionally greater on small vessels (-75.7%) at the 10th percentile but the relative distribution of impacts across vessels of differing sizes was similar at all other percentiles.

Table 204 - Proportional change in gross annual revenues by vessel size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternative 2A and 2B

Impact by Gear/Length Groups

For trawl gear there was little difference among small, medium or large vessels in the distribution of revenue impacts (Table 205). For example, revenue impacts without a TAC backstop among the most negatively affected trawl vessels ranged from -32.4% for medium vessels and -35.1% for small vessels. Median impacts also fell within a relatively narrow range of -12.6% to -15.0% for large and medium trawl vessels, respectively. With a hard TAC backstop the relative distribution of impacts across trawl vessels was similar although estimated revenue impacts were consistently greater for small followed by medium then large vessels at the 10^{th}, 25^{th}, and 50^{th}

percentiles. At higher percentiles medium-sized vessels tended to be most impacted compared to other trawl vessels.

Both with and without the hard TAC backstop, small hook and small gillnet vessels tended to be comparatively more impacted than larger hook or gillnet vessels although both gear/size groupings were disproportionately affected relative to either trawl or gillnet gears. Without the TAC backstop, both small and larger gillnet vessels were similarly affected up to the 25th percentile but median impacts were lower for small gillnet vessels (-6.0%) compared to medium gillnet vessels (-14.4%). These larger gillnet vessels were estimated to experience larger revenue changes at higher percentiles as well. With the TAC backstop, efficiency gains from the increase in the GOM cod trip limit are lost as TACs. The TAC backstop, once reached, reduces overall fishing opportunities.

Table 205 - Proportional change in gross annual revenues by gear group and vessel size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternative 2A and 2B(cont.)

Impacts by Home Port State

Without a TAC backstop, Alternative 2 measures would have least impact on New Jersey vessels and would have greatest overall impact on Massachusetts vessels (Table 206). The median vessel impact (-23.2%) was greater for Massachusetts vessels than any other state and the impact on the most affected vessels was -58.8% or more which exceeded the next closest state (New Hampshire) by almost 19 percentage points.

The overall impact on gross annual revenues was similar for Rhode Island and for New York/Connecticut vessels as revenue impacts ranged from -20.7%/-17.2% to no change/+0.7% in Rhode Island and New York/Connecticut respectively. Among the remaining states the relative impact on New Hampshire vessels was greater than that of Maine vessels since the estimated revenue change was more deleterious at all percentiles for New Hampshire than for Maine vessels.

The hard TAC backstop would increase estimated revenue reductions but the overall pattern of effects across differing state would be unchanged. The state of Massachusetts would still be most impacted followed by New Hampshire and Maine. The relative distribution of impacts on Rhode Island and New York/Connecticut would still be roughly equivalent and New Jersey vessels would be least affected.

Table 206 – Proportional change in gross revenue by home port state for Alternative 2A and 2B

Impacts by Port Groups

Across all ports and port groups the largest reduction in annual fishing income would be in the port group of Chatham/Harwich with three-fourths of all vessels losing at least 29.7% of fishing revenue and half of all vessels losing more than half of fishing income. The impacts on these ports are directly related to the reduction in the GB cod trip limit as this port group is a center for the Cape Cod hook and gillnet fleet that relies heavily on GB cod for fishing revenue.

The Chatham/Harwich port group would still be the most impacted area under a TAC backstop with three-fourths of all vessels losing nearly 50% of annual fishing income. Among the most impacted vessels the estimated revenue loss was at least 77%.

Without a hard TAC backstop, the distribution of revenue changes was similar for the ports of Provincetown, Gloucester, Portland, Portsmouth, South Shore Massachusetts, New Hampshire Seacoast, New Bedford and Boston. Thus, even though the revenue impacts among these ports do differ, Alternative 2 does not disproportionately disadvantage these ports over one another. Ports that may be expected to experience lowest revenue impact include Point Judith and the Eastern Long Island port group.

The hard TAC backstop would change the relative distribution of impacts across port groups. As noted previously, Chatham/Harwich would be most impacted but Gloucester would also be disproportionately affected whereas the relative distribution of impacts on the ports of New Bedford, New Hampshire Seacoast, Portland, Portsmouth, Provincetown, and Upper Mid-Coast Maine would be similar.

Table 207 - Proportional change in gross annual revenues by port group for Alternative 2A and 2B(cont.)

5.4.4.4 Impacts on Vessel Fishing Revenue of Alternative 3

As proposed, other than area-species TACs, Alternative 3 (area management) would not implement any specific new measures as these would be developed later by some yet to be determined form of area management team or other type of governing body. The area closure model was used to estimate the impacts of current measures that would remain in place as well as the economic impact of a hard TAC. As noted previously, the area closure model treats a hard TAC as equivalent to an individual vessel quota and so does not evaluate area-specific quotas without also prorating those quotas by species and areas to individual vessels. However, the area closure model also limits fishing choices to areas that had been fished by a given vessel. This means that the area closure model already incorporates some aspects that would be consistent with assignment of a species-area TAC so the results may reasonably approximate the impact of an area TAC particularly one that is based primarily on logbook records.

Other than area-specific TACs the default management measures including trip limits, area closures and DAS allocations are identical to Alternative 4. For this reason, the economic impact of the Alternative 3 measures with a hard TAC are discussed with Alternative 4. See the following section for that discussion and an analysis of the impacts.

5.4.4.5 Impacts on Vessel Fishing Revenue of Hard TAC Alternatives (3, 4 and 4A)

Alternative 3, 4 and 4A implement a hard TAC in addition to different suites of area closures, DAS allocations, and gear restrictions. In spite of these differences the estimated impact of all three alternatives was approximately the same because the hard TAC becomes the primary measure that constrains individual vessels. Note that the gear differences between the two alternatives could not be taken into account because the base data for the area closure model included catch information for 1998-2001. These years would be consistent with Alternative 4A but would not reflect the effect of current gear restrictions that are also proposed for Alternative 4. How this affects the analysis is unclear. On the one hand, larger mesh associated with Alternative 4 may result in lower catch rates and the TAC might not be reached as quickly while on the other DAS allocations are lower. Relative to Alternative 4A, the former effect might mean that the revenue reduction could be overestimated while the latter effect may offset this potential bias so that the difference in economic effect between Alternatives 4 and 4A would be negligible.

As noted previously, Alternative 3 was modeled in its default form as though it were identical to Alternative 4. Therefore, in the following discussion, Alternatives 3 and 4 are referred to as a single alternative, called Alternative 3/4. Given that the default would likely to be changed once the specific management areas, method for assigning TACs, and most importantly, mechanism for developing measures for each area have been determined, the estimated impact of Alternative 3/4 may be an upper-bound. Presumably, management measures by area would be designed so as to reduce overall economic impacts on area participants but the form that these measures will take cannot be anticipated at this time.

For both Alternative 3/4 and 4A the total revenue loss from all species on groundfish trips was estimated to be $59.9 million. Median revenue loss was estimated to be 35 to 36% (Table 208). Revenue losses for the most affected vessels would be at least 63.2% while revenue losses for the least affected vessels would be approximately 5%.

The relative distribution of impacts for both Alternative 3/4 and 4A are virtually identical. This does not necessarily mean that the two alternatives affect all vessels the same way. That is, the impact on the median vessel (or at any other percentile) may be the same for both alternatives but may not be the same vessel. The primary source of differential impact across Alternative 3/4 and 4A is likely to be the area closures particularly for vessels that fish within a limited range and/or within a relatively short season. However, even though the two Alternatives affect different vessels differently, the overall estimated impact on the groundfish fleet was similar.

		Alternative 3/4		**Alternative 4A**	
	Number of Vessels	Lower	Upper	Lower	Upper

Table 208 - Fleet-wide impacts of Alternative 3/4 and 4A

Impact by Dependence on Groundfish

The impact on gross annual fishing revenue increases with dependence on groundfish (Table 209). Estimated revenue impacts ranged between -13.8% at the 10th percentile to -0.1% at the 90th percentile for vessels that rely on groundfish for less than one-quarter of annual fishing revenue.

By contrast, gross revenues for vessels most dependent on groundfish were estimated to decline by at least 70% for the 37 vessels at or below the 10th percentile. At the 90th percentile vessels were estimated to lose between 35 and 37% of gross revenue for Alternative 3/4 and 4A respectively.

		Alternative 3/4		**Alternative 4A**

Table 209 - Revenue impacts by dependency on groundfish for Alternative 3/4 and 4A

Impact by Entity Size in Terms of Gross Sales

At the 10th percentile estimated revenue reductions ranged from 61 to 67% regardless of the amount of annual gross groundfish sales (Table 210). At the 25th percentile, the revenue reductions were lower (about 40%) for vessels with groundfish sales of $35 thousand or less as compared to vessels with higher groundfish sales (52 to 55%). Similarly, the revenue changes for vessels with the least groundfish sales at higher percentiles were also lower than that of vessels with more than $35 thousand in groundfish sales at the same percentile. However, the relative distribution of revenue impacts was similar for each sales interval above $35 thousand. This means that based on gross sales, neither Alternative 3/4 nor Alternative 4A would have a disproportional impact on about three-quarters of the groundfish fleet.

		Alternative 3/4		Alternative 4A	
Gross Groundfish Sales Intervals	Number of Vessels	Lower	Upper	Lower	Upper
$35,000 or less (n = 209)					
10th Percentile and Below	21	Minimum	-61.0%	Minimum	-62.9%

Table 210 - Revenue impacts by gross sales of groundfish for Alternative 3/4 and 4A

Impact by Gear Groups

The relative distribution of estimated changes in annual fishing revenue was comparable across gear groups for both Alternative 3/4 and 4A (Table 211). Although the estimated revenue reduction at every percentile was consistently ordered from lowest (hook gear) to highest (trawl gear), the difference in impact at each percentile was no more than five percentage points. Thus, even though the total impact would be largest on trawl gear (nearly 70% of total vessels), Alternative 3/4 would not place any given vessel at a competitive disadvantage based solely on gear.

		Alternative 3/4		Alternative 4A	
Gillnet Gear (n= 181)	Number of Vessels	Lower	Upper	Lower	Upper
10th Percentile and Below	18	Minimum	-59.7%	Minimum	-61.5%

Above 90th Percentile	59	-6.1%	Maximum	-6.1%	Maximum

Table 211 - Proportional change in gross annual revenues by gear group for Alternative 3/4 and 4A

Impact by Vessel Length Class

The distributions of estimated revenue reductions were similar for all vessels size classes for both Alternatives 4 and 4A (Table 212). At the 10th percentile estimated losses were largest for small vessels (64.2% for Alternative 4A) as compared to medium (63.2%) and large vessels (58.7%), although these differences are not large. At all other percentiles estimated revenue reductions were higher for medium than for either small or large vessels, but once again, the difference across vessel length categories was less than 10 percentage points.

		Alternative 3/4		Alternative 4A	
Large (n=190)	Number of Vessels	Lower	Upper	Lower	Upper
10th Percentile and Below	19	Minimum	-58.7%	Minimum	-58.7%

50th to 75th Percentile	43	-29.0%	-11.0%	-31.2%	-11.1%
75th to 90th Percentile	26	-11.0%	-2.4%	-11.1%	-2.5%
Above 90th Percentile	17	-2.4%	Maximum	-2.5%	Maximum

Table 212 - Proportional change in gross annual revenues by vessel size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternative 3/4 and 4A

Impact by Gear/Length Groups

Alternative 3/4 and 4A would have similar impacts among hook vessels of differing size although estimated revenue reductions among 10% of the most affected vessels would be greater for small (60.6%) than for large (52.2%) hook vessels. However, the difference between the two size classes of hook vessels is less than five percentage points at all other percentiles.

Small trawl vessels would be comparatively more affected by either Alternative 3/4 or 4A at all percentiles up to the median vessel as compared to either medium or large trawl vessels. Similarly, medium trawl vessels were estimated to incur higher revenue losses than large vessels at all percentiles. Thus, Alternative 3/4 and 4A would tend to have disproportional affects across vessel size classes with large vessels being least impacted followed by medium and small vessels, although the difference in economic affect by vessel size class is not large.

The estimated revenue losses among gillnet vessels of differing size was similar with no more than four to five percentage points separating either size class across all percentiles. Thus, Alternative 3/4 and Alternative 4A would not result in disproportionate economic impacts among gillnet vessels of differing lengths.

		Alternative 3/4		Alternative 4A

Table 213 - Proportional change in gross annual revenues by gear group and vessel size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternative 3/4 and 4A

Impacts by Home Port State

The estimated revenue changes across different states would be similar for New Hampshire and Massachusetts vessels up to the 25th percentile (Table 214). Revenue reductions for Massachusetts (45.8%), Maine (43.5%) and New Hampshire (45.1%) were similar at the 25th percentile, but estimated reductions on New Hampshire vessels were larger than either Maine or Massachusetts at the 75th and the 90th percentiles.

Alternatives 3/4 and 4A would have least impact on New Jersey vessels. The estimated revenue reduction on Rhode Island was similar to that of New York/Connecticut vessels although Rhode Island vessels were more negatively affected at all percentiles.

		Alternative 3/4		Alternative 4A

Table 214 - Proportional change in gross revenue by home port state for Alternative 3/4 and 4A(cont.)

Impacts by Port Groups

Across ports or port groups median estimated revenue losses exceeded 50% in the ports of Gloucester, Portland, and Boston. This means that half of all vessels in these three port groups would lose more than half of annual fishing revenue under either Alternative 3/4 or 4A. Median revenue losses were lower in the port groups of Chatham/Harwich, New Bedford, New Hampshire Seacoast, Portsmouth, Provincetown, and Upper Mid-Coast Maine, but still were at least 44%. By contrast, median vessel revenue losses in Eastern Long Island and Point Judith were 13.5% and 26.1% respectively. (Table 215)

		Alternative 3/4		Alternative 4A	
Port Group	Number of Vessels	Lower	Upper	Lower	Upper
Boston (n=20)					
25th Percentile and Below	5	Minimum	-56.0%	Minimum	-56.0%

Table 215 – Proportional change in gross annual revenues by port group for Alternative 3/4 and 4A(cont.)

5.4.4.6 Impacts on Vessel Fishing Revenue of Hard TAC Alternatives 4 and 4A with a 2009 Rebuilding Date

The Council considered an alternative that would rebuild many stocks by 2009. Because fishing mortality must be lower in order to achieve this goal, the economic impacts differ from those previously described. The impacts of this rebuilding date were estimated for the hard TAC alternative.

The economic impact of adopting a rebuilding time frame that would achieve rebuilding targets by 2009 was evaluated using the Closed Area Model where all management measures for Alternative 4 were specified along with the TACs that would be required for a constant fishing mortality rate rebuilding strategy.

Total estimated impacts on gross fishing revenue were $72 million; an increase in short term impact of $12 million compared to Alternative 4 with a 2014 rebuilding time frame. At a vessel-level median revenue losses would be 44.5% while ten-percent of all vessels would lose at least 75.6% of annual fishing revenue (Table 216).

		Alternative 4 at 2009 Rebuild	
	Number of Vessels	Lower	Upper
10th Percentile and Below	85	Minimum	-75.6%
10th to 25th Percentile	127	-75.6%	-65.2%
25th to 50th Percentile	212	-65.2%	-44.5%
50th to 75th Percentile	212	-44.5%	-18.0%
75th to 90th Percentile	127	-18.0%	-6.8%
Above 90th Percentile	85	-6.8%	Maximum

Table 216 - Fleet-wide impacts of Alternative 4 with 2009 rebuild TACs

Impact by Dependence on Groundfish

The impact on vessels revenue increases with relative dependence on groundfish. The median impacts for vessels that rely on groundfish for three-quarters or more of annual revenue (-68.3%) would be almost ten times that of vessels that rely on groundfish for less than one-quarter of annual revenue (-7.1%), (Table 217). Estimated median vessel impacts were -25.2% and -45.7% respectively for vessels with 25 to 50% dependence and vessels with 50% to 75% dependence on groundfish.

		Alternative 4 at 2009 Rebuild	
Dependence on Groundfish	Number of Vessels	Lower	Upper

Above 90th Percentile	37	-46.3%	Maximum

Table 217 - Revenue impacts by dependency on groundfish for Alternative 4 with 2009 rebuild TACs

Impact by Entity Size in Terms of Gross Sales

Estimated impact on annual fishing revenue would be at least -52.7% for all vessels at or below the 25th percentile within each sales interval (Table 218). Median vessel impacts would be lower for vessels with less than $35 thousand in groundfish sales as compared to vessels with higher sales while revenue impacts on vessels were higher at all percentiles for vessels with groundfish sales of between $100 and $250 thousand. Thus, 197 vessels within this sales interval would be disproportionately affected relative to all others.

		Alternative 4 at 2009 Rebuild	
Gross Groundfish Sales Intervals	Number of Vessels	Lower	Upper

Table 218 - Revenue impacts by gross sales of groundfish for Alternative 4 with 2009 rebuild TACs

Impact by Gear Groups

Across gear groups gillnet gear would be disproportionately affected compared to hook gear and would be disadvantaged relative to trawl vessels at all percentiles up to and including the 75th percentile (Table 219). Compared to trawl gear, hook gear would also be more disadvantaged up to the 25th percentile but trawl gear revenue impacts would exceed hook impacts at the 50th percentile and above.

		Alternative 4 at 2009 Rebuild

Above 90th Percentile	59	-7.7%	Maximum

Table 219 - Proportional change in gross annual revenues by gear group for Alternative 4 with 2009 rebuild TACs

Impact by Vessel Length Class

Among vessels of differing lengths medium vessels would be comparatively more disadvantaged than large vessels at all percentiles (Table 220). Small vessels would be most impacted at the 10th percentile (-79.2%), would incur about the same revenue loss as medium vessels (-68.6%) at the 25th percentile, but would be less affected than medium vessels at all other percentiles.

		Alternative 4 at 2009 Rebuild	
Large (n=190)	Number of Vessels	Lower	Upper
10th Percentile and Below	19	Minimum	-67.2%

Above 90th Percentile	17	-3.9%	Maximum

Table 220 - Proportional change in gross annual revenues by vessel size (Large = +70'; Medium = 50 to 70', Small = Under 50') for Alternative 4 with 2009 rebuild TACs

Impact by Gear/Length Groups

Estimated revenue impacts on small hook vessels would be greater than larger hook vessels at the 10^{th} percentile, the 75^{th} percentile and the 90^{th} percentile but would be less affected at the 25^{th} and 50^{th} percentile (Table 221). Gillnet vessels would be similarly affected up to the 25^{th} percentile regardless of size but larger gillnet vessels would be comparatively more affected at the median and all other percentiles. For trawl gear, both small and medium trawl vessels would be similarly affected as there were only minor differences in estimated revenue impacts at all percentiles. While estimated impacts were still substantial for large trawlers (at least one-third for half of the fleet) they were lower than estimated revenue impacts on smaller trawl vessels.

Impacts by Home Port State

The relative distribution of revenue impacts was slightly higher for Maine as compared to Massachusetts vessels at all percentiles (Table 222). Overall relative revenue impacts were higher for New Hampshire vessels than any other state with median vessel revenue losses of 62.8% as compared to -53.8% and
-58.2% in Massachusetts and Maine, respectively. New Jersey vessels would incur the lowest reduction in annual fishing revenue while the distribution of impacted vessels in Rhode Island was similar to that of New York/Connecticut.

Table 222 - Proportional change in gross revenue by home port state for Alternative 4 with 2009 rebuild TACs

Impacts by Port Groups

Estimated median revenue reductions would be approximately 70% or more in both the Gloucester, and Portland port groups (Table 223). Median revenue losses would be at least 50% in most other port groups (Boston, Chatham/Harwich, New Hampshire Seacoast, Portsmouth, Provincetown, and Upper Mid-Coast Maine) and would be at least 42% in both New Bedford and South Shore Massachusetts. Estimated median revenue impacts would be lower in both the Eastern Long Island and Point Judith port groups. Note that this does not necessarily mean that all vessels in either of these port groups would be less impacted than all other vessels in all other port groups since the most impacted Point Judith vessel may be as affected as the most affected vessels in any other port group.

Table 223 - Proportional change in gross annual revenues by port group for Alternative 4 with 2009 rebuild TACs

5.4.4.7 Comparison of Impacts on Vessel Fishing Revenues Across Alternatives

Alternatives 2A, 2B, and 3 would not meet conservation objectives without a hard TAC as either a primary or as a backstop measure. Alternative 1B would meet the year 1 conservation objectives for the phased effort reduction program but the economic analysis of Alternative 1B only reflect the first year of a four-year phase-in of DAS reductions and is thus not directly comparable to other alternatives. Alternatives that do not meet conservation requirements would have lower economic impact but to compare these ineffective alternatives to ones that are effective would be misleading. Therefore, even though results are presented for all alternatives comparisons across alternatives in the remaining discussion will focus only on versions of alternatives that meet conservation requirements.

Among effective alternatives the Proposed Action would have lowest aggregate loss in total fishing revenue ($40.1 million) while Alternative 2 with the backstop hard TAC would have largest estimated loss of revenue ($64.2 million) (Table 224). The economic impact of the Proposed Action is partially offset by efficiency gains due to the larger increase in the GOM cod trip limit as well as the omission of the October-November closure of blocks 148-155 that are included in Alternative 2. Further, the Proposed Action includes several unique measures that could mitigate some of the estimated impacts (DAS leasing and DAS transfer, sector allocation, and potential use of Category B DAS. While either leasing or sector allocation could have been combined with any of the non-selected alternatives the potential revenue gains that may be captured with the use of either Reserve or Regular B DAS is unique to the Proposed Action.

Among the quota-based alternatives, Alternative 2 would result in highest revenue impact for vessels below the median but that estimated median impacts were similar for all TAC-based alternatives. For the most part, vessels that are comparatively more impacted under Alternative 2 had a higher dependence on Georges Bank cod as the trip limit for Alternative 2 is 500 pounds per DAS as compared to 2,000 pounds per DAS for Alternatives 4/3 and 4A.

Impact by Dependence on Groundfish

Overall, the Proposed Action would have lowest impact on gross annual fishing revenue regardless of level of dependence on groundfish (Table 225). However, the relative distribution of estimated revenue impacts were only modestly lower than Alternative 1A. The difference between the Proposed Action and all other Alternatives is accentuated at levels of groundfish dependence of 50% or more. For example, median impact on vessels that rely on groundfish for 75% of more of annual fishing revenue was -35% for the Proposed Action as compared to -56.1%, -53.0% and -53.1% for Alternatives 2, 4/3, and 4A respectively.

Across all alternatives with a hard TAC, Alternative 2 had the largest deleterious revenue impact. As noted previously, Alternative 2 disproportionately affects vessels with a high dependence on Georges Bank cod (hook and gillnet gears in particular); not strictly due to the hard TAC but because of the more restrictive trip limit. For vessels with little or no dependence on Georges Bank cod, the relative impact across any of the TAC-based alternatives would not appreciably differ.

Table 225 - Revenue Impacts by Dependency on Groundfish by Alternative

Impact by Entity Size in Terms of Gross Sales

Impacts on estimated annual fishing revenue were consistently lowest for both the Proposed Action and Alternative 1A at nearly all percentiles and all levels of groundfish sales, but in particular at levels of groundfish sales of $100 thousand or less (Table 226). , For vessels with groundfish sales above $100 thousand the revenue impacts up to the 50th percentile were consistently lowest for the Proposed Action by at least six percentage points when compared to all alternatives except 1A. However, the estimated impacts at the 75th percentile and above (i.e. vessels with lower estimated revenue changes) were similar across all alternatives. Thus, for about 11% of all vessels (all of which had annual groundfish sales of more than $100 thousand and would experience least revenue change within a given sales interval) the revenue impacts were approximately the same with either a large DAS reduction or a hard TAC. For the remaining 89% of the groundfish fleet the revenue impacts would be lower with a DAS reduction alternative than a TAC-based alternative.

Impact by Gear Groups

The Proposed Action would have least revenue impact on both gillnet and hook vessels (Table 227). Compared to the other TAC alternatives (4/3 and 4A) Alternative 2 would have greatest impact on hook and gillnet vessels dependent on Georges Bank cod (note estimated impacts at the 25th percentile and below). By contrast, the relative distribution of impacts was similar across TAC-based alternatives for both gear groups at the 50th percentile and above.

Trawl vessels would be less affected under the Proposed Action at all percentiles. However, among the least affected trawl vessels (at the 75th percentile and above) the difference in estimated revenue impact between the Proposed Action, Alternative 1A and all alternatives with a hard TAC were negligible.

Table 227 - Proportional Change in Gross Annual Revenues by Gear Group by Alternative

Impact by Vessel Length Class
Estimated revenue impacts on both medium and small vessels would be lower under the Proposed Action than they would be for either Alternative 1A, Alternative 2, 4/3, or 4A (Table 228). This difference in impact is greatest for small vessels since many of these vessels would use either gillnet or hook gear which would benefit proportionally more from the higher GOM and GB cod trip limit under Alternative 1A as compared to the trip limits under other alternatives.

Medium vessels would also be less affected under Proposed Action but the difference between the Proposed Action and Alternative 1A and other alternatives is not quite as substantial as compared to small vessels particularly for vessels at or above the 75th percentile. Similarly, the relative distribution of estimated revenue impacts on large vessels differed by no more than four percentage points at the 50th, 75th and 90th percentiles. Thus, the impact on annual fishing revenue for half of large vessels would be approximately the same under either an alternative with a large DAS reduction or a hard TAC with a lower reduction in DAS. By contrast, the other half of large vessels would be less affected by the DAS reduction under Proposed Action than they would be under the hard TAC of Alternatives 2, 4/3, or 4A.

Impact by Gear/Length Groups
Both hook and gillnet vessels would be less affected under Proposed Action than any of the hard TAC alternatives regardless of vessel size (Table 229). This is also the case for small trawl vessels. However, both medium and large trawl vessels would be similarly affected across all effective alternatives at the median and above. Among the most affected medium and large trawl vessels (the 25th and 10th percentiles) the estimated revenue changes were lower for Proposed Action or for Alternative 1A than they were for Alternatives 2, 4/3, and 4A.

Table 229 - Proportional Change in Gross Annual Revenues by Gear Group and Vessel Size (Large = +70'; Medium = 50 to 70', Small = Under 50') by Alternative (cont.)

Impacts by Home Port State
Vessels with a Maine, Massachusetts, or New Hampshire homeport would be less affected under the Proposed Action than they would be under Alternative 1A or a hard TAC. This difference was particularly large for Alternative 2 for Massachusetts vessels because comparatively more vessels from Massachusetts are disproportionately affected by the Georges Bank cod trip limit proposed under Alternative 2 (Table 230.

For vessels from either Rhode Island or New York/Connecticut the relative impacts were similar at all percentiles across all effective alternatives (Proposed Action, 1A, 2, 4/3, and 4A). Only New Jersey vessels would have lower revenue impacts under a hard TAC as compared to Proposed Action.

Impacts by Port Groups
Across port groups estimated annual revenue losses for vessels with home ports of Gloucester, New Hampshire Seacoast, Chatham/Harwich, Portland, Portsmouth, Provincetown, South Shore Massachusetts, and Upper Mid-Coast Maine would be lower under Proposed Action than under Alternative 1A or any of the alternatives that include a hard TAC (Table 231). Revenue impacts at and below the median on vessels with either a Boston or a New Bedford homeport would be lower for Proposed Action but would not be substantially different at the 75th percentile and above. Estimated revenue impacts on vessels from either Point Judith or Eastern Long Island port groups would be approximately the same under Proposed Action, Alternative 1A or Alternatives 2, 4/3, or 4A.

5.4.5 Days-at-sea Requirements for the Multispecies Fishery

The most direct way to analyze the economic impact of days-at-sea (DAS) reductions would be to estimate impacts on vessel profitability. While information on vessel costs and revenue are available, the coverage on costs is not extensive enough to provide reliable estimates of fishing vessel profitability. Instead, this analysis first estimates the number of DAS needed by vessels of different gear and size classes to cover operating and annual costs before returns are divided among crew and owner. Then, the number of days needed to cover return to labor and owner are estimated. Comparing these DAS requirements with current allocated DAS and knowing the average daily return by vessel class, provides an indication of how close vessels are to being unable to realize adequate returns to labor and the owner, and to pay down debt under new restrictions.

The reason for partitioning DAS requirements this way is because, when faced with lower returns, vessel owners often adjust crew payments. Labor payments on fishing vessels are made on a trip basis with the crew sharing the risk of variable levels of catch. Generally, a crew share formula is used which deducts trip expenses from the revenue received on a trip and then divides the remainder among the crew and the vessel owner (or, the revenue is divided first then certain expenses deducted from the crew's share). The reason for not including a daily labor cost in the calculation of DAS requirements is that crew share formulas are often adjusted, or crew size is reduced, when revenue declines. They may also make other cost-saving adjustments but the risk sharing found in commercial fishing may lead to first making adjustments in crew payments.

With the reduced DAS proposed by Amendment 13, fishing vessel owners will evaluate their ability to meet expenses, crew payments, debts, and an owner's return given their new allocation[2]. Returns from other fisheries will be a factor, but this analysis only considers groundfish DAS requirements. Since groundfish DAS are annual allocations, the DAS requirements are expressed as annual needs.

Crew share payments are made on a trip basis so crew is normally paid before overhead expenses are paid. However, vessel owners are likely to project the effect of reduced DAS on their ability to pay all expenses. The decision to take an individual trip may be based on expected daily return and daily expenses, including crew payment and owner's return. But with limited DAS, the additional return needed to pay overhead expenses should also be considered.

Since crew payments and owner return can be adjusted in response to DAS reductions, this analysis shows the DAS required to meet all non-labor expenses and then treats DAS requirements for labor and owner's return separately. In reality, a vessel owner will decide to get out of fishing long before crew payments and owner's return approach zero (but may continue for the short term if conditions are expected to change). This analysis, however, provides estimates of where returns would equal zero then reports the additional DAS needed to provide a level of crew payments that approximate wages found in alternative shore-side occupations.

5.4.5.1 Data Used to Estimate DAS Requirements

Cost data was collected through surveys of fleet sectors involved in catching groundfish. The University of Rhode Island surveyed the small trawl vessel fleet in 1996 (Lallemand et al. 1998) and the large trawl vessel fleet in 1997 (Lallemand et al. 1999). The University of Massachusetts Dartmouth surveyed the hook fleet in 1996 (Georgianna and Cass 1998). Both surveys were funded through NMFS's Cooperative

[2] Note that ownership arrangement (owner operated vs. hired captain) will impact the return to owner.

Marine Education and Research (CMER) Program and the data provided to NMFS. Cost data for the gillnet fleet comes from economic questions asked by observers on sea sampling trips in 2000. Cost data from 1996-97 was adjusted for inflation with the GDP implicit price deflator and is in 2000 dollars.

The cost surveys collected data on all fishing business costs - both variable and overhead. Variable costs include fuel, oil/lubrication, ice, food/water, bait (where applicable), offloading, consignment, supplies, and other miscellaneous trip costs. Overhead costs include association fees, permits, haul out, insurance, mooring, office expenses, professional fees, business taxes, vehicle, interest, repair/maintenance (includes repairs and maintenance to engines, generators, fishing gear, electronics, and other miscellaneous items), and other miscellaneous overhead expenses. Periodic vessel improvements are not counted in the fixed costs. The variable cost questions asked by observers are limited to fuel, oil/lubrication, ice, food/water, and bait (which is not applicable to gillnet vessels). The only overhead cost question asked by observers is the cost of insurance. For this analysis, overhead costs for gillnet vessels are assumed to be the same as long-line vessels.

Based on the number of observations and the range of vessel sizes in the cost data, the vessels were separated into length classes. There are two length classes for each gear group except trawl vessels which have three length classes. This grouping of vessels by gear and size is unique to the DAS requirements analysis. Further sub-divisions by port or other criteria were not possible due to limited numbers of observations.

Fishing year 2000 (May 2000 through April 2001) revenue data was generated by applying average fish prices from the Northeast Fisheries Science Center (NEFSC) dealer data to logbook trips with groundfish landings. Observations were limited to those vessels with a limited access multispecies permit. Therefore, DAS would have been used on these trips. Revenue from all species was summed for the trip then divided by DAS used to get revenue per DAS. Trips were then categorized by gear type and vessel length class.

5.4.5.2 Overhead DAS Analysis

DAS requirements are estimated in two stages. The first stage estimates DAS requirements for non-labor expenses. Here, a daily return is calculated by subtracting variable costs per day from revenue per day. The software package *BestFit* was used to fit distributions to the cost data[3]. Table 232 shows the distribution names and parameters. Daily returns by vessel group are shown in Table 233.

[3] *BestFit* software is developed by the Palisade Corporation in Newfield, NY.

Vessel Category	Distribution Name	Minimum	Maximum	Mean	Mode	Median	Standard Deviation
Long-line < 40 feet: revenue per day	Not Specified			1,539		1,500	1,088
Variable costs per day	Normal			362	362	362	213
Yearly overhead costs	Triangular	3,824	66,703	26,630	9,362	24,244	14,254
Long-line >= 40 feet: revenue per day	Not specified			1,694		1,175	1,346
Variable costs per day	Lognormal			344	184	279	248
Yearly overhead costs	PearsonV			34,018	25,463	30,578	15,285
Trawl < 50 feet: revenue per day	Not specified			1,407		1,299	761
Variable costs per day	PearsonVI			268	151	216	203
Yearly overhead costs	Beta	1,469	56,526	30,073	33,680	30,384	14,505
Trawl 50 to 70 feet: revenue per day	Not specified			2,195		2,110	939
Variable costs per day	PearsonV			363	251	316	194
Yearly overhead costs	PearsonVI			66,937	20,835	42,894	99,217
Trawl >= 70 feet: revenue per day	Not specified			3,497		3,462	1,671
Variable costs per day	Logistic			814	814	814	376
Yearly overhead costs	Beta	51,831	223,010	135,092	112,312	134,284	47,795
Gillnet < 40 feet: revenue per day	Not specified			1,981		1,678	1,261
Variable costs per day	Lognormal			50	27	41	36
Gillnet >= 40 feet: revenue per day	Not specified			2,285		2,124	1,153
Variable costs per day	Lognormal			94	55	79	63

Table 232 – Revenue and cost distributions (dollars)

Long-line vessels < 40 feet	$1,177
Long-line vessels >= 40 feet	$1,350
Trawl vessels < 50 feet	$1,139
Trawl vessels 50 to 70 feet	$1,832
Trawl vessels >= 70 feet	$2,683
Gillnet vessels < 40 feet	$1,931
Gillnet vessels >= 40 feet	$2,191

Table 233 – Average daily returns by vessel group

Even though crew share payments are a variable cost (paid at the end of a trip based on the catch and expense levels), these costs are not considered in the first stage. The latter part of the first stage divides the yearly overhead costs by the daily return to get the minimum number of DAS needed to cover overhead expenses. These will be referred to as overhead DAS and are reported in Table 234.

The second stage (see Additional DAS Requirements) looks at the return from additional DAS which would go to the crew and owner.

Since a groundfish trip was defined as a trip where at least a pound of groundfish was landed by a vessel with a limited access permit and since revenue from all species was summed for that trip, the number of DAS reported here are what is needed to meet overhead expenses if only allocated multispecies DAS are used. As is the case with many vessels, additional revenue is earned by targeting other species during the year. That activity is not counted here.

5.4.5.3 Additional DAS Requirements

A vessel owner's ability to pay the crew and get a return on his investment (and any principal payments) will be impacted by the new DAS restrictions. To assess how the DAS allocations proposed for Amendment 13 may impact these returns the additional DAS needed to compensate the crew are given in Table 234. For example, the average daily return is $1,177 for long-line vessels less than 40 feet. If an annual salary of $25,000 per crew member (based on the Department of Labor's 2000 National Compensation Survey for shore-side occupations in New England) is assumed and there are two crew members, it would take an additional 42 DAS to meet that wage. Additional days are then required for the owner to receive a return (which may be in addition to the captain's portion of the crew share if the owner is also the captain). The average crew size is also given in Table 234. Adding average overhead DAS and the crew compensation DAS yields an estimate of the point where crew is paid but there is no return to the owner.

There are many different functions performed by crew members which require different sets of skills. Some crew members are employed as deck hands, others as engineers, cooks, and captains. To account for these skill differences, the additional DAS requirements to meet shore-side alternative occupation salary levels was calculated at two additional levels - $35,000 and $50,000 per year (see Table 234). Note that in each case the salary represents an average across all occupations that may be represented on a fishing vessel.

	Average Crew Size Including Captain (min, max)	Average Overhead DAS	Additional DAS Needed for Crew Compensation			Total DAS Requirements		
			$25k	$35k	$50k	$25k	$35k	$50k
Long-line vessels < 40 feet	2 (1, 4)	23	42	59	85	65	82	108
Long-line vessels >= 40 feet	3 (2, 4)	25	56	78	111	81	103	136
Trawl vessels < 50 feet	2 (1, 4)	26	44	61	88	70	87	114
Trawl vessels 50 to 70 feet	3 (1, 7)	37	41	57	82	78	94	119
Trawl vessels >= 70 feet	5 (2, 10)	50	47	65	93	97	115	143
Gillnet vessels < 40 feet	3 (1, 4)	14	39	54	78	53	68	92
Gillnet vessels >= 40 feet	3 (2, 5)	16	34	48	68	50	64	84

Table 234 – DAS requirements to meet overhead and crew compensation

5.4.5.4 Comparison of Alternatives

To compare the DAS allocated to limited access multispecies permit holders against overhead DAS, vessels were re-assigned to a gear group based on which gear (used on groundfish trips) contributed most to annual revenue. This grouping is slightly different from the previous grouping where gear group assignments were based on gear used on a particular trip.

While a strict application of average overhead DAS (as opposed to its distribution) is not advised, comparing allocated and used DAS to overhead DAS can help illustrate the relative financial position of vessel groups. Table 235 shows the average used, and allocated DAS under each alternative by gear and size group. The allocations in Table 235 can then be compared to the average overhead and total DAS requirements reported in Table 234.

To further assess how crew and owners will fare under Amendment 13, Table 236 summarizes the DAS for vessels with allocations greater than overhead DAS.

There appears to be an inconsistency between the additional crew compensation DAS in Table 3 (columns 4-6) and the average used DAS greater than overhead DAS (third column in Table 236). That is, some of the figures in Table 236 are lower than those in Table 234 which seem to indicate that, on average, owners have not been getting a return and crew has been under-compensated. While this may be true in some cases, it is also the case that daily returns from other fisheries have been used to pay fixed expenses and compensations. It should be noted again that the DAS requirements in Table 234 assume no revenue contribution from other fisheries (activity where groundfish DAS are not used).

Vessel owners are likely to decide to get out of fishing for groundfish at a point where returns to crew and owner are inadequate (a point higher than the total DAS requirements reported in Table 234) rather than wait until owner's return is zero. As mentioned above, there may be some adjustments in crew payments which make it difficult to determine that particular point. Certainly, vessels will be unable to continue fishing for groundfish (assuming they are not engaged in other fisheries) if their allocation falls below overhead DAS. There are, however, some vessels that currently have used DAS that are less than overhead DAS. These vessels are most likely relying on revenue from fisheries other than groundfish to meet their overhead expenses, and returns to labor and owner. Therefore, the impacts of DAS reduction should be considered separately from vessels having used DAS above overhead DAS levels. Table 237 shows those vessels with used DAS that already fall under overhead DAS levels.

	Number of Vessels	Average Used DAS 1996 - 2001 (min, max)	Average 2002 DAS (alts 2,3,4) (min, max)	Alternative 1A Avg. DAS (min, max)	Alternative 1B Avg. DAS (min, max)

Table 237 – Vessels with used DAS less than overhead DAS, by vessel group

Grouping Vessels by DAS Allocation

Table 238 through Table 241 assign vessels into one of three categories for each alternative (Table 238 is all vessels and Table 239 through Table 241 are vessels dependent on groundfish, that is 50% or more of their revenue is from groundfish). The first category is vessels that have DAS allocations less than overhead DAS. These vessels are considered most at risk since they do not have enough DAS to meet expenses, let alone pay crew salaries, generate owners' returns, or pay off debt.

The second category is vessels with DAS allocations greater than overhead DAS but less than the total DAS requirements. These vessels are also at risk because, while able to pay expenses, they are unable to pay an average crew salary of $25,000, $35,000, or $50,000 per year. While they may be able to negotiate lower crew share payments or reduce crew size, it will be difficult to retain a crew if salaries from alternative occupations become relatively more attractive. This group is also at risk because very little will be left over for a return to the owner.

The third category of vessels may be considered the least at risk since they have enough DAS to cover expenses and pay an average yearly crew salary of $25,000, $35,000, or $50,000. Some vessels are certainly closer to the total DAS requirements point than others and may not be receiving adequate owner returns. Table 238 shows that there are 240 vessels, of which, 237 are dependent on groundfish (see Table 239) with alternatives 2, 3, and 4 (2002 DAS) DAS allocations greater than the total DAS requirements at the $25,000 salary level. Under alternatives 1A and 1B there are 8 and 131 vessels (with all the 1A vessels and 128 of the 1B vessels dependent on groundfish), respectively. Table 240 and Table 241 show the groundfish dependent vessel break-downs at the $35,000 and $50,000 per year levels. As expected, increasing the crew compensation assumptions results in higher total DAS requirements, and therefore, fewer vessels with allocated DAS greater than overhead and total DAS.

DAS Sharing

The discussion above about the financial position of vessels which fall below overhead DAS or total DAS requirements assumes that there will not be a regulatory change that allows for DAS consolidation, DAS leasing or sector shares. Under these kinds of arrangements, the total DAS allocated to a group could remain constant but how the vessels within the group re-allocate DAS could be based on their cost/revenue structure and other financial considerations.

To provide an indication of how DAS sharing could help alleviate some of the financial burden of greater DAS restrictions, the last row in Table 238 through Table 241 shows the total number of DAS over or under total DAS requirements. At the $25,000 salary level (Table 238) there are 3,893 Alternative 2, 3, and 4 DAS above the total DAS requirement. Vessels with allocations less than overhead DAS are short a total of 8,559 DAS and those vessels with allocations between overhead and total DAS are short 8,424 DAS. Even though there are not enough DAS to fully make up the deficit, trading or sharing DAS could help some vessels. Under Alternatives 1A and 1B, however, benefits from DAS sharing would be more difficult to achieve since the DAS over total DAS requirements are significantly less and DAS deficits significantly greater.

Implications of Losing Unused DAS

Some vessel's allocations are greater than what they used in recent years. Even so, the immediate loss in revenue is the difference between revenue from used DAS and revenue from reduced DAS. Losses will continue for each year that DAS are restricted. In cases where all allocated DAS are not used, revenue losses should not be based on reductions from allocated DAS since all revenue potential was not realized. However, it does not mean that there is not a financial impact from losing unused DAS. The DAS associated with a groundfish permit has value since it provides a means for earning revenue. The value of a vessel with a groundfish permit will be worth less, when sold, with fewer associated DAS. This reduction in the value of the vessel and permit is a real financial loss to the vessel owner. However, the reduction in business equity will not affect the short-run decision to continue fishing with fewer DAS. That decision will be based on expected revenues and costs given the new allocations. The purpose for providing estimates of DAS requirements is to show where that decision point may be for different types of vessels.

5.4.5.5 Management Affects on Fishing Revenue

As mentioned previously, caution should be used when applying averages, and the results from using those averages, to individual vessels. While this analysis provides a broad indication of how vessels may fare under DAS alternatives, individual vessel performance will vary based on actual costs incurred and revenue earned. In particular, the average revenue by vessel class used in the above analysis was based on a gross average across all vessels for each gear/size class. However, since implementation of Amendment 7 a variety of management measures have been implemented affecting the ability to generate fishing revenue. In particular, cod trip limits and rolling closures in the Gulf of Maine have constrained opportunities to generate fishing revenue for vessels that fish in the Gulf of Maine. For example, for fishing year 2000 average revenue per day from the Gulf of Maine was lower than in other areas for all gear/size categories except trawl vessels greater than 70 feet (Table 242).

The differences in revenue potential suggest that vessels that fish exclusively in the Gulf of Maine under prevailing management measures may have had higher DAS requirements than vessels that fish elsewhere given the same overhead and operating cost. Under any of the Amendment 13 alternatives the Gulf of Maine cod trip limit would increase so the difference between revenue opportunities between the Gulf of Maine and Georges Bank may narrow particularly with Alternative 1 (800 pounds vis-a vis 500 pounds per DAS for Alternative 2, 3, and 4). The increased Gulf of Maine cod trip limit would have a greater impact on revenue per day for gillnet and hook vessels as cod represents a larger proportion of fishing revenue compared to trawl gear.

Just as a change in the cod trip limit would improve opportunities to generate fishing revenue in the Gulf of Maine, a reduction in the Georges Bank cod trip limit (Alternatives 2, 1C and 1D) would reduce revenue opportunities for vessels that fish on Georges Bank. As was the case for Gulf of Maine vessels, the impact of a reduction in average revenue per day on break-even DAS would have a larger affect on Georges Bank hook and gillnet vessels as compared to trawlers.

	Revenue per day from the Gulf of Maine	Revenue per day from non-Gulf of Maine areas
Long-line vessels < 40 feet	$1,057	$2,039
Long-line vessels >= 40 feet	$1,444	$2,004
Trawl vessels < 50 feet	$1,329	$1,693
Trawl vessels 50 to 70 feet	$2,114	$2,271
Trawl vessels >= 70 feet	$3,883	$3,541
Gillnet vessels < 40 feet	$1,793	$2,548
Gillnet vessels >= 40 feet	$2,106	$2,448

Table 242 – Revenue per day on Groundfish trips from Gulf of Maine vs. non-Gulf of Maine (FY2000)

5.4.6 Short-term Impacts on Coastal Sub-Regions

An input/output (I/O) model was employed to assess the relative short-term economic losses (sales, personal income, and employment) associated with the proposed management alternatives on the New England regional economy. This approach evolved out of collaborative research between the Marine Policy Center of the Woods Hole Oceanographic Institution and the Northeast Fisheries Science Center as part of a grant received through the Marine Fisheries Initiative (MARFIN) in 1999 (see Marine Policy Center 2000).

The I/O approach provides the ability to estimate how changes in the economic activity of a particular industry will affect other industries from which it purchases and to which it sells goods and services. Thus, in addition to reductions in harvesting revenues, this analysis captures losses associated with the commercial fishing industry buying fewer inputs and the upstream losses that result from less product being available to local seafood dealers and processors. For example, as purchasers of inputs, the commercial fishermen support a number of other industries such as net manufacturers and boat building and repairing. If fishing revenues decline, commercial fishermen demand fewer inputs from these and other supporting industries. In addition, forward linked purchasers of seafood such as seafood dealers and processors may also experience reductions in sales, income, and employment if the management measures result in a diminished supply of local seafood.

The total regional economic effects of the proposed management measures consist of three components: (1) direct, (2) indirect, and (3) induced. In this analysis, direct impacts are considered to be the reductions in sales, income, and employment associated with commercial fishing, seafood dealers, and seafood processors in each of the eleven subregions. Indirect impacts are the associated reductions in sales, income, and employment of all the industries that supply commercial fishermen, seafood dealers, and seafood processors within each of the eleven subregions. These indirectly affected industries, in turn, purchase fewer goods and services from their suppliers and this cycle of reduced purchases continues until the amount remaining within a particular subregion is negligible. Induced impacts represent the reduction in sales, income, and employment attributable to employees of the direct and indirect sectors earning less income. Lower personal income leads to reduced spending on food, housing, entertainment, etc. The summation of the direct, indirect and induced impacts represents total impacts. In the analysis presented here, the total impacts on sales, personal income, and employment are shown for 11 different coastal subregions as well as the non-coastal New England subregion.

Data and Methods

The subregions designated herein were based on several criteria. First and foremost, data particularly on the non-fishing industrial sectors were available only at a county-level. Thus, the subregional impact area designations represent either an individual county or groups of counties within each of the five New England states. Data obtained from Northeast vessel trip reports, Northeast dealer weigh-out slips, Northeast permit applications, and County Business Patterns information on processors were used to classify subregions that have similar economic networks and fishing-related attributes. In general, these data provided the ability to identify the regional distribution channels of seafood as it flows from harvesters through dealers and finally on to processors in New England. Eleven of the twelve subregional designations mainly consist of a coastal county or groups of coastal counties, for these are the counties where the majority of the losses accrue and where the harvesters, dealers, and processors reside (Figure 26, subregions 1-11). A near coastal New England subregion was also included in the analysis to examine the impacts that the proposed management measures will have on businesses located in non-maritime

New England (Figure 26, subregion 12). These subregions generally mirror the community groups identified in the Affected Human Environment (Section 9.4.5).

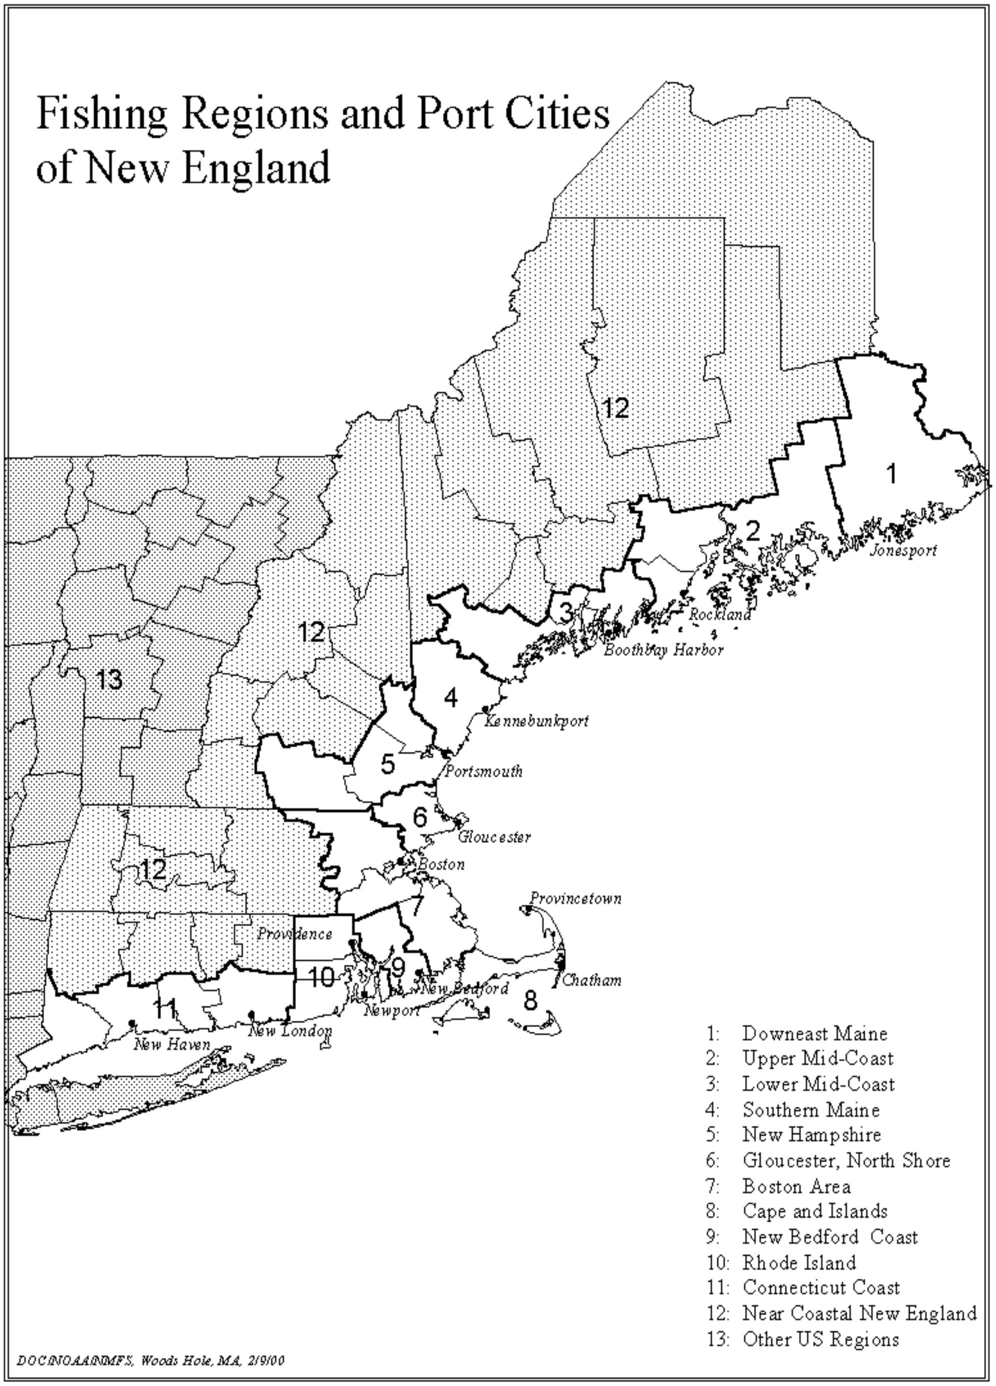

Figure 215 - Map of subregions considered in analyses
Economic analyses exclude subregion 13.

The I/O analysis was constructed using the IMPLAN software system (Minnesota IMPLAN Group, Inc. 1997). The IMPLAN system provides secondary industry data collected from national, state and local government reports and a user-friendly media for customizing I/O models to an application. These regional data were based on calendar year 1998 so all adjustments and the resulting impact estimates are based on 1998 conditions. However, estimated impacts are reported in 2001 dollars using deflators to convert 1998 monetary values to 2001 values.

The default IMPLAN models provide detailed county-level estimates of business activity for up to 528 sectors in each subregion. However, much of these data had to be refined to account for specific features of fishing-related industries. In particular, the five commercial fishing gear sectors that land groundfish in each subregion were incorporated into the default models: bottom longline, gillnet, small trawl, medium trawl, and large trawl vessels. The sales estimates (i.e., ex-vessel revenues) for these sectors were derived from 1998 Northeast dealer weigh-out slips for each subregion except for the Connecticut Seacoast subregion. For Connecticut, data collected from Northeast vessel trip reports on landings by gear type were used to prorate the Northeast dealer data which is reported in aggregate terms across all gears. Fishing cost data for each of the gear sectors were obtained from several sources. First, average fishing costs for small, medium, and large trawlers were obtained from surveys conducted by researchers at the University of Rhode Island in 1996 and 1997 (see Lallemand et al. 1998 and Lallemand et al. 1999). Fishing costs for longline vessels operating in New England were obtained from the University of Massachusetts Dartmouth, which surveyed longline vessels in 1996 (see Georgianna and Cass 1998). Finally, cost data for the gillnet fleet were obtained through the Northeast Fisheries Science Center's sea sampling program in 1997. These data were used to develop production functions for each of the five gear sectors that land groundfish in New England. In I/O models, production functions delineate the proportions of inputs required to produce one dollar of ex-vessel revenue. Employment estimates for the five gear sectors were calculated by prorating the IMPLAN default values for the commercial fishing sectors in each subregion according to ex-vessel revenue shares within each subregion.

Seafood dealer sectors were also incorporated into each subregional model. Total seafood dealer sales within each subregion were estimated from 1998 Northeast dealer weigh-out data. This database provides the origin of seafood purchases by gear type and subregion. Thus, it was possible to determine the quantities of seafood purchased from each gear sector within the subregion and the amount that was imported from outside the subregion. Separate production functions for seafood dealers in each subregion were developed from information contained in a Kearney/Centaur report that estimated national economic impacts of commercial fishing, processing, and distribution in the United States (Kearney/Centaur 1986), and from Northeast dealer data on the origin of seafood purchases. Thus, the production functions reflect the actual seafood purchasing activities of dealers from each gear sector within each subregion. The seafood dealer mark-up or margin varied by subregion and was estimated by summing the gear sector coefficients in each seafood dealer production function and subtracting this value from one. In other words, since a production function accounts for all expenditures required to produce one dollar of sales, the sum of all of the non seafood coefficients in the dealer production function measures the additional value seafood dealers must charge to cover their fixed and variable operating costs.

The impacts of the proposed management measures on the flow of seafood from local dealers to processors within each subregion were also examined in the analysis. The IMPLAN system includes a fresh and frozen seafood processing sector in the default data base so it was not necessary to create a new fish processing sector for each subregion.

Impact Assessments

In the I/O model presented here, total economic impacts are calculated by applying estimates of direct revenue changes to IMPLAN generated multipliers that measure the indirect and induced relationships between industries and households in each subregion. Therefore, prior to calculating the total estimated losses (direct + indirect + induced) of each alternative, it was necessary to determine the direct revenue changes associated with the 5 gear sectors, the seafood dealer sector, and the seafood processing sector in each subregion.

Direct revenue losses for the five affected gear sectors in each subregion were estimated by multiplying the total value of all species landed by vessels in these gear sectors that landed groundfish by the proportional loss in total fishing income. The latter was based on aggregating the estimated revenue changes reported earlier to compute expected revenue changes by gear sector and subregion. These direct revenue changes are based on the constant fishing mortality rebuilding strategy.

Direct revenue losses associated with seafood dealers in each subregion were estimated in the following manner. First, the summation of the estimated direct revenue losses associated with the 5 harvesting sectors in each subregion were multiplied by the proportion of total dealer groundfish purchases that were derived from local harvesters (i.e. purchased from harvesters within a particular subregion). This results in an estimate of the value of groundfish harvested in a particular subregion that was purchased by seafood dealers in that same subregion as well as an estimate of seafood purchases by dealers from vessels in other subregions. The proportions used in these calculations were determined from the 1998 Northeast dealer data base and ranged from a low of .17 for New Hampshire Seacoast dealers to a high of .99 for Upper Mid-Coast Maine dealers. Secondly, the results from the first step were multiplied by the dealer mark-ups or margins in each subregion to obtain the estimated direct revenue losses for seafood dealers in each subregion. A description of the steps followed to calculate seafood dealer margins was provided in the previous section.

For purposes of this analysis, seafood processors in each subregion were also estimated to be directly impacted by the proposed management measures. According to IMPLAN default data it was estimated that about 60% of the total groundfish value sold by seafood dealers within each subregion was exported out of New England, either as domestic or foreign exports, and thus were not available to be purchased by local seafood processors or any other sectors in the model. In addition, it was assumed that only the seafood processing sector would be affected by a reduction in seafood dealer sales. Several other sectors purchase groundfish from seafood dealers as an input into their production process, such as eating and drinking establishments, hospitals, hotels and lodging, and amusement and recreation services, but it was assumed that these forward-linked establishments have the ability to purchase substitutes or replace local supply with imports to minimize or eliminate associated losses. According to the data contained within IMPLAN seafood processors purchase approximately 50% of the dealer sales that remain in New England (the remainder is purchased by the aforementioned businesses). As such, the estimated direct revenue losses for the seafood dealer sectors were first multiplied by 0.6 (to eliminate exports) and then by 0.5 to obtain the value of groundfish purchased by seafood processors. These values were then multiplied by the appropriate seafood processing margins to obtain the estimated direct revenue losses for seafood processors in each subregion. Seafood processing margins were calculated by subtracting the seafood dealer coefficient in the processing production function from one. This margin measures the additional value seafood processors charge to cover their fixed and variable operating costs (including profits and taxes).

After the direct revenue losses were estimated for the 5 gear sectors, the seafood dealer sectors, and the seafood processing sectors within each subregion, total economic losses were calculated by applying the revenue losses to the appropriate IMPLAN generated multipliers. Considerable effort was employed to ensure that the impacts were not double counted. The losses associated with seafood dealers exclude the losses associated with the 5 commercial harvesting gear sectors, and the losses associated with seafood processors exclude those attributable to the seafood dealers and the commercial harvesters. Thus, the losses associated with reductions in supply to these sectors can be summed to obtain the total effect on sales, income, and employment within each subregion and to the New England region as a whole.

No attempt was made to estimate forward linked impacts beyond the processing sector because reductions in groundfish supply at the harvesting level are not likely to significantly alter the cost of groundfish for restaurants, hospitals, and supermarkets pay in each subregion. In fact, according to data contained within IMPLAN, less than 2% of the processed seafood purchased by upstream industries is actually derived from processors within each subregion. According to this data, imports from other areas supply the majority of retail-level purchases from processors. Although retail-level purchases of locally processed groundfish may differ from these statistics, it was assumed that no forward-linked impacts would occur in each subregion beyond the seafood processing sector.
The I/O framework is based on a set of inter-industry and household purchases made over a particular calendar year. The annual time frame means that the impact of seasonal fluctuations in supply is not captured. The fact that the production relationships are assumed fixed means that all goods and services produced in the economy will be bought and sold in the same proportions with or without a change in fisheries management. These two factors mean that adaptations by individual establishments or changes in market relationships are not fully captured.

In general terms, seafood consumers are assumed to be unaffected (in terms of their aggregate consumption of seafood although prices may increase) by changes in groundfish management. That is, consumers will still purchase seafood but the mix of species may change as substitute products are made available: farm-raised salmon or shrimp, for example. However, certain segments of the distribution network from harvest to retail may experience very different impacts as a result of groundfish management.

Although an oversimplification, seafood distribution may be segmented into two markets; one that services specialty restaurants, hotels, and retail seafood markets and one that services large restaurant chains, grocery chains, and large institutions. These two markets compete for the same supply of raw material but operate in different ways.

The specialty seafood market consists of a large number of buyers with each one purchasing relatively small quantities of seafood. These purchases are made on a daily or short term basis where changes in market price due to reduced supplies can be passed on to their clientele. With respect to groundfish, this means that the specialty market (the Fulton fish market in New York and to a lesser extent Philadelphia and Baltimore) will tend to bid away groundfish supplies from New England processors that serve the restaurant and grocery chain market. Because buyers in the specialty market operate on very short term supplies and face a relatively inelastic demand (i.e. quantities demanded in consumer markets are relatively insensitive to price) this market segment may not be appreciably affected by the Amendment 13 management alternatives. Note, however, that the extent to which hard quotas result in derby-style fishing would still be very disruptive as market supplies would be very volatile.

Unlike the specialty market the chain market operates over a longer planning horizon, faces a more elastic demand (i.e. consumer demand is much more price sensitive), has fewer buyers but purchases are made in large quantities, and relies on processors to provide finished products for resale. Chain markets usually plan specific seafood promotions that may be planned one-quarter in advance. This marketing strategy requires predictability in terms of both supply and price. In order to meet these requirements, processors must, in turn, be able to source the raw product in consistent quantities at predictable prices. In a time of fluctuating groundfish supplies, New England processors may be able to commit to provide limited quantities to their clients. In this setting localized spikes in landings may result in depressed ex-vessel price not because processors lack the capacity to handle the supply, but because they have no market to accept their product. In this manner, unpredictability in supply has a cascading effect from processors back to harvesters. Note that while some ability to source alternative supplies of groundfish from international imports may be possible, stocks throughout the North Atlantic are depressed and New England processors would have to outbid European buyers.

The fact that business arrangements at the processor level require a longer term commitment to provide agreed upon supplies at agreed upon prices also means that business relationships are developed over time and the inability to provide consistent supplies of groundfish means that buyers in the chain market will turn to alternative seafood products. These buyers will tend to develop longer term relationships with alternative seafood providers meaning lost market share for New England groundfish will be difficult to recover.

For New England processors the primary impact of Amendment 13 will be in how any given management measure affects variability in supply. This means that alternatives with hard TACs or other measures that causes volatility in landings would have a comparatively larger impact on processors. Note that even alternatives that promise reasonably consistent supplies could have comparatively larger impact on New England processors where total supplies are limited. For example, given that specialty markets will outbid processors for groundfish supplies, if half of the market goes to processors and half goes to specialty markets, a 20% reduction in groundfish supply would be absorbed by New England processors resulting in a 40% reduction to New England processors.

The following provides the economic impacts associated with the proposed management alternatives where evaluation of alternatives was limited to consideration of alternatives (1A, 2 with a backstop TAC, 3, 4, and 4A) that meet the conservation objectives for Amendment 13. Alternative 1B and Alternative 2 without a hard TAC backstop do not meet this criterion. Note that the estimated economic impacts of these alternatives would be lower than anything presented below but only because landings would not be consistent with needed fishing mortality rates.

5.4.6.1 New England Regional Economic Impacts of the Proposed Action

The direct economic impact of the Proposed Action consists of the sum of the reduction in gross sales by vessels ($39.0 million), seafood dealers ($15.4 million), and processors ($22.9 million) for a total direct impact of $77.3 million. Note that to avoid double counting the reduced value in dealer and processor sales is measured in terms of sales net of the cost of purchasing seafood from the next lower market level. This direct impact results in an additional $58.2 million in indirect and induced impacts for a combined total impact of $135.5 million to the New England economy (Table 243). However, compared to the New England economy as a whole this impact represents less than 0.02% of total sales in the combined five coastal New England states.

Across sub-regions, the Boston area (20%) would be the most impacted sub-region even though the local Boston-area represented only 9.3% of total loss in combined direct commercial fishing, dealer, and processor sales impacts. However, the Boston-area is an important center of economic activity that provides a large amount of manufacturing, transportation, wholesale trade, financial services and other business services to other New England sub-regions such that the Boston-area indirect plus induced impacts represented 31.1% of total New England-area indirect plus induced impacts. By contrast, the New Bedford area was estimated to account for 36.2% of total direct impacts but only accounted for less than 3% of indirect plus induced impacts. Thus, the total sales impact in the New Bedford was still second only to Boston (19.2% of total New England impact) but the proportion of total New England impact was much less than the New Bedford sub-region's share of direct impact. This highlights the importance of taking into account the inter-industry linkages both within and across sub-regions. For example, the direct impact on the Connecticut Seacoast sub-region was only 1% of total direct impacts but represented almost 20% of total indirect and induced impacts. Combined, the total impact on the Connecticut Seacoast sub-region represents 9.1% of New England economic impacts. As was the case, for New England as a whole, the economic impact in any one sub-region represents, at most less than 0.1% of total sales. This means that while the impacts would, in fact, be concentrated in a few specific industrial sectors the economic viability of any one of the sub-regions would not be threatened even though a specific locality within a sub-region may be relatively more affected.

The estimated impact on personal income was a loss of $55.4 million (Table 244). In general, the share of impact across sub-regions followed a similar pattern to that of gross sales except that the New Bedford sub-region would have a larger loss in personal income than the Boston area. This difference is due to the fact that compared to other industries the share of gross sales going to make personal income payments is much larger. Since the New Bedford direct sales impact for commercial fishing was larger than the Boston sub-region the direct income impact was also larger that when combined with the direct and induced effects, the total income effect was larger than that of the Boston sub-region.

Region-wide the Proposed Action was estimated to impact about 1,900 jobs (Table 245). Of these jobs, almost 800 would be associated with commercial fishing, almost 400 would be in seafood wholesale trade and about 150 would be in the seafood processing sector. The remaining nearly jobs would be in a variety of economic sectors spread throughout the New England coastal states. Across sub-regions, the New Bedford area would be slightly more affected than the Boston area followed by Lower Mid-Coast Maine, and Gloucester. Other than the non-maritime sub-region employment impacts would represent less than 6% of total region-wide impacts.

Table 245 – Proposed Action, Total New England Coastal Region Employment Impacts

5.4.6.1.1 Potential impacts of DAS reductions on vessel location

Public comments on Amendment 13 identified Maine's proximity to offshore groundfish fishing grounds, and the increased steaming times required to reach those grounds, as an intrinsically linked component of DAS reductions that will disproportionately impact the Maine groundfish industry. The specific problem identified appears to be the perception that Maine vessels will relocate to Massachusetts. This issue has also attracted attention in local media both inside and outside of Maine (see "Task force will help protect both fish, groundfishermen," Portland Press Herald, Sept 4, 2003, among others). While public comments focused on Maine, similar arguments could be made for other states.

The theory is investigated in several ways. Changes in documented homeport and principal port locations are tracked as an attempt to understand the "baseline" level of state-to-state vessel transfer over time. Landings and fishing patterns for Maine-based vessels are quantified in an attempt to determine which vessels and which ports are likely to be impacted. Product caught on Georges Bank and landed in Maine ports is quantified, losses due to differential transit times for affected fishing trips are modeled, and the opportunity costs associated with landing Georges Bank fishing trips in Maine is estimated. An upper bound estimate of potential losses for the Maine economy is provided. Finally, the issue of steaming time for offshore trips is put in perspective by comparing the percentage of time spent steaming on offshore and inshore fishing trips.

The results show that Maine's groundfish fleet has shrunk by roughly 40% since 1995, which is consistent with the reduction in multispecies permit holders region-wide (35%). Groundfish revenues in Maine are up approximately 50% from their late-1990's lows. Total revenues generated by Maine vessels but landed outside of Maine have remained constant at roughly 10% of total groundfish revenues from 1995 through 2002. Of 159 active groundfish vessels in Maine in 2002, only 29 reported making trips in statistical areas that are farther from Maine ports than Massachusetts' ports (areas 514, 521 and 522, principally). Twenty Maine vessels landed trips from these statistical areas in Massachusetts in 2002, and this number has remained nearly constant since 1999. Costs associated with steaming time for trips occurring in these statistical areas were roughly 20% of per-trip groundfish revenues for trips reported in statistical area 514, but only 3% of gross revenue in statistical areas 521 and 522. Analysis of steaming time for inshore and offshore trips shows that vessels fishing inshore may spend a significantly greater percentage of their trip time steaming than do vessels fishing offshore trips. Finally, lobster landings data from these areas highlights one potential source for increased revenues for Maine trawlers, demonstrating that the opportunity costs of fishing in Georges Bank statistical areas may be compensated.

Relevant background information on the groundfish fishery in New England

To properly frame the issues surrounding potential economic impacts associated with vessel transfers out of Maine, it is important to understand the trends in vessel movement between states and the efficacy of potential data fields available for conducting such and investigation.

Choosing an indicator of economic impact: the homeport and principal port data fields

The primary impact being discussed in this investigation is that of product landed. Therefore, the homeport and principal port data fields are investigated to determine their comprehensiveness as indicators of the impacts of landed product in any particular state. The results show that homeport state is not an accurate indicator of a vessel's landings activity. Table 246 indicates that, for example, roughly 55% of groundfish revenue by Maine homeported vessels is landed in Maine. Basing estimations of direct impacts of this nature on the homeport data field will likely miss an important portion of vessels with strong ties to the Maine economy. Instead, the principal port data field (Table 247) reveals a much stronger tie between port state and state of primary landing. While a credible argument can be made that homeport is reflective of the communities (and states) in which vessel owners and crew reside, and therefore spend their incomes, landings more often occur in the principal port state than the homeport state. For this reason, the principal port state data field is used for the remainder of this investigation.

Changes in homeport and principal port in New England

New England vessels routinely change ports for any number of reasons: vessel sale or ownership change, changes in fishery/target species and improved access to markets or dealers are just some of the many reasons a vessel may change it's documented homeport. Table 248 shows the total change in the number of permits listing each state as their documented principal port (Table 249, which shows the same data for the homeport data field, is included for reference). In these tables, only vessels possessing a valid limited access multispecies permit are counted.

Over the eight-year time series, groundfish vessel retention in Maine was roughly consistent with the overall reduction in fleet size across the New England region. With the results of the groundfish vessel buyback program figured in (Table 250), Maine's groundfish fleet has shrunk by 27% since 1995 (the total fleet has been reduced by 24%).

Table 250 – Principal port state locations for vessels/permits purchased in the 1996 and 2002 buyback programs.

As an attempt to gauge where vessels that departed Maine went, and where vessels that changed their principal port to Maine came from, Table 251 and Table 252 track those changes that occurred intra-year (i.e., vessels that ended the year with a different principal port state than they began the year with). This list is not comprehensive, as it does not track vessels that changed principal ports on their annual permit renewal application—only vessels that changed principal port during the year are tracked here. This does, however, provide insight into vessel transfers.

5.4.6.2 Preliminary data regarding the groundfish fishery in Maine

Overall, the number of vessels actively fishing for groundfish has declined across New England by 23% over the eight-year time series (Table 253). During this time, the number of vessels principally-ported and landing in ME has decreased 34%. Pro-rated VTR-reported revenues have increased 58% for New England as a whole, while ME pro-rated VTR-reported revenues have rebounded from a steep decline into the late 1990's and are now showing revenues approximately equal to those in 1995 when adjusted for inflation. Non-Maine vessels landing in Maine are contributing less to the state in terms of revenue now than in the late 1990's.

Rolling closures and the GOM cod trip limits likely contributed to declines in revenue and, possibly, the disproportionate decrease in active groundfish vessels (relative to New England as a whole). The state prohibition on landing lobsters may also disadvantage Maine ports relative to their New Hampshire and Massachusetts counterparts. Average distance to the fishing grounds, discussed in some detail later in this section, may contribute as well, but is likely to be much less significant.

Table 254 – Number of vessels listing Maine as their principal port state but landing outside of Maine; breakdown by state of landing (source: prorated vessel trip reports; revenue in 2002 dollars).

annual % change	ME		NH		MA		RI		NY	
	pp state	transient	pp state	transient	pp state	transient	pp state	transient	pp state	transient
# vessels	-7%	-13%	3%	-4%	-3%	-13%	-5%	11%	-6%	11%
revenue	3%	9%	11%	-3%	11%	5%	21%	85%	22%	175%

Table 255 – Annual rate of change in number of vessels landing groundfish at least once and total revenue of landings for each state, distinguished between vessels listing the landing state as their principal port state (pp state), and vessels with principal port states that differ from the state they landed the trip in (transient) (source: vessel trip reports and vessel permit database).

Table 254 shows that a number of vessels with their principal port state listed as Maine currently land some groundfish outside of Maine. The total amounts of these landings range from seven to eleven percent of the total groundfish revenue generated by Maine principal-ported vessels. What is significant is that these vessels appear to have established ties with dealers outside of Maine, thereby decreasing (albeit to an unknown degree) one source of potential cost increases associated with landing product outside of a principal port state. Table 255 shows that, while the number of registered vessels landing trips in their principal port state has declined for all states except New Hampshire, overall revenues have increased for all states. Maine, notably, has shown the smallest average rate of annual revenue increase among those states where groundfish are typically landed.

Quantifying the potential impacts of DAS reductions on Maine
This section attempts to quantify the impacts of DAS reductions on Maine, first by determining which trips and which vessels are most likely to be impacted, second by estimating the opportunity costs imposed upon impacted trips, and third by providing an upper-bound estimate for potential overall impacts on the Maine, and New England, economies.

Determining potentially impacted trips
Amendment 13 DAS reductions may range anywhere from 35% to 65% in allocated DAS, bringing the pre-settlement agreement Fleet DAS allocation from 88 DAS down to between 57 and 31. Individual DAS allocations will be reduced similarly. This portion of the analysis utilizes extant 2002 trip-level data and therefore the impacts are not reflective of future DAS reductions. The non-linear relationship between utilized DAS and fleet revenues means that these results should not necessarily be reduced by a corresponding factor to accommodate DAS reductions. Furthermore, because the necessary inputs data has a spatial component it is not possible to factor in anticipated stock-specific F reductions to calculate potential impacts. Actual trip-level data is therefore deemed to be the be the best for these purposes but, due to the significant reductions proposed, the resulting estimates are likely to be high.

To determine who may be affected, and by how much, the following criteria are used to sort trips and create an appropriate data set:

- 2002 landings data

Trips by vessels listing Maine as their principal port state
Trips landing groundfish in Maine
Trips reporting fishing in statistical areas other than 511, 512, 513, and 515

Because the perceived problem is the direct shift of product and revenues from Maine to Massachusetts, trips made by Maine vessels and landed in Maine are the focus. 2002 data is utilized to reflect current regulatory and stock status environments. Trips occurring in areas closer to MA than ME are assumed to be potentially impacted and, consequently, trips reported to have occurred in statistical areas 511, 512, 513 and 515 are eliminated from consideration (leaving the focus on areas 514, 521 and 522).

Figure 215 and Table 256 show landing by statistical area for all Maine vessels—note that these data show the vast majority of Maine groundfish landings coming from statistical areas 512, 513 and 515. This begins to show that the differential impacts of DAS reductions may not affect a large portion of the Maine groundfish fleet. Recent landings from statistical areas 521 and 522 have increased; this increase has been fueled in large part by a dramatic rise in haddock landings (Figure 217), which increased four-fold between 1998 and 2002 as the stock size increased and trip limits were raised.

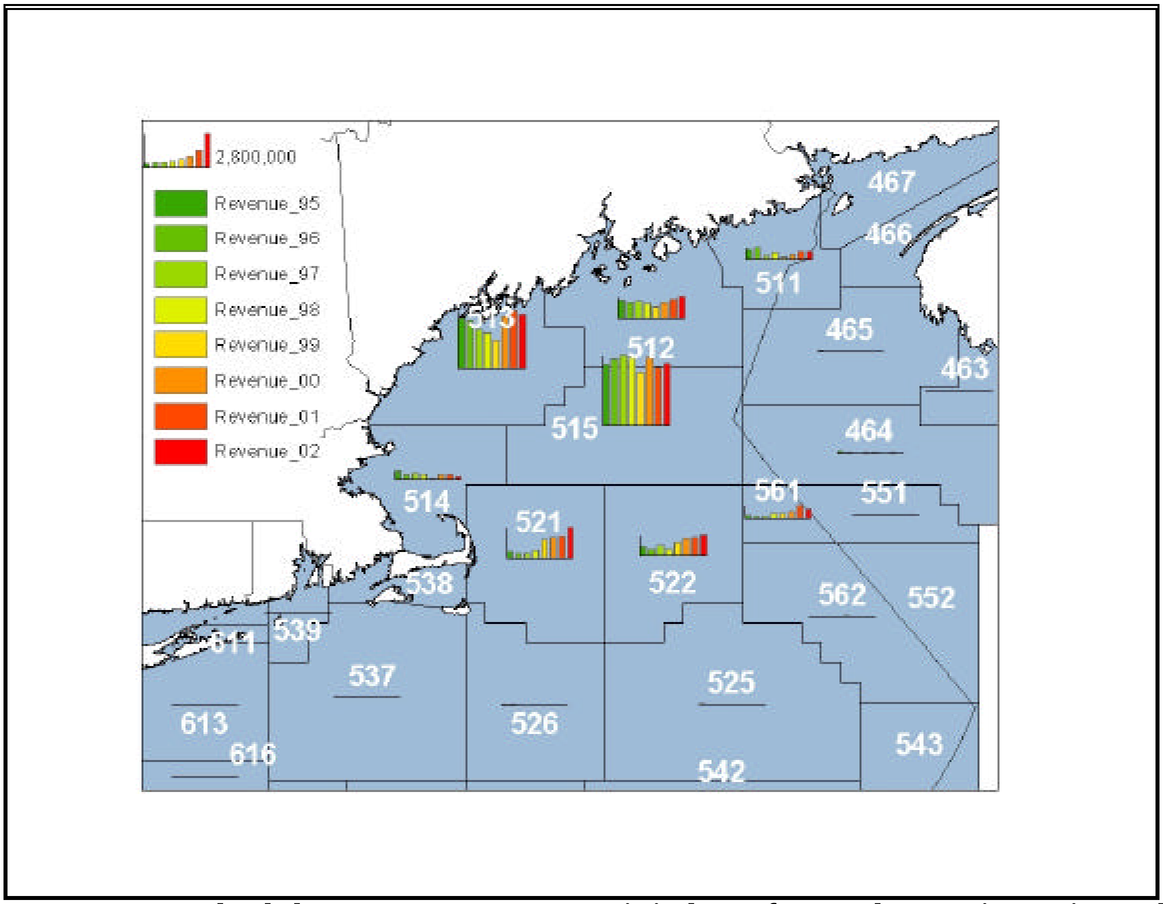

Figure 216 - Average landed revenue per year per statistical area for vessels reporting Maine as their principal port state (source: prorated vessel trip reports, revenues in 2002 dollars).

	1995	1996	1997	1998	1999	2000	2001	2002
511	$1,112,000	$1,096,000	$300,000	$593,000	$234,000	$439,000	$879,000	$862,000

561	$326,000	$134,000	$94,000	$457,000	$445,000	$729,000	$1,335,000	$926,000
562	$12,000			$4,000	$89,000	$1,000	$22,000	$31,000
SNE	$163,000	$99,000	$12,000	$33,000	$73,000	$36,000	$28,000	$19,000
other	$432,000	$465,000	$491,000	$230,000	$224,000	$223,000	$246,000	$144,000
total	$20,797,000	$16,782,000	$15,016,000	$15,116,000	$14,021,000	$19,085,000	$20,857,000	$21,509,000

Table 256 – Landings revenue by statistical area for vessels listing Maine as their principal port state (source: prorated vessel trip reports).

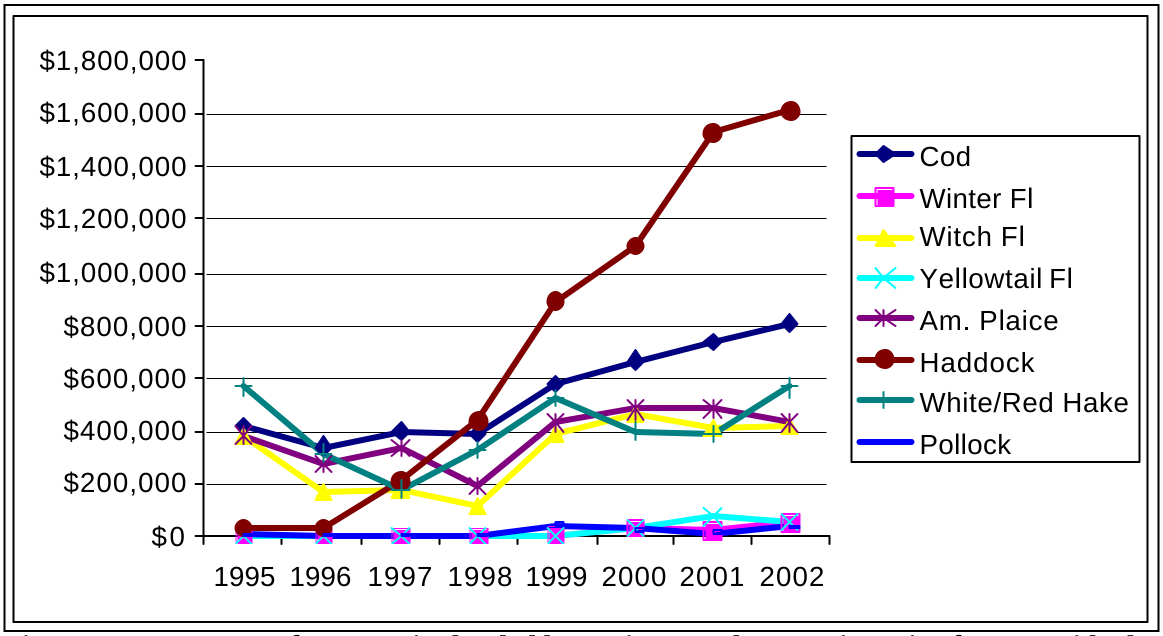

Figure 217 - Revenues from species landed by Maine vessels reporting trips from outside the Gulf of Maine from 1995 through 2002 (source: prorated vessel trip reports, revenues in 2002 dollars).

Table 258 shows that the impacts of Maine vessels fishing on Georges Bank were, in 2002, roughly 22% of the total groundfish revenues for that state. This percentage has increased since the mid-1990's, but has remained relatively constant over the most recent three years Table 258). Thus, it can be estimated that revenues from the fishing trips most likely to be impacted at a differential rate (relative to Massachusetts-based vessels) comprise roughly 20-25% of the total groundfish revenues in Maine. Note that the number of vessels listed in Table 258 refers to all vessels landing at least once in (or out) of Maine; hence, the same Maine vessel may be counted both as landing in and outside of Maine. Table 258 also shows that Maine vessels that do fish on Georges Bank, on average, derive roughly 25-30% of their annual revenue from Georges Bank trips. These data, however, are very noisy (Figure 218) and a handful of vessels earn a significant percentage of their groundfish revenue from the Georges Bank statistical areas.

Table 258 – Percentage of total groundfish revenues landed in Maine reported to have come from trips on Georges Bank; and, percent of total annual per-vessel revenue landed from Georges Bank-fished trips for all Maine vessels (source: prorated vessel trip reports).

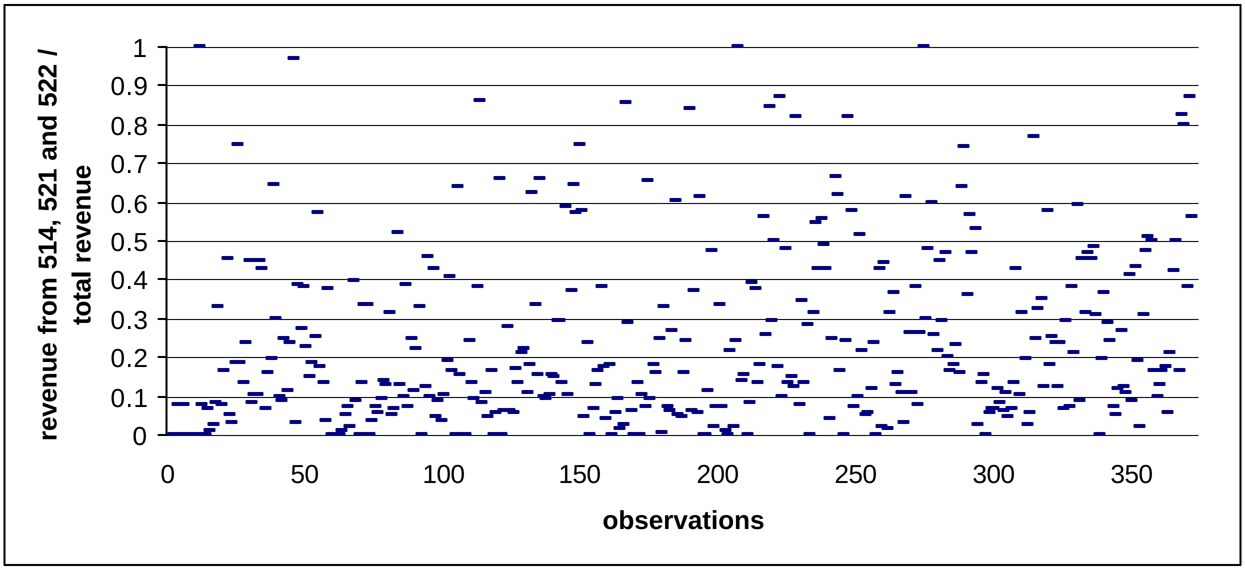

Figure 218 – Scatter plot of George's Bank trips divided by annual revenue for all vessels reporting at least one trip in statistical areas 514, 521 and 522 (source: prorated vessel trip reports).

Quantifying the opportunity costs of additional steaming time

Maine vessels have farther to travel to gain access to Georges Bank than Massachusetts-based vessels. Table 259 shows, for trips landing in various MA and ME ports, the average distance from port, average days absent, per-trip value and per-day value of product landed, and the total number of trips meeting the criteria. It is interesting to note that Maine vessels, on average, produce more revenue per day than their counterparts from other ports for all statistical areas except 522, where they rank second to Gloucester-based vessels. This may be due to the characteristics of the particular vessels (horsepower, gross tonnage, etc), levels of technology present aboard the vessels, or the skill of their captains. In any case, it seems logical that only those vessels able to fish with a high rate of success venture to the Georges Bank fishing grounds.

NEMAREA 514	avg dist (nm)	days absent	value	daily value	# trips
Chatham	44.6	1.24	$1,412	$1,032	194
Gloucester	23.25	1.17	$888	$661	43,652
New Bedford	70.27	4.42	$6,919	$1,867	1,025

Table 259 – Avg. distance of reported trips from various ports, with avg. days absent, total value, avg. daily value and number of trips reporting lat/long. VMS_demarc info is for reference only and applies to all vessels reporting landing in New Bedford (source: prorated vessel trip reports 1995 - 2002).

In order to assess the estimated value of lost time due to steaming, the distances listed above were used to determine the differential distance between any two ports (in this case, Gloucester and Portland were used). An adjusted revenue per day absent (RPDA) was computed by subtracting transit time, assuming that the point location provided on the vessel trip report was the beginning and end point for the fishing trip and that fishing did not occur between this point and the landing port. Transit speed was estimated to be 9 knots. The adjusted RPDA was used to estimate the potential for revenue gain based on the reduced distance traveled from Gloucester instead of Portland (assuming that the additional catch does not result in a decrease in RPDA). The following flow chart summarizes this process:

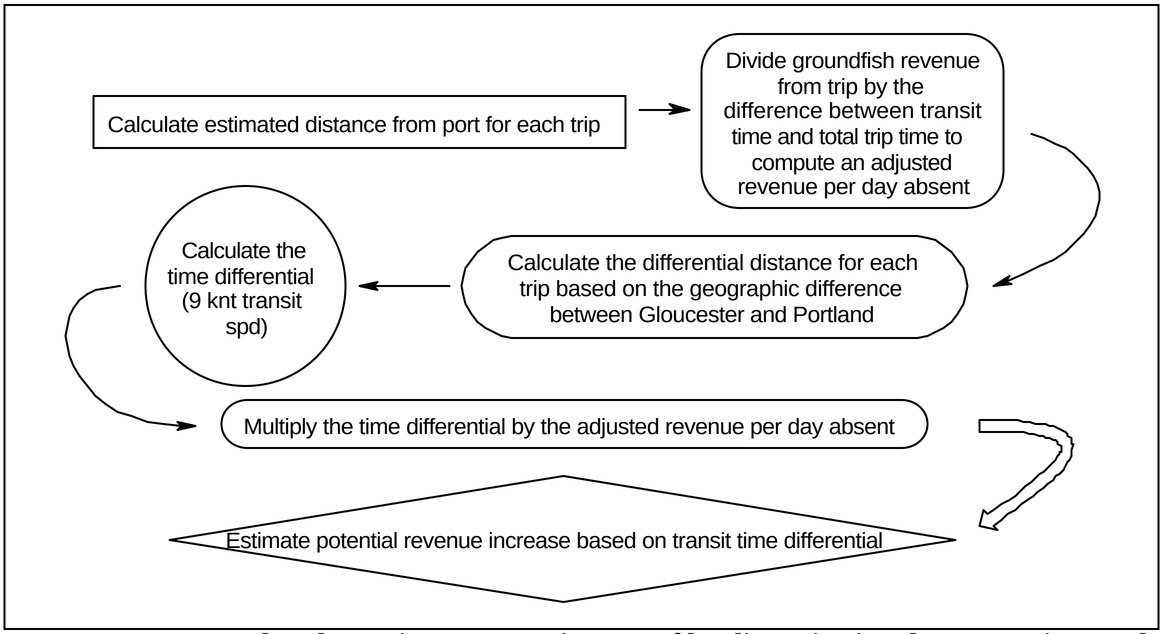

Figure 219 – Process used to determine opportunity cost of landing trips in Gloucester vice Portland.

	Assumed difference in distance to fishing grounds (nm)	Assumed difference - round trip	Assumed add'l hours per trip @ 8 knots transit spd	RPDA	Standard-ized RPDA	# Trips by Portland-based vessels	Potential DAS-based revenue increase through relocation (per trip)	Estimated 2002 potential gross revenue gain (all trips)	Total 2002 gross revenues from areas	Potential percent increase in revenue if trips were made from Gloucester and not Portland
514	95.8	191.54	23.94	$1,989	$2,470	29	$2,191	$63,526	$326,000	**19%**

Table 260 – Opportunity cost estimates of Maine -based vessels landing Georges Bank trips in Portland vice Gloucester (data based on prorated 2002 vessel trip reports).

Table 260 shows that vessels landing selected trips in Gloucester instead of Portland could expect to increase their revenues by roughly 20% for trips in statistical area 514, and less than five percent for trips in statistical areas 521 and 522. This steaming time opportunity cost likely explains why a relatively few trips are made from Portland in area 514. The roughly five percent opportunity cost for trips in areas 521 and 522 is likely to be compensated by the difference between expected revenues closer to Portland (i.e. statistical areas 513 and 515) and the revenues expected from trips in either 521 and 522 for the trips in these areas. If expected revenues in 513 and 515 were higher at other times during the year, vessels would be expected to continue using Portland as their principal port. If, however, expected revenues on average throughout the year are anticipated to be higher in the Georges Bank statistical areas, Portland-based vessels may be better off (in terms of recouping their opportunity cost) by relocating to Gloucester. A more in-depth, temporally-based investigation would be required to determine when vessels typically make trips to the George's Bank, and what percentage of their overall revenue (vice groundfish revenue, which is used here) is generated from such trips. If vessels have sources of revenue in addition to groundfish, and that revenue is more readily available close to Maine ports, the opportunity cost of landing trips in Maine vice Massachusetts may be significantly more tolerable than if such trips comprised a high percentage of their overall revenue.

Vessel re-location: an upper-bound estimate

It may be possible to quantify, in very rough terms, an upper-bound estimate of the impacts of vessels shifting their fishing operations from Portland to Gloucester. If one is to assume that every trip occurring in statistical areas 514, 521 and 522 in calendar year 2002 will relocate to Gloucester, the direct and indirect impacts of the landed product shift from the Upper and Lower Mid-Coast region of Maine, to the Gloucester region of Massachusetts. In 2002, these vessels landed a total of $4.09 million dollars of groundfish. Using the I/O model, the shift in landed product shows some interesting results (Table 266, Table 267, and Table 268).

The overall adverse impact on the Maine economy is roughly $8 million, while the overall positive impact on the Massachusetts economy is only $7.6 million. The primary reason for this is that the production functions embedded in the model assume that seafood landed in Portland is distributed more locally, while Gloucester has greater economic connectivity outside of Massachusetts and, in fact, outside of the New England region. The overall impact of such a shift on the New England region, consequently, is roughly -$0.3 million. This implies that some economic benefit resulting from the increased landings in Massachusetts are distributed outside of New England.

The model estimates that the overall impact on Maine incomes would be approximately -$3 million based on this upper-bound estimate. However, the overall impact on incomes within the New England region is positive ($142,000) under this scenario (Table 267). This is due to the model's estimates of productivity in the various sectors. Essentially, the model assumes that it takes fewer people to process seafood in Maine than it does in Gloucester and, consequently, more people are employed overall by the shift of product from one region to the other. Similarly, Table 268 shows a positive net impact on 7 jobs for New England as a whole while this hypothetical change would adversely impact 120 jobs in Maine.

Table 261 presents the estimated impacts on Maine (without the consequent impacts on Massachusetts or New England economies noted) in comparison to the contribution of all groundfish fishing, all fishing, and finally all commerce on the Maine economy. These estimates, which likely dramatically over-estimate the impacts as it is unlikely that *all* trips reported in areas 514, 521 and 522 would land their product in Gloucester in order to realize a gain of between five and 20 percent, clearly comprise a very small portion of the fishing economy in Maine. This is not to say that the consequences are insignificant as they are not. If certain business entities have production thresholds below which they cannot remain profitable, the I/O model does not incorporate the impacts of a total shutdown of that entity. With no data to evaluate such situations, however, no further conclusions may be drawn.

	Direct output impacts of vsls relocation	Total output impacts of vsl relocation	Total output impacts of groundfish overall	Total output impacts of all commercial fishing	Total output of local economy (all fishing and non-fishing related impacts)	Vsl relocation output impacts as a percent of all fishing impacts	Vsl relocation output impacts as a percent of all economic impacts
Maine	-$4.03	-$8.00	$63.24	$530.22	$42,949.49	-1.509%	-0.019%

Table 261 – Upper-bound estimates of potential impacts if all vessels fishing at least one trip in statistical areas 514, 521 and 522 relocate to Gloucester from Portland (in millions of dollars).

Steaming time for offshore versus inshore fishing trips

Steaming time is commonly thought to occupy a larger portion of an individual trip's dock-to-dock time for trips farther from shore than for those trips closer to shore. This hypothesis is tested for the Gulf of Maine and northern/central Georges Bank by comparing the percentage of time steamed for trips reporting less than 1.5 days absent and fishing in statistical areas 512, 513, 514 and 521 with trips reporting more than 1.5 days absent and fishing in statistical areas 515, 521, and 522 (see Figure 8 for statistical area locations). This methodology makes the assumption that fishing begins and ends at the point (latitude/longitude coordinates) reported on the vessel trip report. While this is obviously not an accurate assumption, no data exists to indicate if the assumption is individually biased for either group.

A t-test for two independent samples is conducted to test the hypothesis that the mean percent of steaming time is the same for both types of trips. Table 262 and Table 263 show that, for data with both equal and unequal variance, the probability of seeing these two data sets if the mean steaming time percentage were actually the same for the two trip types is less than .0001—or, very unlikely. Essentially, the mean steaming time is dramatically different between the two trip categories, with inshore trips spending a significantly greater percentage of their fishing time steaming than offshore trips.

When these data are viewed on a per-port basis, it is interesting to note that for both inshore and offshore trips, Portland has a lower steaming time percentage than either Gloucester or New Bedford. Chatham and Provincetown have the lowest average steaming times for both categories of trips. Table 265 converts the percentage of steaming time to a mean time per DAS used. For trips taken from a specific port, there is little difference between the amount of time spent steaming for each DAS used. Indeed, the values are remarkably similar with the exception of those for Provincetown (lower in all cases), Chatham (lower for offshore trips), and New Bedford (higher for inshore trips).

Table 268 – Total New England regional employment impacts from shifting selected product landed in Maine to Gloucester; an upper-bound estimate.

5.4.6.3 New England Regional Economic Impacts of Alternative 1A

The direct economic impact of Alternative 1A consists of the sum of the reduction in gross sales by vessels ($44.1 million), seafood dealers ($17.4 million), and processors ($25.8 million) for a total direct impact of $87.3 million. Note that to avoid double counting the reduced value in dealer and processor sales is measured in terms of sales net of the cost of purchasing seafood from the next lower market level. This direct impact results in an additional $65.9 million in indirect and induced impacts for a combined total impact of $153.2 million to the New England economy (Table 269). However, compared to the New England economy as a whole this impact represents less than 0.03% of total sales in the combined five coastal New England states.

Across subregions, the Boston area (20%) would be the most impacted subregion even though the local Boston-area represented only 11.6% of total loss in combined direct commercial fishing, dealer, and processor sales impacts. However, the Boston-area is an important center of economic activity that provides a large amount of manufacturing, transportation, wholesale trade, financial services and other business services to other New England subregions such that the Boston-area indirect plus induced impacts represented 31.1% of total New England-area indirect plus induced impacts. By contrast, the New Bedford area was estimated to account for 31.3% of total direct impacts but only accounted for less than 3% of indirect plus induced impacts. Thus, the total sales impact in the New Bedford was still second only to Boston (19.1% of total New England impact) but the proportion of total New England impact was much less than the New Bedford subregion's share of direct impact. This highlights the importance of taking into account the inter-industry linkages both within and across subregions. For example, the direct impact on the Connecticut Seacoast subregion was only 1% of total direct impacts but represented almost 20% of total indirect and induced impacts. Combined, the total impact on the Connecticut Seacoast subregion represents 9.1% of New England economic impacts. As was the case, for New England as a whole, the economic impact in any one subregion represents, at most less than 0.2% of total sales. This means that while the impacts would, in fact, be concentrated in a few specific industrial sectors the economic viability of any one of the subregions would not be threatened even though a specific locality within a subregion may be relatively more affected.

The estimated impact on personal income was a loss of $62.4 million (Table 270). In general, the share of impact across subregions followed a similar pattern to that of gross sales except that the New Bedford subregion would have a larger loss in personal income than the Boston area. This difference is due to the fact that compared to other industries the share of gross sales going to make personal income payments is much larger. Since, the New Bedford direct sales impact for commercial fishing was larger than the Boston subregion the direct income impact was also larger that when combined with the direct and induced effects, the total income effect was larger than that of the Boston subregion.

Region-wide Alternative 1A was estimated to impact over 2,100 jobs (Table 271). Of these jobs, almost 900 would be associated with commercial fishing, almost 450 would be in seafood wholesale trade and about 150 would be in the seafood processing sector. The remaining nearly 700 jobs would be in a variety of economic sectors spread throughout the New England coastal states. Across subregions, the New Bedford area would be slightly more affected than the Boston area followed by Lower Mid-Coast Maine, and Gloucester. Other than the non-maritime subregion employment impacts would represent less than 6% of total region-wide impacts.

Table 271 - Alternative 1A Employment Impacts by Region (# of jobs)

5.4.6.4 New England Regional Economic Impacts of Alternative 1B

Region-wide the estimated impact on sales of all goods and services was estimated to be $95 million (Table 272). These sales impacts were similar for the Boston ($18.9 million) and the New Bedford subregions ($18.4). Estimated sales impacts were also similar on the Gloucester ($12.3 million) and the Lower Mid-Coast Maine subregions ($10.8 million). In all other areas the sales impacts were less than $10 million.

Income impacts in the New England region were estimated to be $39 million (Table 273). Across subregions the income impacts ranged from a low of less than $0.2 million in the Southern Maine (York County) subregion to a high of $8.5 million in the New Bedford subregion. Other than New Bedford the only other subregion with estimated income impacts greater than $5 million was the Boston subregion.

Alternative 1B would affect an estimated 1,300 jobs in the New England coastal state region (Table 274). The employment impacts in the New Bedford and Boston subregions would be similar; between 250 and 275 jobs. The employment impacts on the Lower Mid-Coast and Gloucester subregions were approximately 200 jobs but were less than 100 jobs in all other coastal subregions.

Table 274 - Alternative 1B Employment Impacts by Region (# of jobs)

5.4.6.5 New England Regional Economic Impacts of Alternative 1C

Region-wide the estimated impact on sales of all goods and services was estimated to be $165 million (Table 275). These sales impacts were similar for the Boston ($33.0 million) and the New Bedford subregions ($31.3). Estimated sales impacts were also similar on the Gloucester ($21.4 million) and the Lower Mid-Coast Maine subregions ($18.2 million). In all other areas the sales impacts were less than $15 million.

Income impacts in the New England region were estimated to be $67.3 million (Table 276). Across subregions the income impacts ranged from a low of less than $0.2 million in the Southern Maine (York, county) and Downeast (Washington, county) subregions to a high of $14.5 million in the New Bedford subregion. Other than New Bedford the only other subregion with estimated income impacts greater than $10 million was the Boston subregion.

Alternative 1C would affect an estimated 2,300 jobs in the New England coastal state region (Table 277). The employment impacts in the New Bedford and Boston subregions would be similar, about 460 jobs. The employment impacts on the Lower Mid-Coast and Gloucester subregions were approximately 320 jobs but were less than 125 jobs in all other coastal subregions.

Table 277 - Alternative 1c Employment Impacts by Region

5.4.6.6 New England Regional Economic Impacts of Alternative 1D

Region-wide the estimated impact on sales of all goods and services was estimated to be $110.5 million (Table 278). These sales impacts were similar for the Boston ($22.0 million) and the New Bedford subregions ($21.2). Estimated sales impacts were $14.2 million on the Gloucester subregion while impacts were $11.8 in the Lower Mid-Coast Maine subregion. In all other areas the sales impacts were $10 million or less.

Income impacts in the New England region were estimated to be $45.2 million (Table 279). Across subregions the income impacts ranged from a low of less than $0.1 million in the Southern Maine and Downeast subregions to a high of $9.8 million in the New Bedford subregion. Other than New Bedford the only other subregion with estimated income impacts greater than $5 million were the Boston, Gloucester, and Lower Mid-Coast Maine subregions.

Alternative 1D would affect an estimated 1,500 jobs in the New England coastal state region (Table 280). The employment impacts in the New Bedford and Boston subregions would be similar; between 306 and 316 jobs. The employment impacts on the Lower Mid-Coast and Gloucester subregions were approximately 215 jobs but were less than 100 jobs in all other coastal subregions.

Table 280 - Alternative 1d Employment Impacts by Region

5.4.6.7 New England Regional Economic Impacts of Alternative 2

The estimated region-wide impact on gross sales was $217 million (Table 281). Impact on gross sales was largest in the Boston area ($43 million) followed by the New Bedford subregion ($39 million) and the Gloucester subregion ($31 million). The impact on gross sales would exceed $20 million in the subregions of Lower Mid-Coast Maine and in Non-Maritime New England while sales impacts would be between $10 and $20 million in the New Hampshire Seacoast, Cape and Islands, Rhode Island and Connecticut subregions. Note that economic impacts on Downeast Maine would be about $2 million even though there were no estimated direct impacts associated with commercial fishing. However, the Downeast Maine subregion is still linked to the general New England economy through a variety of economic sectors, principally seafood processing and agriculture.

The value of gross sales includes both the cost of producing goods and services and payments that are made in the form of employee compensation and business profits. Given that costs that are not borne represent cost savings or reduced resource use that would still be available for future use, it is the loss of personal income that represents the larger impact on a region's economic health. Aggregate losses in personal income were estimated to be $88 million for Alternative 2 (Table 282). Of these losses about 20% would occur in both the Boston and New Bedford areas. Note that this does not mean that these losses would be strictly to either city since many ports are included in each subregion and the indirect and induced impacts would likely to be broadly distributed throughout the subregions even though the direct impacts on commercial fishing would be more localized.

Alternative 2 would impact approximately 3,000 jobs, of which, at least two-thirds would be in the commercial fishing, dealer, or seafood processing sectors (Table 283). Job impacts would be largest in the Boston area (601 affected jobs) but employment impacts would exceed 400 jobs in the subregions of Lower Mid-Coast Maine, Gloucester, and New Bedford. Employment impacts would be between 150 and 400 jobs in the New Hampshire Seacoast, Cape and Islands, Rhode Island, Connecticut Seacoast, and Non-Maritime subregions.

Table 283 - Alternative 2 Employment Impacts by Region (# of jobs)

5.4.6.8 New England Regional Economic Impacts of Alternatives 3/4 and 4A

As noted previously, in its default form, Alternatives 3 was modeled as though it was identical to Alternative 4 even though the realized impacts of Alternative 3 may differ depending on which option is selected to assign species-area TAC. The estimated impacts of Alternatives 4 and 4A were also found to be virtually indistinguishable. Therefore, the estimated economic impacts for Alternative 4 are representative of that of Alternatives 3 and 4A.

Total impact on New England gross sales was estimated to be $203 million (Table 284). Gross sales in the Boston area were estimated to decline by $40 million while sales impacts in New Bedford and Gloucester; the second and third most affected subregions, were $36 and $29 million respectively. Impacts in other subregions would be about $20 million in Lower Mid-Coast Maine, Connecticut Seacoast, and Non-Maritime New England while sales impacts would be $11 million or less in all other subregions.

Aggregate income impacts were estimated to be $82 million (Table 285). Income effects were largest in the Boston subregion although only slightly more so than the New Bedford subregion. Note that the combined income impacts for commercial fishing, dealers and processing in the New Bedford subregion was greater than that of the Boston subregion. This means that much of the income impacts in the New Bedford subregion would be borne by businesses and households most directly involved in fishing and fishing related industries. By comparison, the income effects would be similar in aggregate but would be more broadly distributed across the spectrum of economic sectors based in the Boston subregion.

Alternative 4 would affect an estimated 2,800 jobs (Table 286). As was the case for other alternatives, the employment impacts would be largest in the Boston and New Bedford subregions with employment impacts on the Gloucester and Lower Mid-Coast Maine subregions running between 400 and 500 jobs most of which would be in fishing or fishing related sectors. Employment impacts in the New Hampshire Seacoast, Cape and Islands, and Connecticut Seacoast were approximately 150 jobs while Rhode Island was the only remaining coastal subregion with employment impacts of more then 100 jobs.

Table 286 - Alternative 3/4 Employment Impacts by Region (# of jobs)

5.4.6.9 Impact on Coastal New England Sales, Personal Income, and Employment of a 2009 Rebuilding Date

The direct impact of reduced sales on commercial fishing, seafood dealers, and seafood processing was estimated to be $138 million to the coastal region consisting of the five New England coastal states (Table 287). The total impact (including indirect and induced effects) was $242 million. Across coastal subregions about 20% of this total impact would accrue to the Boston subregion while sales losses in New Bedford and Gloucester would represent 16.3% and 14.6% of total New England region sales impacts.

Gross sales represent both the cost of producing goods and service as well as income payments to workers and business profits. At least a portion of a reduction in sales actually represents cost savings since no production costs would be incurred but income payments would also be lost. These forgone income payments represent a more accurate measure of the economic loss to a subregion of a reduction in commercial fishing landings. The total loss in personal income for the New England region was estimated to be $98 million (Table 288). Income losses were almost $20 million in the Boston subregion; $18 million in New Bedford; and more than $14 million in Gloucester. Income losses were more than $12 million in the Lower Mid-Coast subregion but were less than $10 million in all other subregions.

Alternative 4 with TACs set to achieve conservation objectives by 2009 would affect more than 3,400 jobs in the New England region (Table 289). Across subregions, employment impacts would exceed 500 jobs in Lower Mid-Coast Maine, Gloucester, Boston, and New Bedford. Employment impacts in the New Hampshire Seacoast, Cape and Islands, Rhode Island, and Connecticut Seacoast subregions would range from 150 to 215 jobs but would be less than 100 in all other coastal subregions.

Table 289 - Alternative 4 with 2009 Rebuild TACs Employment Impacts by Region (2001 $'s)

5.4.6.10 Comparison of Sales, Income and Employment Impacts Across Alternatives

Among alternatives designed to meet the fishing mortality rates consistent with the constant fishing (Table 290), personal income (Table 291) or employment (Table 292) while Alternative 2 would have largest impact. The Proposed Action was designed to meet a suite of fishing mortality rates consistent with Fmsy for some stocks and phased fishing mortality for other stocks. This mixed approach results in lower sales impacts than either Alternatives1A, 2 or 3/4.

Alternative 1A sales impacts would be $64 million lower than Alternative 2 and $50 million less than Alternative 4. The Proposed Action sales impacts would be even lower by about $18 million. Note that the differential impact on personal income across alternatives is much less than the sales impacts with the Proposed Action having income effects $33 million less than Alternative 2 and $27 million less than Alternative 4. Employment impacts of Proposed Action would be less than two-thirds that of Alternative 2 and about three-quarters as greater as Alternative 4.

Alternative 1B was designed to meet fishing mortality rates for the first year of the Phased rebuilding strategy for all stocks that are higher than that of the constant fishing mortality. For this reason landings and revenues under Alternative 1B would be higher and the estimated reduction in gross sales relative to the Status Quo was lower ($95 million as compared to $135 million under Proposed Action). However, the phased rebuilding strategy would require additional reductions in fishing mortality at least in 2005, 2006 and 2007 which means that landings, hence revenues may decline in each of four consecutive years beginning in 2004. Thus, the estimated impacts presented herein do not capture the full impact of Alternative 1B relative to the Proposed Action, Alternatives 1A, 2, or 3/4.

In general, the economic impact in terms of sales, income and employment may be expected to follow a pattern similar to that of the projected landings streams. These projections suggest that over a relatively short time frame the phased rebuilding strategy would yield higher revenue streams from 2004 to 2008 would be about the same in 2009 but would be lower for at least the next ten year as compared to the constant fishing mortality rate strategy. This means that Alternative 1B might result in comparatively more favorable region-wide impacts on sales, personal income, and employment for about the first five years of the rebuilding period but would have less favorable economic impacts over a much longer period of time.

Table 292 - Comparison of Employment Impacts Across Alternatives (2001 $'s)

5.4.7 Economic Impacts of Recreational Fishing Regulations

Changes in recreational measures will affect anglers across all modes and will affect charter/party operators directly, through regulatory action, or indirectly, through reduced passenger loads, if any one measure causes anglers to choose to reduce their fishing activity. Of the proposed recreational measures, the change in the minimum fish size for Atlantic cod would affect all recreational anglers while the seasonal change and imposition of the party/charter GOM cod trip limit would affect only those anglers in the Gulf of Maine. The year-round exemption letter would have a direct affect on charter/party operators.

Economic effects on anglers are manifested in a reduction in the value or satisfaction that they derive from taking a recreational fishing trip. If the primary motivation for fishing is based on catching fish, then changes in measures affecting keep rates without affecting catch may have a relatively small impact on recreational fishing value. Conversely, to the extent that anglers are motivated primarily by keeping fish, measures that affect keep rates would result in comparatively greater loss in economic value. Research indicates that recreational anglers are motivated by a variety of different factors, but it may be assumed that groundfish anglers are more motivated by keeping fish rather than for sport.

Data to determine the welfare loss associated with the proposed measures are not available. However, the combined effects of any given alternative having varying degrees of bag limit changes and an increased size limit may be expected to substantially reduce keep opportunities for anglers that target cod and would, therefore, result in a corresponding reduction in recreational fishing value. This reduced value may be partially offset by substitution of alternative target species, but this would still result in some welfare loss, assuming that cod would have been the preferred species choice.

Of the proposed alternatives, Option 3 would likely result in least welfare loss because it would induce less change in recreational keep opportunities for all modes and for both cod stocks. Both Options 1 and 2 would result in some welfare loss relative to regulatory measures that had been in place prior to May 1, 2002. However, an ordinal ranking of these two options in terms of welfare change is difficult because Option 2 would increase keep opportunities for haddock relative to Option 1 but would impose a closed season. Under Option 1, anglers would at least be able to fish year-round. The relative difference between Options 1 and 2 would depend on angler's valuation of being able to keep more haddock for most of the year as compared to being unable to retain anything from December to March.

In addition to some loss in economic welfare, an area closure may result in fewer recreational trips being taken if no suitable alternative target species are available. Note the proposed possession and minimum fish size limits may also discourage trip-taking decisions, if anglers believe that these limits would not justify taking a trip. To the extent that anglers do take fewer trips other secondary economic impacts may accrue in the form of reduced angler expenditures.

An input/output (I/O) model was employed to assess the potential economic losses (sales, income, and employment) associated with implementation of the proposed management options, across six coastal Northeast states (ME through NY). Reductions in sales, income, and employment in these states could occur if anglers reduce fishing effort, and hence, expenditures, in response to the new regulations. Unfortunately, no empirical information is available to determine how sensitive the affected anglers might be to the proposed changes. Therefore, economic losses were estimated for two hypothetical scenarios: (1) a 25% reduction in the number of fishing trips that are predicted to be affected by implementation of the management measures from ME through NY; and (2) a 50% reduction in the number of fishing trips that are predicted to by affected from ME through NY.

Reductions in anglers' trip-related purchases will have a direct effect on the sales, income, and employment of businesses that supply goods and services to saltwater fishermen. Businesses providing these goods and services must also purchase goods and services and hire employees, which in turn, will affect the sales, income, and employment of many additional businesses.

Three levels of economic impacts result from purchases by saltwater fishermen: (1) direct, (2) indirect, and (3) induced. Direct effects occur when anglers spend money at retail and service oriented fishing businesses (e.g., purchases of ice at convenience stores or access fees paid to owners of for-hire vessels). Indirect effects occur as the retail and service sectors purchase fishing supplies from wholesale trade businesses and manufacturers, and pay operating expenditures (e.g., the retailer must purchase fishing rods from the manufacturer or wholesaler and pay electric bills). These secondary industries must then, in turn, purchase additional supplies and this cycle of industry to industry purchasing continues until the amount remaining within the region of interest is negligible. Finally, induced effects result when employees of the direct and indirect sectors make purchases from retailers and service establishments in the normal course of household consumption (e.g., convenience store employees spend money on groceries and pay federal and state taxes). The summation of direct, indirect, and induced effects are total effects.

5.4.7.1 Data and Methods

Input-output (I/O) analysis is the most common approach available for determining the direct, indirect, and induced effects associated with an overall change in economic activity in a particular region. For the analysis presented here, a ready-made regional I/O modeling system called IMPLAN Pro (Impact analysis for Planning) was used to determine the economic losses associated with the hypothetical reductions in fishing trips under each option. The IMPLAN Pro system is a widely used, nationally recognized tool that provides detailed purchasing information for 528 industrial sectors and a user-friendly media for customizing input-output models to specific applications (Minnesota IMPLAN Group, Inc. 1997).

Angler expenditures in the Northeast (NE) by state and mode for marine fishing were obtained from Steinback and Gentner (2001). These expenditure data were produced from extensive surveys of marine recreational fishermen in the NE in 1998. The surveys were conducted as part of the Marine Recreational Fisheries Statistics Survey (MRFSS). Average fishing trip expenditures were provided for each state and mode of fishing (i.e., private boat, party/charter, and shore) in the NE in 1998. Trip-related expenditure categories shown in the report included food, lodging, travel costs, boat fuel, party/charter fees, access or boat launching fees, equipment rental, bait, and ice. In addition to trip-related expenditures, Steinback and Gentner (2001) also estimated anglers' expenditures for semi-durable items (e.g., rods, reels, lines, clothing, etc.) and durable goods (e.g., motor boats, vehicles, etc.). However, expenditures for these items are not likely to change after implementation of the proposed regulations since semi-durable and durable items can be used for many fishing trips. Thus, in the analysis presented here, it is assumed that the proposed management measures will only affect anglers' trip-related expenditures.

The economic losses associated with reductions in private boat and party/charter angler expenditures[4] were estimated by applying the product of the estimated number of affected trips and the average trip expenditure estimates from Steinback and Gentner (2001) to the appropriate IMPLAN sector multipliers in each state. The multipliers measure the direct, indirect, and induced relationships between industries and households. Input-output models require all values to be in producer prices (manufacturer prices) so each of the angler expenditure categories was associated with its corresponding IMPLAN producing sector. In IMPLAN, margins are used to convert the retail-level prices paid by anglers into the appropriate producer values. Margins ensure that the correct value is assigned to products as they move from producers, to wholesalers, through the transportation sectors, and finally on to retail establishments.

[4]Anglers that fish for cod from the shore are not projected to be affected by the measures proposed under the three options.

Economic losses were estimated for sales, income, and employment. Sales reflect the aggregate reductions in total dollar sales generated from expenditures by anglers across the six coastal states. Income represents the aggregate reductions in wages, salaries, benefits, and proprietary income generated from angler expenditures across the coastal states. Employment includes both full-time and part-time workers and is expressed as aggregate reductions in total jobs across states.

5.4.7.2 Results

The projected economic losses in the six coastal NE states associated with the hypothetical reductions in affected marine recreational fishing trips are shown in Table 293. The measures proposed under option 3 result in the lowest sales, income, and employment losses because this option is projected to affect the fewest fishing trips. A 25 % reduction in fishing trips that are projected to be affected by option 3 results in a total loss of $306 thousand in sales, $125 thousand in income, and about 8 jobs in the six coastal NE states. The losses are about twice as high given a 25% reduction in fishing trips that are affected by the more restrictive option 1 measures ($642 thousand in sales, $261 thousand in income, and 17 jobs). The projected losses under the option 2 measures are even higher. The same pattern results given the hypothetical 50% reduction in affected trips because the measures proposed under option 2 affect the fewest trips, followed by those proposed under option 1, and finally, those proposed under option 3.

If the measures proposed under the three options induce reductions in fishing effort, approximately 80% of the total sales, income, and employment losses are projected to be generated by anglers fishing aboard party and charter boats. Losses associated with reductions in angler expenditures that fish from private boats are projected to comprise 20% of the total reduction in sales, income, and employment. This is because party/charter anglers spend more, on average, then private boat anglers, and the measures proposed under all three options effect more party/charter trips than private boat trips.

	Option 1		Option 2		Option 3	
Mode of Fishing	25% Reduction	50% Reduction	25% Reduction	50% Reduction	25% Reduction	50% Reduction
	Sales (thousand dollars)					
Party/Charter	502	1,004	559	1,118	233	466
Private Boat	139	279	138	276	73	146

Private Boat	3	7	3	7	2	4
Total	17	33	18	36	8	16

Table 293 - Projected economic losses associated with hypothetical reductions in affected marine recreational fishing trips across six coastal states in the Northeast (ME through NY), by mode.

Estimates shown are in 1998 dollars

5.4.7.3 Summary

The measures proposed under all three management options will affect a portion of the recreational fishing trips that catch Atlantic cod. Unfortunately, although we can generally predict how many trips will be affected by the proposed measures, we do not know how anglers' trip taking behavior will change in response to the additional restrictions. If the measures result in an overall reduction in angler effort, expenditures associated with these trips will be foregone, and reductions in sales, income, and employment will occur for businesses that supply goods and services to saltwater fishermen. In addition, the sales, income, and employment of many businesses that supply the directly affected businesses could also decline. On the other hand, if the proposed measures do not induce a change in overall angler effort, total angler expenditures would remain unchanged, and there would be no effect on supporting businesses.

Given the uncertainty surrounding how anglers will respond to the proposed measures, total potential reductions in sales, income, and employment to businesses in six coastal NE states (ME to NY) were estimated for two hypothetical scenarios: (1) a 25% reduction in the number of fishing trips that are predicted to be affected by implementation of the management measures; and (2) a 50% reduction in the number of fishing trips that are predicted to by affected. Losses are predicted to range from $306 thousand in sales, $125 thousand in income, and 8 jobs under a 25% reduction for option 3 to $697 thousand in sales, $284 thousand in income, and 18 jobs under a 25% reduction for option 2. Losses associated with a 50% reduction in affected trips are projected to be about double those shown for the 25% reduction scenario under all three management options.

The projected economic losses shown here do not capture losses borne by individual anglers. The input-output approach followed in this analysis projects the change in goods and services produced by different businesses that are linked to purchases by marine anglers, but it does not provide estimates of angler welfare losses. These welfare losses are generally defined as the additional value above opportunity costs (usually taken to be expenditures of time and money) that anglers would be willing to pay in order to fish. Angler welfare values are intrinsically connected to many variables, including the potential size distribution of the catch and keep rates. Therefore, since the proposed measures include more restrictive possession and size limits, it is likely that angler welfare values will decline for at least some of the anglers that fish for Atlantic cod.

5.4.7.4 Charter/Party Impacts

Charter/party operators would be directly affected by the enrollment requirement, and indirectly affected, should any one of the recreational measures result in a reduction in passenger demand. The enrollment program would remove the possibility of a charter/party vessels switching back-and-forth between commercial fishing and carrying passengers for hire for those vessels that still want to be able to take recreational passengers into any one of the rolling closure areas. Vessels that forego the exemption program would still be able to switch between commercial and recreational activities, but may sacrifice some charter/party business to competitors if catch rates are actually higher, or even perceived to be higher, inside the closed areas.

A review of relative dependence on passenger income vis a vis commercial fishing income suggests that most operators in the Gulf of Maine derive the majority of total income from the party/charter business.

These vessels would not likely be impacted by an enrollment program since they do not depend on commercial fishing income. Further, experience in past enrollment programs under similar circumstances suggests that enrollees had relatively little commercial fishing income (only 7 of the 27 enrollees in 1999 and 2 of 23 enrollees in 2000).

Given the increase in the minimum size limit, charter/party vessels may experience a reduction in passenger demand. However, the minimum fish size increase will have a relatively small effect on charter/party keep opportunities. Experience following implementation of the minimum fish size increase in 1996 and 1997 indicates that passengers and trips have been increasing over the past 2-3 years. Further, among alternative management measures, size limits are generally supported by the recreational fishing public. Therefore, the change in minimum size does not seem likely to result in a substantial reduction in passenger demand for charter/party trips in the GOM or GB.

All options would continue a bag limit on charter/party anglers fishing for Atlantic cod in the GOM. Industry representatives have indicated in the past that passenger demand is, in part, driven by angler expectations and that one important component of angler expectations is the opportunity to have a big trip. As the argument goes, even though these expectations are realized on only a small fraction of trips, imposition of a bag limit would cause individuals to lose interest in taking a charter/party trip. The extent to which anglers would respond in the manner described is not known, nor have there been any studies that document angler response to changes in charter/party bag limits. Party/charter VTR data for FY2002 may provide some insight into the issue but as of now these data are not yet available.

Based on VTR reports, the number of charter/party operators reporting trips where GOM cod were landed ranged between 103 and 114 from 1997 to 2000. Of these vessels, approximately 20 percent, in any given year, took 60 percent of total trips that landed GOM cod, carried 70 percent of total passengers on those trips, and landed 80 percent of the total GOM cod. Thus, it is likely that the majority of economic impacts will be borne by the 20-25 operators whose primary business is in offering groundfish trips to their recreational fishing customers.

5.4.8 Economic Impacts of Alternatives to Minimize Adverse Effects of Fishing on Essential Fish Habitat

This impact assessment characterizes the magnitude of social and economic impacts likely to result from the alternatives considered in the Draft Environmental Impact Statement for the Essential Fish Habitat Components of Amendment 13 to the Northeast Multispecies Fishery Management Plan.

5.4.8.1 Methods and Data

Potential economic impacts of the EFH closure options were analyzed using Arcview GIS software. Location information from the VTR data base was used to determine which trips were reported as having taken place during calendar year 2001 within any given closure area. Revenues associated with any affected trip were assumed to be lost. All other things being equal, this "no displacement" assumption is likely to result in an upper bound estimate of revenue impact since vessels would attempt to maintain fishing incomes by redirecting effort to alternative fishing locations. In addition to this assumption a number of other assumptions were also required.

Price or value information is not recorded on VTRs. An estimate of trip value was obtained by assigning a monthly average price by species calculated from dealer data to reported landings. Although this approach would account for seasonality in average prices, it would not capture price differences across ports or premiums that individual vessels may receive for product quality or by market categories. Industry level impacts would not be appreciably affected by using an average price but impact assessments would be biased with increasing levels of disaggregation. Unfortunately, it is not possible to determine the directionality of bias as it may be port- or even vessel-specific.

The potential difficulties with using VTR data have been documented elsewhere but the most important issue affecting the social and economic impact assessment is associated with reported location information. Principle concerns with location information (i.e. latitude – longitude) include 1) no reported location, 2) misreported or miscoded location, and 3) assignment of an entire trip to a single latitude-longitude coordinate. Approximately 23% of all records representing about one-third of the estimated total value of landings either did not record any location information or could not be plotted within coastal or EEZ waters of the Northeast region and had to be discarded. Note that just because a record could be plotted, does not necessarily mean that the location for that particular trip was either accurately reported or correctly coded. Further, since only a single location coordinate is provided in the VTRs it is not possible to take into account impacts on trips that may have transited through a closure area. The latter is particularly problematic for mobile gear. Given these considerations, VTR data that were retained for analysis should be regarded as a sample of potentially affected effort and that the impacts of any given habitat option may be underestimated.

A final consideration is the fact that VTR data include information only for Federal permit holders that are subject to mandatory reporting. Some habitat options (Alternative 5A,-D in particular) include closure areas that would affect state waters fisheries. The relative amount of state waters activity that would be affected is not known.

As noted above, omitted data will tend to result in a downward bias in estimated social and economic impacts. However, also as noted previously, the assumption of no effort displacement would tend to result in an upward bias in estimated impacts. The relative contribution of these two counterbalancing effects is not known with certainty. If there is no systematic bias in the omitted data then the relative impacts for the omitted trips should be similar to that of the included trips. If this is the case, then the computed relative change in gross revenues for the included trips would be representative of the fishery as a whole. This would also provide some indication as to the potential effort displacement that would be needed in order to offset the habitat closure losses.

The potential impacts on the surf clam/ocean quahog fishery were evaluated separately using methods similar to that which was used for other fisheries. However, because landings in the clam VTRs are reported in bushels rather than pounds, an average price from dealer records (reported in terms of $ per pound meat weight) could not be assigned. For this reason impacts are reported in physical rather than dollar units and are aggregated at the state level.

5.4.8.2 Aggregate Analysis

For all VTR records retained for analysis, the total estimated gross revenue from all species reported during calendar year 2001 was $296.3 million. For a Level 1 habitat closure the relative change in total gross revenues ranged from a low of 1.3% for Alternatives 6 and 10B to a high of 12.8% for Alternative 5b (Table 1). The remaining alternatives all ranged between 1.4 and 8% in total revenue impact with little appreciable difference between Alternatives 3a (7.8%) and 3b (7.4%); Alternatives 6 (1.3%), 10A (1.4%) and 10B (1.3%) or between Alternatives 4 (5.3%) and 5d (5.6%)

Alternative	Total Revenue Loss	Monkfish Revenue Loss	Scallop Revenue Loss	Squid/Whiting Revenue Loss	Other Species Revenue Loss	Groundfish Revenue Loss	Fluke, Scup, Black Sea Bass Revenue Loss
Alternative 3a	7.8%	6.0%	6.5%	0.1%	5.7%	17.4%	0.1%
Alternative 3b	7.4%	5.1%	6.5%	0.1%	5.4%	16.1%	0.1%
Alternative 4	5.3%	3.5%	3.3%	0.1%	4.2%	13.4%	0.1%
Alternative 5a	6.7%	18.3%	1.4%	2.9%	6.5%	13.7%	4.5%
Alternative 5b	12.8%	18.2%	10.8%	3.3%	11.4%	21.6%	1.9%
Alternative 5c	8.4%	16.4%	1.5%	3.3%	12.7%	16.3%	4.7%
Alternative 5d	5.6%	11.1%	1.0%	0.8%	5.4%	13.4%	5.6%
Alternative 6	1.3%	1.8%	0.3%	0.2%	3.5%	1.7%	0.1%
Alternative 10A	1.4%	3.6%	0.4%	0.1%	2.9%	1.6%	0.1%
Alternative 10B	1.3%	3.6%	0.4%	0.1%	1.9%	1.8%	0.1%

Table 294 - Relative Loss in Gross Revenues by Alternative for Level 1 Habitat Closure

Revenue impacts across species were more varied across alternatives than total revenue impacts. The impact on monkfish revenue was between 11 and 18% under any of the variants of Alternative 5 a-d. By contrast, scallop revenue impacts were largest under Alternative 5b (10.8%) but were less than 1.5% for Alternatives 5a, c, and d. Revenue losses for small mesh fisheries for whiting and squid were similar (about 3%) for Alternatives 5a, b, and c but were less than 1% for all others. Revenue losses for combined "other" species (dogfish, skates, lobster, shrimp, herring, mackerel, tunas, and clams) were greatest for Alternatives 5b (12.7%) and 5c (11.4%) but were similar all other habitat alternatives (from 3.5 to 6.5%). Revenue losses for groundfish were highest for Alternative 5b (21.6%) and lowest for Alternative 10A (1.6%). With only a few exceptions revenue losses for groundfish exceeded that of all other species across all alternatives. Revenue losses for combined summer flounder, black sea bass, and scup were 0.1% for all alternatives other than the variants of Alternative 5. Among these alternatives, revenue losses were similar for Alternatives 5a, c, and d.

A Level 3 habitat closure would mitigate revenue impacts on stationary bottom tending gear, and as a result, total revenue impacts would be lessened. The revenue losses for a Level 3 closure ranged from 8.1% (Alternative 5b) to 0.5% (Alternatives 6, 10A and 10B) (Table 295). Compared to the Level 1 closure effects, the revenue losses for the remaining alternatives were lowered by about 1 to 2%. However, revenue losses for specific species groups were substantially reduced. Since a large proportion of monkfish are landed with gillnet gear the Level 3 closure would mitigate a substantial proportion of estimated monkfish revenue losses. Similarly, revenue losses for the "other" species group would be mitigated under a Level 3 closure because a significant proportion of these revenues are comprised of lobster using trap gear. Revenue losses for groundfish would be partially offset by a Level 3 closure since gillnet and hook segments of the groundfish fishery would not be affected. However, trawl gear accounts for the majority of groundfish effort so groundfish revenue losses would still range between 9 and 14% for all alternatives except Alternatives 6, 10A, and 10B.

Alternative	Total Revenue Loss	Monkfish Revenue Loss	Scallop Revenue Loss	Squid/Whiting Revenue Loss	Other Species Revenue Loss	Groundfish Revenue Loss	Fluke, Scup, Black Sea Bass Revenue Loss
Alternative 3a	6.1%	2.9%	6.5%	0.1%	1.8%	14.1%	0.1%
Alternative 3b	5.9%	2.7%	6.5%	0.1%	1.8%	13.3%	0.1%
Alternative 4	4.0%	2.2%	3.3%	0.0%	0.9%	11.3%	0.1%
Alternative 5a	3.8%	6.3%	1.4%	2.9%	1.0%	10.6%	4.4%
Alternative 5b	8.1%	6.3%	10.8%	3.3%	1.4%	14.0%	1.9%
Alternative 5c	4.5%	6.4%	1.5%	3.3%	1.1%	13.3%	4.6%
Alternative 5d	3.1%	3.4%	1.0%	0.7%	0.7%	9.3%	5.6%
Alternative 6	0.5%	0.6%	0.3%	0.2%	0.2%	1.3%	0.1%
Alternative 10A	0.5%	0.5%	0.4%	0.1%	0.1%	1.1%	0.1%
Alternative 10B	0.5%	0.5%	0.4%	0.1%	0.2%	1.2%	0.0%

Table 295- Relative Loss in Gross Revenues by Alternative for Level 3 Habitat Closure

Overall, the relative difference between a Level 1 and Level 3 habitat closure mitigates about 22% of total revenue losses for Alternatives 3a, 3b, and 4 (Table 296). For the Alternative 5 variants the revenue losses are reduced by as much as 46% (Alternative 5c). Much of this reduction in revenue impact is associated with savings of monkfish gillnet and lobster trap fishery revenues. A Level 3 habitat closure would have the largest mitigating effect on Alternatives 6, 10A, and 10B.

Alternative	Level 1	Level 3	Reduced Impact ($)	Reduction in Loss (%)
3a	23,237,630	18,098,883	5,138,747	22%
3b	22,042,497	17,498,370	4,544,127	21%
4	15,599,271	11,970,233	3,629,039	23%
5a	20,251,311	11,730,565	8,520,746	42%
5b	38,394,041	24,470,730	13,923,311	36%
5c	25,289,695	13,780,403	11,509,291	46%
5d	16,738,994	9,208,996	7,529,998	45%
6	3,990,045	1,436,544	2,553,501	64%
10A	4,162,998	1,345,937	2,817,060	67%
10B	3,768,834	1,570,002	2,198,832	58%

Table 296-Summary of Revenue Impacts by Alternative and EFH Level

As a share of total revenue loss, groundfish losses for a Level 1 closure range from a low of 24% for Alternative 10A to a high of 54% for Alternative 4 (Table 297). Revenue losses for scallops represent about one-quarter of revenues loss for Alternative 4 and nearly one-third of total losses for Alternatives 3a, 3b, and 5b. Monkfish revenue losses were 7% or less of total revenue losses for Alternatives 3a, 3b, and 4 but were at least 12% of revenue losses for all other alternatives.

		Groundfish	Scallops	Monkfish	Fluke, Black Sea Bass, Scup	Squid & Small Mesh Species	Other Species	TOTAL Impacted Revenue ($)
Alternative 3a - Level 1

Table 298- Summary of Revenue Impact and Species Composition by Alternative for Level 3 Habitat Closure

Since a Level 3 habitat closure does not provide any relief to fisheries using mobile bottom-tending gear the share of revenue impact for fisheries that are dominated by these mobile gears increases relative to other fishery impacts. For example, the combined share of groundfish and scallop revenue losses is at least 70% for all Alternatives and is as much as 90% of revenue impact for Alternative 4 (Table 298).

For the surf clam/ocean quahog fishery, aggregate landings from retained VTR records were 5.6 million bushels for calendar year 2001. Based on locations provided in these data no trips were reported as having occurred inside the confines of any of the specified habitat closure for Alternatives 3a, 3b, or 4. Therefore, the habitat closures for these three alternatives would have no impact on the surf clam/ocean quahog fishery. The remaining alternatives would affect between 2 and 7% of total fishery landings (Table 299).

5.4.8.3 Short-term Impacts on Coastal Sub-Regions

An input/output (I/O) model was employed to assess the relative short-term economic losses (sales, personal income, and employment) associated with the proposed habitat alternatives on ten subregions in New England. This approach evolved out of collaborative research between the Marine Policy Center of the Woods Hole Oceanographic Institution and the Northeast Fisheries Science Center as part of a grant received through the Marine Fisheries Initiative (MARFIN) in 1999 (see Marine Policy Center 2000). The details of this approach (including data and methods) are described in section 5.4.6.

The results of this I/O model cannot be directly combined with the I/O results presented in section 5.4.6. This is because while both sets of measures will impact the fishing industry, the measures interact in ways that are not captured by analyzing each independently. In addition, there are significant differences between the approach used in the closed area model and that used in the habitat analysis. The closed area model allows displaced effort to be used in other areas, while the habitat model assumes all displaced effort vanishes. It may be possible, once final management choices are made, to combine the two analyses in a way that captures the total impacts on coastal sub-regions.

5.4.8.3.1 Impact Assessments

In the I/O model presented here, total economic impacts are calculated by applying estimates of direct revenue changes to IMPLAN generated multipliers that measure the indirect and induced relationships between industries and households in each subregion. Therefore, prior to calculating the total estimated losses (direct + indirect + induced) of each alternative, it was necessary to determine the direct revenue changes associated with the gear sectors, the seafood dealer sector, and the seafood processing sector in each subregion.

Direct revenue losses for the affected trips were summed by gear sector in each subregion. Direct revenue losses associated with seafood dealers in each subregion were estimated in the following manner. First, the summation of the estimated direct revenue losses associated with the harvesting sectors in each subregion were multiplied by the proportion of total dealer purchases that were derived from local harvesters (i.e, purchased from harvesters within a particular subregion). This results in an estimate of the value of seafood harvested in a particular subregion that was purchased by seafood dealers in that same subregion. The proportions used in these calculations were determined from the Northeast dealer data base and ranged from a low of .17 for New Hampshire Seacoast dealers to a high of .99 for Upper Mid-Coast Maine dealers. The remainder of purchases by seafood dealers were derived from imports (i.e., purchased from outside a particular subregion) and assumed to be unaffected by the proposed management measures. Although a small portion of the imports may have been purchased from the affected gear sectors in neighboring subregions, these effects are not part of this analysis since separate models were constructed for each subregion. Secondly, the results from the first step were multiplied by the dealer mark-ups or margins in each subregion to obtain the estimated direct revenue losses for seafood dealers in each subregion.

For purposes of this analysis, seafood processors in each subregion were also estimated to be directly impacted by the proposed habitat alternatives. According to IMPLAN default data it was estimated that about 60% of the total value sold by seafood dealers within each subregion was actually purchased by seafood processors in those same subregions. Thus, in the subregional models, 40% of the dealer sales in value were assumed to be exported out of each subregion, either as domestic or foreign exports, and thus were not available to be purchased by local seafood processors or any other sectors in the model. In this analysis it was assumed that only the seafood processing sector purchases fish from seafood dealers. Several other sectors purchase fish as an input into their production process, such as eating and drinking establishments, hospitals, hotels and lodging, and amusement and recreation services, but it was assumed that these establishments purchase from seafood processors and not seafood dealers. As such, the estimated direct revenue losses for the seafood dealer sectors were multiplied by 0.6 to obtain the value of fish purchased by seafood processors within each subregion. These values were then multiplied by the appropriate seafood processing margins to obtain the estimated direct revenue losses for seafood processors in each subregion. Seafood processing margins were calculated by subtracting the seafood dealer coefficient in the processing production function from one. This margin measures the additional value seafood processors charge to cover their fixed and variable operating costs (including profits and taxes).

After the direct revenue losses were estimated for each gear sector, the seafood dealer sectors, and the seafood processing sectors within each subregion, total economic losses were calculated by applying the revenue losses to the appropriate IMPLAN generated multipliers. Note that losses associated with seafood dealers exclude the losses associated with the commercial harvesting gear sectors, and the losses associated with seafood processors exclude those attributable to the seafood dealers and the commercial harvesters. Thus, the losses associated with reductions in supply to these sectors can be summed to obtain the total effect on sales, income, and employment within each subregion.

No attempt was made to estimate forward linked impacts beyond the processing sector because reductions in groundfish supply at the harvesting level are not likely to significantly alter the cost restaurants, hospitals, and supermarkets pay for groundfish in each subregion. In fact, according to data contained within IMPLAN, less than 2% of the processed seafood purchased by upstream industries is actually derived from processors within each subregion. According to this data, imports from other areas supply the majority of retail-level purchases from processors. Although retail-level purchases of locally processed groundfish may differ from these statistics, it was assumed that no forward-linked impacts would occur in each subregion beyond the seafood processing sector. Note also that the impact assessment was conducted only for the Level 1 habitat closure options. For this reason the reported results should be regarded as an upper bound estimate on potential economic impacts.

5.4.8.3.2 Results

The Input/Output model used for this analysis was based on a set of sub-regional models for New England states only. A similar modeling framework is currently under development for the Mid-Atlantic region but is not available at this time. Therefore, the economic impacts associated with any one of the habitat alternatives that accrue to regions outside of the New England area could not be estimated. This omission may be particularly problematic for Alternatives 5a – d because these alternatives include closures that would impact several fisheries that are important to states in the Mid-Atlantic region.

The total direct impact of any given habitat alternative is the sum of the commercial fishing, seafood dealer, and seafood processing sector revenue losses. The sum of these New England coastal region losses plus the multiplier effects of the indirect and induced impacts ranged from $12.4 million for Alternative 10B to $150.3 million for Alternative 5b (Table 300). The gross sales impacts for Alternative 3a, 3b, and 5c were similar at approximately $100 million. Gross sales impacts for Alternatives 4, 5a, and 5d were also similar in magnitude averaging about $68 million while sales impacts for Alternatives 6, 10A, and 10B all ranged between $12.4 and $15.6 million.

The total loss of New England coastal region income ranged from a low of $4.4 million for Alternative 6 to a high of $43.1 million for Alternative 5b (Table 301). As was the case for gross sales there were only small differences in income impacts between Alternatives 3a, 3b, and 5c ($28 to $30 million). There were also relatively small differences in income impacts for Alternatives 4, 5a, and 5d ($19 to $21 million). Likewise there were only small differences in income impacts for Alternatives 6, 10A, and 10B.

The total employment impacts followed a pattern similar to that of the sales and income impacts with Alternative 10B resulting in the lowest employment impact (175 jobs) and Alternative 5b affecting more than two thousand jobs. Alternative 3a and 3b would affect about 1,400 jobs and Alternative 5c would affect 1,300 jobs. Alternatives 4, 5a, and 5d would affect between 850 and 1,000 jobs.

Table 302- Total New England Coastal Region Employment Impacts

Across New England sub-regions the New Bedford area (all ports within Bristol County, MA but principally the city of New Bedford itself) would bear at least two-thirds of the gross sales impacts under Alternatives 3a, 3b, and 4 (Table 303). This level of impact is largely due to the importance of New Bedford groundfish, monkfish, and scallop fisheries; fisheries that would be most affected by habitat closures. Note that with the exception of monkfish, both scallops and groundfish would still be particularly affected even by a Level 3 closure so that while the magnitude of impact would be lower, the proportional impact on the New Bedford sub-region would not be likely to change and may be even greater. Other than the New Bedford sub-region, gross sales impacts on only the Boston, Gloucester, and the Cape and Islands sub-regions would be 10% or more for any of the habitat alternatives.

Sub-Region	Alt 3a	Alt 3b	Alt 4	Alt 5a	Alt 5b	Alt 5c	Alt 5d	Alt 6	Alt 10A	Alt 10B

Table 303- Relative Distribution of Gross Sales Impacts by Sub-Region

5.4.8.3.3 Summary

The impacts on gross sales, income and employment in the New England coastal would be greatest for habitat alternative 5b while either habitat alternative 6, 10A or 10B would reduce these impacts by nearly ten-fold. The impacts are likely to be an upper bound estimate since the potential impacts of Level 3 vis a vis Level 1 were not estimated. In between these extremes, the remaining alternatives form two clusters each having similar impacts within a cluster. Specifically, habitat alternatives 3a, 3b and 5c form one of these clusters with gross sales impacts of about $100 million; income losses of about $30 million; and employment losses of up to 1,400 jobs. Alternatives 4, 5a, and 5d form a second cluster with lower impacts of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs.

Across sub-region the Massachusetts sub-regions of New Bedford, Gloucester, Cape and Islands, and Boston account for between 70 and 90% of economic impacts regardless of alternative. The New Bedford sub-region would be particularly affected followed by Gloucester and the Cape and Islands sub-region. For New Bedford the Level 3 habitat closure may not provide substantial relief because of the importance of scallops, monkfish, and groundfish in the New Bedford seafood economy.

In general, impacts across all forms of analysis identified habitat alternative 5b as having the greatest impact and habitat alternatives 6, 10a, and 10b as having the least. In between these extremes, more severe impacts (gross sales impacts of about $100 million; income losses of about $30 million; and employment losses of up to 1,400 jobs) will result from alternatives 3a, 3b, and 5c. Less severe impacts (losses of about $70 million in sales, $20 million in income losses, and losses of less than 1,000 jobs) will result from habitat alternatives 4, 5a, and 5d.

5.4.9 Other Economic Impacts

The previous sections focused on the quantitative economic impacts of the program to rebuild overfished stocks, including estimates of the distributive impacts of the alternatives to address rebuilding requirements. There are also economic impacts of other measures, many that can only be addressed in a qualitative manner.

5.4.9.1 Rebuilding Trajectories for Overfished Stocks

The net benefits of different rebuilding trajectories are described in a previous section. As discussed, these estimates are useful for comparing different rebuilding strategies. Some issues, however, may not be captured by this quantitative assessment.

The analysis of the different trajectories assumes that target fishing mortalities are achieved. The interactions within the multispecies fishery make it difficult to precisely control fishing mortality. In any given year, mortality rates may be higher or lower on a particular stock than that designed in the rebuilding program. As an example, reducing effort to protect GB cod may inadvertently reduce mortality (and landings) of GB haddock or GB yellowtail flounder. If fishing mortality deviates from the program design, landing streams will also change and the actual economic returns may differ from those estimated. Similar economic impacts could result if actual conditions deviate from the assumptions used in the projection methodology. For example, if recruitment of a stock is significantly higher or lower than projected, resulting economic returns from that stock will also change. For the proposed action, there is a closer link between the expected impacts of the measures the proposed strategy. The projected economic impacts of the proposed action should more closely match the realized impacts.

All rebuilding trajectories result in reduced landings in the early years of rebuilding – for some stocks, significant reductions are likely. This may have impacts on the infrastructure in the fishery that is not entirely captured by the analysis. As discussed in the cumulative impacts section, loss of infrastructure to purchase and sell groundfish, or the loss of markets that results from a reduced supply of groundfish, may limit the ability of the industry to use increased landings in future years. One of the benefits of the proposed action is that the reduction in landings and revenue in the early years is less than the other strategies. This means that the impact on infrastructure may not be as great, providing a better opportunity for the industry to weather the early years of the rebuilding program and benefit from the increased landings expected in the future. While it is likely that businesses will adjust if there is a future opportunity to buy and sell increased amounts of groundfish, there may be a lag between stock rebuilding and when the industry can absorb the increased catches. Temporary periods of depressed prices (from a large supply of fish) may result. These effects may be partially captured by the price model used in estimating the economic impacts.

One aspect that all the rebuilding trajectories have in common is what happens when a stock is rebuilt. In many cases, rebuilding fishing mortality rates are lower than the rate that is allowed on a rebuilt stock. The economic analysis assumes that catches increase immediately. As discussed in the previous paragraph, a sudden increase in the supply of fish may be more than the market can efficiently absorb, and there may be a temporary period of depressed prices. This sudden increase would be most problematic for the phased reduction approach and in particular for the constant catch approach. Both of these trajectories have very low fishing mortality rates in the final years of the rebuilding program. The constant catch approach has no increase in landings as stocks increase. In contrast, the constant fishing mortality rate approach has less of a jump from the final year to the first year of fishing on a rebuilt stock. In addition, under this strategy landings gradually increase over time.

5.4.9.2 Fishery Program Administration

5.4.9.2.1 Fishing Year

The economic impact of a change on the fishing year would depend on whether or not a rebuilding alternative with a hard TAC is implemented. The proposed action did not adopt a hard TAC. Without a hard TAC a change in the fishing year would probably have minimal economic impact. Business plans would need to accommodate reduced DAS allocations but trip decisions would still be based on relative economic returns from using a DAS in May as compared to January. Presumably, a vessel that is weather limited would still choose to fish during favorable weather months regardless of when the fishing year started or ended. The proposed action did not adopt a change in the fishing year and as a result did not adopt a method to pro-rate DAS.

5.4.9.2.2 Periodic Adjustment Process

The proposed action changes the periodic adjustment process. No economic impacts on the fishery are expected under No Action or if the adjustment process is changed by combining the MSMC and the PDT. Neither of these alternatives would have any impact on the fishery but revising the PDT does have the potential to reduce administrative costs and streamline the annual adjustment process. Even though the membership of the MSMC and PDT overlaps, the responsibilities of these advisory groups as well as the timing of tasks do differ combining the responsibilities may streamline the process somewhat.

A biennial adjustment process would reduce administrative costs over time. With fewer adjustments being made the entire management process would become more stable and may reduce uncertainty over what regulatory regime will prevail over the coming year. This reduced uncertainty may enable vessel owners to make longer term planning decisions that could enhance fishery productivity and economic performance over time.

5.4.9.2.3 US/Canada Resource Sharing Understanding

The management of GB cod, haddock, and yellowtail flounder is complicated because these stocks are harvested by both U.S. and Canadian fishermen. The M-S Act requires that these stocks be managed as a unit, even though U.S. regulations only apply to fishing in U.S. waters. The total catch that can be removed must be consistent with the M-S Act, whether it is caught by U.S. or Canadian fishermen. This means that if the catch by fishermen from both countries is not carefully coordinated, the total catch may damage the resource unless stringent limits are placed on U.S. fishermen. As an egregious example, if Canadian fishermen harvested all the GB cod that can be taken consistent with the M-S Act, regulations would have to prevent U.S. fishermen from harvesting any GB cod. While this extreme example is unlikely because of the similarities between U.S. and Canadian management goals, it highlights the need to coordinate harvest levels between the two countries.

In the past, U.S. target TAC levels for these stocks were set by assuming a Canadian harvest. Often the assumed harvest did not match the actual Canadian harvest. When the assumed harvest was higher than the actual Canadian harvest, opportunities for U.S. fishermen were limited by an unnecessarily low target TAC. When the assumed harvest was less than the actual Canadian harvest, there was increased risk for exceeding biological limits that would result in further restrictions in following years.

Implementing a U.S./Canada resource sharing agreement does not change the total catch that can be taken from these stocks. It does, however, allocate a portion of that catch to each country based on an agreed formula. The primary economic benefit that results is predictability in the allowed harvest by U.S. fishermen from year to year. While catches will change because of changing resource conditions, there is a degree of certainty that the catch by respective countries will be coordinated and will not disadvantage either country. There is a reduced possibility that excessive Canadian catches will result in additional restrictions on U.S. fishermen.

The resource sharing agreement would require implementation of specific measures to assure that the domestic allocation of quota is not exceeded which would require identification of participating and monitoring of the U.S. quota as a hard TAC. A hard TAC will be implemented for a year at a time. Management if the hard TAC may use a trigger (70-90 percent of the TAC) after which a restrictive trip limit would be implemented or by using a combination of conservation measures that could include specific gear configurations, controlled access, or trip limits designed to preserve the cod TAC. Since the cod TAC would be most constraining, the difference in economic effect between these two approaches comes down which alternative would allow for the most haddock and yellowtail to be taken at least cost.

Under a hard TAC alternative once the hard TAC for a given species has been reached possession of that species may be prohibited or the area may be closed to all gears capable of catching cod, haddock, or yellowtail flounder. A prohibition on possession would still allow fishing in the area for the remaining species but may still result in discarding. A closure would provide greater assurance that any TAC overage would be minimized but would have greater economic impact.

A target TAC alternative may be implemented using a suite of measures that would become increasingly restrictive as the TAC is approached or as a suite of up-front measures that would be restrictive enough so that no in-season adjustments would be needed. The former approach would be more costly to monitor, administer, and enforce since it may require several in-season adjustments. However, the latter may be more costly to vessel owners since it would require more restrictive measures for the entire season.

Participants may be required to have a VMS unit installed or may be required to enroll in an access program. The latter would require vessels to bear the acquisition and operating cost of a VMS unit. The former would be less costly in terms of cash outlays but would reduce vessel flexibility because enrollment would be for a minimum fixed period of time.

None of the alternatives for reporting would have any appreciable impact on participating vessels. If VMS is selected then reporting via the VMS system would add no additional cost to participating vessels. If an enrollment program is selected then reporting would be through an interactive voice reporting system. This would require a phone call upon completion of a trip but this would not have any appreciable affect on operating costs.

5.4.9.2.4 Administration of Certified Bycatch/Exempted Fisheries

The proposed action allows changes in the standard for certification of a bycatch fishery. A change in the standards for certification would provide greater flexibility to accommodate specific resource conditions particularly as stocks recover. The current standard does not take into account different stock status for different species that may merit a higher standard for approval while a lower standard may be acceptable for others. This change would increase potential economic opportunities and may encourage more innovative gear designs as the focus shifts from groundfish as a complex and to the specific components that may be of particular concern.

The proposed action does not adopt a scheduled review of certified/bycatch fisheries. Proposals to establish a review schedule for certified bycatch/exempted fisheries will increase administrative costs. In addition, for participants in a bycatch/exempted fishery, costs may increase in order to collect and provide information necessary for that review. While much of the information necessary to review a fishery or gear should be provided through a combination of the normal reporting and observer programs, participants may decide to supplement this information to insure the fishery is allowed to continue.

5.4.9.2.5 Special Access Programs

The management measures required to rebuild all groundfish stocks are likely to result in reductions in fishing mortality rates that may be appropriate for some stocks while being overly restrictive for others. The special access program structure will provide economic benefits to the industry and may serve to mitigate some of the expected reductions in revenue that will result from the rebuilding programs. The application process for a SAP will create a need to collect (or collate) information on the proposed program and submit an application. This process will increase costs, but if the program is approved, presumably the economic returns will be positive.

Georges Bank Yellowtail Flounder Access Program

The Georges Bank yellowtail flounder access program will provide positive economic benefits to those vessels that can access the offshore area. This will primarily be trawl vessels, though some trip gillnet vessels may also be able to take advantage of this program. Landings of GB yellowtail flounder have reached a plateau between 3,000 – 4,000 mt. Given the large effort reduction expected to result from the rebuilding alternatives, it is likely that absent additional incentives, these landings will decline in the future. At the same time, the rebuilding stock can support a harvest of 10,000 – 12,000 mt over the next ten years. Even assuming a Canadian harvest of 3,000 mt, there is a considerable gap between recent landings and the available yield. Each 1,000 mt of yellowtail flounder is worth roughly $1- 2 million (at $.50 - $1/pound). If this program encourages enough effort to the Georges Bank area that the entire GB yellowtail TAC is taken, it will increase revenues about $3 - $6 million from the no action alternative.

The program also alleviates the DAS reductions by not charging DAS for the trip out to CAII. For a vessel making the allowed two trips per month, this is the same as adding nearly one full DAS for each month. Participation will require purchase of a VMS unit. However, a VMS requirement is also included in several other alternatives including the US/Canada resource sharing agreement which would likely involve the same vessels as that which would participate in this special access program. If not, participation would still be voluntary and would not place any obligation on any other vessels.

Southern New England/Mid-Atlantic Winter Flounder Incidental Catch Program

This incidental catch program would allow vessels that participate in the fluke fishery to increase trip income by retaining up to 200 pounds of winter flounder per trip. Vessels would have to enroll in this program for a minimum of 30 days but there would be no cost to the vessel, other than the time required to apply for the program. There is likely to be an increase in revenues for vessels that catch winter flounder while fishing for fluke. In calendar year 2001, roughly 200 mt (440,000) pounds of winter flounder were reported discarded on fluke trips. Assuming that all of these discards could be converted to legal landings (that is, none of it is undersized fish), at a price of $1.00 – 1.50 per pound, this would amount to an increase in vessel revenues of $440,000 - $660,000. These increases in revenues would accrue to vessels from the southern New England/Mid-Atlantic area, helping to mitigate the impacts of other management measures.

In addition to revenue increases resulting from converting discards into landings, this measure would also remove the requirement that vessels fishing for fluke use a DAS to land small quantities of winter flounder. Vessels would then be able to use those DAS at other times of the year on dedicated groundfish trips, further mitigating the impacts of the reductions in effort from the management program.

US/CA Resource Sharing Understanding Special Access Program

If adopted, this SAP will facilitate catching eastern GB haddock and yellowtail flounder, providing additional income to those vessel that can fish in the offshore area. The SAP is likely to be used primarily by trawl vessels because generally they are larger and travel farther offshore. All gear types, however, are eligible to participate. This program will help mitigate the impacts of the other regulations and will provide additional income to those vessels that are able to take advantage.

5.4.9.2.6 Closed Area Administration

The Council did not adopt a review of the rational for closed areas, but will require that rational be carefully specified in the future. A review of the rationale for closures would have no direct economic impact on the fishery. The cost that may be associated with conducting this review should also be relatively low. Changes to access to closed areas and any changes to current exempted gears would afford qualifying vessels with an opportunity to improve fishing income. Neither retention nor elimination of the Flexible Area Action System would result in any noticeable economic costs or benefits. While the regulatory framework exists it has not been used so its removal would not have any measurable economic impact.

5.4.9.2.7 Leasing of DAS

Leasing of DAS would provide individual vessel owners an opportunity to offset the DAS reductions that were implemented in August, 2002 and any further reductions that may become necessary upon implementation of Amendment 13. Note that all but one of the management alternatives contains a hard TAC as either a backstop or a primary effort control mechanism. Should any of the TAC alternatives be selected DAS leasing may become an unattractive business decision since there would be no assurance that the lessee would be able to use that DAS since the TAC may cause a fishery shut down. The relative impact of DAS reductions will depend on the dependence on groundfish for total fishing income and other fishing opportunities or permits that may be available. For some vessels with a high dependence on groundfish and few alternatives the DAS reductions could be sufficient to place these vessels at risk of business failure.

Given the lack of experience with DAS leasing the economic impacts are difficult to predict since the number of likely participating vessels is not known. The following analysis was prepared for the proposed DAS leasing program as part of the Emergency Action to extend FY2002 measures through April, 2004. While patterned after one of the DAS leasing alternatives developed by the Council, the particulars of that leasing program differ from the alternatives described herein. However, the analysis of economic impacts was conducted to gain an understanding of how DAS leasing program might perform in more of a general sense, so that analysis should still be relevant for consideration of DAS leasing under Amendment 13.

As noted previously, DAS leasing will provide small fishing entities with greater flexibility to adapt to the Amendment 13 regulatory framework. The following provide some insights as to how DAS leasing might affect individual vessels. However, DAS leasing could have broader seafood market implications as DAS are moved from one fishing platform to another. For example, there could be changes in the mix of species available to seafood buyers and distributors. Another possibility is that there could be regional changes in seafood supplies. Although, the aggregate supply of groundfish is not expected to differ, changes in the distribution of landings could result in increases in supply in one port while supplies in other ports may decline.

Based on an analysis of vessel break-even DAS requirements (for a full description see section 5.4.5) assuming that all vessels were to make a minimum crew share payment of $25,000 per person there would be 268 vessels that would be able to cover overhead costs but would not have enough DAS to make this minimum labor payment. The remaining 278 vessels would have more enough DAS to cover all overhead and crew costs. The total number of excess DAS for these vessels was 11,935 and the total number of DAS that would be needed to bring all other vessels up to a break-even level would be 11,080. At this relatively low crew payment, DAS leasing could make it possible for vessels to redistribute DAS so that all vessels could operate at or above break-even. Note that even in this situation no payments would be available for owner profits. Assuming an average crew payment of $35,000 or $50,000 per person even with a leasing program, there would not be enough DAS available to lease (among the vessels that rely on groundfish for 50% or more of total gross revenue) to allow all vessels to break-even. To obtain more DAS this pool of vessels would need to lease DAS from vessels with lower dependence on groundfish.

The break-even analysis was based on the minimum DAS necessary to cover all annual costs on groundfish trips alone and was based on average values derived from survey data. An alternative way of examining potential supply and demand for DAS leasing is to simply compare observed DAS use to DAS allocations. For this analysis, DAS used during FY2001 were compared to DAS allocations resulting from the Settlement Agreement. A total of 1,014 vessels used DAS in FY2001. Of these vessels, 614 used more DAS in that year than they were allocated for FY2002-2003. These vessels would need to be able to lease a total of 13,412 DAS in order for them to fish as many DAS as they did in FY2001. Total DAS that might be available from the 400 vessels that used fewer DAS than they were allocated are 10,010 DAS. Thus, the potential demand for DAS would exceed the potential supply by 3,402 DAS. With a larger DAS reduction this deficit would increase.

A Simulated DAS Leasing Market

In order to estimate the possible economic effects of a DAS leasing program, mathematical programming models were used to simulate a leasing market which might emerge given constraints placed on individual vessels. The model maximized industry profits by choosing the days each vessel will fish (if any) of their own allocation, days they will lease from other vessels, and the number of their days they will lease to other vessels. Each vessel can only fish a maximum number of days at sea, which is the sum of their Category A DAS and their FY 2001 allocation. Days fished above their allocation of Category A DAS must be leased from other vessels. Vessels were also not allowed to be both a lessee and lessor, although in reality this could happen. Restrictions were placed on the model that did not allow days to be leased by larger vessels from smaller vessels, which were consistent with the restrictions passed by the Council. Results from the model yielded a very efficient outcome in terms of maximizing industry profit with as few vessels as possible. In reality, the actual leasing of quota among industry participants may not be as profitable as projected by the model. An individual vessel's activity level[5] chosen by the model is determined by its productivity, the maximum allowable days it can fish, the lease price for days at sea, daily fishing costs, and the prices of each species, and a restriction which prohibit leasing of days from

[5] When vessels lease days from vessels of lower horsepower class, each day at sea is reduced by an adjustment factor. If the adjustment factor is 0.9 for example, 1 leased day will only be able to be fished 0.9 days.

smaller vessels by bigger vessels. The model does not differentiate between areas fished, where vessels land their fish, and a variety of other factors that will influence the amount of quota leased, including other fisheries in which the vessel can participate, and it assumes perfect information among participants.. The model also assumes perfect information for all permit holders, no transaction costs, and instantaneous transfers. None of these three conditions is likely to be present in a real leasing market place. While the model does not represent an actual leasing market, it does show the optimum level of leasing activity that could occur under perfect conditions and also identifies how DAS are likely to flow between vessels.

Vessels were grouped together regardless of gear type, and then stratified into fleets of 100 vessels[6]. Each fleet was then paired with itself, and then with every other fleet to simulate trades between all 1,345 vessels that could potentially lease quota. For each sector pair, the model was run fifty times in order to incorporate a stochastic lease price, which was generated based on results from a previous linear programming model. Lease prices used in the model ranged from $218 to $2,093, with a mean of $1,029. Results from the simulations were used to examine changes in profitability that would occur from allowing days at sea leasing.

Results

Results from the simulation runs were stratified by gear type and length of vessel. Class 1 vessels were less than 50 feet; class 2 vessels were between 50 and 69 feet, and class 3 vessels were 70 feet and greater. The three gear types examined were hook (50 vessels), trawl (1,126 vessels) and gillnet (169 vessels). There were more vessels in the model than had Category A DAS in the proposed action. Because vessels can fish up to the total of their Category A DAS and their FY 2001 allocation, vessels with zero Category A DAS can still lease days at sea, and therefore need to be included in the model. Because the model is attempting to maximize industry profit, under a DAS sea leasing scheme, fewer vessels will fish (Table 378). However, mean profits for all vessels will be higher than if days at sea trading were not allowed, and all vessels fished their allocation (Table 379). Mean profits are also higher than the mean profit levels generated during calendar year 2002 by vessels actually fishing.

Vessels which choose to lease all their quota can greatly enhance their profit since the owner is getting all the revenue from the lease without incurring any costs, and in particular not having to pay labor costs. The decision from a vessel perspective on whether to lease quota *to* other vessels is based on whether they can lease their quota for more then they would earn after paying crew share and covering other expenses[7]. If a vessel decides to lease quota *from* other vessels, it is based on whether they can earn more from a leased day at sea than what they will pay for the lease plus what they will pay to the crew, and to cover other expenses.

Model results generally showed the flow of lease days going from larger vessels to smaller vessels. Trawl and Gillnet vessels less than 50 feet in length were projected to use more days at sea than in 2002 under a DAS leasing scheme (Table 380). Trawl and Gillnet Vessels greater than 50 feet saw their days at sea

---

[6] The size of the non-linear programming model limited the maximum fleet size which could be analyzed, while incorporating a stochastic lease price.

[7] The particular costs faced by each vessel depend on the particular lay system they employ. For the purposes of this model, it was assumed the vessel paid the variable operating costs such as fuel and ice, and then paid the crew. This simplified the model slightly, but may underestimate the profit that each vessel owner would earn under a days at sea leasing program if they decide to fish.

usage decline from 2002 levels. Hook vessels were also projected to see their days at sea increase. Restrictions on DAS trading make it difficult for larger vessels to lease from smaller vessels, but the opposite does not hold. Small vessels have a large potential number of vessels that they can lease from, which is what model results show. Examination of both tables 2 and 3 show that larger vessels can profit by leasing their days to smaller vessels. For example, length class 2 trawl vessels average profit was $68,387 using an average of 36.92 days of effort under a DAS leasing scheme, while their average profit was $31,428 using 46.13 days of effort in 2002. Small trawl vessels average profit was $41,111 using 31.9 days of effort under days at sea leasing, while their 2002 average profit was $12,271, and their average days at sea was 25.13. This demonstrates that both sectors would be better off with a DAS leasing program than fishing at their calendar year 2002 effort levels.

Additionally, the average profit levels were projected to be higher under days at sea leasing than if the vessels fished at their allocated 2004 levels. This demonstrates days at sea leasing provides substantial regulatory relief to vessels compared with no leasing.

5.4.9.2.8 Recreational Fishing Permit

The proposed action does not adopt a recreational fishing permit. Depending upon whether a fee to obtain a recreational fishing permit is collected, the requirement for a recreational fishing permit will impose few costs on fishermen, but could result in increased costs to administer the management plan. The requirement could be implemented through a web-based application. For example, a recreational fisherman could fill out a web-based form and immediately print out a permit, minimizing administrative costs to the government and simplifying the permitting process. There will still be a requirement to establish and maintain the web site and recreational permit database. Total costs will be directly the result of the number of persons that request a permit.

5.4.9.2.9 "Running Clock" Alternatives

The proposed action does not modify the "running clock" regulations. The "Running Clock" alternatives would have varying levels of economic impact. Option 1 would not add any new economic benefits or costs. However, in the Environmental Assessment of the Settlement Agreement Between Parties the modified "running clock" was shown to reduce potential trip income by almost 50% for trips taken in the Gulf of Maine. Option 2 would increase monitoring costs that would have to be borne by industry. The actual amount of these costs is not known, however, so it is not known whether the potential gains from a weighmaster program would offset these costs. Option 3 would provide an economic benefit as the amount of overages that would be allowed to be retained would increase.

The realized economic benefits of a "running clock" are not altogether clear at the level of DAS allocations contemplated in this Amendment. The opportunity cost of running DAS off the clock while tied to the dock may be quite high. However, for vessels and gears that target cod, the "running clock" may still be used to increase efficiency. For example, a vessel that is able to retain 2 days-worth of cod but incur only one days-worth of costs would realize higher profit than if forced to fish two days for the same amount of cod. The potential economic advantage of running the clock may actually increase in the event that an alternative with a hard TAC is selected. Depending on how a hard TAC is administered, running the clock while the trip limit is relatively high may be worth the DAS cost if the vessel anticipates that the fishery will shut down or will be subject to much more restrictive trip limits once the TAC has been reached.

5.4.9.2.10 Observer Coverage

At present, observer coverage is funded by NMFS and carrying an observer does not impose direct costs on fishing vessels. Any increase in the number of observers will increase directs costs for NMFS and also will impose additional administrative burdens. There is some inconvenience to carrying observers. There is also a requirement that vessels meet certain safety standards in order to carry an observer, which may increase costs for fishing vessels.

5.4.9.2.11 VMS Requirements

At present, vessels using VMS must send position information throughout the year, unless the vessel is hauled out. This option would allow a vessel owner to declare out of the fishery for a fixed length of time and suspend VMS operations. Because vessels pay for VMS transmission costs, this option would reduce vessel operating costs. Current messaging costs are as high as $3 per day (see section 5.4.9.2.14). Since all vessels fish for less than 200 days per year, the potential savings exceed $500 annually per vessel. Another possible benefit is that removing this requirement may encourage more vessel operators to purchase and use VMS.

5.4.9.2.12 Day Gillnet Block Out of the Fishery

The proposed action does not change these requirements and will impose no added economic benefit or cost. Removing the requirement to take time out of the fishery may improve day boat gillnet vessel's ability to make trip planning decisions. Although removing the blocks-out requirement is not likely to have a large economic benefit to day gillnet vessels it would provide some ability to improve overall business efficiency.

5.4.9.2.13 DAS Counting

The proposed action does not change the was DAS are counted. Changes to the way DAS are counted could result in substantial economic impacts. Any changes to the way DAS are counted would affect much of the analysis in this amendment. The closed area model – the foundation for the biological and economic impacts analysis – is based on existing DAS counting. Revisions to the counting of DAS would necessitate a major revision to the model and would result in completely revised impacts analysis. Given the three options for counting DAS, the different rebuilding strategies, and the number of other management alternatives proposed, it is not possible to run the closed area model for every combination of DAS counting and other alternatives.

In general, any changes to the way DAS are counted will have negative economic impacts on all vessels, but the impacts will vary in part based on a vessel's normal fishing practice. Establishing a minimum number of hours for each trip will affect vessels that make day trips the most. These vessels, which can use partial DAS, will be charged a full DAS for every trip they make. One possible response is for vessels to fish the full minimum period. For vessels that make partial day trips with minimum crews, this could cause safety concerns as fatigue increases. Vessels that make longer trips may be affected, but only on the first or last day of a trip (the only partial days fished). These vessels may be able to adjust their departure and arrival time to minimize the impacts of any change.

In addition, changing the way DAS are counted would raise the issue of whether DAS allocations should be re-calculated. The alternatives in this Amendment that reduce DAS are based on the current methods for counting those DAS. If DAS counting is changed, the DAS for each alternative should be recalculated in order to achieve the targeted mortality reduction. If that is not done, the DAS reductions proposed may result in excessive mortality reductions that will prevent attaining optimum yield.

5.4.9.2.14 Reporting Requirements

Dealer Reporting Requirements

Option 1 No Action
This option was not selected. The No Action option would not change any aspects of the current mandatory dealer reporting system. If this alternative is selected there would be no economic impacts on dealers. This does not necessarily mean that maintaining the status quo is not without cost since many aspects of the management support system including monitoring of target TACs, annual reviews by monitoring committees, stock assessments, and economic and social impact assessments rely on the a combination of dealer and vessel reporting. These transactions costs could be reduced by improving the timeliness of reporting and establishing a clear link between dealer and vessel reporting. Note that because of these two issues the No Action alternative would not be a viable alternative if a hard TAC alternative is selected.

Option 2 Trip Identifier Reporting
This option was not selected. Selection of Option 2 would change the dealer reporting requirements by adding two data elements. Adding the data elements would increase reporting burden but probably add little to dealer operating costs. Of the two data elements, the intended disposition of purchases would be less burdensome because the likely product use is probably known at the point of sale. While reporting the trip identifier would be comparatively more burdensome the responsibility for providing the trip identifier would be on the vessel so the dealer would be relieved from the cost of obtaining a unique identifier for the transaction.

The economic benefits of election of Option 2 would accrue in quality of information available to fishery managers. The trip identifier would resolve one of the primary difficulties encountered in monitoring, evaluation, and assessment of fishery performance. However, as was the case for Option 1, Option 2 would not be feasible if a hard TAC alternative is selected because paper reporting takes too long to process to permit real-time monitoring of TACs.

Option 3 Daily Electronic Dealer Reporting
This is the proposed action. Like Option 2, Option 3 would include two new data elements and would replace the paper report with daily electronic reporting. As noted above, adding the trip identifier and the disposition of the species purchased would not likely increase dealer costs. However, daily electronic reporting may require the purchase of or have access to equipment necessary to make electronic reporting possible, installation of new software, and may require subscription to an internet service provider. Most dealers are likely to at least have a computer with a modem and internet capability. Depending on the number of transactions that would need to be reported a web-based system may be cumbersome without subscription to a DSL or broadband service. A web-based system would probably not require installation of any specific software but would require compatibility with a chosen browser. A file transfer system may require installation of specific software to assure compatibility between both the sender (dealer) and receiver (NMFS).

The requirement for daily reporting would mean that dealers would have to make sure that someone is available every day to actually code and transmit all transactions. For some dealers that may manage current reporting requirements with part-time staff may need adjust work schedules or hire staff on a full-time basis.

Option 4 Daily Electronic Dealer Reporting With Exemption for Small Dealers
This option was not selected. Selection of Option 4 would not change the economic impact of daily electronic reporting for vessels that would not be exempted under this option . For years for which

complete data are available (Fishing years 1999 to 2001) approximately 60% of dealers issued a permit have reported no purchases of any of the 10 regulated large mesh species and about 22% purchased more than 5,000 pounds over an entire fishing year. Thus, Option 4 would exempt about 45% of dealers that purchase regulated groundfish.

Vessel Reporting Requirements

Option 1 No Action
This option was not selected. Taking no action would result in no added costs to vessels that are currently subject to mandatory reporting. However, as noted previously, no action would continue to be a barrier to more effective monitoring and assessment of stock status as well as the effectiveness of any given regulatory regime. This action would not be feasible if a hard TAC option is selected.

Option 2 Trip Identifier Reporting
This option is the proposed action. Selection of Option 2 would not change the timing of reporting but would add one data element to the VTR. Specifically, a trip identifier would need to be included with each trip report. The method for generating this identifier has yet to be determined but it would likely be generated through a mechanism that (a call-in confirmation or a VTR serial number) that would essentially be provided to each vessel. Vessels would still be required to report this number to each dealer. In cases where vessels sell to multiple dealers this trip identifier would have to be reported for every separate transaction. Note that this option would not be viable should a hard TAC option be selected.

Option 3 VMS Reporting for all Limited Access Multispecies DAS Vessels
This option was not selected. Selection of this option would place a VMS unit on every multispecies vessel with a DAS allocation. The cost of acquiring VMS units for the entire groundfish fleet subject to this requirement was estimated to be $4.3 million. This would be a one-time acquisition though and the longer term impact on vessel operating costs would be associated with the subscription cost of operating the VMS unit itself. Note that VMS requirements are included in several management options (area management, special access programs, and EFH) so these VMS costs would not necessarily be wholly assignable to VMS reporting. That is, if VMS is required to be on, then reporting through VMS would not add any increased operational costs but it would require that the Captain take the time to report all landings within a statistical area upon exiting or upon trip completion if fishing was conducted entirely within a single statistical area.

In addition to the VMS requirement, this Option would still require submission of a paper log that would include a trip identifier to be reported to each dealer. This option would also require that all non-DAS vessels that catch regulated groundfish (Category C limited access vessels and open access vessels) to report catches through a separate call-in system. Unlike DAS vessels these vessels would not be required to report in real-time if they fish in more than one statistical area. Instead, landings by statistical area would be reported upon completion of a fishing trip. Vessels exempted from VMS requirement would not be required to purchase any specific equipment or subscribe to any particular service and so would not bear any increase in business cost beyond that which would be associated with the time required to complete the phone call.

Option 4 VMS Reporting for Limited Access Multispecies Vessels Greater Than 45 Feet
This option was not selected. Selecting this option would differ from Option 3 only the respect that it would exempt more vessels from the VMS requirement. Exempted vessels would be required to report

through a call-in system described above. Based on permit application data for fishing year 2002, about 55% of all permitted vessels with multispecies DAS would be exempted from the VMS requirement under Option 4. This means that the fleet-wide acquisition cost would be reduced from $4.5 million to $2.0 million and annual operating costs would be reduced from $73 thousand to $33 thousand. Note that these exempted vessels would still be required to report landings upon trip completion via the proposed phone system.

Option 5 Declaration into One Fishing Area
This option was not selected. Option 5 would provide a different way of providing vessels with flexibility to select a reporting procedure other than uniform adoption of VMS. Option 4 provides flexibility but only based on a vessel's overall length. This option provides flexibility based largely on an individual's fishing practice and not a single physical characteristic. Specifically, vessels that choose not to purchase a VMS system would be able to obtain a Letter of Authorization that would require that the vessel fish exclusively in a single statistical area for a minimum of 30 days. Vessels that chose to obtain an LOA would also be exempted from having to report landings through the proposed phone system since all landings would still be reported via daily dealer reports. Statistical area information would not need to be reported since all landings would be automatically assigned to the single area listed in the LOA.

Option 5 may offer only limited flexibility since any participating vessel would lose the flexibility to fish in multiple statistical areas on a trip-by-trip basis. Thus, vessels would be faced with a trade-off between reduced VMS costs but less choice in terms of area fished. Some components of the groundfish fleet do fish exclusively within a single statistical area for the entire groundfish landings while others may fish in several different statistical areas but may do so on a seasonal basis. Vessels that fish in this manner may elect to obtain an LOA based on this seasonal pattern.

Option 6 Call-In System Modification
This option was not selected. Selection of Option 6 would not require VMS but would change the information reported when a vessel calls to terminate a DAS trip. This option would not increase the number of times vessels would be required to call-in but would increase the amount of time required to complete the call. Vessels that are not currently subject to DAS controls (hence no call-in requirement) would be required to participate in the call-in system.

Option 7 Various Electronic Reporting for All Vessels
This option was not selected, but the proposed action is very similar. Once operational, an electronic reporting system for vessels would be made available to vessels. Vessels that adopt this technology would be relived from the responsibility of submitting a paper logbook but may be required to purchase any hardware and software that may be needed. Since this would be voluntary, any vessel that does so may be presumed to gain some advantage from its participation.

VMS Considerations

To cover the entire fishing fleet of 1484 vessels, at $2900 per unit including the PC, would cost $4.3 million initially, or less than 1% of the ex-vessel value of New England fisheries ($681 million in 2000). Although fishing effort is reduced to half the 73,063 DAS allocated, it is expected that the vessels will place those days-at sea (one-for-one) in other fisheries, in order to stay in business. With 73,063 days-at-sea (with the VMS shut off while the vessel is tied to the dock) adds $73 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $70 thousand annually. Safety may be enhanced by including distress buttons on each unit, and costs $1.6 million for the 1484 boats and vessels, but this is not a requirement for groundfish management.

However, the benefits of total fleet coverage, especially to a multispecies fishery like that managed by the groundfish FMP, are much greater than tallying the official DAS and protecting the large, fixed closed areas. If all vessels require VMS, even partial closed areas become somewhat more inviolate because the enforcement agencies can identify every boat that enters them at any time. Likewise, corroboration of other reporting will be comprehensive rather than piecemeal, as it is with less than full VMS coverage. Safety at sea coverage will be comprehensive, and the extra $1100 per unit for this purpose adds only $1.6 million, to protect nearly 1500 U.S. vessels at sea. Any requirements for sampling at sea will be greatly enhanced with full VMS coverage, because the density of fishing vessel activity in the various fish stock areas will be known. Observer and Homeland Security programs will be enhanced, in similar fashion. Finally, trip limits, gear restrictions, fish sizes and other management measures may be affected.

Optionally, to cover that portion of the fishing fleet that has over 10 DAS allocated will eliminate VMS costs on vessels minimally involved in the multi-species fishery. These 1083 vessels, at $2900 per unit including the PC, would cost $3.1 million initially. Their 72,473 days-at-sea (with the VMS shut off while the vessel is tied to the dock) add $72 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $69 thousand annually. Additionally, safety would be enhanced by including distress buttons on each unit, and costs $1.1 million for the 1083 boats and vessels.

Finally, to cover that portion of the fishing fleet that has over 20 DAS allocated will eliminate VMS costs on even more vessels involved in the multi-species fishery. These 988 vessels, at $2900 per unit including the PC, would cost $2.8 million initially. Their 71,074 days-at-sea (with the VMS shut off while the vessel is tied to the dock) add $71 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $68 thousand annually. Additionally, safety could be enhanced with distress buttons on each unit, and costs $1.1 million for the 988 boats and vessels.

The benefits of such programs are reduced, somewhat, from those attainable with total VMS coverage, particularly the enforcement effectiveness on secondary measures like partial closures and trip limits. The costs are reduced fleet-wide, but are the same for each vessel in the program. The downside for vessels in the program is that, although they pay the same cost, the effectiveness and thus the benefits of management are reduced proportionate to the percent of the fleet with mandatory VMS. The incentive, however, is that mandatory-VMS vessels may participate in exempted fisheries in the closed areas.

Device	Boatracs	Thrane & Thrane 3022D	Thrane & Thrane 3026M	Comments:
Cost	$6,000	$2,650	$*1,550*	Inmarsat has *no* service connection fee
Communication (flat fee; add'l amount above some limit)	$3/day two-way	$1/day two-way (requires PC)	$1/day two-way (requires PC)	e.g. Thrane & Thrane sells a terminal for $1,350
Distress buttons	Yes	Yes	No	
Delay	5-10 minutes	5-10 minutes	5-10 minutes	No transmit, no cost with Inmarsat
Maintenance	Replacement parts available	2 year warranty	2 year warranty	

Table 307 - Comparison of VMS Vendors

Note: Trimble is dropped from consideration; they no longer provide Inmarsat based units. Likewise, Argos is dropped because it is only approved for use in Alaska.

Option: (boats)	Initial Cost ($1550 plus $1350 PC per boat)	Communication Cost ($1 per DAS)	Pinging Cost* (24/DAS)	Safety ($1,100 per boat)

Option 2 & 3	None	n.a.	n.a.	n.a.

Table 308 - Cost of VMS Across Rebuilding Alternatives

Note: currently, NE OLE pays all costs associated with the advisory email messaging and extra positioning costs when a vessel enters a closed area; monthly charges average $1,500.

** Boatracs cost 7 cents per ping, or $1.68 per DAS for 24 pings; Inmarsat, 4 cents, or $0.96. Pinging costs are shown using Inmarsat.*

5.4.9.2.15 Hand Gear-Only Permit Alternatives

Preliminary Assessment of Qualification

A preliminary assessment of numbers of potential qualifiers by hand-gear only permit category was conducted using VTR data for fishing years 1997-2000. The VTR data were used instead of dealer data because dealer records from both Connecticut and Delaware do not identify unique vessels. Fishing year 2001 was not included in the analysis because VTR records are not yet complete. The total number of open access hand-gear only permits has increased by about 150 permits in each year from 1998-2000 (Table 309). Of these permits, 10 to 11 percent reported landings of either cod, haddock, or pollock

(CHP) in any given fishing year. Of the vessels that did report landing of CHP at least 65% did not report landings in excess of 500 pounds for the entire fishing year.

	1997	1998	1999	2000
Number of Open Access hand Gear Permits	1,392	1,330	1,471	1,637
Number of Permit Holders Reporting Cod/Haddock/Pollock	151	151	151	184
Number of Permit Holders Landing >= 500, < 1000 lbs C/H/P (Category A)	47	48	42	65
Combined Landings Category A	105,210	172,159	123,974	165,465
Combined Landings Category B	15,685	37,042	12,227	16,786

Table 309 - Open Access Hand-Gear Permit Category Activity (Fishing Years 1997-2000 VTR)
Note: landings in pounds

The total number of vessels that landed 1,000 pounds or more of CHP was 79 while 61 vessels landed at least 500 but less than 1,000 pounds in any one of the four fishing years used for analysis (Table 309). The former would qualify for a Category A permit while the latter would qualify for a Category B permit. Based on permit data for fishing year 2001, 23 of these Category A qualifiers and 19 Category B qualifiers did not hold an open access hand-gear only permit in fishing year 2001. The majority of potential Category A (44) or B (25) permit holders reported a Massachusetts port as their permit application for FY2001.

	Category A	Category B	Total Vessels
Connecticut	2	35	37
Delaware	0	6	6
Massachusetts	69	781	850
Maryland	0	9	9
Maine	1	307	308
North Carolina	0	18	18
Other	0	12	12
New Hampshire	10	96	106
New Jersey	0	130	130
New York	9	168	177
Rhode Island	7	110	117
Virginia	0	42	42
No FY 2001 Permit	42	0	42
Total	140	1,714	1,854

Table 310 - Number of FY2001 Permit Holder Qualifiers by State (Principal State)
Note: landings in pounds

Alternative 1 would not change any economic benefits or costs relative to current regulations. However, in the Environmental Assessment of the Settlement Agreement Between Parties vessels holding these permits were estimated to lose an average of 2% of total fishing revenues and 5.8% of groundfish revenue. Alternative 2 would not change the trip limits but would remove the prohibition of issuing permits to vessels that had never held any such permit. Alternative 2 would have no additional economic impact on vessels that may participate in the fishery but would provide, albeit limited, an opportunity for new participants.

The proposed action, Alternative 3 would convert the hand-gear only permit category into a two-level limited access hand-gear only permit and an open access category. Regardless of permit qualification, economic opportunities for both haddock and yellowtail flounder but would improve compared to Alternatives 1 and 2. Vessels that qualify for the highest limited access category (Category A) would see improved economic opportunities as the cod trip limit would be higher than under Alternatives 1 or 2. However, VTR reports for roughly half of these vessels suggest that even the lower trip limit would have minimal economic impact as they had few, if any, occasions where the cod trip limit would have been exceeded. Even so, some of these Category A vessels may still be able to increase overall fishing income if they can increase catches of haddock or other groundfish species.

The proposed action retains the open access hand-gear only permit but would set the cod trip limit at 75 pounds rather than 200 pounds under Alternative 1 or Alternative 2. In terms of potential impact this would appear to provide for reduced economic opportunities relative to Alternative 1 or 2. However, only about 10% of vessels holding an open access hand-gear only have actually reported landing groundfish in any given year. Vessels that had relied on groundfish to any substantial degree would be more than likely to qualify for one of the limited access permit categories. Therefore, the lower trip limit assigned to the Category B may have relatively little realized economic impact on current permit holders. In the longer term, however, new participants would find their income potential constrained by the Category B cod trip limit as compared to Alternative 2. Note that compared to Alternative 1 where they would not be able to obtain a permit, new participants would still be better off under Alternative 3.

5.4.9.3 Sector Allocation

By creating a process for the formation of self-selecting sectors, this Amendment creates an opportunity for groups of vessels to adapt their fishing behavior so that they remain economically viable in the face of increasing restrictions imposed to rebuild groundfish stocks. The ability to form a sector could be an important component of providing flexibility to small commercial fishing entities to mitigate the economic impacts of the Amendment. Further, depending on the geographic location of the membership of a given sector, sector allocation could also provide an opportunity for fishing communities to reduce economic impacts.

5.4.9.3.1 GB Hook/Gillnet Sector

The creation of a voluntary sector for longline/hook and gillnet vessels on Georges Bank provides an opportunity for vessels to mitigate the impacts of the management alternatives. By organizing into a cooperative, vessels may be able to develop more efficient ways to harvest groundfish and minimize the inefficiencies that result from the regulations.

While it is not possible to estimate the economic impacts of a sector until the actual participants are known, the pool of participants will probably be the vessels that have used longline or gillnet gear to fish on GB in the past. For fishing years 1996 through 2000, 182 vessels reported using longline gear to catch GB cod, and 294 vessels reported using gillnet gear. Some vessels used both gear – these two numbers represent 488 individual vessels. For fishing year 2001, there were 85 gillnet vessels in the GB cod fishery and 32 vessels that used hook gear. Gillnet vessels landed 14 percent of the GB cod in fishing year 2001, and hook vessels landed 10 percent of the GB cod (see Appendix VI). Gillnet vessels harvested 19 percent of the GB cod landed in fishing year 2000, while hook vessels harvested 9 percent (see MSMC 2001). About 86 percent of the GB cod landed from 1996 though 2000 by these two gears was landed in Chathem/Harwichport, MA, suggesting that this community is the one most likely to benefit if vessels choose to participate in this sector. Another 10 percent of GB cod was landed in Gloucester, MA by these two gear types.

This alternative also includes access to CAI to harvest haddock. From 1996 through 2000, 44 hook vessels and 71 gillnet vessels reported landing GB haddock, roughly one-fourth of the total number that reported landing GB cod. Allowing access to CAI for vessels that choose to participate in the sector may increase the ability of these vessels to target GB haddock, further mitigating the impacts of the rebuilding programs.

Depending upon the selected management alternative a sector allocation for this particular sector could be the difference between financial viability and business failure. Alternative 2 would reduce the Georges Bank cod trip limit from 2,000 to 500 pounds per day. The economic analysis of this alternative indicates that this change would have a disproportional impact on hook and gillnet vessels that depend on Georges Bank cod in general and on vessels with a home port of Chatham/Harwich in particular. Thus, relative to other gear sectors in other ports, the proposed Georges Bank Hook/Gillnet Sector Allocation may be an important component in regulatory design to offer small entity flexibility in the Chatham/Harwich fishing community.

VMS Considerations

VMS is required for both the 33 vessels in the longline sector and the 62 vessels in the gillnet sector. These 95 vessels, at $2900 per unit including the PC, would cost $275 thousand initially for VMS units. Their days-at-sea are unknown, thus communications and double-pinging costs are unknown as well. Safety could be enhanced with distress buttons on each unit, with an additional $104 thousand.

5.4.9.4 Economic Impacts of Measures to Control Capacity

Each of the capacity alternatives is designed to provide greater economic opportunity and flexibility in all fisheries while maintaining the character of the existing fleet and to achieve some long-term reduction in the number of vessels permitted to fish in Northeast fisheries. Many of these alternatives require that with the transfer of its permits the selling vessel must retire from fishing in state or federal open and limited access fisheries. While this expands economic opportunities for some vessels, it eliminates participation of others in the groundfish and other fisheries. This may reduce participation in the capacity reduction programs. Measures which define effective effort may have widely varied impacts on permit holders depending on their history in the groundfish fishery, benefiting some and severely limiting others.

5.4.9.4.1 Alternative 1 - DAS Absorption

This option was not selected.

Probable participants

The only permits that cannot be transferred or acquired under current regulations are limited access multispecies permits for scallop vessels or scallop limited access permits for multispecies limited access vessels. Under existing regulations, all other permits can be acquired and combined on vessels within the replacement and upgrading restrictions of the fisheries in question. As a result, only limited access multispecies and scallop permit holders would be affected by this alternative.

The permit holders most likely to give up or transfer their groundfish or scallop permits under this alternative are those who are likely to get a net economic benefit from doing so. This group probably would consist largely of either (1) permit holders who are not actively using a multispecies or scallop permit and therefore not realizing a current economic return on the permits or (2) permit holders/vessel operators who wish to retire from either fishery. Under this alternative, transactions between vessels that hold limited access scallop permits and vessels that hold limited access multispecies permits are assumed to be most likely.

There are the following practical constraints suggested by industry members that would limit participation under this alternative.

- Given the relative value of the fisheries, scallop vessels are more likely to buy groundfish permits than vice versa.
- It is expensive and difficult (sometimes not practical) for groundfish boats to re-rig to be able to tow large dredges.
- Allow vessels to diversify into other fisheries.

Impacts

To determine how this alternative may be utilized, a series of hypothetical permit exchanges between limited access scallop and limited access multispecies vessels was examined. Only vessels greater than 50 GRT were included in the analyses since the majority of limited-access scallop vessels are this size or greater. Separate data sets describing fishing activity of multispecies and scallop vessels were sorted by vessel length. Multispecies and scallop vessels were matched according to compatible vessel length.

Each data set contained information on all limited access permits assigned to vessels for permit year 2000. Active days were assumed to be based on time reported through either the call-in or VTR records. To retain consistency between this proposal and all others, the quantity of active days was estimated as the maximum days used (not to exceed current DAS allocations) from the call-in or days absent computed from the VTR on trips where regulated multispecies were landed from fishing years 1994 to 1999. A random sample of 100 vessels was taken from each data set. After sorting by vessel size, these data were merged. This process was repeated 25 times to develop a range estimate of the potential effects of the permit absorption proposal.

In a set of hypothetical exchanges between 100 scallop and 100 multispecies vessels, 212 limited access permits would be absorbed at the median. Given the three options for a transfer tax, the median multispecies DAS allocations would be reduced from 9,003 to

a) 8336 in Option 1a (0/20% tax)
b) 7769 in Option 1b (10/20% tax)
c) 6536 in Option 2 (20/40% tax)
d) 3668 in Option 3 (50/75% tax)

Given the three options for a transfer tax, the median scallop DAS allocations would be reduced from 10,476 to

a) 10,218 in Option 1a (0/20% tax)
b) 9299 in Option 1b (10/20% tax)
c) 8123 in Option 2 (20/40% tax)
d) 4916 in Option 3 (50/75% tax)

In addition to allowing all vessels to hold a groundfish and a scallop permit, the permit absorption proposal would result in nearly all vessels holding limited access dogfish, fluke, lobster, and monkfish permits. Most vessels would also possess a limited access black sea bass, scup, and loligo squid permit.

5.4.9.4.2 Alternative 2 – Permit Transfer

This option was not selected.

Probable participants

This proposal would allow a multispecies vessel to transfer its limited access permits to more than one vessel. As a result, this proposal could interest the owners of many of the following vessels and permits:

- Inactive permits (either permits for which there are no existing vessels or permits for vessels not landing groundfish)
- Active scallop permit holders wishing to acquire a groundfish permit
- Active groundfish vessels wishing to acquire a scallop permit
- Other fishing vessels wishing to acquire a groundfish permit

The permit holders most likely to give up or transfer their groundfish or scallop permits under this proposal are those who are likely to realize an economic benefit from doing so. This group probably would consist largely of inactive permit holders because they are not realizing a current economic return on their permits or permit holders/vessel operators who wish to retire from a particular fishery.

Impacts

- Multispecies permits with associated DAS allocations that have not been fully used by their current permit holders could be transferred to other vessels. This affords vessels more flexibility in the use and transfer of their DAS allocations.

- Because this proposal does not allow DAS to be combined ("stacked"), the multispecies DAS would have to be acquired by vessels not already holding limited access multispecies permits. This would remove DAS from the multispecies fishery.
- Based on data in the *Analysis of Latent Fishing Effort in the Northeast Multispecies Fishery*, about 23,000 DAS were allocated to history permits (permits for which there are no existing vessels) or Category 1 permits (no fishing activity 1994-1998). Although this is an overestimate of the DAS allocations for history and Category 1 permits, it was used to approximate the total DAS that possibly could be transferred from these permits for the purpose of analysis. If all DAS are transferred, there will be a reduction of 4,600 unused (latent) DAS and a potential increase of 3,680 DAS per year (under a 20%/yr reactivation rate) up to a maximum of 18,400 after 5 years. If the 10%/yr activation rate option were used, there would be the same reduction of 4,600 unused DAS and potential increase of 1,840 DAS per year up to the 18,400 DAS maximum.

Permit transfer would allow vessel owners to sell individual limited access permits to other vessel owners. However, unlike the permit absorption proposal, the transferring vessel would not be able to obtain any fishing permits (state or federal) in the future. Individuals that may want to retire from fishing or individuals that own a vessel that has not been used in any fishing activity over the past several years may be most likely to take advantage of the permit transfer proposal.

Although the actual number of owners that may be willing to permanently remove their vessel from all state and Federal fisheries is not known, it may be assumed that vessels that have not been actively fishing over some period of time may be most likely to participate. For purposes of analysis, two scenarios were constructed. In the first scenario vessels that did not record any fishing activity either through dealer or VTR records in any year from 1994 to 1999 were assumed most likely to participate in a permit transfer program. The second scenario was constructed under the assumption that all limited access multispecies permit holders were equally likely to participate.

The analysis was conducted in a manner similar to that of the permit absorption alternative. Specifically, 100 vessels were randomly selected for each scenario. The limited access permits and DAS that would become available would then depend upon the mix of permits and DAS allocations of the selected vessels. Active DAS were estimated in the same manner as described for the Permit Absorption alternative (#1). A total of 25 replicates were performed to construct minimum, median, and maximum estimates of available permits and DAS that would become available for transfer.

Scenario 1
Under the assumption that less active vessels are the most probable participants in the permit transfer program, an additional 331 limited access permits are likely to participate. Given the three options for a transfer tax, the median DAS available for transfer would be reduced from 8,372 allocated DAS to:

a) 6994 in Option 1a (0/20% tax)
b) 6990 in Option 1b (10/20% tax)
c) 5248 in Option 2 (20/40% tax)
d) 2194 in Option 3 (50/75% tax)

Scenario 2
Under the more general assumption that all vessels are equally likely to participate, in addition to the 100 multispecies permits that would become available there would be 425 other limited access permits. Given

the three options for a transfer tax, the median DAS available for transfer would be reduced from 8,990 allocated DAS to:

a) 8293 in Option 1a (0/20% tax)
b) 7743 in Option 1b (10/20% tax)
c) 6945 in Option 2 (20/40% tax)
d) 3624 in Option 3 (50/75% tax)

5.4.9.4.3 Alternative 3 – DAS Transfer

This option is part of the proposed action.

Potential Participants

In this option, only limited access multispecies permit holders could acquire multispecies DAS from another multispecies permit holder. For the reasons stated earlier in the report, the most likely sellers are inactive or retiring multispecies permit holders and the most likely buyers are active multispecies permit holders who could use more DAS.

Impacts
Based on data in the *Analysis of Latent Fishing Effort in the Northeast Multispecies Fishery*, about 23,000 DAS were allocated to history permits or Category 1 permit holders. This amount overstates the number of DAS for these categories for the period 1994-1999 because it reflects DAS for vessels in these categories in any single year. However, it allows an estimate of the total potential DAS that could be transferred from these permits. If all DAS were transferred, there would be a reduction of about 20,700 unused (latent) DAS and a potential increase of 460 DAS per year (under a 20% reactivation rate) up to a maximum of 2,300 DAS after 5 years.

DAS transfer would allow vessels to sell DAS at differing rates depending upon activity from 1994 to 1999. The DAS transfer proposal was analyzed by constructing a data set containing permit information, current DAS allocations, vessel category, and active DAS for every limited access vessel except permit category C since these vessels are exempted from DAS controls. All permit information was based on permit year 2000. Similarly, DAS allocations were also based on the 2000 permit year. Vessel categories were equivalent to those described in the DAS transfer proposal. Data used in previous analysis of latency in Northeast multispecies for the Capacity Committee were used to designate vessel categories. Active DAS were estimated by summing DAS call-in and VTR data by year (1994 to 1999) and selecting the maximum DAS. Due to larger DAS allocation, active DAS exceeded current allocations prior to fishing year 1997 for some vessels. In these cases, active DAS were set equal to current allocations.

As was the case for permit absorption, it is difficult to predict the number of vessels and the circumstances under which vessels would be willing to buy or sell DAS. Given this uncertainty, two scenarios were constructed. In the first, a set of hypothetical exchanges between selling and buying vessels were selected at random from all limited access permit holders. For this scenario, randomly selecting 100 sellers and matching these sellers with 100 randomly selected buyers modeled a total of 100 simulated exchanges. Buyers and sellers were sorted by vessel length to assure that all simulated exchanges took place among vessels that would be within (or approximately so) the upgrade restrictions. In the second scenario, it was assumed that vessels that would be most likely to sell DAS would be individuals that may want to retire from fishing or may not intend to continue groundfish fishing. Conversely, individuals that may be most interested in purchasing additional DAS might be owners for whom current DAS allocations are constraining. To account for these two conditions, a potential seller was defined as any vessel that used 25% or fewer of current DAS allocations and a potential buyer was defined as any vessel that used 50% or greater of current DAS allocations. DAS transfers were modeled as in Option 1 (i.e. by matching 100 randomly selected buyers and sellers sorted by vessel length).

A total of 25 replicates were conducted for each scenario. Also, in each case, sellers were required to sell all of their DAS. Thus, the difference between sellers' allocated DAS and transferred DAS represents a reduction in total allocated DAS. In each scenario, selling vessels were assumed to be required to surrender all Federal permits while purchasing vessels were assumed to be allowed to activate acquired DAS at the proposed rate of 20% each year. An activation schedule of 10% per year is also provided in the analysis.

The median number of transferred DAS was 3,845 and 1,168 DAS transferred for scenarios 1 and 2 respectively. Under Scenario 1 the median number of eliminated DAS due to the conservation tax applied to active and inactive DAS was 6,186 DAS. The median reduction DAS was higher at 7,613 DAS for Scenario 2 because the sample of potential sellers was restricted to vessels that had higher incidence of inactive DAS. This is evidenced by the median inactive DAS of 8,201 DAS as compared to 3,148 inactive DAS for Scenario 1. Assuming vessels were allowed to activate DAS in a graduated schedule of 25% each year, the median number of available days in year 1 would be 644 DAS for Scenario 1 and 217 DAS under Scenario 2. If each selling vessel were also required to surrender all Federal permits then either scenario would result in a reduction of 100 groundfish permits. Note that under Scenario 2 every individual allocation vessel (Category A) used more than 50% of available DAS and were not included in the sellers pool. The less active pool of sellers under Scenario 2 also held fewer limited access permits to fisheries other than groundfish.

	Scenario 1: All Permits			Scenario 2: Buyers Use < 25%, Sellers DAS Use > 50%

Table 321 - Summary of 25 Replicates of Simulated Transactions Under DAS Transfer Proposal

5.4.9.4.4 Alternative 4 – Freeze on Unused DAS

This option was not selected.

The permit freeze in this alternative would improve predictability associated with activation of latent effort. Also, the 5% annual reduction provision might stimulate interest to sell latent permits to buyers under the permit absorption or permit transfer proposals. However, this is not a long-term solution and only defers the problem to a later date. In addition, this action would constitute a long-term commitment to participants and would reduce the Council's flexibility to deal with uncertainties in the future.

The freeze on unused DAS would apply to vessels that fall into latency categories 1 and 2 (as per the DAS transfer proposal definition). Based on these definitions there were a total of 356 vessels that recorded no groundfish landings in any year from 1994 to 1999 inclusive. With very few exceptions, every one of these vessels had a fleet allocation permit during multispecies fishing year 1999. Therefore, simulating the effect for 100 fleet allocation vessels and varying the assumed participation level can approximate the effect of a freeze on DAS.

Assuming that the freeze duration would be five years, DAS allocations after the freeze would be the same for participating vessels as they were prior to it (i.e. 8,800 DAS for 100 fleet allocation vessels). The DAS reductions increase as the assumed participation level in the freeze declines. Specifically, if only 10% of the inactive vessels enroll in the freeze, aggregate DAS allocations would be 23% lower after five years.

Table 322 - Summary of DAS Allocations Under the Permit Freeze Proposal

5.4.9.4.5 Alternative 5 – DAS Reserve

This option is part of the proposed action. Because vessels enter and exit the fishery, and because of changes in the fishery that resulted from resource conditions and management actions, there are a number of options for defining "effective" effort. This "effective" effort is shown in Table 323.

A brief description of these alternatives, and the impact of choosing each, is described below. In all cases, "landing" refers to the commercial landing of fish for sale, and not to landings by recreational or charter/party fishing vessels. Regardless of the option selected, an appeals process will be necessary to resolve discrepancies between vessel and NMFS records or to consider unusual circumstances. Examples of issues that might be considered in determining effective DAS for individual vessels could include participation in experimental fisheries or scientific research programs. The distributive effects of this proposal are illustrated by permit category, length class and homeport state. Options for further consideration are listed.

Each table includes the distributive impacts of the NMFS latent permit buyback program of 2002. In other words, the historical DAS usage by the permits that participated in the buyout has been subtracted from the overall distributive impacts table. This allows the reader to better understand the long-term impacts of choosing one option over another.

Table 323 includes distributive impact data by permit category, length class and homeport state for the recommended options for defining effective effort. In 2002, NMFS completed a latent effort permit buyback program for the multispecies fishery. The vessels that participated in the buyout program were removed from the fishery in Spring 2002. Since these vessels will not participate in the fishery any longer, the fishery impacts from the options for defining effective effort have been calculated without the inclusion of these vessels. It is important to get a clear picture of what the fishery would look like with the normal level of participation. Since the definition of normal participation has changed due to the buyout, the resulting distributive impacts have been modified to account for these removals. Please refer to the NMFS Northeast Regional Office in Gloucester, MA for detailed information regarding the buyout program of 2002.

The different alternatives for defining effective effort not only result in different total allocations of DAS but also results in different allocations by vessel and would have implications for how vessels may be affected by a DAS reduction. Specifically, for a given target level of Category A DAS the most liberal definition of effective DAS would have disproportional impacts on the most active vessels since these vessels would wind up taking a larger proportional cut in used DAS. In effect, DAS would be transferred from more active vessels to accommodate DAS allocations to less active vessels.

There has been extensive debate over the merits of the DAS allocations resulting from the FW 33 court order, as opposed to adding an additional year to the qualification period and including a "filter" to award DAS only to vessels that actively fish(ed) for regulated groundfish. Option 8 would leave DAS allocations for FY2002 in place and Option 9 would add an additional year to the call-in qualification period but would add the provision that only DAS use in years where landings of regulated groundfish exceeded 5,000 pounds. Effectively, this means that if regulated groundfish landings were less than this threshold, DAS use would be set equal to zero regardless of how many DAS a given vessel may have called-in. A formal analysis of how Option 9 would affect current permit holders is not possible at this time because of the need to simultaneously account for DAS and landings history. The former has been established for the purpose of allocating DAS under the Settlement Agreement while the latter has not been merged with landings data to provide a complete record of DAS and landings for each permit holder.

To provide a preliminary assessment of how Option 9 might affect DAS allocations compared to Option 8 an analysis that simply tracked DAS and landings performance over time was developed. Although individual allocations would differ, using this approach does yield estimates of aggregate DAS allocations that are reasonably close to what would eventually be implemented if Option 9 were to be implemented.

To assure comparability, both Option 8 and Option 9 were evaluated using the same methods. This means that the estimated DAS allocations for Option 8 will not be precisely the same as what was actually implemented for FY2002. Landings history was tracked using dealer data for fishing years 1996 to 2001. In addition, the Option 8 baseline is compared to the Option 9 baseline, even though Option 8 imposes an additional 20 percent reduction on DAS – in essence, incorporating a reduction to help achieve mortality goals into the baseline calculation.

Total DAS allocations under Option 8 were estimated to be 72,856 and were 68,718 DAS under Option 9 (See Table 326 through Table 328for summary information by permit category, length class, and home port state), Of a total of 1,442 permitted vessels 599 would receive the same allocation under either Option 8 or 9. A total of 272 vessels would receive higher allocations under Option 9 than Option 8 while 177 vessels would receive a lower allocation. A total of 394 vessels that received an allocation of 10 DAS under Option 8 would receive no allocation at all under Option 9.

5.4.9.4.6 Alternative 6 – Mandatory Latent Effort Categorization

This option was not selected. The Groundfish Plan Development Team originally designed Alternative #1 so that the DAS available for use in Amendment 13 would be commensurate with current resource status, possibly, in lieu of other management tools for groundfish (e.g. trip limits, etc). The original intent of the PDT was to define effective effort as the number of DAS used in the most recent fishing year. In fishing year 1999, this would have resulted in 53,500 DAS. However, since that time, the Capacity Committee have chosen a suite of options for defining effective effort for #4, 7, 8a and 8b which allow for a range of category A DAS between 67,000 and 75,000. This range automatically indicates an increase in fishing mortality if all Category A DAS were fished upon implementation of Amendment 13. It also indicates that more Category A DAS allowed at the start of Amendment 13 will lead to greater reductions for the fleet as a whole to meet target mortality reductions.

If the Council, in the development of Amendment 13, decides not to take a DAS cut and does not define Category B days, then it is assumed that Category C DAS cannot be reactivated until other measures used to achieve the goals of Amendment 13 are removed (e.g. closures and trip limits). If this is the case, then the Council should be concerned a potential increase in effort in the groundfish fishery if the number of Category A DAS exceed current fishing levels. Allowing permit transfers may cause fishing effort to increase.

No additional analyses.

5.4.9.5.2 No Action

No additional analyses.

5.4.9.5.3 Alternative 1

No additional analyses.

5.4.9.5.4 Alternative 2

VMS Considerations

VMS is required for the 76 vessels that fish in both the Gulf of Maine and Georges Bank areas, and the 116 vessels expected to participate an exempted fishery for yellowtail in closed area II on Georges Bank. These 192 vessels, at $2900 per unit including the PC, would cost $556 thousand initially. Their days-at-sea are unknown, thus communications and double-pinging costs are unknown as well. Additionally, safety could be enhanced with distress buttons on each unit, and costs $211 thousand for these 192 boats.

5.4.9.5.5 Alternative 3 – Area Management

Area Fished Restrictions

This alternative includes several options that limit the ability of fishermen to move between proposed management areas. This could inhibit their ability to target specific species and may result in a loss of revenue. Option 5, the most restrictive of these options, proposes to limit vessels to one management area over the course of the year. To illustrate how many vessels might be affected by this restriction, VTR records were examined to determine the number of management areas vessels fished during a given year for the 1996 through 2000 fishing years. Only reports with valid positions were used. Results are shown in

Table 329. Analysis was limited to vessels that reported landing one of the ten large mesh groundfish species using trawl, longline, or gillnet gear.

For all area management options except Option 5, about two-thirds of the permitted vessels fished in only one management area during the entire time period. Option 5 areas, however, show that roughly one-third (37 percent) of the vessels fished in one area, and about three-fourths (73 percent fished in only two areas during the entire time period. The patterns of activity are fairly constant when individual fishing years are examined. Generally, about 80 percent of the vessels fish in one area defined in five of the six management areas during any of the fishing years between 1997 and 2000. The percentage is roughly two-thirds in 1996, lower than the following years. In all years, about three-fourths of the vessels fished in two of the management areas defined in Option 5, and about 10 to 15 percent of vessels fished in only one of these areas between 1997 and 2000.

In summary, if area management options 1, 2, 3, 4, or 6 are adopted, and vessels are restricted to one management area during a given fishing year, roughly three-fourths of the vessels will not have to alter the way they fished during fishing years 1996 through 2000. Differences between these options are very minor, but Option 2 appears to have the least impacts on the observed patterns of fishing activity if vessels are restricted to one management area during a fishing year. If Option 5 were adopted, however, far more vessels would be impacted by a restriction to one area. These expected results could be influenced by changing distributions of fish as stocks recover, or if new management measures move vessels into different areas.

Table 329 – Number of proposed area management areas fished by vessels, fishing years 1996 through 2000.

VMS Considerations

VMS is required for all vessels moving between areas within a single trip. This includes options 1 through 4 and 6, but not option 5 (one management area per fishing year), for vessel movement between areas. Five of the area configurations (options 1-4 and 6) result in about 20% of the vessels expected to move between areas on a fishing trip. These 152 vessels, at $2900 per unit including the PC, would cost $440 thousand to purchase VMS. Their days-at-sea are unknown, thus communications and double-pinging costs are unknown as well. Additionally, safety could be enhanced with distress buttons on each unit, and costs $167 thousand for these 152 boats.

The other area configuration (option 5) results in at least 80% of the vessels expected to move between areas on a fishing trip. These 762 vessels, at $2900 per unit including the PC, would cost $2.2 million to purchase VMS. Their days-at-sea are unknown, thus communications and double-pinging costs are unknown as well. Additionally, safety could be enhanced with distress buttons on each unit, and costs $838 thousand for these 762 boats.

5.4.9.5.6 Alternative 4 – Hard TAC

VMS Considerations

This alternative has three options for reporting, two of which (options 2 and 3) do not require VMS.

To cover the entire fishing fleet (option 1) of 1484 vessels, at $2900 per unit including the PC, would cost $4.3 million initially. Although fishing effort is reduced to half the 73,063 DAS allocated, it is expected that the vessels will place those days-at sea (one-for-one) in other fisheries, in order to stay in business. With 73,063 days-at-sea (with the VMS shut off while the vessel is tied to the dock) adds $73 thousand per year. Double-pinging to protect closed areas or participate in exempted fisheries add $70 thousand annually. Safety may be enhanced by including distress buttons on each unit, and costs $1.6 million for the 1484 boats and vessels, but this is not a requirement for groundfish management.

However, the benefits of total fleet coverage, especially to a multispecies fishery like that managed by the groundfish FMP, are much greater than tallying the official DAS and protecting the large, fixed closed areas. If all vessels require VMS, even partial closed areas become somewhat more inviolate because the enforcement agencies can identify every boat that enters them at any time. Likewise, corroboration of other reporting will be comprehensive rather than piecemeal, as it is with less than full VMS coverage. Safety at sea coverage will be comprehensive, and the extra $1100 per unit for this purpose adds only $1.6 million, to protect nearly 1500 U.S. vessels at sea. Any requirements for sampling at sea will be greatly enhanced with full VMS coverage, because the density of fishing vessel activity in the various fish stock areas will be known. Observer and Homeland Security programs will be enhanced, in similar fashion. Finally, trip limits, gear restrictions, fish sizes and other management measures may be affected.

5.4.10 Tuna Purse Seine Vessel Access to Groundfish Closed Areas

There are five quota categories in the Atlantic Bluefin Tuna (BFT) fishery, with a total of 24,179 permitted vessels (Table 330). The primary market for bluefin tuna caught by the General and Purse Seine category vessels is Japan. As a fresh fish market, ex-vessel prices are highly sensitive to market supply. Carrol (1998) found that ex-vessel prices were correlated negatively with the quantity of U.S. catch. An increase of one percent in the supply results in a 0.05 percent drop in price for a single fish.

Quota Category	Number of Permitted Vessels
General	9,226*
Harpoon	44
Purse Seine	5
Longline and Trap	287
Angling	14,617
TOTAL	24,179

Table 330 – Number of permitted tuna vessels, 2000. *Includes Charter/Headboat permitted vessels. Source: NMFS Atlantic Tunas Vessel Permit Database. (NMFS 2001b)

The General Category fishery is managed through a quota that is distributed over the course of the year through time period sub-quotas. The sub-periods are June through August, September, and October through December. There are typically large spikes in bluefin tuna landings at the beginning of a sub-period, particularly if the previous period closed (Scida, pers. comm.). The findings of Carrol (1998) suggest that these surges in landings probably depress the price received by General Category vessels. This may be supported by the lower average ex-vessel price received by this permit category, as compared to the tuna purse seine vessels, in 1998 and 1999 (Table 331).

Category	1998 Gross Revenues (Avg. Price)	1999 Gross Revenues (Avg. Price)
General	$7,472,566 ($6.26)	$9,855,686 ($8.16)
Purse Seine	$3,161,708 ($7.23)	$3,457,119 ($7.82)

Table 331 – Gross revenues for General and Purse Seine category tuna vessels, 1998 and 1999. Source: NERO Bluefin Tuna Dealer Report Database. (NMFS 2001b)

5.4.10.1 Option 1 – Status Quo

This option was not selected . Under this option, there are no changes to current fishing practices. Fishing vessel revenues and operating costs are not expected to change. Therefore, there is no net change in the economic impacts under this option. As a result of the status quo, however, tuna purse seine vessels are limited in the area that they can fish. This may constrain their ability to fish at times that avoid the seasonal glut of tuna landings that result from the General Category sub-period openings. If this occurs and purse seine vessels land their catches at the beginning of a sub-period, ex-vessel prices could be depressed resulting in lower gross revenues for both the General and Purse Seine category vessels. It is not possible to predict how often this may occur, since the distribution of tuna varies considerably over time.

5.4.10.2 Option 2 – Access With Restrictions

This option was not selected. This option will allow tuna purse seine vessels to fish in all groundfish closed areas, but limits fishing in closed areas to water depths of 30 fathoms or greater (or alter nets to less than the depth of water) and excludes the vessels from any HAPC.

Allowing vessels to fish in closed areas may reduce vessel operating costs because it expands the area available to locate and fish on tuna schools. While allowing tuna purse seine vessels to fish in three areas presently closed to them may decrease vessel costs, this option also significantly changes current access to the seasonal closures in the Gulf of Maine and the WGOM closed area. Most of the seasonal closures occur in the winter and early spring and are not in effect during the purse seine fishing season. The Cashes Ledge closure (July through October, November if triggered) and the October and November closures of thirty minute square blocks 124 and 125 do occur during the purse seine season. In addition, the year round WGOM closure area may also be important to purse seine vessels.

As a result, because this alternative improves access in some areas but limits access in others (compared to the status quo), the economic benefits are likely to be neutral or negative. The precise impact will depend on the distribution of tuna and fishing effort, which can change significantly from year to year. If vessels choose to alter their nets to fish in shallower water, operating costs are likely to increase and as a result net revenues will decline.

It is unlikely that this option will have any significant impacts on groundfish landings or revenues. The bycatch of groundfish resulting from this option is not likely to be significant enough to affect stock rebuilding plans or current fishing activities. As a result, it should not have any economic impacts on groundfish vessels.

This option does provide some increased ability for purse seine vessels to avoid fishing during periods of high landings from General category vessels because it allows partial access to all groundfish year round closed areas. This may reduce the likelihood and extent of market gluts and result in higher ex-vessel prices for both categories of vessels.

Because certain types of fixed gear are allowed in the groundfish closed areas (lobster and hagfish pots), allowing tuna purse seine vessels into these areas may increase the likelihood of gear conflicts. NMFS enforcement has not received and recent reports of gear conflict incidents, and none were reported during the experimental fishery in Closed Area I in 2000. Given the small number of tuna purse seine sets, the likelihood of significant gear conflicts is very low.

5.4.10.3 Option 3 – Access Without Restrictions

This is the proposed action. This option increases the area available for tuna purse seine fishing vessels. As a result, it may reduce purse seine fishing costs, increasing net revenues. While there may be some groundfish bycatch within the closed areas, it is not clear that this will represent an increase in bycatch or just a shift in the location of the low bycatch levels that may be occurring. In either case, the amount of groundfish bycatch is unlikely to be sufficient to affect either rebuilding programs or current fishing activities. As a result, it should have little or no economic impact on groundfish vessels.

This option also provides the greatest flexibility for purse seine vessels seeking to avoid fishing during periods of high landings from General category vessels. While it is not possible to predict the extent that this will reduce the likelihood of market gluts, if it does help spread landings of tuna over time it should increase ex-vessel prices and gross revenues for both permit categories.

Because certain types of fixed gear are allowed in the groundfish closed areas (lobster and hagfish pots), allowing tuna purse seine vessels into these areas may increase the likelihood of gear conflicts. NMFS enforcement has not received and recent reports of gear conflict incidents, and none were reported during the experimental fishery in Closed Area I in 2000. Given the small number of tuna purse seine sets, the likelihood of significant gear conflicts is very low.

5.4.11 Northern Shrimp Fishery Exemption Area

5.4.11.1 Background

While there is significant literature on the biology of *Pandalus borealis*, detailed economic statistics on the New England shrimp industry have not been compiled and described since the 1986 ASMFC FMP for northern shrimp. There are, however, recent sources (Clark et al. 2000; Hall-Arber and McCarron, unpub. draft) that contain descriptive information on economic aspects of the current fishery.

The following excerpt is from Hall-Arber and McCarron:

"Traditionally, Maine landings dominated the shrimp fishery. It began in the 1930s as a winter inshore fishery, rising to landings of a half-million pounds by 1945 before a steady decline ensued. In the 1960's landings increased again, reaching a total of 23,553,000 pounds (12,800 mt) in 1968-69. By this time, the small Maine fleet had grown from a handful of inshore, side-rigged trawlers to over 200 draggers, including stern trawlers. In addition, a portion of the fleet worked year-round and offshore. New Hampshire boats also joined in the fishery in 1966, though landings were minor through the 1970s. Massachusetts' boats had a nominal presence up until 1969, but rapidly increased in numbers thereafter. Nevertheless, Maine's landings far exceed those of any other state, landing 72% of Atlantic's marine shrimp catch in 1997, 67% in 1998, 41% in 1999, and 70% in 2000. Looking only at New England, Maine's catch in 1997, 1999 and 2000 was 86% of the total, slipping only in 1998 to 82% of New England's total landings."

The following excerpt is from Clark et al.:

"Participation in Maine has been based both on potential economic returns between lobsters, scallops, groundfish and shrimp and vessel size. Maine participants have succeeded by being versatile, re-rigging their vessels in response to costs, ex-vessel prices and availability of target species. When shrimp are available in sufficient quantity and ex-vessel prices are high, they are attractive to larger numbers of the more versatile vessels and total effort may increase dramatically. Maine vessels have continued to operate primarily out of Portland and smaller ports further east.

New Hampshire landings increased rapidly in the mid-1980s and vacillated around an average of 10% of the total through the 1990s, exceeding those of Massachusetts in some years. New Hampshire's fleet fishes out of only three small ports.

The Massachusetts fishery expanded rapidly in the 1980's; landings surpassed the Maine total from 1979 to 1981 and remained significant until 1992. The number of participating vessels increased to about 80 by the end of the decade, but then declined, with the exception of a brief resurgence in 1995 and 1996. The decline in recent years reflects a number of factors including fleet reductions associated with severe restrictions in the groundfish fishery and federal "buyback" programs, recent declines in abundance and quality of shrimp with concomitant poor prices, and availability of other options during the shrimp season. Less than 30 vessels participated during the 1998 fishing season, and Massachusetts accounted for only 6% of the total during that year. As was the case for earlier years shrimp have been landed primarily in Gloucester and smaller ports further north.

...Currently, the shrimp fleet is comprised of lobster vessels in the 9-14 m *(30-46 ft.)* range that re-rig for shrimping, small to mid-sized stern trawlers in the 12-17 m *(39-56 ft.)*, and larger trawlers primarily in the 17-24 m *(56-79 ft.)* range."

Hall-Arber and McCarron further stated:

"The numbers of vessels involved in the fishery also varies from year to year... [I]n 1996 when landings reached 9,500 mt, there were 350 vessels in the fleet. The following year, when landings dropped, there were only 260 boats in the fleet. The sizes of the vessels also vary. At one time, the 30 ft. boats predominated, now boats as large as 90 to 100 ft. might rig over...

...The majority of the shrimp boats work out of smaller ports, though not necessarily the same small ports every year...

...Lower Mid-Coast Maine predominates in shrimping compared to the other sub-regions in Maine. Portland, Cundy's Harbor, Boothbay Harbor and South Bristol are all in Lower Mid-Coast Maine. The Portland Fish Exchange holds a daily shrimp auction in season. Maine's largest processor of shrimp is located in Portland. Boothbay and South Bristol each have a local shrimp processor, though they also ship some shrimp to Portland for processing...

...The small ports where shrimp constitutes a significant proportion of landings consider fishing an important feature of their economy...

... Shrimp is an essential component of the year's fishing returns for individual vessels from Rye, Hampton and Portsmouth and for both of New Hampshire's fishing cooperatives. Furthermore, boats from Newburyport (Massachusetts) and York (Maine) are shrimp-landing members of the Yankee and Portsmouth Coops, respectively, so the shrimp networks clearly extend beyond the borders of states and sub-regions in New England...

...According to *Fisheries of the U.S*., commercial landings of shrimp in New England in 1999 were 3,812,000 pounds worth $3,579,000. In 2000, 5,361,000 pounds were landed valued at $4,335,000. Maine's statistics are by shrimp season, so they reported 3,148,326 pounds in 1998-99, 3,795,098 in 1999-2000, and 1,326,537 in 2000-2001. These numbers are in great contrast with 1997-98's 6,698,817 pounds."

Maine DMR issued 561 licenses for the 2000-2001 season. For 1999-2000, 566 licenses were issued. Of those license holders who reported in 1999-2000, 38% reported not fishing.

The following summary statistics from the NMFS Dealer and Permit Databases (provided by NEFMC staff) represent values for gross revenues and landings by federal multispecies permit holders using shrimp trawls during 1994-2000:

Year	No. vessels*	Landings (lbs.)**	Revenue
1994	260	12,419,759	$11,652,785
1995	292	15,736,254	12,004,664
1996	300	14,899,863	11,777,977
1997	279	8,360,126	7,798,372
1998	212	3,092,773	2,764,960
1999	217	4,507,649	3,529,628
2000	197	1,603,521	1,305,416

*represents only vessels using shrimp trawls and holding multispecies permits
**represents all non-multispecies landings (could include species other than shrimp)

These numbers may be indicative of some trends in the shrimp fishery, but likely do not represent the Maine fishery very well, as most of the Maine shrimp fleet are not multispecies permit holders.

5.4.11.2 Option 1 No Action

This Option would not change the economic conditions in the shrimp fishery. It was not selected.

5.4.11.3 Option 2 Eliminate Area Restriction for the Northern Shrimp Fishery

This option is the proposed action. The area outside the 25600 line that holds any appreciable amount of shrimp is very limited compared to the area of the rest of the Gulf of Maine that would become available if the preferred alternative is put in place. The 25600 line bisects three general areas in the vicinity of Cashes Ledge that were traditional spring fishing grounds. The fishermen want these areas reopened to shrimping.

Shrimp in the GOM are patchy in abundance and migrate differentially with age. Males migrate offshore over a two year period from their place of birth. They function as males offshore and then remain there for the next year, transforming into females. They will mate as females in the following summer and will then migrate inshore as the eggs develop during the fall and early winter. They will remain inshore until larval release has occurred and then migrate offshore to repeat the process.

Thus the occurrence of shrimp offshore, outside the 25600 line, in the spring and therefore the desire to have a fishery there is a function of the strength of the 'resident' year class offshore, ie. the transitionals, and the rate of movement offshore of the males and females. This last May, 2001 the resident year class was the 1998 year class, which was the weakest on record in the history of the survey (since 1983). Also, the female shrimp were delayed in their offshore migration possibly due to the inshore waters of the GOM remaining colder than normal through the late winter and early spring. Thus there were no shrimp, or very few to be found in the area where the experimental fishing was done. This is not always the case. Historical records from the Maine port sampling program show an average of 179 pounds per hour towing in the vicinity of Cashes Ledge between Platts Bank and Jeffreys Bank (Table 2). Samples were collected for trips made between 1988 and 1999. Not all years are represented as not all years had a May fishery and shrimp were not present in attractive enough numbers during some years, at least fishermen's choice did not place the sampled trips there.

There are currently 50 fishing vessels with a LOA of at least 50 feet registered in Maine for the taking of shrimp. Of these, about a dozen actively fish in the neighborhood of the 25600 line during the spring fishery in years when there is a concentration of shrimp there. From NMFS records, the number of trips in May in the shrimp fishery are minimal compared to the winter months (Appendix III, Table 3). These trips are likely to be two to three days in duration whereas the winter trips are uniformly day trips. Assuming an average spring trip to be two days duration, the effort expended on the shrimp fishery in days fished is still small in the spring compared to the winter in any one season. Few vessels, if any from New Hampshire or Massachusetts would travel the distance required to fish outside the current boundaries of the Small Mesh Exemption Area due to their size and their relatively greater distance from the likely offshore shrimp beds.

The number of vessels that will participate in the spring shrimp fishery is not estimated to change appreciably if the area outside the 25600 line is opened. Also, the choice whether or not to fish for shrimp will probably not be affected severely. Thus the fishery is expected to maintain its traditional spring fishing effort level and the extent to which the area outside 25600 is accessed will simply be a spreading out of effort, diminishing effort inside the line. Whether or not there are more shrimp outside the line than inside in any given year will determine where the fishery will be. In some years there may be a higher concentration of shrimp in the vicinity of the line, rather than well inside the line and in those years there will probably be effort expended there. The line bisects offshore beds that shrimp will move into if they move that far offshore. Shrimp are not known to move beyond these beds in any great concentrations based on spring (NEFSC), summer(ASMFC) and fall (NEFSC) survey data. Thus in those years when the shrimp move that far offshore, the fishing will be spread out over the whole bed, rather than over the inside half of the bed. The fishing offshore usually lasts two to three weeks and usually occurs as late as possible in the spring. Benefit to the fishermen may accrue with the opening of the full beds by having their CPUE remain higher over time as their fishing, spread out over the entire bed, will not disturb and thus disperse the shrimp as much. The increased mortality of shrimp must be measured as the difference between CPUE inside the line if the line were not removed and both inside and outside the line if the line were removed. Given the area involved and the numbers of fishing trips that occur in May, this difference is not expected to be very great, but may well exist.

5.4.12 SNE General Category Scallop Exemption Program

This program will mitigate the economic impacts of the proposed restrictive groundfish regulations. In the scallop fishing year from March 1999 through February 2000, 69 vessels with a general category permit used dredges to land over 61,000 pounds of sea scallops worth about $500,000 (2001 Scallop SAFE Report), an average of about $7,200 per vessel. There are 815 vessels limited access multispecies vessels with general category permits (this number could increase, as it is an open access permit). If all of these vessels were to participate in the program (an unlikely proposition given the location of the area), revenues of $5.8 million will accrue. Vessels most likely to take advantage of this program are those adjacent to the area - vessels homeported in Rhode Island, southern Massachusetts, or New York.

5.4.13 Impacts on Other Fisheries

Management measures adopted in Amendment 13 may impact other fisheries (and the stocks managed by those fisheries) in two different ways. First, regulations implemented to manage groundfish may also directly restrict catches of other stocks. For example, many fishermen catch skates, monkfish, and dogfish while fishing on groundfish DAS. Reducing effort in the groundfish fishery will likely result in reduced catches of these stocks as well. Another way other fisheries will be affected is if additional closed areas are adopted with restrictive access provisions, whether to reduce groundfish mortality or to minimize the adverse effects of fishing on habitat. Second, fishermen may increase their participation in other fisheries in order to make up revenue lost because of restrictive groundfish regulations. This may exacerbate effort control problems in those fisheries and result in a cascading need for additional management action to achieve OY in those fisheries.

5.4.13.1.1 Impacts of Closed Areas

A number of alternatives in this Amendment, if adopted, will change existing year round closed areas, to minimize the adverse effects of fishing on essential fish habitat to the extent practicable. The "worst case" impacts of additional closed areas can be estimated by assuming that vessels are not able to replace the catches taken from a newly closed area – in other words, there is "no displacement" of effort into other areas to make up the lost catches. For sedentary species like scallops, this may be a reasonable approximation of the losses that may accrue. It does not, however, take into account the stock dynamics of the resource and thus may under-estimate impacts for a stock with rapid growth and high fecundity, or a stock that is rapidly rebuilding. This approach does not analyze the possible distributive effects of the closures. Finally, this approach does not take into account management choices that can mitigate the impacts – such as a closed area access program for scallop vessels (assuming the closures are not also closed to minimize adverse effects of fishing on habitat). The results should only be used to compare alternatives and to indicate the relative magnitude of the impacts, but should not be viewed as predictions of actual revenue declines.

The general approach used to analyze closed area impacts, and the analysis of the various habitat closure alternatives are described in section 5.3.10.

5.4.13.1.2 Impacts of Gear Requirements/Restrictions

Scallop Twine Top Requirementin the Inshore GOM

Rebuilding Alternative 2 would have implemented a requirement for the use of a ten-inch twine top for scallop dredges fishing in thirty minute squares 114, 115, 123, 124, and 125. The purpose of this requirement is to reduce the bycatch of CC/GOM 9.4.2.8.3.7. According to SAW-36, scallop dredge discards account for approximately 30 percent of the CC/GOM yellowtail flounder discards, though the percentage declined in 2001 and was only 30 mt out of a total of 484 mt of discards. Given the large reductions in fishing mortality necessary to rebuild CC/GOM yellowtail flounder, however, 30 mt of discards is about 15 perent of the total catch in 2004.

The use of large mesh twine tops to reduce finfish bycatch has shown promising results in recent experiments. Draft Amendment 10 to the Atlantic Sea Scallop Fishery Management Plan contains a summary of these experiments, and the following information was extracted from that document.

Smolowitz et al (1997) reported that increases in the mesh size of the twine top significantly reduced the number of flatfish captured by the dredge. Comparisons of a 6" diamond mesh twine top with that of an 8" square mesh resulted in a 37% reduction in the harvest of yellowtail flounder (1,674 versus 1,042; 78 tows). A similar experiment comparing a 6" diamond mesh twine top with that of a 10" diamond mesh resulted in a 45% reduction in the harvest of yellowtail founder (605 versus 300; 50 tows). The reductions in the number of yellowtail harvested by the dredge using the larger mesh twine tops were statistically different at the 95% confidence level. The use of a 10" twine top reduced the amount of scallops captured.

In 1998, DuPaul and Kerstetter (unpublished data) tested the use of larger mesh twine tops to reduce the bycatch of summer flounder in the mid-Atlantic. A comparison between a 6" diamond mesh twine top with that of an 8" diamond mesh produced inconsistent results that were not statistically different (292 versus 265; 28 tows). A comparison of a 6" diamond mesh twine top that of a 9.5" knotcenter diamond mesh hung on the diagonal significantly reduced the catch of summer flounder by

42% (543 versus 310; 66 tows). Hanging the twine top on a diagonal resulted in an "open diamond" configuration similar to a square mesh. The harvest of scallops during this test was highly variable from tow-to-tow due to rough weather and a scarcity of scallops (1-3 baskets per dredge per tow). No conclusions relative to the harvest of scallops could be made.

In 1998, during the cooperative NMFS/Industry/Academia survey of the Georges Bank Closed Area II (CAII), comparative tows using larger mesh twine tops were made both inside and outside the boundaries of CAII (DuPaul et al 1999). A comparison between an 8" diamond mesh twine top with that of an 8" square mesh produced no significant reductions in the catch of yellowtail flounder (p=0.233) and blackback flounder (p=0.670) during the survey within the boundaries of CAII (224 tows). The catch of scallops were not statistically different. In a second experiment outside the boundaries of CAII, an 8" diamond mesh twine top was compared with that of a 12" square mesh. Significant reductions in the capture of blackback flounder (p=0.004), windowpane flounder (p=0.003) and monkfish (p=0.041) were observed. The reduction in the catch of yellowtail flounder was not significant (219 versus 188; p=0.082). There was a highly significant reduction in the harvest of scallops (p=0.000). A total of 34 tows were made.

These recent studies indicate that increasing the mesh size of the twine top can be effective in reducing finfish bycatch in the sea scallop dredge fishery. However, it is also apparent that increases in mesh size must be balanced with undesirable losses in scallop production.

5.4.13.1.3 Displacement of Effort Into Other Fisheries

Groundfish vessels owners may increase their activity in other fisheries as a result of restrictive groundfish regulations. Their ability to shift into other fisheries will depend on what permits they hold. Limited access multispecies permit holders may hold permits to several other fisheries that would permit them to enter these. To examine what permits are held by these vessels and whether they have participated in alternative fisheries, permit data for permit year 2002 were merged with calendar year 2001 dealer data. Permit categories not regulated by DAS controls were excluded. With the exception of general category scallop and herring permits, the query on permits for other fisheries was limited to limited access or moratorium permits only since the ability to redirect effort to other fisheries will be limited if the vessels does not hold a necessary permit. Dealer data was summed by permit holder to ascertain 1) whether a given vessel had any record of fishing activity; 2) relative dependence on groundfish; and 3) evidence of activity in fisheries other than groundfish. For the latter, activity was defined as having recorded any sale of the given species through the dealer reporting system. Note that this may provide a biased estimate of activity and dependence on groundfish for vessels in Connecticut and Delaware, particularly if the vessel does not land in any other state.

During calendar year 2001 279 of the 1,391 limited access permit holders reported no activity in the dealer data. Of the vessels that did report activity 157 did not report landing any of the 10 large mesh species; 235 relied on groundfish for less than 25% of fishing revenue; 134 depended on groundfish for 25% or more but less than 50% of revenues; 190 depended on groundfish for 50% or more but less than 75% of revenues; and 396 vessels relied on groundfish revenue for 75% or more of total fishing revenue. Of the vessels most dependant (50% or more) on groundfish, nearly three-quarters had permits for bluefish, dogfish, lobster, monkfish, illlex and/or loligo squid, and general category scallop permits. Vessels with lower dependence on groundfish typically held a similar suite of permits but a large proportion of these vessels also held a summer flounder permit.

Holding a permit does not necessarily mean that a vessel participates in the permitted fishery. Of the alternative permits held by vessels most dependent on groundfish, only monkfish and summer flounder were used by 50% or more of the vessels that held these permits. The number of fisheries where this criterion is met increases as dependence on groundfish decreases. For example, fisheries with 50% or greater participation for vessels in the 50-75% dependence interval included black sea bass, summer flounder, monkfish, squid, and small mesh multispecies. For vessels below 50% dependence bluefish and scup are added to the list. Note that vessels that were active but did not land any groundfish tended to have participation limited to black sea bass, summer flounder and squid and to a lesser extent monkfish.

The economic analysis indicates the vessels that will be most affected by the Amendment 13 alternatives are those vessels that are dependent on groundfish for a 75 percent or greater of their gross revenues. A large number of these vessels have monkfish, dogfish, general category scallop, or bluefish permits. Ability of these vessels to move into the monkfish or dogfish fisheries is constrained by current regulations in those fisheries. Currently, limited access groundfish vessels are charged a groundfish DAS when fishing for monkfish, which means if the amendment constrains groundfish DAS they will not be able to expend much additional effort on monkfish. Dogfish quotas are very restrictive. If additional effort is shifted into that fishery, season will close even more rapidly than at present and the derby nature of that fishery will be exacerbated. If significant numbers of vessels begin to use their General Category Scallop permits, it will complicate scallop management and the possible development of the scallop rotational area management system in Amendment 10.

Less than 10 percent of the vessels that rely heavily on groundfish have squid permits, limiting the impacts of shifts in effort from these vessels. At lower levels of groundfish dependence, there are 244 vessels with squid permits and 82 percent reported landing squid in fishing year 2001. This suggests it will be relatively easy for these vessels to redirect effort into the squid fishery. This fishery is also managed through seasonal quotas, and increases in effort will likely exacerbate the derby fishery nature of quota fisheries. Smaller groundfish vessels may also fish for tuna or enter the party/charter fishery. Other opportunities for groundfish trawl vessels include the open-access whiting and herring fisheries. The low prices and competitive markets may limit the ability of vessels to move into these fisheries.
